A Novel Optomechanical Module that Enables a Conventional inverted Microscope To Provide Selective Plane Illumination Microscopy (iSPIM)

Description of Technology: The invention describes an optomechanical module that, when engaged with a conventional inverted microscope, provides selective plane illumination microscopy (iSPIM). The module is coupled to the translational base of the microscope whereby a SPIM excitation objective is engaged to one portion of the mount body, and a SPIM detection objective (having a longitudinal axis perpendicular to that of the excitation objective) is engaged to another portion of the mount body. Such a system offers the advantages of SPIM (optically sectioned, high-speed volumetric interrogation of living samples), enabling the study of developmental or neuronal dynamics at high frame rates, while maintaining the flexibility and sample geometry of commercially available inverted microscopes (thus additionally allowing wide-field, TIRF, confocal, or 2 photon imaging of samples).

Potential Commercial Applications: The microscope can be used for:
- Imaging of live whole animals (e.g. worms) (demonstrated already).
- Superresolution (photoactivated localization microscopy) with minimal bleaching of dye molecules.
- High speed investigation of neuronal dynamics at high frame rates.

Competitive Advantages:
- The system offers the advantages of SPIM, while maintaining the flexibility and sample geometry of commercially available inverted microscopes.
- In this system the sample can be easily mounted on a rectangular coverslip and may be translated using an automated 3D mechanical stage and additionally imaged using the conventional light path built into the inverted microscope frame.

Development Stage:
- Prototype.
- In vivo data available (animal).

A Vaccine for Shigella sonnei for Both Children and Adults

Description of Technology: There is currently no vaccine widely available for shigellosis, which affects over 150 million people worldwide and causes over 1 million deaths a year, mostly children. The present invention discloses a novel immunogen to be used in a vaccine for both children and adults. The immunogen, a low-molecular mass O–SP-core fragment, generates high antibody responses in animal studies, which means reduced number of vaccinations. The immunogen is easy to isolate for ease of manufacturing. Additionally, the methods of manufacturing, times and protocols of preventing and/or treating Shigellois had been carried out in the present invention.

Potential Commercial Applications: Shigella sonnei vaccines and diagnostics.

Competitive Advantages:
- Vaccine can be used in both children and adults.
- Doses of vaccine are reduced.
- Immunogen is easy to isolate for easy vaccine production.

Development Stage:
- Prototype.
Antibodies Against TL1A, a TNF-Family Cytokine, for the Treatment and Diagnosis of Autoimmune Inflammatory Diseases

Description of Technology:
Autoimmune inflammatory diseases occur in greater than five percent of the United States population; this disease group includes asthma, multiple sclerosis, rheumatoid arthritis, and lupus. Treatments generally include immunosuppressants or anti-inflammatory drugs, which can have serious side effects; recently, more specific immunomodulatory therapies such as TNF-alpha antagonists have been developed.

In experiments with mice, NIAMS inventors have shown that the interaction between the TNF family ligand TL1A with its receptor, DR3, is critical for development of disease in asthma, inflammatory bowel disease and multiple sclerosis. They have also developed anti-TL1A antibodies that prevent disease in mouse models of rheumatoid arthritis and inflammatory bowel disease.

This technology describes anti-mouse TL1A and anti-human TL1A monoclonal antibodies that may be useful for the development of diagnostics and therapeutics for autoimmune inflammatory disease, as well as methods of treating such disease by blocking the interaction between TL1A and DR3.

Potential Commercial Applications:
- Antibody-based therapeutics for autoimmune inflammatory disease.
- Diagnostics for autoimmune inflammatory disease.
- Research tools to probe the role of TL1A–DR3 interactions in the development of autoimmune disease.

Competitive Advantages:
- Specific immunomodulatory effect provides potential for potent therapy without inducing global immunosuppression.
- Anti-TL1A monoclonal antibodies available for further development.

Development Stage:
- Early-stage.
- In vivo data available.
- In vivo data available (animal).

Inventors: Richard M. Siegel, Francoise Meylan, Yun-Jeong Song (NIAMS).

TL1A Transgenic Mice for the Study of Inflammatory Bowel Disease (IBD) and Allergic-Type Immune Responses

Description of Technology: TL1A is a TNF family cytokine that co-stimulates T-cell proliferation and cytokine production through its interactions with the TNF family receptor DR3. TL1A–DR3 interactions have been shown to be important for the development of autoimmune inflammatory diseases, including inflammatory bowel disease (IBD).

In order to probe the role of TL1A–DR3 interactions in IBD, NIAMS inventors have developed transgenic mice that constitutively express TL1A in T cells or in dendritic cells. These mice spontaneously develop inflammatory small bowel pathology that is IL-13 dependent, and that closely resembles intestinal responses to allergens and to nematode infection.

These mice represent a unique model for the study of IBD, and in particular, the role of IL-13 in the development of this disease. They may also be used as a platform for investigating agents that block TL1A–DR3 interactions and the pathology associated with chronic TL1A expression.

Potential Commercial Applications:
- Studies of small bowel inflammation/IBD.
- Studies of the role of TL1A–DR3 interactions in the development of autoimmune inflammatory disease.
- Investigation of TL1A–DR3 blocking agents for the treatment of IBD or other TL1A–DR3 dependent diseases.

Competitive Advantages:
- Lines available with transgene expressed in T cells (under CD2 promoter) or dendritic cells (CD11c promoter).
- Models are IL–13 dependent.
- No major defects in systemic immunity.

Development Stage: In vivo data available (animal).

Inventors: Richard M. Siegel and Francoise Meylan (NIAMS).

Human Monoclonal Antibodies Cross-reacting to Insulin-like Growth Factors IGF–I and IGF–II as Potential Antitumor Agents

Description of Technology: The type 1 insulin-like growth factor (IGF) receptor (IGF1R) is over-expressed by many tumors and mediates proliferation, motility, and protection from apoptosis. Agents that inhibit IGF1R expression or function can potentially block tumor growth and metastasis. Its major ligands, IGF–I, and IGF–II are over-expressed by multiple tumor types. Previous studies indicate that inhibition of IGF–I, and/or IGF–II binding to its cognizant receptor negatively modulates signal transduction through the IGF pathway and concomitant cell proliferation and growth. Therefore, use of humanized or fully human antibodies against IGFs...
represents a valid approach to inhibit tumor growth. The present invention discloses the identification and characterization of a fully human monoclonal antibody designated m708.5 that has been affinity matured against IGF–I and IGF–II and displays extremely high affinities for IGF–I and IGF–II in the picoM range. The m708.5 antibody potently inhibited signal transduction mediated by the IGF–1R interaction with IGF–I and IGF–II and blocked phosphorylation of IGF–IR and the insulin receptor. Further, this antibody inhibited migration in the MCF–7 breast cancer cell line at the picoM range. Therefore, this antibody can be used to prevent binding of IGF–I and/or IGF–II to its concomitant receptor IGFIR, consequently, modulating diseases such as cancer.

Potentially Commercial Applications:
- Therapeutic for the treatment of various human diseases associated with aberrant cell growth and motility such as breast, prostate, and leukemia carcinomas.
- Research regent to study IGF–I and/or IGF–II binding and its association with tumor growth.

Competitive Advantages:
- Antibodies against the ligands IGF–I and IGF–II, such as this invention, inhibit the interaction with IGF–IR yet likely do not have the type of toxicity associated with IGF–1R antibodies.
- High concentrations of IGF–II are several fold higher than IGF–I; thus this cross-reacting IGF–1/IGF–II antibody could be more effective than existing IGF–IR and/or IGF–I currently in the clinic.
- This novel IGF antibody may provide therapeutic intervention for multiple carcinomas.

Development Stage:
- Pre-clinical.
- In vivo data available.

Transgenic Mice Expressing Human Arginase II Gene in Endothelium: Useful for Studying Atherosclerosis and Other Vasculopathies

Description of Technology:
Cardiovascular disorders associated with endothelial dysfunction, like atherosclerosis, have decreased endothelial nitric oxide (NO) bioavailability. L-arginine, the primary substrate for endothelial nitric oxide synthase (eNOS), is important in the regulation of NO production. Arginase competes with eNOS for L-arginine and has been implicated in the endothelial dysfunction. NIH investigators have generated transgenic mice with human ArgII (hArgII) gene under control of endothelial-specific Tie2 promoter. In these mice, hArgII was expressed at very high levels in all tissues except liver. Analysis has shown that expression of hArgII was endothelium-specific. Overexpression of hArgII neither led to significant changes in plasma level of arginine, citrulline, NOHA, ADMA, SDMA and ornithine, nor to changes in plasma lipid levels. Level of arginase activity in peritoneal macrophages isolated from the transgenic mice also was unchanged. However, ArgII overexpression induced signs of endothelial dysfunction. In apoE–knockout mice hArgII led to 2-fold increasing in aortic area with atherosclerotic lesions. The Tie2hArgII transgenic mouse can be useful as a new model for investigating the role of ArgII in endothelial function and development of atherosclerosis.

Potential Commercial Applications:
- Useful to study the role of arginase II gene in endothelium.
- Useful for testing the drugs for treatment of the endothelial dysfunction related to eNOS insufficiency, including hypertension.
- Useful to study mechanisms of atherosclerosis.

Competitive Advantages: Better model system to study functional significance of arginase II.

Development Stage:
- Early-stage.
- Pre-clinical.
- In vivo data available (animal).

National Center for Complementary & Alternative Medicine; Notice of Closed Meeting

Pursuant to section 10(d) of the Federal Advisory Committee Act, as amended (5 U.S.C. App.), notice is hereby given of the National Advisory Council for Complementary and Alternative Medicine (NACCAM) meeting.

The meeting will be open to the public as indicated below, with attendance limited to space available. Individuals who plan to attend and need special assistance, such as sign language interpretation or other reasonable accommodations, should notify the Contact Person listed below in advance of the meeting.

The meeting will be closed to the public in accordance with the provisions set forth in sections
