Source: Office of Regulatory Analysis, OSHA based on PP&E (2009) and ERG (2012)

As shown in Table VI–3, approximately 75,000 firms, in over 90,000 establishments, create hazardous chemicals (*i.e.,* products, substances, or mixtures) for which a label and SDS are required in accordance with the OSHA HCS. In response to testimony presented on the proposed rule, OSHA has revised its estimate of the number of SDSs (and corresponding container labels) potentially affected by the revisions to the HCS from approximately 0.9 million SDSs to approximately 1.4 million SDSs.[10] OSHA estimates that the adoption of GHS will not significantly change the numbers of labels and SDSs produced.

In many instances, firms may be already producing several different versions of SDSs and labels for the same product to satisfy different regulatory requirements in different jurisdictions, including SDSs and labels consistent with GHS criteria. For these products, the revisions to the OSHA HCS will be satisfied relatively easily and may result in a reduction in overall compliance costs by reducing the number of different labels and SDSs needed for each affected product.

The second category of industries and establishments affected by the revisions contains those that do not produce labels or SDSs but are required to provide their employees with access to SDSs supplied by others as part of a hazard communication program covering chemicals to which employees may be exposed in the workplace. The effects on these establishments will generally involve promoting employee awareness of and management familiarization with the revisions to SDSs and labels.

As shown in Table VI–3, an estimated 41 million employees are potentially exposed to hazardous chemicals in these workplaces and are covered by the OSHA HCS. Including employees working in establishments that produce labels and SDSs, a total of 44 million employees would potentially need to become familiar with the revisions to SDSs and labels. The estimated number of employees to be trained, as shown in Table VI–3, is equal to the number of production employees in all affected industries. As also shown in Table VI–3, OSHA estimates that there are over five million workplaces where employees may be potentially exposed to hazardous chemicals.

OSHA received comment from the American Wind Energy Association and Duke Energy Business Services, LLC that asserted that the Agency had underestimated the number of employees that would need to be trained in the electric power generation industry (Document ID #0386 and 0453). OSHA estimated that approximately 49 percent of employees were production employees in this industry who would need to be trained to familiarize them with the revisions to the HCS and that an additional 11,000 managers and logistic personnel would receive training as well. The commenters felt that 60 to 70 percent of employees would need to be trained. OSHA evaluated the concerns of the AWEA and Duke Energy and has decided to defer to their expertise on the subject and adopt their recommendation (by changing the percentage of employees who would need to be trained in NAICS 2211 Electric power generation, transmission and distribution to 65 percent). The change from 49 percent of employees to 65 percent of employees to be trained results in a negligible change to the costs to this industry. Increasing the number of production employees needing training from 245,715 to 315,623 results in an increase of about $39 per firm in annualized costs to this industry, and the costs as a percent of revenues would increase from 0.0052 percent to 0.0060 percent.

D. Benefits

OSHA estimates that the promulgation of the revisions to the HCS will result in substantial benefits from a variety of sources. OSHA's estimates of the benefits include improvements in occupational safety and health and a corresponding reduction in the annual number of injuries, illnesses, and fatalities sustained by employees from exposure to hazardous chemicals; cost reductions for producers of hazardous chemicals; increased efficiencies in the handling and use of hazardous chemicals; reduced costs to provide HCS training to new employees; and other benefits as described in this section.

OSHA expects the revisions to the HCS will result in an increased degree of safety and health for affected employees and a reduction in the numbers of accidents, fatalities, injuries, and illnesses associated with exposures to hazardous chemicals.

As explained in detail in Sections IV and XIII of this preamble, the design of GHS was based on years of extensive research that demonstrated the effectiveness of pictograms, specific signal words, and a standardized format.[11] As a result of this research, OSHA is confident that the GHS revisions to the HCS for labeling and safety data sheets will enable employees exposed to workplace chemicals to more quickly obtain and more easily understand information about the hazards associated with those chemicals. Warning labels on products covered by the standard, which provide an immediate visual reminder of the chemical hazards involved, would be made more intuitive, self-explanatory, and logical, and the nature and extent of any associated hazards would be more readily understood as a result of the training required under the standard. Relatedly, the revisions are expected to improve the use of appropriate exposure controls and work practices that can reduce the safety and health risks associated with exposure to hazardous chemicals.

In addition, the standardized format of the safety data sheets would enable critical information to be accessed more easily and quickly during emergencies. This can reduce the risk of injury, illness, and death to exposed employees and to rescue personnel and can also reduce property damage.

It is difficult to quantify precisely how many injuries, illnesses, and fatalities will be prevented due to the revisions to the HCS. The benefits associated with the current HCS may help provide a general sense of the potential magnitude of the benefits of these revisions. A discussion and analysis of the benefits that would result from the implementation of the current OSHA HCS were included as part of the rulemaking process for the promulgation of the current standard in the 1980s.

The current HCS was originally promulgated in two parts. First, a final rule covering the manufacturing industry was published in the **Federal Register** in 1983 (48 FR 53280, Nov. 25, 1983); a second final rule covering other general industries, maritime industries, construction industries, and agricultural industries was published in the **Federal Register** in 1987 (52 FR 31852, Aug. 24, 1987).

For both of these final rules, OSHA conducted research specifically

[10] A representative from the Independent Lubricant Manufacturers Association suggested that OSHA had underestimated the number of SDSs produced per firm in the lubricating oils industry and that the average firm in the industry produces approximately 1,700 lubricating products requiring an SDS. OSHA has considered this testimony and accepted the estimate of 1,700 SDSs produced per firm in NAICS 324191: Petroleum lubricating oil & grease manufacturing. With 329 affected establishments in this industry, OSHA's estimate of the number of affected SDSs has increased by approximately 0.4 million SDSs in the FEA (as compared to the PEA). The industry profile has been revised accordingly (Document ID #0495 Tr. 296–7).

[11] See Sections IV and XIII of this preamble for a discussion of the studies related to these issues.

regarding the benefits that could be expected from the promulgation of these standards, as described in the preambles to the final rules. In addition, through the rulemaking process, OSHA evaluated the best available evidence, including the data and comments submitted by the public.

The information, data sources, analyses, and findings related to the estimation of the benefits associated with these standards are included in the public records for the rulemakings. The complete rulemaking records for these standards can be found in OSHA public dockets H–022B and H–022D.

The estimated benefits associated with the Hazard Communication Standards were published in the **Federal Register** with the promulgation of the final standards (48 FR 53329, Nov. 25, 1983 and 52 FR 31872, Aug. 24, 1987). OSHA estimated that compliance with the various Hazard Communication Standards would produce annual benefits that would include the prevention of 31,841 non-lost-workday injuries and illnesses, 20,263 lost-workday injuries and illnesses, 6,410 chronic illnesses, and 4,260 fatalities.

Using a willingness-to-pay approach for valuing these benefits, OSHA determined that the annual safety and health benefits would be over $18.2 billion annually, expressed in 1985 dollars. Applying the BLS inflation calculator, the $18.2 billion of benefits in 1985 is equivalent to $36.7 billion of benefits in 2010 after adjusting for inflation of 102 percent of the period.[12] [13]

Based on the material presented in this preamble, OSHA expects that the revisions to the HCS will result in incremental improvements in employee health and safety above that already achieved under the current HCS. In the PEA, OSHA estimated that compliance with the revisions to the HCS would result in benefits equal to 1 percent of the health and safety benefits attributed to the current HCS. It is conceivable that actual benefits might be somewhat lower, but because GHS is expected to result, in some situations, in more timely and appropriate treatment of exposed workers, OSHA expects that actual benefits may be larger, perhaps several times larger.[14] OSHA solicited comment on the anticipated health and safety benefits of the revisions to the HCS and received numerous comments indicating that stakeholders anticipate increased worker protection as a result of the revisions. The Alliance of Hazardous Materials Professionals responded that they believed that these revisions to the HCS would yield ''benefits in preventing injuries and illnesses'' (Document ID #0327) and DuPont Company reported that they ''believe domestic implementation of the GHS will serve to further enhance worker protection through a more standardized approach to hazard classification and communication'' (Document ID #0329). The National Association of Chemical Distributors said that their association members ''believe that there are benefits associated with preventing injuries, illnesses and fatalities through clearer and more accessible information'' (Document ID #0341) and likewise, the Communications Workers of America reported that they believed that application of the elements of the revised HCS ''would lead to a reduction in the incidence of workplace injuries, illnesses, and fatalities'' (Document ID #0349). This sentiment was echoed by the American Health Care Association, National Center for Assisted Living who felt that the revised HCS will ''reduce incidence of chemical-related illnesses and injuries'' (Document ID #0346), and the Associated General Contractors of America who felt that the revisions ''will allow employees to easier understand hazard information and will assist in better job planning and injury prevention'' and that they ''should reduce eye and skin contact injuries'' (Document ID #0404). The U.S. Chamber of Commerce stated that they ''(b)elieve * * * the new rule will improve workplace safety'' (Document ID #0397). One commenter (Document ID #0033), representing an organization whose membership includes first responders and emergency management, wrote the following in response to the Advance Notice of Proposed Rulemaking (ANPR):

> The emergency planning and first responder community depends upon MSDS information for life and safety. The ability to immediately examine an MSDS and glean hazard and response information at the scene of an incident is critically important. The lives of first responders, employees of the facility and the public depend upon the accuracy and ease of use of the MSDS.

Some stakeholders questioned whether the revisions would result in any health and safety benefits. For example, the Society of Plastics Industries, Inc. felt that there was a ''serious question as to what improvements to workplace safety and health can reasonably be expected'' (Document ID #0392), and the U.S. Chamber of Commerce was concerned that OSHA ''overestimated the utility and benefits of this proposed revision to the HCS'' (Document ID #0397). However, even this commenter suggested the rule '' ''* * * will promote consistency in the identification, classification, and labeling of chemicals, improve workplace safety, and facilitate business growth and international trade.'' (Document ID #0392). The Agency feels that the record supports that these revisions to the HCS will reduce confusion and lead to better hazard communication, which will translate into fewer accidents, illness, injuries, and fatalities. OSHA's estimate that these revisions will provide one percent of the benefits attributed to the original HCS rulemaking represents a very small and easily realized improvement of workplace safety and health. The Agency did not receive additional comments on what level of benefits commenters believed would be more reasonable or accurate and therefore OSHA has retained the estimated health and safety benefits as part of the FEA. OSHA is confident that its initial estimates of the reductions in injuries, illnesses, and fatalities is a minimal estimate given the general agreement by almost all parties that the rule will have safety and health benefits.

OSHA prepared a sensitivity analysis to test the effect of variations in its estimates and found that, even if the estimated health and safety benefits were overstated by a factor of 2 (or even if the health and safety benefits were omitted altogether—see Table VI–1), the benefits would still exceed the costs of the final rule. Those results can be seen in Section VI.L: Sensitivity Analysis in this preamble.

Using the 1 percent estimate, OSHA anticipates that once all requirements take effect for the final rule, they would result in the prevention of an additional 318 non-lost-workday injuries and illnesses, 203 lost-workday injuries and illnesses, 64 chronic illnesses, and 43 fatalities annually. The monetized value of these health and safety benefits is an estimated $367 million annually in 2010 dollars.

[12] *http://data.bls.gov/cgi-bin/cpicalc.pl.* The BLS inflation calculator was used on January 18, 2011.

[13] Using OSHA's current willingness-to-pay estimates of $8.7 million per life saved and $62,000 per injury avoided, those benefits are equivalent to about $38.7 billion worth of benefits in 2010 dollars. OSHA decided to use the lower benefits estimate in the text ($36.7 billion), which is consistent with the estimation procedure used for the proposed rule.

[14] OSHA believes that a reasonable range for the magnitude of the health and safety benefits resulting from the proposed revisions would be between 0.5 percent and 5 percent of the benefits associated with the current HCS. These ranges are considered in the sensitivity analysis presented in Section VI.L of this preamble.

In order to obtain a sense of how realistic these estimated safety and health benefits are in light of the current level of occupational injuries, illnesses, and fatalities that are chemically related, OSHA reviewed relevant BLS data for the periods 1992–2007. OSHA's examination of these data shows a 42 percent decline in chemically related acute injuries and illnesses over the period, but both remain significant problems—55,400 chemically related illnesses and 125 chemically related fatalities in 2007. However these readily measurable reported acute illnesses and fatalities are dwarfed by chronic illnesses and fatalities. For chronic illness fatalities, there is little information available, and certainly no annual time-series data. The most recent estimate is that there were 46,900 to 73,700 fatalities due to occupational illnesses in 1992 (Document ID #0274). OSHA believes these more recent data from 1992–2007 suggest that the HCS has had a desirable effect on chemically related illnesses and injuries, but there remains a very significant role for further and better hazard information, as would be provided by aligning the current HCS with the GHS.

The annual health and safety benefits associated with the revisions to the OSHA HCS are estimated to begin after full implementation of the changes and associated employee training. The phase-in period for the main provisions of the final rule is approximately four years from the date of publication. Thus, in order to calculate the estimated annualized health and safety benefits over a twenty-year period associated with this rule in a manner that would be comparable to the corresponding annualized costs, the delay in the realization of the benefits was incorporated into the calculation. Using a discount rate of 7 percent, the estimated annual benefits of $367 million, beginning four years after the effective date of the final rule, were multiplied by 0.6803 to calculate the annualized benefits over a twenty-year period beginning with the effective date of the final rule.[15] Thus, the annualized monetized benefits associated with the reduction in safety and health risks attributable to the revisions to the HCS are an estimated $250 million.

[15] The formula for annualizing the benefits is equal to: $[(1.07)^{-4}] * [(1—(1.07)^{-16})/0.07] * [0.07/(1—(1.07)^{-20})]$,where the first term in brackets reflects the four year delay until annual benefits are realized; the second term in brackets reflects the present value of sixteen years of annual benefits (from years 5 through 20), and the third term in brackets annualizes the present value of benefits over a 20-year period.

Other substantial benefits, in addition to the improved occupational safety and health of affected employees, are also expected to result from this rulemaking, as discussed in the following paragraphs.

The harmonization of hazard classifications, safety data sheet formats, and warning labels for affected chemicals and products would yield substantial savings to the businesses involved in these activities. Fewer different SDSs would have to be produced for affected chemicals, and many SDSs would be able to be produced at lower cost due to harmonization and standardization. The record supports these savings with comment from Stericycle, Inc. stating that they anticipate that ''less time will be spent in reviewing new chemicals due to the changed format and better characterizations of the hazard'' (Document ID #0338), from the Ecological and Toxicological Association of Dyes and Organic Pigments Manufacturers (ETAD), which felt that these revisions to the HCS would ''ultimately increase efficiency and reduce time needed to prepare labels and SDSs'' (Document ID #0374), and from ORC Worldwide, which said that the ''use of one harmonized classification system is expected to significantly reduce the time needed to classify global products'' (Document ID #0123). The American Chemistry Council reported that they would ''expect a positive economic and time impact on developing and reviewing SDSs'' (Document ID #0393) as a result of these revisions to the HCS. Troy Corporation reported that they believed that ''providing harmonized SDSs will reduce development and maintenance time'' (Document ID #0352) and that there ''will be tangible savings when materials only have to be classified once instead of multiple times'' (Document ID #0128). Two commenters suggested that harmonization could lead to a 50 percent time savings in classification (Document ID #0313 and 0327). The benefits represented by these cost reductions would primarily affect businesses involved in chemical manufacturing.

In addition, reductions in operating costs are also expected as a result of the promulgation of the revisions to the HCS for many businesses that purchase or use hazardous chemicals. The current non-uniformity of SDSs and labels received by establishments in many industries requires employees and managers to spend additional time on a daily basis to ascertain the appropriate way to handle and store the hazardous chemicals in their workplaces. Under the revised standard, the presence of uniform and consistent information would help employers and employees to make decisions more efficiently and save substantial time. There is ample evidence in the record that stakeholders anticipate that the revisions to the HCS will improve the quality of the SDSs and labels and that the standardization of the SDS and label elements will increase the consistency of the hazard information and better communicate the hazards to users (*See* Document ID #0313, 0327, 0329, 0334, 0335, 0336, 0339, 0341, 0344, 0347, 0351, 0352, 0354, 0357, 0363, 0365, 0370, 0372, 0374, 0377, 0379, 0382, 0386, 0389, 0390, 0399, 0404, 0405, 0408, 0409, 0410, and 0414). Stakeholders reported that they expected that simplification and reduction in ''the number of documents that we manage * * * will reduce expenses'' (Document ID #0018), and Tom Duffy testified on behalf of the United Steelworkers of America at the Pittsburgh, PA, public hearing that a uniform system for SDSs would result in time savings (Document ID #0499 Tr. 171–72). These sentiments were echoed by Gary Valasek, who represented the Intercontinental Chemical Corporation (Document ID #0499 Tr. 63–64), the National Association of Chemical Distributors, which stated that standardized SDSs and labels would ''create a more efficient process for chemical distributors'' (Document ID #0341), and Wacker Chemical Company, which reported ''that uniformity in SDS and labels will help employees and customers * * * find needed information'' (Document ID #0335). The International Brotherhood of Teamsters reported that the ''standardized, specific approach to labels and SDSs with a set format, content, and order will help with consistency and comprehensibility, and improve the SDSs ability to communicate hazard info to workers'' (Document ID #0357). The American Industrial Hygiene Association felt that ''standardized label elements will make hazard identification easier'' (Document ID #0365). The American Petroleum Institute commented that the revisions to the HCS would ''improve downstream hazard assessments'' (Document ID #0376). OSHA solicited comment on its estimated monetized benefits in the PEA arising from increased efficiency in handling hazardous materials. While a few stakeholders questioned OSHA's benefits estimates, they did not offer an alternative methodology for estimating potential time savings; nor did they offer quantitative alternatives for OSHA

to evaluate. As demonstrated throughout this preamble, stakeholders were largely supportive of OSHA's estimates.

For the benefits estimated in the PEA, PP&E worked closely with stakeholders, conducting multiple interviews and extensive research on the processes that companies use to classify chemical hazards, to develop SDSs and labels, and to handle, store, and use hazardous chemicals. Based on interviews with hazardous materials professionals in more than a dozen affected establishments, PP&E evaluated how these processes would be affected by the proposed revisions to the HCS and analyzed the potential savings that could reasonably be expected as a result of adopting these revisions.

For the PEA, OSHA used the PP&E 2009 report (Document ID #0273) to develop estimates of the cost reductions that the affected companies would expect to obtain as a result of the revisions to the OSHA HCS.[16] Among the various benefits expected to be realized as a result of the implementation of the revisions, as described in this section, OSHA quantified two general categories of cost savings in the PEA and has maintained the methodology employed to create those estimates [17] but used the most recent available economic data in arriving at the estimates of costs presented in this final analysis.

In the PEA (74 FR 50280, 50322, Sept. 30, 2009), OSHA estimated the number of hours that each industry would save by improving the efficiency and productivity of personnel who use SDSs in performing their job functions. OSHA estimated that the amount of time spent during affected activities in the manufacturing sector could be reduced by 3 percent for health and safety supervisors and by 15 percent for logistics personnel specializing in handling hazardous chemicals.[18] The Agency updated the number of health and safety supervisors and logistics personnel for this FEA to reflect the most recent data and estimated that the time reductions for handling hazardous chemicals, and the associated cost savings, would apply to about 7,000 health and safety supervisors and 49,000 logistics personnel in the manufacturing sector and would yield annualized benefits of approximately $475 million.[19] Similar potential time and cost savings as a result of the revisions to the OSHA HCS were not quantified for the non-manufacturing sectors.

As part of the PEA (*Id.* at 50322–23), OSHA also estimated that, for the manufacturing sectors, the costs associated with the creation and revision of SDSs in future years would be reduced as a result of the revisions to the HCS. The methodology for creating this estimate has been retained for the FEA but new economic data were incorporated where available. The creation and revision of individual SDSs will be less burdensome, and, in addition, fewer different versions of SDSs would need to be produced for affected chemicals and products. OSHA estimated that, depending on firm size, the combination of these two effects would result in annual savings equivalent to between 2.5 and 4 hours of a professional's time per existing SDS and a total annualized savings of $32 million.[20]

Combining the improved productivity of personnel who use SDSs and the improved efficiency of those who revise SDSs and labels, OSHA concluded that the annualized productivity savings for companies would be an estimated $507 million.

Another area in which the final rule is likely to provide cost savings to industry is in the provision of hazard communication training to new employees after the transition period. Both the current HCS and the revised HCS require employers to provide training on the safe handling of chemicals, on understanding SDSs and labels, and on being familiar with other information crucial to worker safety. Employers are permitted to offer training for categories of hazards (such as flammability or carcinogenicity) rather than training individually on each chemical. The primary sources of information for this training are the SDSs supplied by manufacturers, and the primary method for employees to determine the hazard associated with a specific chemical they are using is through the manufacturer's HCS-compliant label.

Under the revised HCS, SDSs and labels produced in the United States will all be formatted in the same way. As more countries and regions adopt the GHS, fewer variations of SDSs and labels will be seen in the workplace. Information will be located in the same place on every SDS and label an employee will encounter. Employers will no longer have to train on as many SDS formats; nor will they need to devote as many resources to gather information on work practices, PPE, etc. SDSs and labels will be required to provide complete hazard information, and the language that the hazard information is presented in will be uniform across labels and section 2 of the SDSs. The inclusion of the pictograms and standardized hazard statement removes or, at least reduces, training time spent on interpreting various—and in some cases ambiguous—hazard warnings that current SDSs and labels may bear. The standardized labels and elements based on the detailed criteria for each hazard also greatly simplify training by facilitating training on ''categories of hazard'' rather than having to cover every chemical individually where the hazard determination is based on broad definitions. All of these changes can be expected to reduce the costs of training employees to recognize chemical hazards in the workplace.

The rulemaking record included numerous descriptions of the difficulties for both employees and

[16] The full final report from PP&E detailing the extensive process by which these estimates were derived is available on the rulemaking docket. See Document ID #0550.

[17] There is no indication that two years would have been sufficient time to affect the processes involved with handling hazardous chemicals, and therefore OSHA did not feel it necessary to re-estimate the savings parameters established through PP&E's research.

[18] For example, as described by PP&E (2009, Document ID #0273), the job of a logistics person, depending on the company, consists of the following tasks: (1) Receive hazardous chemicals; (2) gather the associated SDSs—either those that are attached to the shipment or those that are attached to the invoice; (3) extract the relevant information from the SDSs and enter it in the plant's SDS management system; (4) insert paper copies of the SDSs into the (hard copy) SDS management folder; (5) if the information is not available (particularly in the older 9-section SDSs), then look for 12-section SDSs prepared by some other manufacturer; (6) prepare in-plant labels; (7) determine special storage and use requirements, make appropriate arrangements for short-term and long-term storage, and distribute information to different process lines or field offices; (9) participate in the training of line supervisors and production workers; (10) train new employees; and (11) carry out other logistics duties at the plant. The GHS standard, by making the structure and content of SDS uniform, would help to reduce the time it takes to perform each of the above tasks.

[19] These estimates assume 2,000 hours of work a year for 7,070 health and safety supervisors and 49,486 logistics personnel specializing in handling hazardous chemicals in the manufacturing sector; an hourly wage of $66.01 and $45.17, respectively; and a time savings of 3 percent and 15 percent, respectively, for health and safety supervisors and logistics personnel. The resulting annual savings of $699 million was multiplied by 0.6803 to annualize the savings over a twenty-year period with savings not accruing until four years after the effective date of the revisions (Document ID #0273).

[20] These estimates assume ⅓ of the estimated 1,414,636 SDSs are reviewed each year; savings per SDS is between 2 ½ and 4 hours, depending on firm size (with an average per SDS of about 3.2 hours); personnel reviewing the SDSs receive an hourly wage of $66; and existing compliance rates are between 1 percent and 75 percent, depending on firm size (with an average per SDS of about 53 percent). The resulting annual savings of $47 million was multiplied by 0.6803 to annualize the savings over a twenty-year period with savings not accruing until four years after the effective date of the revisions.

employers associated with training under the current HCS (see Document ID #0307, 0499 Tr. 92–3, 0499 Tr. 167–8, 0499 Tr. 175, 0527) and supported the idea that training would be easier—and therefore cheaper—under the revised HCS (see Document ID #0123, 0338, 0408, 0414, 0494 Tr. 74–5, 0495 Tr. 308–9, 0497 Tr. 95–6, 0499 Tr. 93, 0499 Tr. 96, 0499 Tr. 190–91). Nevertheless, given that the annualized benefits of the final rule already significantly exceed the costs, OSHA did not feel it was necessary to try to develop, from the limited data available, a quantified estimate of the monetized savings resulting from simplified training.[21]

An additional benefit of the adoption of GHS is that it would facilitate international trade, increasing competition, increasing export opportunities for U.S. businesses, reducing costs for imported products, and generally expanding the selection of chemicals and products available to U.S. businesses and consumers. The Society for Chemical Manufacturers and Affiliates, for example, stated in their comment that while ''SOCMA member companies do not foresee significant savings from the change * * * for companies that do business globally there will be'' (Document ID #0402). While OSHA did not take quantitative benefits for these savings, the Agency believes that firms that operate globally may realize a cost savings as a result of the adoption of the GHS (Document ID #0336, 0339, 0361, and 0405). As a result of the direct savings resulting from the harmonization and the associated increase in international competition, prices for the affected chemicals and products, and the corresponding goods and services using them, should decline, although perhaps only by a small amount.

Finally, the GHS modifications to the OSHA HCS would meet the international goals for adoption and implementation of the GHS that have been supported by the U.S. government. Implementing GHS in U.S. federal laws and policies through appropriate legislative and regulatory action was anticipated by the U.S. support of international mandates regarding the GHS in the Intergovernmental Forum on Chemical Safety, the World Summit on Sustainable Development, and the United Nations. It is also consistent with the established goals of the Strategic Approach to International Chemical Management that the U.S. helped to craft.

A number of commenters suggested that the benefits OSHA estimated will result from this rule were incorrect or overstated. The National Association of Homebuilders expressed a belief that OSHA's ''assumption that the proposed revisions to the HCS [would] result in cost reductions * * * due to productivity gains is false'' (Document ID #0372), while the American Composites Manufacturers Association voiced concern that the benefits OSHA had estimated were speculative (Document ID #0407). Southern Company submitted that ''the benefits of adopting the GHS are minimal at best'' (Document ID #0378). Applied Safety and Ergonomics, Inc., urged OSHA to adopt a more conservative view of the expected benefits as they asserted that ''it is possible that many of the implied or expected benefits of the proposed changes to the HCS may not materialize'' (Document ID #0396). OSHA takes these comments seriously and evaluated all concerns raised by stakeholders on the estimated benefits of this standard. Unfortunately, most commenters did not include adequate detail or data that would allow the Agency to evaluate alternative benefits estimates. While future benefits (or costs) cannot be estimated with scientific precision, OSHA believes that the estimated benefits associated with this standard are based on sound data and that the resulting estimates are reasonable and have largely been supported by testimony and comment from stakeholders. It should be noted that many commenters who raised questions or concerns over OSHA's benefits estimates still largely supported the overall aim of the rulemaking and wished to see OSHA proceed with promulgation. The Agency addresses the inherent uncertainty in the economic analysis in Section VI.L Sensitivity Analysis in this preamble. In that section, various parameters are adjusted to evaluate the impact on the overall cost and benefits of the rule, and OSHA finds that even if estimated benefits were grossly overstated, this standard's benefits would still exceed costs.

E. Technological Feasibility

In accordance with the OSH Act, OSHA is required to demonstrate that occupational safety and health standards promulgated by the Agency are technologically feasible. OSHA has reviewed the requirements that would be imposed by the rule, and has assessed their technological feasibility. As a result of this review, OSHA has determined that compliance with the requirements of the rule is technologically feasible for all affected industries.

The revisions to OSHA's HCS would require employers that produce chemicals to reclassify chemicals in accordance with the new classification criteria and revise safety data sheets and labels associated with hazardous chemicals. Compliance with these requirements is not expected to involve any technological obstacles. A comment in the record indicated that ''[s]ome of the work [* * *] has already been done in order to comply with GHS implementation in Asian countries'' (Document ID #0405; see also Document ID #0352, 0377, and 0410). In addition to stakeholder comments, a January 4, 2011 press release from the European Chemicals Agency (ECHA) announced that the ECHA had received 3,114,835 notifications of 24,529 substances for the Classification and Labelling Inventory. Industry was required to notify the classification and labeling of all chemical substances that are hazardous or subject to registration under the Registration, Evaluation and Authorization of Chemicals (REACH) regulation and placed on the EU market in accordance with the GHS criteria. NIOSH is also currently working to update its International Chemical Safety Cards and Pocket Guide to incorporate the GHS classifications, which will further reduce the technological burdens of reclassification borne by manufacturers. (For a more detailed discussion of the EU implementation of the GHS and NIOSH's classification work, *see* Section XIII. Summary and Explanation of the Final Rule in this preamble.) This evidence lends support to OSHA's assertion that the requirements of the revisions to the HCS will not prove technologically infeasible. The rule would also require employers whose workplaces involve potential exposure to hazardous chemicals to train employees on the relevant aspects of the revised approach to hazard communication. Affected employees would need additional training to explain the new labels and safety data sheets. Compliance with these requirements is not expected to involve any technological obstacles.

The revisions to the HCS will require establishments that package or label hazardous chemicals to affix labels that include hazard warning pictograms enclosed in a red bordered diamond. While some establishments may not currently be printing labels in colors other than black and white, color printing technology is widely available

[21] However, in the sensitivity analysis presented in Section VI.L of this preamble, OSHA develops an estimate of monetized cost savings from simplified hazard communication training based on one commenter's estimate of the percentage reduction in training time resulting from the final rule.

and printing labels with a red bordered diamond or purchasing preprinted labels with a red bordered diamond is not expected to involve any technological obstacles. Research conducted by ERG (2010) under contract for OSHA found that printer technology is rapidly evolving—resulting in lower costs for printers and printing supplies and making better technology available to a wider range of buyers. Combined with currently available printing technology, this clearly demonstrates that printing product labels in color is technologically feasible.

Compliance with all of the requirements of the rule can be achieved with readily and widely available technologies. Businesses in the affected industries have long been required to be in compliance with the existing HCS, which includes similar requirements. The revised HCS would simply require modifying the labels and SDSs for hazardous chemicals, adding some training to ensure employees are familiar with these changes, and upgrading printing technology with widely available color printers or purchasing preprinted color labels. No new technologies are required for compliance with the modifications to the HCS. OSHA is aware that many U.S. businesses in the affected industries have already begun implementing many of the requirements of the GHS in order to meet the new foreign requirements for exported products. Therefore, OSHA believes that there are no technological constraints associated with compliance with any of the requirements of the revisions to the HCS.

F. Costs of Compliance

Introduction

This section presents the estimated costs of compliance for the revisions to the OSHA HCS. The estimated costs of compliance represent the additional costs necessary for employers to achieve full compliance with the new requirements of the final rule. They do not include costs associated with firms whose current practices are already in compliance with the new requirements.

The costs of compliance with the revisions to the HCS consist of four main categories: (1) The cost of reclassification and revision of SDSs and labels, (2) the cost of management familiarization and other management costs associated with the administration of hazard communication programs, (3) the cost of training employees, and (4) the cost of printing labels for hazardous chemicals in color. The first three categories are considered to be one-time transitional costs and were included in the PEA in support of the proposed rule. The fourth category is new and was developed in response to comments on the proposed rule. It includes both one-time transitional costs and costs that recur throughout the life of the rule.

The estimated compliance costs are based on a determination made by the Agency that the revisions would not significantly change the number of chemicals or products for which an SDS will be required. This also means that there will be no change in the number of establishments that are required to implement a hazard communication program. OSHA received no comments as part of the rulemaking record for this standard challenging this determination.

Other than the direct costs of reclassification and relabeling, the estimated compliance costs do not include any further costs or impacts that may result from the reclassification or relabeling of chemicals and products already subject to the HCS, such as possible changes in production or demand for products. Theoretically, such impacts, if any, with regard to possible changes in the uses and applications of affected chemicals, could be positive as well as negative. OSHA has determined that such effects, if any, will not be significant, and received no comment from stakeholders disputing this determination.

In addition to the revisions to the HCS, the rulemaking also includes related revisions to other OSHA standards. The revisions to the other standards generally ensure that all OSHA requirements related to hazard communication remain consistent with each other and become consistent with the revised HCS. OSHA has determined that the revisions to the other standards would not impose significant costs beyond those reflected in the compliance cost estimates for this rulemaking.

In order to have compliance costs presented on a consistent and comparable basis across various regulatory activities, the costs of compliance for this rule are expressed in annualized terms. Annualized costs represent the more appropriate measure for assessing the longer-term potential impacts of the rulemaking and for purposes of comparing compliance costs and cost-effectiveness across diverse regulations with a consistent metric. In addition, annualized costs are often used for accounting purposes to assess the cumulative costs of regulations on the economy or specific parts of the economy across different regulatory programs or across years. Annualized costs also permit costs and benefits to be presented in a comparable manner.

A seven percent discount rate was applied to costs incurred in future years to calculate the present value of these costs for the base year in which the standard becomes effective, and the same discount rate was then applied to the total present value costs, over a 20-year period, to calculate the annualized cost.[22]

Table VI–4 shows the estimated annualized compliance cost by cost category and by industry sector. All costs are reported in 2010 dollars. As shown in Table VI–4, the total annualized cost of compliance with the rulemaking is estimated to be about $201 million. Of this amount, the annualized cost of chemical hazard reclassification and revision of SDSs and labels is an estimated $22.5 million, the annualized cost of training employees is an estimated $95.4 million, the annualized cost of management familiarization and other management costs is an estimated $59.0 million, and the additional annualized label printing costs, incurred to comply with the requirement of a black pictogram surrounded by a red-bordered diamond, is an estimated $24.1 million.

As shown at the bottom of Table VI–4, most of the compliance cost associated with chemical hazard reclassification and revision of SDSs and labels would be borne by the chemical manufacturing industry (shown as the total for industries that produce SDSs and labels). Table VI–4 also shows that compliance costs are spread across all industries in the U.S. economy subject to OSHA jurisdiction, reflecting the fact that employee exposures to hazardous chemicals occur in almost every industry sector.

Other than the costs of printing labels in color, OSHA expects that all compliance costs would be incurred over a period of four years, as the rule would incorporate a four-year transition

[22] OSHA annualized costs for this rule over a 20-year period in accordance with Executive Order 13563, which directs agencies ''to use the best available techniques to quantify anticipated present and future benefits and costs as accurately as possible.'' In addition, OMB Circular A–4 states that analysis should include all future costs and benefits using a ''rule of reason'' to consider for how long it can reasonably predict the future and limit its analysis to this time period. Annualization should not be confused with depreciation or amortization for tax purposes. Annualization spreads costs out evenly over the time period (similar to the payments on a mortgage) to facilitate comparison of costs and benefits across different years. In this analysis, OSHA estimated a lifetime for hardware purchases (5 years for printers, for instance) which is unrelated to the annualization period. OSHA felt that an annualization period much shorter than 20 years (say, 10 years) would have been inappropriate for this rule because of the lagged phase-in of provisions (some of which will not take effect until five years after the final rule is published).

period into the compliance schedule for the standard. Specifically, for purposes of estimating the annualized compliance costs, OSHA assumed that the compliance costs associated with employee training and management familiarization would be incurred in the two-year period following the effective date of the final standard, and that other one-time compliance costs would be incurred in the four-year period following the effective date of the final standard. Initial printer costs to facilitate color printing would also be incurred during the four-year period following the effective date of the final standard, but all other color-printing costs would occur subsequent to the four-year transition period on a recurring annual basis.

BILLING CODE 4510–26–P

Table VI-4.
Annualized Costs of Compliance

NAICS Code	Industry	Cost of Reclassification and Revision of SDSs and Labels	Management Familiarization and Other Costs	Cost of Training Employees	Additional Label Printing Costs	Total Annualized Costs
11	**Agriculture, Forestry, Fishing & Hunting**					
113	Forestry & Logging	$0	$93,551	$65,009	$0	$158,560
114	Fishing, Hunting and Trappinig	$0	$8,438	$6,320	$0	$14,758

Note: Costs are expressed in 2010 dollars

Source: Office of Regulatory Analysis, OSHA based on PP&E (2009) and ERG (2012)

In the appendix to this cost section, Table VI–8 shows, by industry and by cost element, total non-annualized (non-discounted) compliance costs of about $2.1 billion estimated to be incurred during the four-year phase-in of the revisions to the HCS.

OSHA received numerous comments on additional costs that had not been considered as part of the PEA. OSHA has carefully evaluated those comments on costs and prepared the following responses.

Stakeholders were concerned about the costs associated with relabeling current inventory. Procter & Gamble reported that they felt ''the largest economic impact of GHS compliance to our business will be in the area of re-labeling'' (Document ID #0381) and numerous other commenters echoed those concerns (Document ID #0386, 0392, 0393, 0400, and 0402). OSHA anticipates that the four-year phase-in for the revisions to the OSHA HCS (increased from three years in the proposed rule) will provide adequate time for companies to deplete inventory and replace in-house containers that are labeled in accordance with the original OSHA HCS and therefore will mitigate any costs associated with relabeling in-house containers or products in inventory.

The Society of Chemical Manufacturers and Affiliates was concerned that OSHA had not considered the costs associated with mailing revised labels, stating that ''a large portion of label revisions will go via the mail service. If a chemical manufacturer produces 75 chemicals and has 50 customers at 70 cents a mailing, it could cost the company as much as $2625.00'' (Document ID #0402). The revisions to the HCS do not require that establishments mail revised labels to customers. Manufacturers are only required to provide products labeled in accordance with the GHS criteria by the effective date. OSHA did consider the costs associated with mailing updated SDSs and determined that manufacturers are currently providing updated paper or electronic SDSs to customers as they are revised and would not incur additional costs associated with this standard.

Some comments felt that OSHA had overlooked the time and costs associated with relabeling in-house containers with GHS compliant labels (Document ID #0378 and 0386). The phase-in period for the revisions to the HCS provides adequate time for firms to deplete products in inventory that are not labeled with GHS-compliant labels and to replace workplace containers or signs/permanent labels (such as regulated area signs) in the course of the normal cycle for wear-and-tear replacement. OSHA believes that any costs incurred that are outside the costs that would normally be incurred to replace in-house containers would be negligible and has not estimated a cost for this activity.

Some stakeholders anticipated costs associated with translating labels and SDSs into Spanish (Document ID #0381 and 0393). While some companies may find it necessary, based on customer demand, to provide products with labels and SDSs printed in Spanish, the revisions to the OSHA HCS do not contain any requirement for translating labels or SDSs into Spanish. OSHA has not taken costs related to translating labels and SDSs as part of this FEA.

OSHA received comment that firms will incur costs associated with managing multiple SDSs during the transition period. For example, the Society of Plastics Industry, Inc., reported that ''multiple suppliers of the same chemical [may] switch over to the GHS on different schedules'' and that ''additional time will be required for personnel to sort out and implement appropriate measures for managing this situation'' (Document ID #0392, 0402, 0415, and 0452). OSHA appreciates that there may be some time during the transition period where some SDSs are GHS-compliant while others are not. However, given the non-uniformity of SDSs currently circulating to firms, the Agency feels that users will already have a system in place for managing multiple SDSs for identical products and that no additional costs will be incurred as a result of the transition to new SDSs.

The U.S. Chamber of Commerce expressed concern that ''employers will also incur legal costs for counsel to review and analyze the revised SDSs to make sure the SDSs provide appropriate explanations and protection from liability'' (Document ID #0397). However, the final rule primarily changes the format of SDSs, and generally does not make substantial changes to the categories of information that must be included in the SDS. OSHA does not see why a new legal review to protect against tort liability would be necessary in such circumstances. In addition, the Agency believes that such legal costs would be relatively rare and not representative of the vast majority of employers. Furthermore, such legal costs as occur may simply be an alternative to other in-house professional review services that OSHA has already included in the costs. Finally, employers incurring such legal costs for SDS review arguably have been regularly incurring these costs under the existing HCS as part of periodic SDS changes; in that case, they are costs not attributable to this final rule.

The Society of Chemical Manufacturers and Affiliates felt that costs would be incurred because ''someone will have to inventory all of the MSDSs, make the required changes and then communicate those changes to customers and other affected personnel'' (Document ID #0402). The revisions to the OSHA HCS do not require manufacturers to provide new SDSs to customers who have purchased a product and received an SDS in the past. This final rule also includes a four-year phase-in period for firms to update their SDSs and requires only that those updated, GHS-compliant SDSs be provided to users who purchase a company's product after the effective date. OSHA realizes that some firms may choose to provide updated SDSs to past purchasers of their products, but the updates to the OSHA HCS do not require that they do so. Subsequently, OSHA has not taken any costs related to this activity.

Ferro Corporation's comment in the rulemaking record expressed concern that OSHA did not take into account conversion costs for ''MSDSs and labels for experimental products that are being resampled'' (Document ID #0363). OSHA's analysis does not make a distinction between commercial and experimental products, but it does not exclude costs associated with experimental products. The Agency feels that this economic analysis captures those costs as well as the transitional costs for products that are sold commercially.

The Society of Plastics Industry, Inc. expressed concern that the revisions to the OSHA HCS would require employers ''to perform new personal protective equipment (PPE) hazard assessments, select new PPE or select PPE for workers who did not previously use it'' or ''to add or modify ventilation systems or to have their employees use respiratory protection to address newly discovered hazards, and to implement respiratory protection programs'' (Document ID #0392). The scope of hazards covered by the GHS is very similar to what is covered by the current HCS as discussed in Section XIII Summary and Explanation. While the revisions to the OSHA HCS could, theoretically, result in some chemicals that were not considered hazardous being classified as such now, OSHA does not expect any significant change in chemicals covered under this final rule and did not receive any specific examples from stakeholders, despite

repeated requests for them. For this reason, OSHA has concluded that there will be no additional costs related to PPE for this standard.

Multiple stakeholders questioned whether OSHA had taken into account the cost to update workplace signs to come into compliance with the revised OSHA HCS. Southern Company reported that the cost to purchase signs for their 29 affected plants would be $58,000 plus the cost of employee time to install the signs (Document ID #0378), and API reported that one of its member companies recently updated the signs at its small refinery at a cost of $200,000 (Document ID #0376). OSHA feels that the four-year phase-in time for these revisions to the HCS, combined with the limited number of affected workplace signs, will minimize any cost that firms may incur. The phase-in period will allow firms to update their signs during the normal replacement lifecycle of three to five years for those signs and will result in minimal costs.

Commenters felt that ''costs for re-classification and modification of SDS and labels would need to include substantial consulting fees'' (Document ID #0392). OSHA maintains that any firm preparing labels and SDSs under the current OSHA HCS will not find it significantly burdensome to prepare labels and SDSs under the revised HCS. On the contrary, OSHA expects that the revisions to the HCS would be able to prepare SDSs and labels at lower cost in the future (for which the Agency earlier, in Section VI.D: Benefits, estimated productivity savings). In addition, much reclassification work has already been done by firms that sell to the EU or to Asian markets.

Estimation of Compliance Costs

The remainder of this section explains how the compliance costs arising from the final rule were calculated by describing the data and methodology used to estimate each of the major cost elements. A more complete and detailed description of the estimation of compliance costs can be found in the revised final version of the PP&E 2009 report (Document ID #0273), the ERG (2010, 2011) reports focusing on the costs of printing labels in color, and the updated cost estimates for the final rule in ERG (2012).

The major elements of the revisions to the HCS that involve compliance costs include (1) the classification of chemicals in accordance with the GHS criteria, and the revisions to the safety data sheets and labels corresponding to the affected hazardous chemicals; (2) even though it is not directly a result of any specific requirement included in the revisions to the HCS, the cost for managers and administrators of hazard communication programs to become familiar with the revisions to the standard and to manage, update, and revise their programs as may be necessary to ensure compliance with the revised standard; (3) incremental training for employees already trained under the existing OSHA hazard communication programs to ensure their familiarization with the new formats, information, and symbols that would be introduced into the workplace as a result of the revisions to the HCS; and (4) costs to upgrade label printing technology or purchase labels preprinted in multiple colors in order to comply with the requirement that the pictogram on the label be enclosed in a red-bordered diamond.

The estimated compliance costs presented in this analysis of the revisions to the HCS are largely based on research conducted by PP&E (2009), which was expanded and updated for the FEA by ERG (2010, 2011, and 2012). Both PP&E and ERG performed this research under contract to the Department of Labor specifically for the purpose of developing estimates of compliance costs for, and assessing the potential impacts that may be associated with, revisions to the OSHA HCS in order to implement the GHS.

The estimated costs of compliance with many of the provisions of the final rule involve wages paid for the labor hours required to fulfill the requirements. In some cases, compliance could be achieved by purchasing services or products in lieu of paying employees directly. The estimated compliance costs are intended to capture the resources required for compliance, regardless of how individual establishments may choose to achieve compliance.

Costs Associated With Chemical Classifications and Revisions to Safety Data Sheets and Labels

The revisions to the OSHA HCS continue to require firms that sell hazardous chemicals to employers to provide information about the associated hazards. Information is required to be presented in a safety data sheet (SDS) in the format specified in the revised standard, and some information is also required to be presented on product labels.

The existing OSHA HCS already requires information about hazardous chemicals to be provided in SDSs and on labels. In addition, under the existing standard, SDSs are to be revised within three months after a manufacturer or employer becomes aware of any significant new information about a chemical hazard.

The final rule requires chemicals to be classified into the appropriate hazard classes and categories based on the information about the chemicals that the manufacturers currently have. This information would have been assembled for purposes of conducting a hazard determination under the current HCS. In addition, the current HCS requires chemical manufacturers and importers to remain aware of developments regarding the hazards of the chemicals they produce or import in order to update the labels and SDSs for the chemicals in a timely manner. The classification of the chemicals into the hazard classes and categories under the revised provisions does not require any additional testing, studies, or research to be conducted. Manufacturers would be able to rely on the information they already have in determining how to properly classify their chemicals.

Generally, chemical manufacturers and importers periodically review, revise, and update SDSs and labels. Changes are made as necessary as information regarding specific hazards develops, new information about protective measures is ascertained, or changes are made to product information and marketing materials. Labels and SDSs must also be produced or modified when products are introduced or changed. Therefore, there is a regular cycle of change for these documents for a variety of reasons. The final rule may require more extensive change than would normally occur, but the phase-in period is such that the chemical manufacturers and importers can take advantage of the normal cycle of change to phase in the revisions for all their products over a reasonable time period. This should have less impact on normal operations than a short time period that would require all SDSs and labels to be revised at the same time.

The transition period that would be allowed by the delayed effective date for the requirement to adopt the new format should help ensure that the transition can be completed in conjunction with revisions and updates that would normally be expected to occur even without the implementation of the final rule. In addition, the format for SDSs required by the final rule is consistent with the format adopted by the American National Standards Institute (ANSI) and therefore has already been implemented by many of the affected businesses.

Based on ERG (2012), OSHA developed estimates of the costs that would be associated with the

classification of chemicals in accordance with the final rule and with the revisions to the corresponding SDSs and labels for those chemicals. The estimated compliance costs represent the incremental costs that would be incurred to achieve compliance with the final rule. These estimated costs would be in addition to the costs that would already be incurred to continue to remain in compliance with applicable requirements of the existing HCS.

The revisions to the HCS would allow for a transition period of four years following the publication of a final rule. During this period, even in the absence of any pertinent OSHA rulemaking, producers of affected chemicals would presumably be ensuring that the information provided in their SDSs and labels remains accurate and current. Producers of hazardous chemicals are generally expected to regularly review the available information regarding any hazards that may be associated with their products and to revise SDSs and labels accordingly.

In addition, for every affected product that is newly created, reformulated, mixed with new ingredients, modified with new or different types of additives, or has any changes made in the proportions of the ingredients used, the chemical producer would be required under existing OSHA and other applicable standards to review the available hazard information, to classify the chemical in accordance with applicable hazard criteria, and to develop corresponding SDSs and labels.

The estimated costs of compliance with the final rule do not include the costs associated with activities such as those described in the above paragraphs, but rather reflect only the additional costs that chemical producers would not already be expected to incur.

The estimated compliance costs associated with the reclassification of hazards and changes to SDSs and labels are directly related to the numbers of SDSs affected. Based on ERG (2012), OSHA developed estimates of the number of potentially affected SDSs by industry, for each of the industries producing the corresponding chemicals and products (as shown in Table VI–3). Downstream users, distributors, and wholesalers are generally expected to continue to rely on SDSs provided by manufacturers to fulfill their obligations under the OSHA standard, as has been the practice for decades.

The costs of compliance associated with the classification of chemicals in accordance with the criteria specified in the final rule and with the revisions to the corresponding SDSs and labels for those chemicals were based on PP&E industry interviews and, as described below, are based on the same time and software estimates as those presented in the proposed rule.

Generally, for smaller establishments with relatively few chemicals affected, OSHA estimated the incremental compliance costs to be the equivalent of the cost of seven hours of time of a professional with the requisite expertise for each affected chemical, on average. Based on ERG's (2012) updates to the PP&E 2009 report (Document ID #0273), OSHA estimated the cost of hourly compensation for a professional for this purpose to be $66. As a result, a small establishment (with fewer than 100 employees) with 20 SDSs for 20 chemicals, for example, would have estimated incremental compliance costs of $9,240 (7 hours times 20 SDSs times $66).

In larger establishments with more affected chemicals, the incremental compliance costs were estimated to consist of two parts. First, labor costs were estimated according to the size of the establishment. OSHA, based on PP&E interviews with stakeholders, estimated that entities with 100 to 499 employees would incur, on average, the equivalent of five hours of time of a professional with the requisite expertise for each affected chemical, and that entities with 500 or more employees would incur the equivalent of three hours of professional time per chemical. Again, OSHA estimated the hourly compensation for a professional for this purpose to be $66.

The rulemaking record presented a wide range of estimates for the time required to update SDSs with a low estimate of four hours per SDS (Document ID #0119 and 0123), a few estimates in the range of 25–30 hours per SDS (Document ID #0134 and 0402), and upper bound estimates as high as 150 hours per SDS (Document ID #0341). OSHA evaluated these estimates and felt that the upper estimates are not defensible for the following reasons: (1) Firms will not be required to gather or evaluate additional data; (2) firms currently must update their SDSs periodically, and there was no evidence presented in the record that suggested that updates under the current HCS take anywhere near 150 hours per SDS; and (3) the Agency does not feel that it is clear that these estimates account for only the incremental time needed to prepare an updated SDS, taking into account any time that would be spent updating SDSs during the transition period in the absence of any revisions to the OSHA HCS. The Agency acknowledges that some SDS updates may take longer than the average listed above, but also feels that many chemicals—especially pure substances which will likely already have been classified according to the GHS for the EU or Asian markets—will take less than the estimated time used in the economic analysis. Therefore, OSHA feels that the estimated time to update SDSs used in this analysis represents a reasonable average for most chemicals.

The labor cost per SDS was estimated to be lower for larger companies based on the determination that larger companies produce more SDSs, and would therefore experience efficiencies associated with producing them. These efficiencies include economies of scale, the use of software specifically designed to classify hazards and produce SDSs, and the generally lower cost per SDS associated with many mixtures.

In addition to labor costs, many of these larger establishments may incur additional expenditures to purchase or modify software that can be used to classify chemicals and to produce corresponding SDSs and labels. Such software is available from a variety of vendors; the software can be purchased or used on a subscription basis. Publicly available information about the products and services being offered and sold to businesses for purposes of complying with hazard communication requirements indicates that most of the relevant vendors are aware of and prepared for an upcoming alignment with the GHS. Therefore, their products and services are or will be adapted to enable compliance with the revisions to the HCS. In addition, some firms may purchase custom or proprietary software from private vendors to achieve compliance with existing requirements or future revisions to hazard communication requirements or for other purposes.

Regardless of the particular approach individual companies may choose to most efficiently fulfill their obligations under the existing HCS, OSHA expects that a part of the costs associated with achieving compliance with the final rule would involve costs attributable to software modifications. Based on industry data obtained by PP&E, OSHA apportioned these costs on a per-SDS basis and estimated the cost per SDS to be $208, on average. Numerous stakeholders raised the issue of software updates and modifications in their comments submitted to the rulemaking record (Document ID #0018, 0105, 0114, 0363, 0371, and 0389). In response to the ANPR, the American Chemistry Council reported that their members estimated anticipated software update and conversion costs of up to $70,000. The ACC also reported that their

members typically have hundreds, if not thousands, of SDSs (Document ID #0105). Using OSHA's per-SDS cost of $208, a firm that produced 336 SDSs (which would fall within the typical range for ACC members) could expect to incur costs of $70,000. This example suggests that OSHA's estimated cost-per-SDS is a reasonable one.

Based on ERG's (2012) updates to the PP&E 2009 report (Document ID #0273), OSHA estimated the numbers of SDSs produced in each industry that would potentially need to be revised under the final rule. As shown in Table VI–3, a total of about 1.4 million SDSs, one for each type of chemical produced by an individual manufacturer in the United States, were estimated to be in potential need of revision.

In developing estimates of the compliance costs associated with the rule, PP&E also considered the extent to which many firms have already performed the necessary reclassifications of chemical hazards and revisions to SDSs. Some chemical hazards have already been reclassified as would be required by the OSHA final rule because the U.S. Department of Transportation has required such classifications as part of their regulations for the transportation of hazardous chemicals (49 CFR Parts 171–180). The criteria for physical hazard classifications for purposes of transport have been internationally harmonized for some years, and these criteria formed the basis for the physical hazard criteria in the GHS. Therefore, many products intended for transport have already been classified under the new physical hazard criteria as well as the existing criteria in the HCS.

Many current SDSs are already produced to varying degrees in accordance with the requirements of the OSHA final rule because the widely followed ANSI industry consensus standard already reflects many of these requirements in its relevant criteria. In addition, many firms have implemented or are beginning to implement hazard reclassifications, SDS revisions, software modifications, and other changes in accordance with the requirements of the final rule, because these provisions are generally anticipated to be adopted as part of the implementation of the GHS in countries and regions around the world. Since some other countries are already implementing the GHS, companies in the U.S. that ship to those countries are already having to comply with the GHS for products being exported. Stakeholder comment in the docket suggested that some of the work related to reclassification has already been done (*e.g.,* Document ID #0352, 0377, 0405, and 0410), lending support to OSHA's baseline estimates of current compliance rates.

Research conducted by PP&E indicates that all of these factors contribute to a substantial degree of current compliance with the requirements of the final rule, even if the existing OSHA HCS standard remains unchanged.[23] Based on the ERG (2012) updates to the PP&E (2009) report (Document ID #0273), OSHA estimates that, on average, about 53 percent of the gross costs that would otherwise be associated with the revisions to the HCS have already been incurred by firms. However, this average is a result of very different levels of current compliance for different sizes of firms. PP&E estimated that the percentage of firms in current compliance with the final rule—with the exception of employee training—is 75 percent for firms with over 500 employees; 25 percent for firms with 100 to 500 employees; 5 percent for firms with 20 to 99 employees; and 1 percent for firms with fewer than 20 employees. OSHA used these percentages to reduce the number of affected firms reported in Table VI–3, for purposes of estimating the costs for affected firms to comply with the final rule (again, with the exception of employee training).

Based on the preceding analysis, OSHA estimates an annualized cost of approximately $22.5 million for the classification of chemicals in accordance with the criteria specified in the final rule and for revisions to the corresponding SDSs and labels for those chemicals.[24]

As discussed below, OSHA received some comments from the public regarding the estimated costs associated with chemical classifications and revisions to safety data sheets in response to the ANPR published by OSHA in the **Federal Register** on September 12, 2006 (71 FR 53617) and the Proposed Rulemaking published by OSHA in the **Federal Register** on September 30, 2009 (74 FR 50280). The comments received are publicly available as part of the rulemaking record, accessible through regulations.gov, in docket OSHA–H022K–2006–0062. Relevant information submitted by the public was incorporated into the development of the methodology and estimates presented in this economic analysis.

Some commenters provided examples of cost estimates that generally support the estimates of the preliminary economic analysis. Information from other commenters provided a wide range of cost estimates. The figures presented in some comments appeared to correspond to gross costs of creating SDSs, and in other cases it was not clear whether gross or incremental costs were being presented. In general, commenters did not provide the rationale underlying their cost estimates.

Comment from the Fragrance Materials Association of the United States (Document ID #0061) and the Flavor and Extract Manufacturers Association of the United States (Document ID #0062) stated that these Associations' best assessment is that it would take anywhere from two to eight hours to review information and prepare new labels and safety data sheets for each hazardous chemical

One company that produces and distributes about 4,000 different hazardous chemicals estimated that it will take four to six hours per product to prepare a GHS SDS. (Document ID #0026).

The National Paint and Coatings Association stated that it would take approximately five hours to research the information for a product SDS/label at a small company, at a cost of about $300 per product; it also estimated that, at a medium-sized company, this same task would take from 3–5 days to 3 weeks at a cost of approximately $1,000 to $1,800, and that at a larger company, the task would be even more expensive (Document ID #0050).

The National Association of Chemical Distributors estimated that converting an existing SDS to the new GHS format would require about 150 hours as

[23] By current compliance, OSHA means firms that have already reclassified chemicals and prepared SDSs and labels in accordance with GHS requirements specified in the final rule and would therefore be ready to introduce these modifications at negligible additional cost when GHS becomes effective.

[24] This annualized estimate of $22.5 million reflects software costs of $55 million and labor costs of $226 million, both multiplied by 0.079932 to annualize these costs (incurred over the first four years) over a 20-year period. The $55 million in software costs is the result of about 264,000 modified SDSs [(929,000 SDSs for large establishments × 25% not in existing compliance × 95% requiring modification) + (233,000 SDSs for establishments with 100–500 employees × 75% not in existing compliance × 25% requiring modification)] at a cost of $208 per SDS. The $226 million in labor cost is the result of about 666,000 affected SDSs multiplied by an average of 5.14 hours of professional time per SDS (from 3 to 7 hours per SDS) multiplied by $66 per hour. The annualization factor, 0.079932, is equal to:

$[(1/4) * [(1-(1.07)^{-4})/0.07] * [0.07/((1-(1.07)^{-20})]$,

where the first term in brackets reflects the fact that these costs are assumed to be spread equally over the first four years; the second term in brackets calculates the present value of the costs, and the third term in brackets annualizes the present value of the costs over a 20-year period.

compared to about 100 hours currently to revise an MSDS (Document ID #0060 and 0341).

Another commenter, Merck, which produces, imports, or distributes about 500 hazardous chemicals annually, estimated that, on average, it takes approximately 3 weeks to generate a single safety data sheet at an average cost of $1,500. Merck also stated that with a sufficient transition period of three to six years, the costs of moving to GHS would be minimal. Merck noted that the time and cost for additional changes to the GHS format should be minimal because it had already converted its SDSs to the 16-section ANSI/GHS format several years ago (Document ID #0072).

One trade association estimated that the costs associated with revising SDSs and labels for the 1,600 firms in the cleaning product formulator industry would total $575 million, not including the time needed to review changes to hazard classifications. The total numbers of SDSs per establishment are generally higher for the establishments represented by the trade association than the OSHA estimates for the industry category as a whole (Document ID #0032).

This trade association also provided some of the details underlying its cost estimates for individual companies. Cost estimates provided by the trade association for individual companies included costs per SDS as low as $30 and $80, and as high as $600 or more. One company (identified as Company #11) estimated the cost to revise the label and SDS would be $120 per product; another company (Company #2) estimated that this cost would be $2,600 per product. Some of the higher compliance cost estimates appear to be unrealistically high; for example, the estimated costs associated only with revising labels for company #3 appear to represent about 3 percent of total annual sales. While acknowledging that some firms may incur higher costs than others to revise SDSs and labels, these data generally appear to support that, at least for several firms in the industry, the costs minimally necessary to achieve compliance would be close to or less than the costs estimated by OSHA.

Ameren, an electric and gas services provider, estimated that all 9,000 of their employees would need one hour of training initially at a total cost of $450,000. The company estimated that it would take 100 hours to update their SDSs (fewer than 25) at a total cost of $6,500 and that updating the 25,000 SDSs in their database would take five minutes per SDS for a total cost of $102,700 (Document ID #0330).

The Independent Lubricant Manufacturers Association surveyed their members and reported that, with one SDS per product, their members could be expected to incur costs of $340,000 to $559,000 ($329 or $200 per SDS multiplied by 1700 SDSs per firm) to update SDSs. One member company estimated costs associated with update software at $200,000 in the first year and $1,000 per SDS in subsequent years to maintain the software and SDSs. Another company estimated that software would cost $50,000 and would include an additional $300,000 in staff time (Document ID #0371).

Another trade organization, The Society of Chemical Manufacturers and Affiliates, felt that it would take ten hours to revise a label or an SDS (Document ID #0402).

Several other commenters provided cost estimates related to the adoption of GHS requirements for chemical classifications and revisions to safety data sheets and labels. (*See,* for example, Document ID #0015, 0018, 0024, 0036, 0079, 0105, 0107, 0116, 0128, 0141, 0145, 0327, 0341, and 0377, among others.) Many estimates are broadly consistent with OSHA's estimates; in addition, some estimates appear to be similar to, but may actually be substantially lower than, OSHA's estimates to the extent they include costs attributable to the existing standard rather than just the incremental costs associated with the revisions to the HCS. Other estimates are substantially higher, but many of these also appear to represent gross costs associated with fulfilling hazard communication requirements without consideration of the incremental nature of the compliance costs for the revisions to the HCS, as discussed above.

Management Familiarization and Other Management-Related Costs

The implementation of GHS as part of the OSHA HCS would require that employees currently covered by the standard become familiar with the new system. The nature and extent of the familiarization required would vary depending on an employee's job and business. OSHA considered separately various training needs that may be imposed by the revisions.

Although it would not be explicitly required by the final rule, some establishments may choose to provide training to managers and other employees that are not directly covered by the training requirements of the HCS. Other management-related costs may include making revisions, if necessary, to existing hazard communication programs; promoting awareness of and providing information about the revisions to hazard communication programs; coordinating and integrating changes to hazard communication programs with other programs, processes, and functions; serving as an in-house resource for supporting the general adoption of the revised HCS; creating supplemental capacity for providing training and assistance to affected employees; and other ancillary costs for company-specific changes and general hazard communication program administration that may be incurred at some establishments.

These management costs could be considered discretionary since they are not explicitly required by the regulatory provisions. However, OSHA recognizes that these costs may be incurred in practice due to the manner in which some companies have implemented and integrated hazard communication programs in their facilities. These costs reflect the fact that hazard communications programs often are not implemented solely for purposes of complying with the OSHA standard, but may serve a variety of other purposes that are part of and that benefit the overall production process.

In some cases, health and safety supervisors, logistics personnel, and other personnel involved in administering, implementing, and ensuring compliance with the requirements of the HCS in affected establishments would be expected by company managers to become familiar with the revisions to the HCS. The responsibilities of these employees may include modifying written hazard communication programs as necessary, reviewing and preparing training materials, and training new and existing employees regarding the changes. A commenter asserted that OSHA had overlooked the cost to train the employees who would be providing training to production workers (Document ID #0392), and the American Chemistry Council also questioned whether OSHA had considered the necessary training for fire, EMS, or other emergency workers (Document ID #0393). The Agency has included these occupations in the cost estimates, allocating eight hours for training on the revised HCS elements, and included employees responsible for providing training as part of the management training and familiarization costs and has continued to include them in estimated the costs of the rule for this FEA.

In the PEA, OSHA estimated 8 hours of time, or an equivalent cost, would be associated with the necessary familiarization and implementation of

revisions to hazard communication programs in affected establishments in the manufacturing sector. Comments received on the topic of management familiarization yielded a wide range of time needed for this task. Some estimates were what OSHA considers to be unreasonably high (ranging from 16 to 56 hours (Document ID #0372)) and may not represent incremental costs only. OSHA did receive a comment that ''eight hours * * * [may be enough to gain] a basic understanding'' of the revisions to the OSHA HCS but went on to say that ''as much as a week * * * [may be needed to gain an] understanding of the details'' (Document ID #0392). OSHA believes that under the current HCS, managers spend some time each year reviewing and updating their hazard communication program. So, while a manager may spend more than 8 hours total reviewing and familiarizing themselves with the revised HCS, a portion of that time would not fall under new costs resulting from the promulgation of the rule. OSHA did not feel that commenters presented a strong case for changing the estimate of incremental time needed for familiarization with the revised HCS and has therefore maintained the estimate of 8 hours.

In many potentially affected establishments that do not produce SDSs, and that have few affected chemicals or few affected employees, a very basic hazard communication program may achieve compliance with the OSHA standard. For these establishments, outside of the manufacturing sector, that have a health and safety supervisor, the incremental management and administrative costs associated with the revisions to the OSHA standard were estimated to be two hours per establishment. For establishments outside of the manufacturing sector that do not have a health and safety supervisor, OSHA estimated that these costs would be negligible.

Based on the preceding analysis, OSHA estimates an annualized cost of approximately $59 million for management familiarization and other related management activities in response to GHS.[25]

Costs Associated With Training Employees

Production employees who are currently covered by and trained under the provisions of the existing HCS would need to receive some additional training to become familiar with the changes to SDSs and labels.

In many potentially affected establishments that do not produce SDSs, and that have few affected chemicals or few affected employees, a very basic hazard communication program may achieve compliance with the OSHA final rule. In these establishments, the incremental employee training costs associated with the revisions to the HCS may be relatively small. In other cases, employers may be able to integrate the necessary training into existing training programs and other methods of distributing safety and health information to employees, and thus may not incur much additional cost. Nevertheless, in general, employers will need to devote real time and resources to provide the necessary training in order to ensure that workers are familiar with the new hazard communication system.

In response to comments in the rulemaking record, the training time associated with the revisions to the OSHA HCS has been increased from those presented in the PEA. OSHA increased the estimated training time from 30 minutes to 60 minutes for most employees; from 15 minutes to 30 minutes for employees with minimal contact with hazardous chemicals; and from 5 to 10 minutes for employees in certain occupations in the transportation sector, where GHS pictograms are already in use. A complete occupation-by-occupation summary of OSHA's estimates is provided in the ERG (2012) revisions to the PP&E (2009) report.

The United Parcel Service, Inc. submitted comment supporting this increase, reporting that ''[i]nitial training takes about 15 minutes currently but will [* * *] double during the phase-in process'' and that ''training time (½ hr) will double to one hour [* * *] for employees who are 'users' '' (Document ID #0369). Other stakeholders also felt that training time was underestimated (Document ID #0330, 0345, 0347, 0363, 0392, 0397, 0400, 0402, 0404, and 0440), with the estimates of additional time needed over and above OSHA's estimates ranging from 15 minutes (Document ID #0330, 0369, and 0378) to 15 hours (Document ID #0400). OSHA's increase of training time by 100 percent over the estimated training time in the PEA represents a significant increase in response to comments, and the Agency believes that these estimates of training times are reasonable. The extra time OSHA has incorporated also addresses concerns of some stakeholders that firms will have to offer two iterations of training —one before the two-year familiarization deadline set forth in the regulatory text, and one closer to the effective date when all products have been converted to GHS-compliant SDSs and labels (Document ID #0339). However, for costing purposes, all training costs for workers to become familiar with GHS requirements were assumed to be incurred within the first two years after the effective date of the final rule. OSHA received comment that additional training time would be required to train employees responsible for reclassifying chemicals under the revised HCS (Document ID #0392). OSHA believes that the changes to the HCS are such that an employer who was capable of classifying chemical hazards under the current HCS would be able to become familiar with the GHS criteria in a relatively short period of time. The Agency has also allocated 3 to 7 hours per product to complete the reclassification and produce an updated SDS, which should allow for additional familiarization time if necessary. OSHA has not included additional training time for training on new hazards disclosed as a part of the transition. This concern was raised by a commenter (Document ID #0339), because it is theoretically possible that some chemicals could be classified with new hazards through the GHS classification schemes that were not previously presented in the workplace. However, the data used for classification is the same used for the current hazard determination, and OSHA believes that few new hazards would actually be introduced through this process. Compliance with the final rule is not expected to impose any additional training costs after the transition period.

[25] This annualized estimate of $59 million reflects total costs of $692 million multiplied by 0.085332 to annualize these costs (incurred over the first two years) over a 20-year period. The $692 million is equal to $6 million for health and safety managers (7,070 affected managers × $1039 per manager (the estimated cost of one day training per manager) × 83% not currently in compliance) plus $15 million for logistics personnel in manufacturing (49,100 affected logistics persons × 8 hours × $66 per hour × 83% not currently in compliance) plus $163 million for health and safety supervisors in manufacturing (370,000 affected health and safety supervisors in manufacturing × 8 hours × $66 per hour × 83% not currently in compliance) plus $508 million for health and safety supervisors in non-manufacturing (3,848,000 affected H&S supervisors in non-manufacturing × 2 hours × $66 per hour × 100% not currently in compliance).

The annualization factor, 0.085332, is equal to:

$[(½] * [(1-(1.07)^{-2})/0.07] * [0.07/((1-(1.07)^{-20})]$,

where the first term in brackets reflects the fact that these costs are assumed to be spread equally over the first two years; the second term in brackets calculates the present value of the costs, and the third term in brackets annualizes the present value of the costs over a 20-year period.

Based on the preceding analysis, OSHA estimates that the annualized cost of training employees in response to GHS would be approximately $95.4 million.[26]

The revisions to the HCS may result in reductions in the costs associated with providing training for employees as required by the existing OSHA HCS. Affected companies could save considerable time and effort in training new employees in the future. The savings may be attributable in part to reducing or eliminating the need to explain the different types of formats used to convey hazard information and the different types of information included in the contents of SDSs and labels. OSHA did not quantify these potential savings in training costs as part of this FEA but, based on stakeholder comment and testimony in the rulemaking record, OSHA anticipates that companies will realize cost savings in future time periods from simplified hazard communication training facilitated by the final rule. A qualitative discussion of these cost savings was presented in Section VI.D: Benefits in this preamble and an estimate of the possible magnitude of these cost savings is presented in the sensitivity analysis in Section VI.L in this preamble.

Cost of Color Printing

The revisions to OSHA's HCS include a requirement that labels include a pictogram enclosed in a red-bordered diamond. The rulemaking record showed widespread (although not unanimous) support for requiring the red-bordered diamond. One commenter felt that ''the use of color to draw attention to a potential hazard is a useful tool and is likely to enhance the communication of safety information'' (Document ID #0327), another stated that ''the color red has been universally accepted as indicating a potential danger or hazard'' (Document ID #0339), and others showed general support for requiring red borders in order to achieve the highest level of harmonization (Document ID #0351 and 0383). Many stakeholders raised concerns that this requirement would result in additional costs to firms since many do not currently print labels in multiple colors or purchase pre-printed labels in multiple colors (Document ID #0120, 0327, 0328, 0344, 0363, 0383, 0389, and 0402). Requiring the red-bordered diamond on the label would mean that some firms would have to upgrade their printer technology or purchase more expensive pre-printed label stock that included the red-bordered diamond.

OSHA estimated the cost impacts of the rule's requirement that pictogram borders be printed in red based on a report on the subject prepared by ERG (2011). That report is based on data provided in an earlier report prepared by ERG (2010). The full ERG reports are available in the rulemaking docket on regulations.gov. To estimate costs for this provision, OSHA estimated the number of hazard labels printed per year, the number of establishments that would incur costs to upgrade their printing technology, and the cost to those establishments to upgrade their printing technology. OSHA estimates that approximately 949 million hazard labels are printed each year and the total incremental cost for establishments to comply with this provision of the OSHA standard is $24.1 million per year. The following section explains how OSHA, using ERG (2010 and 2011), developed estimates of the number of hazard labels printed per establishment, the number of establishments that would need to upgrade printer technology, and the cost to those establishments to comply with this provision of the final rule.

ERG (2011) used data on *Shipment Characteristics by Commodity by Shipment Weight* from the U.S. Census Bureau[27] and DOT's jointly produced Commodity Flow Survey (CFS) (U.S. Census Bureau, 2007).[28] Commodity shipments reported in this survey were classified using the Standard Classification of Transported Goods (SCTG) commodity codes,[29] which ERG mapped to the relevant NAICS industries.

For each of the SCTG commodity codes, the U.S. Census data present shipments of basic chemicals by shipment weight. In order to establish the types of shipments that might fall into each weight class, OSHA relied on preliminary research conducted by ERG (2010) on the weight and capacity of various shipping container units and the weight per gallon of various chemicals. Information was gathered on the types of containers typically used by specific industries and whether those containers would typically ship inside a labeled exterior container. OSHA calculated shipment weights for various chemicals shipped in various container types by multiplying the product weight per gallon by container capacity and adding the weight of the shipping container. As shown in Table VI–5, minimum, maximum, and simple average weights per full container were estimated for the different commodities evaluated in this test case using the Census-reported commodity shipments by shipment weight to establish some bounds on possible shipment types.

[26] This annualized estimate of $95.4 million reflects total costs of $1,118 million multiplied by 0.085332 to annualize these costs (for costing purposes, assumed to be entirely incurred over the first two years) over a 20-year period. The $1,118 million is equal to $785 million in employee hours to receive training (43.8 million affected employees × 0.84 hours × $21 per hour) plus $333 million in management hours to provide the training (6.0 million training sessions × 0.84 hours × $66 per hour). The 0.84 hours is the average estimated training time for all affected employees, with most receiving 60 minutes of training, some receiving 30 minutes of training, and a very few receiving 10 minutes of training. The total number of managers providing training (3.8 million) would, on average, be equal to approximately 8.7 percent of the number of employees receiving training in response to GHS.

[28] U.S. Census Bureau, 2007a. American Fact Finder: Commodity Flow Survey. Available at *http://www.census.gov/econ/census07/index.html*.

[29] The following 13 commodity codes were considered as those that would potentially contain hazardous chemicals: Alcoholic Beverages (Commodity code 8), Gasoline, including Aviation (Commodity code 17), Fuel Oils (Commodity code 18), Other Coal and Petroleum Products (Commodity code 19), Basic Chemicals (Commodity code 20), Pharmaceutical Products (Commodity code 21), Fertilizers (Commodity code 22), Other Chemical Products & Preparations (Commodity code 23), Plastics and rubber (Commodity code 24), Pulp, newsprint, paper, and paperboard (Commodity code 27), Nonmetallic mineral products (Commodity code 31), Base Metal in Primary or Semi-Finished Forms and in Finished Basic Shapes (Commodity code 32), and Miscellaneous Manufactured Products (Commodity code 40).

Table VI-5. Chemical Container Estimated Typical Shipment Weights

Container Type		Estimated Shipment Weight (lbs)			Number of Labels per Container
		Minimum	Typical	Maximum	
250 milliliter jug		0.5	0.7	1.1	1.13[a]
500 milliliter jug		0.9	1.3	2.1	1.13[a]
1 liter jug		1.8	2.5	4.2	1.25[a]
2 liter jug		3.6	4.9	8.2	1.25[a]
1 gallon jug		7	9	16	1.25[a]
2.5 gallon jug		18	24	40	1.5[a]
5 gallon drum		34	48	80	1
30 gallon drum		200	280	470	1
55 gallon drum		360	510	860	1
275 gallon tote		1,800	2,500	4,200	1
330 gallon tote		2,200	3,000	5,100	1
	5,500 gal.	34,000	48,000	82,000	0
Tank Truck	7,000 gal.	43,000	61,000	105,000	0
	20,000 gal.	129,000	182,000	311,000	0
Rail Car	30,000 gal.	186,000	260,000	450,000	0
Barge		2,700,000	3,800,000	6,500,000	0

[a] Assumes 8 units per package for containers smaller than 1 liter, 4 units per package for containers from 1 liter to 1 gallon, and 2 units per package for 2.5 gallon containers.

Source: Office of Regulatory Analysis, OSHA based on ERG (2010)

Based on these calculations, OSHA was able to estimate the number of each type of container that would fall into each of the U.S. Census weight classes. The number of containers that would require a label under the OSHA HCS was refined by estimating the percentage of each commodity that was comprised of nonhazardous products and the percentage of the remaining products that would be sold to consumers. Neither of these types of products fall under the scope of OSHA's HCS and would not require a hazard warning label under the revised rule. For the remaining hazardous non-consumer shipments, assuming one label per container and one label on the outer packaging where applicable, ERG estimated that approximately 949 million hazard labels are applied annually to containers of all sizes.

In most cases one SCTG maps to multiple NAICS industries. In order to divide the number of labels for each SCTG among its constituent NAICS industries, OSHA used receipts data from the U.S. Census Bureau's Statistics of U.S. Businesses to calculate receipts for a particular NAICS industry as a percentage of receipts for all NAICS industries that map to one SCTG. This percentage was used to allocate the estimated number of labels printed for each SCTG among its constituent NAICS industries.

The labels printed per NAICS industry were then distributed among the various size classes based on each size class's share of receipts. In cases where receipts data were not available from the Statistics of U.S. Business (a situation found exclusively within the chemical manufacturing industry in the affected industries for this rule), OSHA calculated the average total receipts and average receipts for each establishment size class for six-digit NAICS in the 325 (Chemical Manufacturing) subsector and the ratio of average receipts for size class to total receipts for six-digit NAICS in 325. This ratio was multiplied by total receipts for the appropriate size class for each industry where receipts data were not available.

Having estimated the number of hazard labels used per year for each NAICS code, OSHA next estimated the costs associated with printing those labels with red pictogram borders. Affected establishments were assigned to one of four categories:

- Category 1: Companies printing only in black who don't own a color printer
- Category 2: Companies printing in black but who own a color printer
- Category 3: Companies using pre-printed stock or labels
- Category 4: Companies printing color labels

Establishments in Category 1 and Category 2 will have to buy new color printers (although Category 2 establishments will have to buy fewer new printers), as well as either color cartridges for laser printers or red ribbons for thermal transfer printers. Establishments in Category 3 will face higher costs for pre-printed stock or labels with red pictogram borders. Establishments in Category 4 will not face higher costs. Relying on conversations with companies and label printers/vendors, ERG allotted establishments into these four categories on the basis of establishment size (as shown in Table VI–6).

Table V1-6. Establishment Distribution

Establishment Size	Category 1	2	3	4	Total
Very Small	30%	10%	40%	20%	100%
Small	30%	10%	40%	20%	100%
Medium	30%	10%	40%	20%	100%
Large	5%	15%	50%	30%	100%
Total	26%	11%	42%	22%	100%

Source: Office of Regulatory Analysis, OSHA based on ERG (2011)

Using the estimates of the percentage of establishments per category by size and the data presented in the industry profile, OSHA was able to estimate the number of establishments per category by size. OSHA used the ratio of SDSs produced by size class to the ratio of total SDSs produced and used that ratio to estimate the number of labels produced per size class per NAICS industry. The results are shown in Table VI–7.

Table VI-7. Establishments and Labels by Category

Size Category	Establishments in Category	Number of Labels Per Year
Category 1: Companies Printing only B&W and no Color Printer		
Very Small	16,237	10,635,815
Small	4,475	18,958,765
Medium	2,267	28,721,211
Large	739	37,746,817
Category 2: Companies Printing B&W but Own Color Printer		
Very Small	5,412	3,545,272
Small	1,492	6,319,588
Medium	756	9,573,737
Large	2,216	113,240,450
Category 3: Companies Using Pre-Printed Stock/Labels		
Very Small	21,649	14,181,086
Small	5,966	25,278,353
Medium	3,022	38,294,949
Large	7,387	377,468,168
Category 4: Companies Printing Color Labels		
Very Small	10,824	7,090,543
Small	2,983	12,639,177
Medium	1,511	19,147,474
Large	4,432	226,480,901
Total, All Categories		
Very Small	54,122	35,452,716
Small	14,916	63,195,884
Medium	7,555	95,737,371
Large	14,774	754,936,337

Source: Office of Regulatory Analysis, OSHA based on ERG (2011)

The number of establishments per category per size class and the number of labels per establishment were then combined with the incremental costs to print in color as opposed to black only to arrive at an estimate of the cost of this provision.

The unit costs by category were estimated as follows.

A low-end laser printer was estimated to cost only a few hundred dollars while a higher-end laser printer can cost upwards of $1,000 to $5,000. OSHA estimates that on average, the incremental cost of buying a color printer instead of a black and white printer is $50 for a low-end laser printer, $100 for a high-end laser printer, $100 for a low-end thermal transfer printer, and $1,000 for a high-end thermal transfer printer. In this analysis, OSHA considers the cost of printers to be a one-time cost that establishments will incur during the four year transition period. The one-time, non-annualized cost to establishments to upgrade printer technology was estimated to be $11.8 million. Printer costs were annualized using a 7 percent interest rate over a five-year period.

The incremental cost of color cartridges for laser printers is a significant driver of costs under the rule. Black cartridges cost approximately $300, while printing in color requires buying four cartridges (cyan, magenta, yellow, and black) at an estimated cost of $1,200. Additionally, printers using black cartridges can print 20,000 labels, while color cartridges can print only 6,000 labels. This results in a per-label cost of $0.015 for black cartridges and $0.20 for color cartridges, for an incremental cost of $0.185.

For companies using thermal transfer printers, the cost of ribbons varies depending on the label material, but is approximately $30 per ribbon for black ribbons and $40 per ribbon for red ribbons. Since both black and red ribbons will be required to print labels under the final rule, the incremental cost of printing in color is the cost of the red ribbon or $40. Both types of ribbons will print approximately 1,000 labels, for a per-label cost of $0.034 for black ribbons and $0.04 for red ribbons, for an incremental cost of $0.01 per label.

For companies using pre-printed stock/labels, the cost of all black labels is estimated to be $0.10 per label while the cost of labels with red pictograms is estimated to be $0.15 per label. This results in an incremental cost of $0.05 per label.

For the purposes of this analysis, OSHA estimated that for those establishments in category 1 (those currently printing labels only with black ink who don't own a color printer) very small establishments will purchase one low-end laser printer, small establishments will purchase two high-end laser printers, medium establishments will purchase three low-end thermal transfer printers, and large establishments will purchase four high-end thermal transfer printers. For establishments in category 2 (those currently printing labels only in black ink but who own a color printer), OSHA estimated that very small establishments will purchase one low-end laser printer, small establishments will purchase one high-end laser printer, medium establishments will purchase two low-end thermal transfer printers, and large establishments will purchase three high-end thermal transfer printers. OSHA estimates that establishments in categories 3 and 4 (those purchasing preprinted black and white labels and those currently printing labels in color) will incur no costs to procure new printers.

Using the estimates described above, OSHA was able to determine the current costs of printing and the cost of printing labels with red-bordered pictograms.

For establishments in Category 1 (those printing black and white labels), the current average cost per label is $0.02 and the average cost per establishment is $132, and for establishments in Category 2 (those printing black and white labels but who own a color printer), the current average cost per label is $0.03 and the average cost per establishment is $344. Establishments in Category 1 and Category 2 will have to buy new color printers (although those in Category 2 will have to buy fewer printers). These establishments will also face higher costs for purchasing color cartridges and ribbons. For these establishments, the cost of purchasing a color printer becomes insignificant when annualized (at a 7 percent interest rate over five years) and when considered on a per-label basis. The main driver of overall costs is the incremental cost of purchasing color cartridges for those establishments using laser printers (establishments that OSHA estimates are small and very small). For very small and small establishments using a laser printer, the cost of cartridges goes from under $0.02 per label for a black cartridge to $0.20 per label for color cartridges. Cost increases are more modest for medium and large establishments using thermal transfer printers, with ribbon costs only increasing from $0.03 to $0.04 per label.

For establishments in Category 3 (those who use pre-printed stock or labels) the current average cost per label is $0.10 and the average cost to purchase labels per establishment is $1,148. Establishments in Category 3 will have to pay more for pre-printed stock or pre-printed labels with red pictograms than for their current hazard labels. OSHA estimates that costs will increase from $0.10 per label to $0.15 per label, increasing printing costs by 50 percent for all establishments in this category.

For establishments in Category 4 (those currently printing in color) the current average cost per label is $0.15 and the average cost per establishment is $1,880. Establishments in Category 4 will not have to pay any more to print red borders as they are already printing color labels.

The annualized cost of printers was calculated by finding the present value of the incremental printer cost incurred four years after the rule is published (to account for the compliance time for the labeling provisions of the rule). This present value was annualized over five years at a 7 percent interest rate to account for the life of the printer. In the cases of printing supplies (*i.e.,* cartridges, ribbons, or label stock), costs are calculated as though they would be incurred over a 20-year period, but would not begin to be incurred until four years after the rule is published. Detailed estimates are presented in Table VI–9 included in the appendix at the end of this section.

For all establishments in all categories, the total costs associated with the requirement to print red pictogram borders are approximately $24.1 million per year, which includes the annualized cost of new printers (approximately $2.4 million) and of 16 years' worth of annual printing supply costs. OSHA feels this estimate is in line with the comments received on the subject as part of the rulemaking record. Betco Corporation estimated that requiring color printing would increase printing costs by 25 percent (Document ID #0389), Dow Chemical estimated that black and white printing was 40 percent less expensive than color printing (Document ID #0353), and The National Paint & Coatings Association, Inc. estimated an increase of 15 percent to 47 percent to print in color depending on the size of the label (Document ID #0328). The Agency also feels that the four-year phase-in period allows adequate time for establishments to exhaust their current stock of labels, which will help ameliorate some cost concerns expressed by stakeholders.

Summary of Unit Cost Estimates

The following list provides a summary of the input estimates underlying the calculation of the compliance costs. It should be noted that these costs are intended to reflect only the incremental costs that would be incurred in addition to the associated costs that would be incurred in the absence of the revisions to the HCS. Except for employee training and color printing, these costs would apply only to those businesses not already in compliance with the revisions.

Reclassifying chemicals and modifying SDSs and labels:

- Large establishments (over 500 employees): an average of 3 hours per SDS; in addition, for 95 percent of establishments, an average of $208 per SDS for software modifications.
- Medium establishments (100–499 employees): an average of 5 hours per SDS; in addition, for 25 percent of establishments, an average of $208 per SDS for software modifications.
- Small establishments (1–99 employees): an average of 7 hours per SDS. Management familiarization and other costs:
- Eight hours for health and safety managers and logistics personnel in the manufacturing sector.
- Two hours for each hazard communication program manager not in the manufacturing sector.

Employee training:

- One hour per production employee in most industries;
- 30 minutes in occupations exposed to few hazardous chemicals and types of hazards;
- 10 minutes per employee in some occupations where GHS-type pictograms are already in use.

Color Printing

- Category 1 establishments (those currently printing only in black & white who do not own color printers): Large establishments $0.02 per label, medium establishments $0.01 per label, small establishments $0.13 per label, and very small establishments $0.14 per label.
- Category 2 establishments (those currently printing only in black & white but who own color printers): large establishments $0.02 per label, medium establishments $0.01 per label, small establishments $0.13 per label, and very small establishments $0.14 per label.
- Category 3 establishments (those currently purchasing pre-printed label stock): large establishments $0.03 per label, medium establishments $0.03 per label, small and very small establishments $0.03 per label.
- Category 4 establishments (those currently producing labels printed in multiple colors): No additional costs related to this provision.

Appendix to Section F: Total Non-Annualized Costs of Compliance

Table VI–8 shows the total non-annualized (non-discounted) compliance costs by industry and by cost element that are estimated to be incurred during the four-year phase-in of the revisions. Except for employee training and color printing, these estimates include no costs for businesses already in compliance with the revisions.

As shown in Table VI–8, the total cost of compliance with the rulemaking over the course of the transition period of four years is estimated to be about $2.1 billion. Of this amount, the cost of chemical hazard reclassification and revision of SDSs and labels is an estimated $281 million, the cost of training employees is an estimated $1,118 million, the cost of management familiarization and other costs such as updates to hazard communication programs is an estimated $692 million, and the one-time printer costs for companies needing to upgrade printing technology to print labels in color is an estimated $12 million.

Table VI–9 summarizes OSHA's estimates for printing costs. It shows annualized per-label costs by category and establishment size ranging from $0.01 to $0.14 and total annualized costs by category and establishment size. Total annualized costs include the cost of printers annualized over five years and the cost of printing supplies incurred over a 20-year period beginning four years after the rule is published.

Table VI-9. Summary of Color Printing Costs

Size Category	Annualized Printer Costs per Label[1]	Annualized Cartridge/Ribbon/Stock Costs per Label	Total Annualized Costs per Label	Total Annualized Costs per Establishment	Total Annualized Costs, All Establishments
Category 1: Companies Printing Only B&W and No Color Printer					
Very Small	$0.01	$0.13	$0.14	$91.74	$1,489,571
Small	$0.01	$0.13	$0.13	$570.41	$2,552,483
Medium	$0.00	$0.01	$0.01	$142.02	$321,896
Large	$0.01	$0.01	$0.02	$1,091.86	$806,560
Category 2: Companies Printing B&W but Own Color Printer					
Very Small	$0.01	$0.13	$0.14	$91.74	$496,524
Small	$0.00	$0.13	$0.13	$551.81	$823,074
Medium	$0.00	$0.01	$0.01	$123.42	$93,242
Large	$0.01	$0.01	$0.02	$905.80	$2,007,345
Category 3: Companies Using Pre-Printed Stock/Labels					
Very Small	$ -	$0.03	$0.03	$22.28	$482,349
Small	$ -	$0.03	$0.03	$144.11	$859,807
Medium	$ -	$0.03	$0.03	$431.02	$1,302,548
Large	$ -	$0.03	$0.03	$1,738.06	$12,839,037
Category 4: Companies Printing Color Labels					
Very Small	$ -	$ -	$ -	$ -	$ -
Small	$ -	$ -	$ -	$ -	$ -
Medium	$ -	$ -	$ -	$ -	$ -
Large	$ -	$ -	$ -	$ -	$ -
Total					$24,074,395

1 - Includes the cost of printers annualized over five years and the cost of printing supplies incurred over a 20-year period beginning four years after the rule is published

$ - entries indicated no costs, while $0.000 entries are non-zero fractions of a penny

BILLING CODE 4510–26–C

G. Net Benefits, Cost-Effectiveness, and Regulatory Alternatives

Table VI–1 provides a summary of the costs and benefits of the revisions to the OSHA HCS, and it shows the net benefits and cost-effectiveness of the revisions to the standard. Net monetized benefits are estimated to be $556 million annually, expressed in 2010 dollars and using a 7 percent discount rate. (Using a 3 percent discount rate instead would have the effect of lowering the costs to $161 million per year and increasing the gross benefits to $839 million per year. The result would be to increase net benefits from $556 million to $678 million per year.) The cost-effectiveness of the standard can be expressed as more than three dollars of benefits for every dollar of cost.

Some qualitative evidence of the cost-effectiveness of the standard was provided by comments submitted in response to the ANPR published by OSHA in the **Federal Register** on September 12, 2006 (71 FR 53617) and the Proposed Rule published by OSHA in the **Federal Register** on September 30, 2009 (74 FR 50280). There was widespread support among the commenters for the adoption of GHS in the United States (Document ID #0340, 0344, 0347, 0349, 0351, 0354, 0357, 0359, 0366, 0382, 0390, 0403, 0408, and 0414). Many stakeholders anticipate that the revisions to the HCS will ''achieve more effective hazard communication'' (Document ID #0344 and 0351), ''enhance the consistency and quality of hazard information for workers'' (Document ID #0347), and ''serve to further enhance worker protection'' (Document ID #0329). These sentiments were echoed in many of the comments submitted to the record and in much of the testimony delivered at the public hearings. This voicing of support included commenters who provided some of the largest estimates of the costs of the revisions (Document ID #0032, 0050, 0329, 0338, and 0341).

The available alternatives to the final rule are somewhat limited since this rule modifies the current HCS in order to align with the provisions of the UN's GHS. In Section III, the Agency qualitatively discussed the two major alternatives presented during this rulemaking process—(1) voluntary adoption of GHS within the existing HCS framework and (2) a limited adoption of specific GHS components and a variation on (1) that would require compliance with GHS but allow an exemption for small businesses to comply with either the current HCS or with the GHS-compliant HCS. All of these alternatives were soundly rejected by stakeholders. To allow certain parties to follow an alternative system or to allow voluntary adoption of the elements of a uniformity standard does nothing to reduce confusion, improve efficiency, or simplify processes. In order for those benefits to be realized, all elements must apply to all affected parties. OSHA has determined that both of the alternatives presented above would eliminate significant portions of the benefits of the rule.

OSHA did not attempt to evaluate the costs and benefits for the regulatory alternatives that involved partial or voluntary adoption of the GHS. The Agency did evaluate two alternatives where the effective dates were altered. For both alternatives, OSHA re-estimated the costs, benefits, and net benefits simply by adjusting the effective dates in its formulas. The results are summarized in Table VI–10.

In the first alternative considered, all elements of the revised HCS would be required to be implemented within two

years. Under this alternative, all transitional costs would be incurred in two years and benefits would be realized beginning in the third year. OSHA estimated that annualized costs under this alternative would increase by $5 million, from $201 million to $206 million, while annualized benefits would increase by $166 million, from $757 million to $923 million. Estimated net benefits would therefore increase by $161 million, from $556 million to $717 million. However, OSHA believes that these estimates fail to capture the difficulty many firms would encounter in meeting these tighter enforcement dates. As a result, initial compliance rates would probably be lower and less effective, leading to reduced benefits. In addition, some compliance costs—such as for labels and signs—were viewed in this final rule as incremental, reflective of taking place within a normal replacement cycle of 3 to 5 years. With implementation required within two years, these costs could no longer be treated as incremental to existing HCS requirements, but would have to be recalculated as total replacement costs.

The second alternative that OSHA evaluated extended the timeline for training to be completed. For this alternative, all elements of the revised HCS (including training) would be required to be implemented by June 1, 2016. Under this alternative, training costs would not be realized for four and a half years (as opposed to the two-year requirement for training in the final version of this rule) while benefits would not be realized for five years (unchanged from the final rule). OSHA estimated that annualized costs under this second alternative would decrease by $12 million, from $201 million to $189 million, while annualized benefits would be unchanged. Estimated net benefits would therefore increase by $12 million, from $556 million to $568 million. However, these estimates fail to recognize that workers will be exposed to (some) GHS-compliant labels and SDS formats well before the 4½ year training date. The Agency would therefore expect an increase in injuries, illnesses, and fatalities as untrained workers are unable to effectively process and respond to the revised labels and SDS formats. As a result, benefits and net benefits would actually decline relative to those estimated for the final rule.

In summary, although both alternatives show greater net benefits, the Agency concludes that the timing of the final rule is preferable because of additional (but unquantified) compliance costs and reduced (but unquantified) benefits under the first alternative and because of reduced (but unquantified) worker health and safety benefits under the second alternative. In addition, OSHA expects that the final rule offers coordination benefits in that its requirements will fully take effect at the same time as the EU completes its transition.

Table VI-10
Regulatory Alternatives

	Years After Promulgation								
	To Complete Training	For Full Implementation	Until Benefits are Realized	Annualized Benefits	Annualized Costs	Annualized Net Benefits	Benefits Relative to Final Rule Implementation Timeline	Costs Relative to Final Rule Implementation Timeline	Net Benefits Relative to Final Rule Implementation Timeline
Alternative 1									
	2 years	2 years	3 years	$923 million	$206 million	$717 million	+ $166 million	+ $5 million	+ $161 million

H. Economic Feasibility and Impacts

This section presents OSHA's analysis of the potential economic impacts of the final rule and an assessment of economic feasibility. A separate analysis of the potential economic impacts on small entities (as defined in accordance with the criteria established by the Small Business Administration) and on very small entities (those with fewer than 20 employees) is presented in the following section as part of the Final Regulatory Flexibility Screening Analysis, conducted in accordance with the criteria laid out in the Regulatory Flexibility Act.

To determine whether a rule is economically feasible, OSHA begins with two screening tests to consider minimum threshold effects of the rule under two extreme cases: (1) All costs are passed through to customers in the form of higher prices (consistent with a price elasticity of demand of zero), and (2) all costs are absorbed by the firm in the form of reduced profits (consistent with an infinite price elasticity of demand).

In the former case, the immediate impact of the rule would be observed in increased industry revenues. While there is no hard and fast rule, in the absence of evidence to the contrary, OSHA generally considers a standard to be economically feasible for an industry when the annualized costs of compliance are less than a threshold level of one percent of annual revenues. Common-sense considerations indicate that potential impacts of such a small magnitude are unlikely to eliminate an industry or significantly alter its competitive structure, particularly since most industries have at least some ability to raise prices to reflect increased costs and normal price variations for products typically exceed three percent a year (OSHA, 2011, Chapter VI). Of course, OSHA recognizes that even when costs are within this range, there could be unusual circumstances requiring further analysis.

In the latter case, the immediate impact of the rule would be observed in reduced industry profits. OSHA uses the ratio of annualized costs to annual profits as a second check on economic feasibility. Again, while there is no hard and fast rule, in the absence of evidence to the contrary, OSHA generally considers a standard to be economically feasible for an industry when the annualized costs of compliance are less than a threshold level of ten percent of annual profits. This is a fairly modest threshold level, given that normal year-to-year variations in profit rates in an industry can exceed 40 percent or more (OSHA, 2011, Chapter VI).

For this final rule, all hazardous chemicals distributed in the United States have to be in compliance with the SDS and labeling revisions to the HCS, and chemical producers and users in most advanced economies will be under comparable GHS requirements (encompassing training, etc.) specific to their own country or economic union. For this reason, affected domestic establishments should not be susceptible to foreign competitors not bound by the requirements of the revisions to the HCS or similar GHS requirements. As a result, OSHA expects that the costs of this final rule will be passed on in higher prices rather than absorbed in lost profits, and therefore the Agency will tend to be primarily concerned with the ratio of industry costs to industry revenues rather than with the ratio of industry costs to industry profits.

In order to assess the nature and magnitude of the economic impacts associated with compliance with the final rule, OSHA developed quantitative estimates of the potential economic impact of the requirements on each of the affected industry sectors. The estimated costs of compliance presented in Section VI.F of this preamble were compared with industry revenues and profits to provide a measure of potential economic impacts. Although Section VI.G also contains estimates of substantial productivity benefits arising from this final rule that more than offset the estimated costs, these cost savings have not been included in estimating the economic impacts of the final rule.

Table VI–11 presents data on revenues and profits for each affected industry sector at the six digit NAICS industry level, along with the corresponding estimated annualized costs of compliance in each sector. Potential impacts in the table are represented by the ratios of compliance costs to revenues and compliance costs to profits.

As is evident from the data and estimates presented in Table VI–6, the costs of compliance for the final rule are not large in relation to the corresponding revenues and profits in each of the industry sectors. The estimated costs of compliance represent about 0.001 percent of revenues and about 0.011 percent of profits on average across all entities; compliance costs represent less than 0.09 percent of revenues or, with the exception of three chemical manufacturing industries, less than 0.9 percent of profits in any individual industry sector. These three chemical manufacturing industries are NAICS 325181 Alkalies & chlorine manufacturing, NAICS 325191 Gum & wood chemical manufacturing, and NAICS 325992 Photographic film, paper, plate, & chemical manufacturing, and their compliance costs as a percentage of profits are 4.3 percent, 2.1 percent, and 2.4 percent, respectively. The cost of printing labels in color is the main cost driver for these industries.

Based on the Agency's two screening tests to determine if the economic impacts of the final rule exceed some minimum threshold level (*i.e.,* costs equal to one percent of revenue or ten percent of profits), OSHA concludes that the rule is economically feasible for the affected industries. In general, the courts have held that a standard is economically feasible if there is a reasonable likelihood that the estimated costs of compliance ''will not threaten the existence or competitive structure of an industry, even if it does portend disaster for some marginal firms'' (*United Steelworkers of America* v. *Marshall,* 647 F.2d 1189, 1272 (DC Cir. 1980)). The potential impacts of employer costs associated with achieving compliance with the final rule fall well within the bounds of economic feasibility in each industry sector. OSHA does not expect compliance with the requirements of the final rule to threaten the viability of employers or the competitive structure of any of the affected industry sectors.

The economic impact of the final rule is most likely to consist of a very small increase in prices for affected hazardous chemicals, of about 0.001 percent on average. Chemical manufacturing companies, all of whom must incur the costs of compliance unless they are already doing so, should be able to pass through costs to customers. The additional costs of a one-time revision to SDS and labeling criteria and one-time investments in printing technology are extremely small in relation to the value of the corresponding products, and there are generally no economic substitutes, or alternatives, that would not be subject to the same requirements. It is unlikely that a price increase of this magnitude would significantly alter the types or amounts of goods and services demanded by the public or any other affected customers or intermediaries. If the compliance costs of the final rule can be substantially recouped with a minimal increase in prices, there would be little or no effect on profits.

Source: Office of Regulatory Analysis, OSHA based on PP&E (2009) and ERG (2012)

In profit-earning entities, compliance costs can generally be expected to be absorbed through a combination of increases in prices and reductions in profits. The extent to which the impacts of cost increases affect prices or profits depend on the price elasticity of demand for the products or services produced and sold by the entity.

The price elasticity of demand refers to the relationship between changes in the price charged for a product and the resulting changes in the demand for that product. A larger price elasticity of demand implies that an entity or industry is less able to pass increases in costs through to its customers in the form of a price increase and must absorb more of the cost increase through a reduction in profits.

In the case of cost increases that may be incurred due to the requirements of the final rule, all businesses within each of the covered industry sectors would be subject to the same requirements. Thus, to the extent potential price increases correspond to costs associated with achieving compliance with the standards, the elasticity of demand for each entity will approach that faced by the industry as a whole.

Given the small increases in prices potentially resulting from compliance with the final rule and the lack of readily available substitutes for the products and services provided by the covered industry sectors, demand is expected to be sufficiently inelastic in each affected industry to enable entities to substantially offset compliance costs through minor price increases without experiencing any significant reduction in revenues or profits.

OSHA expects the overall economic impact of the final rule to be both an increase in the efficiency of production of goods and services and an improvement in the welfare of society.

First, as demonstrated by the analysis of costs and benefits associated with compliance with the requirements of the final rule, OSHA expects that societal welfare will increase as a result of the revisions to the HCS, as the benefits far exceed compliance costs. The final rule is estimated to yield net annualized benefits of over $800 million.

Second, until now, many of the costs associated with the injuries, illnesses, and fatalities resulting from the risks addressed by the final rule have been externalized. For example, the costs incurred by society to supply certain products and services that are accompanied by injuries, illnesses, or fatalities from employee exposure to hazardous chemicals have not been fully reflected in the prices of those products and services. To the extent that fewer of these costs are externalized because of improved employer and employee information about hazardous chemicals in the workplace, the price mechanism will enable the market to produce a more efficient allocation of resources. However, reductions in externalities by themselves do not necessarily increase efficiency or social welfare unless the costs of achieving the reductions (including indirect and unintended consequences of regulatory approaches) are outweighed by the associated benefits, as they are in this instance.

In addition, based on an analysis of the costs and economic impacts associated with this rulemaking, OSHA concludes that the effects of the final rule on employment, wages, and economic growth for the United States would be negligible. This final rule is expected to result in increased import and export opportunities with U.S. trading partners due to the harmonization of the U.S. system with GHS. Hence, the primary effect on international trade, for businesses of all size, is likely to be favorable. This determination was supported by comment in the rulemaking record. For example, the Society of Chemical Manufacturers and Affiliates reported that companies that do business globally would see benefits related to the revisions to the OSHA HCS (Document ID #0402). Other stakeholders anticipate benefits related to global harmonization (Document ID #0382, 0388, 0393, and 0405) and mention that the standardization of the HCS will benefit those who are involved in international trade (Document ID #0410).

Statement of Energy Effects

As required by Executive Order 13211, and in accordance with the guidance for implementing Executive Order 13211 and with the definitions provided therein as prescribed by the Office of Management and Budget (OMB), OSHA has analyzed the standard with regard to its potential to have a significant adverse effect on the supply, distribution, or use of energy.

As a result of this analysis, OSHA has determined that this action is not a significant energy action as defined by the relevant OMB guidance.

I. Final Regulatory Flexibility Screening Analysis

The Regulatory Flexibility Act (5 U.S.C. 601–612), as amended in 1996, requires the preparation of a Final Regulatory Flexibility Analysis (FRFA) for rules where there would be a significant economic impact on a substantial number of small firms. Under the provisions of the law, each such analysis shall contain:

1. A description of the impact of the rule on small entities;

2. A statement of the need for, and objectives of, the rule;

3. The response of the agency to any comments filed by the Chief Counsel for Advocacy of the Small Business Administration in response to the proposed rule, and a detailed statement of any change made to the proposed rule in the final rule as a result of the comments;

4. A statement of the significant issues raised by the public comments in response to the initial regulatory flexibility analysis, a statement of the assessment of the agency of such issues, and a statement of any changes made in the proposed rule as a result of such comments;

5. A description of and an estimate of the number of small entities to which the rule will apply or an explanation of why no such estimate is available;

6. A description of the projected reporting, recordkeeping and other compliance requirements of the rule, including an estimate of the classes of small entities which will be subject to the requirements and the type of professional skills necessary for preparation of the report or record; and

7. A description of the steps the agency has taken to minimize the significant economic impact on small entities consistent with the stated objectives of the applicable statutes, including a statement of the factual, policy, and legal reasons for selecting the alternative adopted in the final rule and why each one of the other significant alternatives to the rule considered by the agency which affect the impact on small entities was rejected.

The Regulatory Flexibility Act further states that the required elements of the FRFA may be performed in conjunction with or as part of any other agenda or analysis required by any other law if such other analysis satisfies the relevant provisions (5 U.S.C. 605(a)).

As explained below, OSHA believes that the final rule will not have a significant economic impact on a substantial number of small entities, and therefore a FRFA is not required by the Regulatory Flexibility Act. Nonetheless, OSHA has prepared this voluntary FRFA to assure the regulated community that the agency has considered the impacts of the final rule on small entities. While a full understanding of OSHA's analysis and conclusions with respect to costs and economic impacts on small businesses requires a reading of the complete FEA

and its supporting materials, this voluntary FRFA will summarize the key aspects of OSHA's analysis as they affect small businesses.

1. A Description of the Impact of the Final Rule on Small Entities

The final regulation requires classification of chemicals, especially chemical mixtures, somewhat different from current hazard determination methods; a standardized format for the organization of MSDSs (now called SDSs); standardized labels and standardized pictograms; and training for affected employees on these changes. (Some commenters argued that GHS would also impose more stringent testing requirements, but as explained in Section III: Need and Support in this preamble, the HCS does not currently require testing of chemicals, and will not require testing with adoption of the GHS.[30])

For the purpose of its cost analysis, OSHA estimated four types of cost:

(1) Costs to chemical producers of classifying chemicals, reformatting SDSs, and developing new labels;

(2) Costs for safety and health managers and logistics personnel to familiarize themselves with the standard (although not required by the regulation, this is a necessary step in its implementation);

(3) Costs of training affected employees on how to find the information they need on SDSs and to comprehend pictograms and standard labels; and

(4) Costs to upgrade printing technology or purchase multi-colored labels to comply with the requirement that the pictograms be presented in a red-bordered diamond.

OSHA believes that, with the exception of the cost of color printing ink or printing cartridges or the cost of purchasing color pre-printed labels, these costs are a one-time cost that would be incurred during the four-year transition period after the final rule is published. OSHA anticipates that, once the final rule is implemented, the costs under the revised OSHA HCS will be only marginally higher than the costs under the existing HCS system and consist solely of the costs associated with color printing supplies. Once chemical producers, distributors, and users set up for and shift to the GHS system, OSHA expects there will be no additional costs arising from the final rule for classification, SDSs, and labeling.

OSHA also anticipates that, after the four-year transition period, the revisions to the HCS—resulting in more consistent chemical classifications and more uniform SDSs and labels—will yield production efficiencies for health and safety managers, logistics personnel, and others who handle hazardous chemicals. These cost savings (in addition to the health benefits for affected workers arising from this final rule) are considered in Section VI.D: Benefits in this preamble.

OSHA's criteria for determining whether there are significant economic impacts on a substantial number of small firms are that, for small entities in any given industry, the annualized costs exceed 1 percent of revenues or 5 percent of profits. All of OSHA's calculations of the economic impacts on small firms totally ignore any offsetting benefits of any kind, even though OSHA estimates that, for most small firms, the benefits of this rule will actually exceed the costs.

OSHA's industry-by-industry analysis, both for small firms (as defined by SBA) and for very small firms (defined by OSHA as those with fewer than 20 employees), shows that in no industry size class do the annualized costs exceed 0.28 percent of revenues or 3.3 percent of profits, and in almost all cases the annualized costs for small and very small firms are below 0.01 percent of revenues and 0.1 percent of profits. For affected small firms as defined by SBA, the average annualized cost per firm of the final rule would be $52 per year, which is equal to 0.001 percent of annual revenue and 0.03 percent of annual profit for the average firm. In terms of chemical-producing industries only, the average annualized cost per small firm as defined by SBA would be $544 per year, which is equal to 0.004 percent of annual revenue and 0.03 percent of annual profit for such a firm. For affected firms with fewer than 20 employees, the average annualized cost per firm of the final rule would be $35 per year (or 0.002 percent of annual revenue and 0.04 percent of annual profit), and the average annualized cost per firm that produces chemicals would be $255 per year (or 0.02 percent of annual revenue and 0.2 percent of annual profit).

Given these results, OSHA concludes that the final rule will not have a significant economic impact on a substantial number of small entities. Thus, a FRFA is not required for this rulemaking. However, recognizing the possible value that such an analysis may provide, OSHA has voluntarily included the elements of the FRFA as part of this Regulatory Flexibility Analysis (RFA) and has analyzed the potential impact of the revisions to OSHA's HCS on small entities. As described in Section VI.D Benefits in this preamble, the revisions to the HCS, on the whole, are expected to result in significant net benefits to employers, as the associated cost savings outweigh the corresponding compliance costs. This same conclusion generally applies to the small entities affected by the final rule.

In order to ensure that any potential significant adverse impact on a substantial number of small entities would be appropriately considered, OSHA also specifically evaluated the impact on small entities of the costs of compliance alone, without regard to the associated cost savings and health and safety benefits.

The total annualized cost of compliance with the final rule for small entities is estimated to be approximately $119 million, as shown by industry in Table VI–12.

To assess the potential economic impact of the final rule on small entities, OSHA calculated the ratios of compliance costs to profits and to revenues. These ratios are presented for each affected industry in Table VI–12. OSHA expects that among small entities potentially affected by the final rule, the average increase in prices necessary to completely offset the compliance costs would be 0.0013 percent. The average price increase necessary to completely offset compliance costs would not exceed 0.18 percent among small entities in any single affected industry sector.

In the event that no costs could be passed through, the compliance costs could be completely absorbed through an average reduction in profits of less than 0.03 percent for affected small entities. For small entities in most affected industries, the compliance costs could be completely absorbed through an average reduction in profits of less than 0.3 percent; the reduction in profits would be no more than 3.3 percent among small entities in any of the affected industries.

BILLING CODE 4510–26–P

[30] OSHA's estimation methodology assumes that firms will undertake the most cost effective method of complying with an OSHA requirement. Therefore, if firms choose to perform testing or to incur other costs not required by an OSHA rule they do so only because they feel there is some benefit to be gained.

Note: Costs are expressed in 2010 dollars
Source: Office of Regulatory Analysis, OSHA based on ERG (2012)

To further evaluate the potential for any adverse effects on small entities resulting from the final rule, OSHA assessed the short-term impacts that may be associated with the compliance costs during the transition period.

The total non-annualized compliance costs for small entities during the four-year transition period are estimated to be $1,330 million, or about $333 million per year for four years. Thus, the potential temporary impact would be about 0.004 percent of revenues or about 0.07 percent of profits, on average, per year for four years for affected small entities.

In order to further ensure that potential impacts on small entities were fully analyzed and considered, OSHA also separately examined the potential impacts of the final rule on very small entities, defined as those with fewer than 20 employees. As shown in Table VI–13, the total annualized costs for entities in this size class would be an estimated $67 million. The annualized costs represent about 0.002 percent of revenues and 0.04 percent of profits, on average, for affected very small entities. The annualized costs did not exceed 0.3 percent of revenues or 3.3 percent of profits for very small entities in any affected industry.

The total non-annualized compliance costs for very small entities during the four-year transition period are estimated to be $789 million, or about $197 million per year for four years. Thus, the potential temporary impact on very small entities would be about 0.005 percent of revenues or 0.1 percent of profits, on average, per year for four years.

In order to more carefully focus on the industry sectors most likely to have significant economic impacts, OSHA carefully examined those industries in the chemical manufacturing and petroleum and coal products manufacturing sectors (''chemical and petroleum producers'') that produce chemicals and SDSs. OSHA examined the extent to which these firms might have significant economic impacts if they produced an unusually high number of chemical products requiring SDSs.

To examine this issue, OSHA examined all small chemical and petroleum producers with respect to their costs as a percentage of revenues and profits. Using the same cost estimation methods as the base analysis, OSHA estimated how many separate chemical products a small firm would have to produce for its annualized costs of compliance with the final rule to exceed 5 percent of profits. OSHA found that the firm would have to produce 7,065 distinct chemical products, each requiring its own SDS. OSHA thinks it very unlikely that there are substantial numbers of small firms (with an average of 27 employees) that produce 7,065 or more distinct chemical products. Swedish data show that less than 0.1 percent of all firms (including large firms) in Sweden produce more than 500 distinct chemical products. (Swedish Chemical Agency, *http://www.kemi.se/templates/Page____2859.aspx*)

OSHA conducted a similar analysis for very small firms with fewer than twenty employees. This analysis found that such firms, with an average of 4.7 employees, would need to produce more than 310 distinct chemical products for costs to exceed 5 percent of profits. OSHA estimates that this would be a very rare situation.

Further, even if small firms could be found that produce more than 7,065 chemical products and very small firms that produce more than 310 chemical products, the costs would probably be much lower than OSHA estimates. First, firms producing this many distinct products probably would not produce SDSs and labels without the assistance of specialized computer software, which OSHA assumes most small firms do not use, but would instead invest in appropriate software to lower their costs, as most larger firms do. Second, firms producing large numbers of chemical products commonly do so because they sell a variety of different mixtures with similar ingredients. Once appropriate data for the ingredients of these mixtures had been developed, using the bridging principles outlined in Appendix A of this preamble, small firms developing SDSs and labels for each mixture would take far less than the 7 hours per chemical product that OSHA has estimated for small firms to convert to the GHS system.

OSHA therefore concludes that there are not a substantial number of small entities or very small entities that would have significant economic impacts from this rule as a result of producing a very large number of distinct chemical products.

2. A Statement of the Need for, and Objectives of, the Rule

OSHA's HCS was first adopted in 1983 for manufacturing (48 FR 53280, Nov. 25, 1983). Later the Agency expanded the scope of coverage to include all industries where employees are potentially exposed to hazardous chemicals (52 FR 31852, Aug. 24, 1987).

The HCS requires chemical manufacturers and importers to evaluate the hazards of the chemicals they produce or import. The current rule provides definitions of health and physical hazards to use as the criteria for determining hazards in the evaluation process. Information about chemical hazards and appropriate protective measures is then required to be conveyed to downstream employers and employees by putting labels on containers and preparing and distributing safety data sheets. All employers with hazardous chemicals in their workplaces are required to have a hazard communication program, including container labels, safety data sheets, and employee training.

Ensuring that this information is available in workplaces helps employers design and implement appropriate controls for chemical exposures, provides employees the knowledge of the hazards and identities of the chemicals, and gives employees the opportunity to participate actively in the successful control of exposures. Together employers and employees can use this information to reduce the potential for adverse effects to occur. The information transmitted under the HCS requirements provides the foundation upon which a workplace chemical safety and health program is built. Without this information, appropriate controls could not be identified and implemented.

OSHA's HCS is designed to disseminate information on chemicals, which will precipitate changes in handling methods and thus protect those potentially exposed to the chemical from experiencing adverse effects. To protect employees and members of the public who are potentially exposed to chemicals during their production, transportation, use, and disposal, a number of countries have developed laws that require information about those chemicals to be prepared and transmitted to affected parties. These laws vary with regard to the scope of chemicals covered, definitions of hazards, the specificity of requirements (*e.g.,* specification of a format for safety data sheets), and the use of symbols and pictograms. The inconsistencies between the various laws are substantial enough that different labels and safety data sheets must often be used for the same product when it is marketed in different nations. For example, Canada has established requirements for labels under its Workplace Hazardous Materials Information System (WHMIS). WHMIS requires that labels include specified symbols within a defined circle. U.S. chemical manufacturers must label their chemicals accordingly for marketing in Canada.

Development of multiple sets of labels and safety data sheets for each product shipped to different countries is a major compliance burden for chemical manufacturers, distributors, and transporters involved in international trade. Small businesses may have particular difficulty in coping with the complexities and costs involved, and it has been argued that these differing requirements may be a technical (non-tariff) barrier to trade.

These concerns led, in June 1992, to a mandate from the United Nations Conference on Environment and Development (UNCED)(Chapter 19 of Agenda 21), supported by the U.S., calling for development of a globally harmonized chemical classification and labeling system. The negotiations were extensive and spanned a number of years. The product resulting from this effort, the Globally Harmonized System of Classification and Labeling of Chemicals, was formally adopted by the new United Nations Committee of Experts on the Transport of Dangerous Goods and the Globally Harmonized System of Classification and Labelling of Chemicals in December 2002.

The final rule incorporates the GHS's requirements into the HCS. They require chemical manufacturers to apply new hazard classification criteria to their chemicals and to prepare and distribute new labels and safety data sheets. Further, these SDSs and labels will be standardized in a way that they are not under the existing HCS. OSHA's current performance-based approach to SDSs and labeling can create confusion among those who seek to use hazard information effectively. For example, labels and safety data sheets may include symbols and hazard statements that are unfamiliar to readers or not well understood. This lack of standardization and the absence of pictograms are particularly a problem for U.S. workers not literate in English. Containers may be labeled with such a large volume of information that important statements are not easily recognized.

OSHA believes that adoption of these new requirements will benefit employers and enhance employee safety. Employers who use chemicals and employees exposed to those chemicals will benefit from receiving the revised labels and safety data sheets prepared in a consistent format. OSHA believes that the information will be easier to comprehend and access in the new approach, allowing it to be used more effectively for the protection of employees. The primary effect in workplaces where chemicals are used but not produced will be to integrate the new approach into the workplace hazard communication program, including ensuring that both employers and employees understand the pictograms and other information provided on the chemicals' labels and SDSs.

OSHA believes that adoption of the GHS will improve labels and SDS comprehensibility through implementation of a uniform approach. The current regulatory system includes a performance-oriented approach to labels and SDSs, allowing the producers to use whatever language or format they choose to provide the necessary information. This result in a lack of consistency makes it difficult for users of chemicals to properly identify their hazards and recommended protective measures, particularly when purchasing the same product from multiple suppliers. Having the information provided in the same words and pictograms on labels, as well as having a standardized order of information on SDSs, will help all users, including employers, employees, and emergency responders, to more easily identify the critical information necessary to protect employees.

In addition, OSHA believes that American employees and employers will receive benefits from the international adoption of GHS. Development of the GHS system required extensive work by a great number of people and resources from many countries and organizations. The reason it received such support is the belief that there are significant benefits associated with implementation of a globally harmonized approach to hazard communication. Countries, international organizations, chemical producers, users of chemicals, and employees working with chemicals would all benefit. There are at least four reasons to expect that GHS will be adopted globally.

First and foremost, the GHS modifications of the HCS will enhance protection of workers and the environment. Occupationally related injuries, illnesses, and fatalities remain a serious problem in the U.S. For example, although likely to contain very

significant underreporting, data from the Bureau of Labor Statistics indicate that, in 2007, employees suffered an estimated 55,400 illnesses attributable to chemical exposures (BLS, 2008), and that some 17,340 chemical-source injuries and illnesses involved days away from work (BLS, 2009). As shown in this FEA, the adoption of the revisions to OSHA's HCS is expected to result in a significant reduction in injuries, illnesses, and fatalities among U.S. employees exposed to hazardous chemicals. In addition, while some countries, such as ours, already have the benefits of protection under existing systems, many do not have such comprehensive approaches. Thus, implementation of the GHS would provide these countries with the important protections that result from dissemination of information about chemical hazards and protective measures. The U.S. expects to improve and build on worker protections it already has.

Second, OSHA believes that the final rule will facilitate international trade in chemicals. It will reduce the burdens caused by having to comply with differing requirements for the same product and facilitate small business participation in international trade.

Third, one of the initial reasons this system was pursued internationally involved concerns about animal welfare and the proliferation of requirements for animal testing and evaluation. Existing systems with different definitions of hazards often result in duplicative testing to produce data related to the varying cut-offs in the different systems. Having one agreed definition will reduce the need for this duplicative testing. It should be noted, however, that OSHA's HCS has never had testing requirements. The HCS is based on collecting and evaluating the best available existing evidence on the hazards of each chemical.

Fourth, information transmittal systems provide the underlying infrastructure for the sound management of chemicals in a country. Those countries that do not have the resources to develop and maintain such a system can use the GHS to build their chemical safety and health programs. Since it has been developed, and will be maintained, through an international approach, national resources used to achieve chemical safety and health can be streamlined. Unlike some other issues, a country's approach to the sound management of chemicals definitely affects others countries. In some cases, bordering countries may experience their neighbors' pollution and other effects of uncontrolled chemical exposures. In all countries, there is a need to acquire sufficient information to properly handle chemicals when they are imported from other countries. Thus having a coordinated and harmonized approach to the development and dissemination of information about chemicals would be mutually beneficial to importing and exporting countries.

In the U.S., there are four primary regulatory agencies that exercise jurisdiction over chemical hazard communication: OSHA; the Department of Transportation, which regulates chemicals in transport; the Consumer Product Safety Commission, which regulates consumer products; and the Environmental Protection Agency, which regulates pesticides and has other labeling authority under the Toxic Substances Control Act. These agencies are not domestically harmonized in terms of definitions of hazards and other requirements. If all four agencies adopt the GHS, the U.S. will have the additional benefit of harmonizing the overall U.S. approach to classification and labeling. Since most chemicals are produced in a workplace and shipped elsewhere, many employers deal with at least two sets of federal requirements. Thus these employers would be likely to obtain some benefits from domestic harmonization.

OSHA has made a determination that the revisions to the HCS will improve the quality and consistency of information provided to employers and employees regarding chemical hazards and associated protective measures. The Agency anticipates this improved information will enhance the effectiveness of the HCS in ensuring that employees are apprised of the chemical hazards to which they are exposed, and in reducing the incidence of chemical-related occupational illnesses and injuries. OSHA estimates that (1) savings in benefits from improved employee health and safety exceed the costs of the final rule, and (2) cost savings to chemical users exceed the costs of the final rule.

An additional and more complete discussion of the reasons why this standard is being promulgated by the Agency is provided in other sections of this preamble.

The primary objective of aligning the HCS with the GHS is to achieve the benefits of the OSHA HCS in a more comprehensive, efficient, and effective manner. The revisions are expected to provide an increased degree of occupational safety and health for employees potentially exposed to hazardous chemicals in the workplace and to provide updated, clear, and comprehensive standards regarding the classification of chemical hazards and the manner in which relevant information about chemical hazards is disseminated to affected employees.

The intent of the HCS is to ensure that all chemical hazards are properly evaluated and that information concerning chemical hazards and associated protective measures is transmitted to employers and employees. The standard achieves this goal by requiring chemical manufacturers and importers to review available scientific evidence concerning the physical and health effects of the chemicals they produce or import to determine if they are hazardous.

For every chemical found to be hazardous, the chemical manufacturer or importer must develop a container label and an SDS and provide both to downstream users of the chemical. All employers with employees exposed to hazardous chemicals must develop a hazard communication program and ensure that exposed employees are provided with labels, access to SDSs, and training on the hazardous chemicals in their workplace.

The three information components in this system—labels, SDSs, and employee training—are all essential to the effective functioning of the program. Labels provide a brief, conspicuous summary of hazard information at the site where the chemical is used. SDSs provide detailed technical information and serve as a reference source for exposed employees, industrial hygienists, safety professionals, emergency responders, health care professionals, and other interested parties. Training is designed to ensure that employees understand the chemical hazards in their workplace and are aware of recommended protective measures. Labels, SDSs, and training are complementary parts of a comprehensive hazard communication program—each element reinforces the knowledge necessary for effective protection of employees.

Information provided in accordance with the HCS serves to reduce the incidence of chemical-related illnesses and injuries in the workplace. This is accomplished by modifying the behavior of both employers and employees. For example, the information contained in the HCS enables employers to implement protective measures in the workplace. Employers will also have information to choose less hazardous alternatives or select appropriate engineering controls, work practices, and personal protective equipment. Improved understanding of chemical hazards by supervisory

personnel results in safer handling of hazardous substances, as well as proper storage and housekeeping measures.

Employees provided with information and training on chemical hazards are able to fully participate in the protective measures instituted in their workplaces. Knowledgeable employees can take the steps required to work safely with chemicals in their workplace and are able to determine what actions are necessary if an emergency occurs. Information on chronic effects of exposure to hazardous chemicals helps employees recognize signs and symptoms of chronic disease and seek early treatment. Information provided under the HCS also enables health and safety professionals to provide better services to exposed employees. Medical surveillance, exposure monitoring, and other services are enhanced by the ready availability of health and safety information.

OSHA believes that the comprehensive approach adopted in the HCS, which includes requiring evaluation of chemicals and the transmittal of information through labels, SDSs, and training, is sound. This final rule does not alter that approach. Rather, the final rule is intended to improve the effectiveness of the HCS by enhancing the quality and consistency of the information provided to employers and employees. OSHA believes this can be accomplished by revising the requirements of the standard to conform to the more specific and detailed provisions of the GHS for classification, labeling, and SDSs.

3. The response of the agency to any comments filed by the chief counsel for advocacy of the small business administration in response to the proposed rule, and a detailed statement of any change made to the proposed rule in the final rule as a result of the comments.

The Office of Advocacy in the SBA did not submit any comments to OSHA in response to the proposed rule.

4. A statement of the significant issues raised by the public comments in response to the initial regulatory flexibility analysis, a statement of the assessment of the agency of such issues, and a statement of any changes made in the proposed rule as a result of such comments.

OSHA received numerous comments in the record about the impact of this rulemaking on small entities. There were concerns about OSHA's preliminary cost estimates and concerns that this rule would have a substantial impact on small manufacturers. OSHA carefully evaluated these concerns and has addressed them below as well as in Section VI.F: Costs of Compliance in this preamble.

Some stakeholders felt that OSHA should convene a Small Business Regulatory Enforcement Fairness Act (SBREFA) panel for this rulemaking (Document ID #0361, 0372, 0397, 0407, and 0411). OSHA evaluated this rule under the provisions of the Regulatory Flexibility Act, which requires that OSHA hold a SBREFA (or SBAR—Small Business Advocacy Review) panel when a rule is expected to have a significant impact on a substantial number of small entities. The modifications to the hazard communication standard do affect a substantial number of small entities, but the costs per firm do not rise to the level where they would impose a significant economic impact on a substantial number of small entities. OSHA defines a significant economic impact on small entities as costs that exceed one percent of revenues or five percent of profits for small entities in any affected industry. The Regulatory Flexibility Act does not define the term ''significant economic impact.'' Instead, as noted in the RFA's legislative history, Congress suggested that agencies refer to SBA guidelines for measuring the impact of rules on small businesses. *See* 126 Cong. Rec. S10,942 (Aug. 6, 1980). In relevant guidance, the SBA's Office of Advocacy states that the impact of a regulation ''could be significant if the cost of the proposed regulation (a) eliminates more than 10 percent of the businesses' profits; (b) exceeds 1 percent of the gross revenues of the entities in a particular sector or (c) exceeds 5 percent of the labor costs of the entities in the sector.'' *See* ''A Guide for Government Agencies: How to Comply with the Regulatory Flexibility Act'' (*http://archive.sba.gov/advo/laws/rfaguide.pdf*). Notably, OSHA's threshold of 5 percent of profits is significantly more protective of small businesses than the Office of Advocacy's suggested threshold of 10 percent.

OSHA's two thresholds have long been a part of the Agency's published SBREFA procedures (*See http://www.dol.gov/dol/regs/appendix.htm,* prepared pursuant to Section 212 of the SBREFA) and were originally developed in close cooperation with the Office of Advocacy (*See* SBA Office of Advocacy, 2003, p. 18).

Furthermore, in employing a dual threshold, based on either revenue or profit impacts, OSHA has taken special pains to identify potentially significant impacts on small entities.[31]

While this rule will be costly in the aggregate, it is not aggregate costs but the significance of impacts on small entities that triggers the need for a SBREFA panel. No panel was or is needed for this rulemaking because costs per small entity do not meet the threshold that OSHA uses to define a significant economic impact on a substantial number of small entities.

Stakeholders also expressed concerns that costs were underestimated and that costs to small entities would be considerable. The U.S. Chamber of Commerce asserted that ''the imposition of a completely new system of classification of chemicals represents huge burdens on small employers with significant costs'' (Document ID #0397). OSHA acknowledges that there will be transitional costs for small businesses but feels that the additional transition time OSHA has incorporated into the final rule and discussed in more detail elsewhere in the FEA, combined with OSHA compliance assistance and the fact that many firms have already made the transition to GHS, should allow small employers to adopt the GHS criteria without overwhelming challenges. The U.S. Chamber of Commerce did not provide additional details, which were solicited as part of both the ANPR and the NPRM, on what types of costs small businesses would incur or the possible magnitude of those costs. Without detailed estimates, OSHA cannot fully evaluate alternative costs for small businesses; nor can OSHA adopt alternative cost estimates without persuasive evidence in the record.

Wacker Chemical Company felt that the changes to the HCS would have a large impact on small businesses ''result[ing] from the lack of personnel and financial resources to implement changes of this magnitude which may involve reclassification of the companies' products, reauthoring SDSs

[31] By comparison, many other agencies, such as EPA and the Department of Homeland Security, rely only on revenue impacts. See also *Aeronautical Repair Station Ass'n, Inc.* v. *F.A.A.,* 494 F.3d 161, 175 (D.C. Cir. 2007). (Federal Aviation Administration made determination that proposed regulation would not have significant economic impact on substantial number of small entities based on its calculation of annualized costs of less than 1 percent of annual median revenue); *Washington* v. *Daley,* 173 F.3d 1158, 1171 (9th Cir. 1999) (parties agreed that economic impact of Department of Commerce regulation would be considered significant if regulation resulted in more than 5 percent reduction in annual gross revenues). It should also be noted that, in OSHA's experience, the 5-percent profitability threshold is much more likely than the 1-percent revenue threshold to trigger a significant impact on a substantial number of small entities. This is supported by the fact that, with profit rates in the United States equal to approximately 6 percent of revenues (as it is, on average, for all firms affected by this final rule), for a firm with profits of 6 percent of revenues, 5 percent of profits will be approximately equivalent to 0.3 percent of revenues.

and labels, and training personnel'' (Document ID #0335), and IBM Corporation expressed concern that small businesses ''may not have the technical resources and skill to generate safety data sheets for [* * *] mixtures'' (Document ID #0334). The Agency believes that small firms have the expertise to make the hazard determinations and meet the other transitional requirements of the revised HCS and, other than comments on the possibility of technical expertise being an issue for small firms asserted by a few firms who do not qualify as small, OSHA did not receive solid evidence that a lack of technical expertise among small firms would actually be a significant issue. Chemical manufacturers and users have been able to comply with the current HCS, and manufacturers have been able to make the classification determinations and label their products in the appropriate manner. In addition, some small firms are likely already complying with the requirements of GHS in order to facilitate international trade. The revised HCS will not be considerably more technical or require considerably more expertise in order to comply than the current HCS. There is also no evidence, from the experiences of firms in the EU or in Asian markets where the GHS criteria for classification of chemicals, label elements, and SDS formats have already been adopted into practice, that small firms are not able to comply due to either overwhelming costs or to a lack of technical expertise required to make the changes.

Many comments expressed general concern that OSHA underestimated the compliance burden on small businesses (Document ID #0336, 0372, 0397, and 0407), and OSHA has increased some costs (for instance, doubling the time required for training) in response to these comments. The comments, while appreciated and insightful, did not contain the level of detail that OSHA would need in order to make a case for changing many of the estimates in the PEA. For the most part, comments received on the issue of costs to and impacts on small businesses simply stated that (in general) costs to small businesses were understated in the PEA or asserted that impacts would be significant without providing data to support alternative estimates. In order to assess the impacts on the cost effectiveness of this standard of possible underestimation of cost parameters, the Agency has included a sensitivity analysis in Section VI.L: Sensitivity Analysis in this preamble. Additional concerns about costs that are not specific to small businesses are addressed further in Section VI.F: Costs of Compliance in this preamble.

Many commenters, including some who voiced concerns about costs, did not support a voluntary adoption approach or any other exemption or modified system for small businesses (Document ID #0324, 0327, 0328, 0329, 0335, 0338, 0351, 0352, 0370, 0376, 0377, 0381, 0382, 0393, and 0410). DuPont felt that dual systems would ''undermine the goal of harmonization [* * * and] be very confusing for employees'' (Document ID #0329). Ferro Corporation expressed the view that ''failure to implement [the requirements of the rule] across-the-board will cause confusion; negate main benefits; and potentially be less protective'' (Document ID #0363).

Many of the commenters who addressed small business issues felt that the benefits to small businesses would be negligible (Document ID #0372, 0378, 0385, 0396, 0397, 0400, 0402, and 0407). Commenters who viewed the primary benefits of adopting the GHS as facilitating international trade were likely to favor an alternative of less than full compliance with GHS. As has been addressed throughout the FEA, however, OSHA's estimates of the benefits of this final rule reflect fewer worker injuries and illnesses, efficiency improvements in the safe handling of hazardous chemicals, and less costly and more effective hazard communication training of new workers. While OSHA recognizes the significant potential trade benefits of this final rule, the Agency did not quantify or monetize these benefits.

In response to numerous comments received in the record, OSHA has extended the phase-in period for this rulemaking and aligned the phase-in of this rule to correspond to the EU's deadline for classification of mixtures. Some of these comments asserted that more time would be especially beneficial to small businesses, reducing the compliance burden significantly (Document ID #0399, 0405, and 0408). For example, the National Association of Chemical Distributors suggested a timeline of 3 years plus 18 months for distributors and downstream users (Document ID #0341). The effective dates in the final rule take these (and other suggestions) into account and provide substantial additional time for implementation. Where the proposal required all labels and SDSs to be in compliance with the new requirements in three years after publication (or August 2014), the final rule requires manufacturers and importers to modify labels and SDSs by June 1, 2015. The final rule also gives distributors an additional six months, until December 1, 2015, to sell stock labeled under the current standard. In addition, employers are given another six months, until June 1, 2016, to update their training and their hazard communication program with any new hazard information received because of the final rule. Finally, the proposal required that exposed employees receive initial training two years after adoption (or August 2013), whereas the final rule gives employers until December 1, 2013 to complete this training.

5. Description of and estimate of the number of small entities to which the rule will apply.

OSHA has completed an analysis of the economic impacts associated with this final rule, including an analysis of the type and number of small entities to which the final rule applies. In order to determine the number of small entities potentially affected by this rulemaking, OSHA used the definitions of small entities developed by the Small Business Administration (SBA) for each industry.

The final standard impacts firms that are the primary producers or distributors of hazardous chemicals, and firms whose employees are exposed to hazardous chemicals. Based on the definitions of small entities developed by SBA for each industry, the final rule is estimated to potentially affect a total of 4,093,543 small entities, as shown in Table VI–12. The rule has its greatest impacts on the 72,040 small firms that produce chemicals that require SDSs and labels.

6. Description of the projected reporting, recordkeeping, and other compliance requirements of the rule.

The final standard includes revised criteria for classification of chemical hazards; revised labeling provisions that include requirements for use of standardized signal words, pictograms, and hazard statements; a specified format for safety data sheets; and related revisions to definitions of terms used in the standard, employee information and training requirements, and other sections of HCS. The final rule also modifies other OSHA standards that contain hazard communication requirements to harmonize them with the requirements of GHS. In addition, certain OSHA standards use HCS terms, and OSHA is making changes to ensure that the scope of those standards is not changed by the GHS revisions.

The preamble to the final standard provides a comprehensive description of, and further detail regarding, the compliance requirements of the rulemaking. A description of the types

of entities which would be subject to the new and revised requirements, and the types of professional skills necessary for compliance with the requirements, is presented in the relevant sections of this economic analysis and the corresponding supporting research, and is summarized below with a summary of unit costs. Except for employee training and color printing, these costs would apply only to those small businesses not already in compliance with the revisions.

Reclassifying chemicals and modifying SDSs and labels:

- Medium establishments (100–499 employees): An average of 5 hours per SDS; in addition, for 25 percent of establishments, an average of $208 per SDS for software modifications.
- Small establishments (1–99 employees): An average of 7 hours per SDS. Management familiarization and other costs:
- Eight hours for health and safety managers and logistics personnel in the manufacturing sector;
- Two hours for each hazard communication program manager not in the manufacturing sector.

Employee training:

- One hour per production employee in most industries;
- Thirty minutes in occupations exposed to few hazardous chemicals and types of hazards;
- Ten minutes per employee in some occupations where GHS-type pictograms are already in use.

Color Printing

- Category 1 establishments (those currently printing only in black & white who do not own color printers): Medium establishments $0.01 per label, small establishments $0.13 per label, and very small establishments $0.14 per label.
- Category 2 establishments (those currently printing only in black & white but who own color printers): Medium establishments $0.01 per label, small establishments $0.13 per label, and very small establishments $0.14 per label.
- Category 3 establishments (those currently purchasing pre-printed label stock): Medium establishments $0.03 per label, small and very small establishments $0.03 per label.
- Category 4 establishments (those currently producing labels printed in multiple colors): No additional costs related to this provision.

7. A description of the steps the Agency has taken to minimize the significant economic impact on small entities.

OSHA has extended the phase-in period for this rulemaking in response to stakeholder concern. The Agency believes that the additional time granted to manufacturers, distributors, and users of chemicals will serve to reduce the transitional costs associated with this rule. Chemical manufacturers currently revise SDSs and labels periodically to include new or updated hazard information, and the extended time frame will allow firms to adopt the GHS criteria into their hazard communication program and to modify SDSs, warning labels, and workplace signs within the normal flow of their operations.

OSHA will be offering guidance materials such as quick cards and fact sheets to aid firms in developing and implementing the training requirements of this rule. OSHA will also be releasing a small business compliance guide to provide additional guidance to small businesses, which will ease the economic impact and compliance burden. The Agency solicited comment from stakeholders as part of the ANPR and NPRM on what compliance assistance tools would be most helpful and has incorporated the suggestions received in the record in the development of guidance materials.

J. Environmental Impacts

OSHA has reviewed the provisions of this final rule in accordance with the requirements of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq.*), the Council on Environmental Quality (CEQ) NEPA regulations (40 CFR Parts 1500–1508), and the Department of Labor's NEPA Procedures (29 CFR Part 11). As a result of this review, OSHA has determined that the final rule will have no significant adverse effect on air, water, or soil quality, plant or animal life, use of land, or other aspects of the environment. OSHA anticipates that the more complete and easier-to-understand SDSs resulting from this rule will, in addition to increasing employee health and safety, have positive effects on the environment.

K. Unfunded Mandates Reform Act Analysis

Section 3 of the Occupational Safety and Health Act makes clear that OSHA cannot enforce compliance with its regulations or standards on the U.S. government ''or any State or political subdivision of a State.'' Under voluntary agreement with OSHA, some States enforce compliance with their State standards on public sector entities, and these agreements specify that these State standards must be equivalent to OSHA standards. Thus, although OSHA may include compliance costs for affected public sector entities in its analysis of the expected impacts associated with the final HCS rule, the rule does not involve any unfunded mandates being imposed on any State or local government entity.

Based on the analysis presented in this economic analysis, OSHA concludes that the final rule would impose a Federal mandate on the private sector in excess of $100 million in expenditures in any one year. Accordingly, this economic analysis of the final rule, concerning revisions to the HCS, constitutes the written statement containing a qualitative and quantitative assessment of the anticipated costs and benefits of the Federal mandate, as required under Section 202(a) of the Unfunded Mandates Reform Act of 1995 (2 U.S.C. 1532(a)).

L. Sensitivity Analysis

In this section, OSHA provides a sensitivity analysis of the major assumptions underlying the Agency's estimates of the annualized costs and annualized benefits of the final rule. The purpose is to determine whether OSHA's conclusion that the final rule yields net benefits is vulnerable to a reasonable change in any one of these assumptions. OSHA's choice of how much to increase unit cost parameters in the sensitivity analysis was intended to reflect an upper bounds (or more) of reasonableness, based on comments, as well as on professional experience and common sense. (As a result, there are almost no estimates provided by commenters of higher unit costs than we used in the sensitivity analysis, and we rejected those few outliers as being unrealistically large and certainly not representative of the average establishment covered by this rule.) OSHA's choice of how much to decrease unit benefit parameters was more subjective and reflected the fact that few commenters provided alternative quantitative estimates. Broadly, the Agency cut unit benefit parameters by at least half in all cases for the sensitivity analysis, which OSHA believes is consistent with the spirit of comments that either supported OSHA's estimates of benefits or thought benefits were somewhat overestimated—the exception being those few commenters who disputed the existence of health and safety benefits or productivity benefits arising from the proposed rule. However, it should be carefully noted that any given benefit category could be reduced to zero and the net benefits would still be positive. This can be seen in Table VI–1, which shows that the estimated net positive annualized benefits of the final rule ($556 million)

significantly exceed the estimated annualized benefits for any individual category of benefits—Reduction in Safety and Health Risks ($250 million); Productivity Improvements for Health and Safety Managers and Logistics Personnel ($475 million); and Savings during Periodic Updating of SDSs and Labels ($32 million).

The sensitivity analysis below shows that OSHA's conclusion that the final rule produces net benefits is not dependent on any particular assumption. In fact, the estimated annualized health and safety benefits of the rule alone, independent of any productivity benefits, exceed the estimated annualized cost of the rule. Further, the broad support from industry for this rule, even from those commenters critical of some of OSHA's estimates of costs and benefits, suggests that industry believes the productivity benefits of the rule exceed the costs.

The methodology and calculations underlying the estimation of the compliance costs, benefits, and economic impacts associated with this rulemaking are generally linear and additive in nature. Thus, the sensitivity of the results and conclusions of the analysis will generally be proportional to variations in the relevant input parameters.

For example, if the estimated time that companies need to reclassify chemical hazards and revise SDSs and labels were doubled, the corresponding labor costs (but not software costs) of reclassification and revision of SDSs and labels would double as well.

OSHA evaluated a series of such changes in input parameters to test whether and to what extent the general conclusions of the economic analysis held up. On the whole, OSHA found that the conclusions of the analysis are reasonably robust, as changes in any of the input parameters tend not to produce disproportionately large changes in the results. The results also show significant net annualized benefits for the rule regardless of the individual revisions to costs, benefits, or discount rate. The results of the individual sensitivity tests are summarized in Table VI–14 and are described in more detail below.

BILLING CODE 4510–26–P

BILLING CODE 4510–26–C

Table VI-14
Sensitivity Tests

Impact Variable	OSHA's Best Estimate	Sensitivity Test	Impact on Annualized Costs or Benefits	Percentage Impact on Costs or Benefits	Adjusted Annualized Costs or Benefits	Adjusted Annualized Net Benefit
Cost				**Percentage Cost Impact**	**Adjusted Costs**	
OSHA's Best Estimate of Annualized Total Cost and Annualized Net Benefits					*$201 million*	*$556 million*
Time to Reclassify Chemicals; Revise SDSs and Labels	5.1 hours	100% increase	$18 million	9%	$219 million	$538 million
Number of SDSs	1,414,636	100% increase	$23 million	11%	$223 million	$533 million
Number of Employees Requiring Training	43.7 million	50% increase	$48 million	24%	$248 million	$508 million
Training Time Per Employee	0.84 hours	100% increase	$96 million	48%	$297 million	$460 million
Cost of Color Printing	$24 million	100% increase	$24 million	12%	$225 million	$532 million
Benefit				**Percentage Benefit Impact**	**Adjusted Benefits**	
OSHA's Best Estimate of Annualized Total and Net Benefits					*$757 million*	*$556 million*
Reduced Injuries, Illnesses, and Fatalities Relative to HCS Estimate	1%	0.5%	$ -125 million	-17%	$632 million	$431 million
	1%	5%	$1,000 million	132%	$1,757 million	$1,556 million
Savings due to Improved Efficiency in Creating and Revising SDSs	3.2 hours	50% decrease	$-17 million	-2%	$740 million	$539 million
Savings due to Improved Efficiency of S&H Managers and Logistics Personnel	3%, 15%	67% decrease	$-315 million	-42%	$442 million	$241 million
Savings due to Simplified Hazard Communication Training of All Affected New Employees in Future Periods	Unquantified	0.5 hours/worker	$285 million	38%	$1,042 million	$841 million
Discount Rate	7%	3%				$678 million

Source: U. S. Department of Labor, OSHA, Directorate of Evaluation and Analysis, Office of Regulatory Analysis.

In the sensitivity test on costs where OSHA doubled the estimated time that companies need to reclassify chemical hazards and revise SDSs and labels, and estimates of other input parameters remained unchanged, as shown in Table VI–14, the estimated total costs of compliance would increase by $18 million annually, or by about 9 percent, while net benefits would also decline by $18 million, from $556 million to $538 million annually.

In a second sensitivity test, OSHA doubled the estimated total number of affected SDSs addressed by this rulemaking, which increased the estimated total cost of reclassification and revision of SDSs and labels. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated costs of compliance would increase by $23 million annually, or by about 11 percent, while net benefits would also decline by $23 million annually, from $556 million to $533 million annually.[32]

In a third sensitivity test, when OSHA increased by 50 percent the estimated number of employees required to be covered by hazard communication programs and to be trained on GHS, the corresponding estimate of the total costs associated with training employees increased by 50 percent. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated costs of compliance would increase by $48 million annually, or by about 24 percent, while net benefits would also decline by $48 million annually, from $556 million to $508 million annually.

In a fourth sensitivity test, when OSHA doubled the estimated incremental amount of time necessary for training employees on GHS, the corresponding estimate of the total costs associated with training employees also doubled. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated costs of compliance would increase by $96 million annually, or by about 48 percent, while net benefits would also decline by $96 million annually, from $556 million to $460 million annually.

OSHA performed a fifth sensitivity test where the estimated incremental per-label cost of printing labels in color was doubled. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated costs of compliance would increase by $24 million annually, or by about 12 percent, while net benefits would also decline by $24 million annually, from $556 million to $532 million annually

OSHA also performed sensitivity tests on several input parameters used to estimate the benefits of the final rule. In one sensitivity test on benefits, OSHA reduced its estimate of health and safety benefits of the final rule from 1 percent to 0.5 percent of the benefits estimated for the existing HCS. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated benefits of the final rule would decline by $125 million annually, or by about 17 percent, while net benefits would also decline by $125 million annually, from $556 million to $431 million annually.

In a second, parallel sensitivity test on benefits, OSHA increased its estimate of health and safety benefits of the final rule from 1 percent to 5 percent of the benefits estimated for the existing HCS. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated benefits of the final rule would increase by $1,000 million annually, or by about 132 percent, while net benefits would also increase by $1,000 million annually, from $556 million to $1,556 million annually.

In a third sensitivity test on benefits, OSHA reduced its estimate of savings due to the improved efficiency in creating and revising SDSs under GHS by 50 percent. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated benefits of the final rule would decline by $17 million annually, or by about 2 percent, while net benefits would also decrease by $17 million annually, from $556 million to $539 million annually.

In a fourth sensitivity test on benefits, OSHA reduced its estimate of savings due to the improved efficiency of safety and health managers and logistics personnel by 67 percent. As shown in Table VI–14, if OSHA's estimates of other input parameters remained unchanged, the total estimated benefits of the final rule would decline by $315 million annually, or by about 42 percent, while net benefits would also decrease by $315 million annually, from $556 million to $241 million annually.

And finally, in the fifth sensitivity test on benefits, OSHA tested the effect of including cost savings from simplified hazard communication training in future periods made possible by the final rule.[33] For this sensitivity test, OSHA added a cost savings of a half hour, on average, in training time per new employee once the transition period ends and the final rule is fully implemented. OSHA chose a half-hour time savings based on the testimony of the one commenter who provided an estimate of the time savings from simplified hazard communication training.[34] As shown in Table VI–14, as a result of adding the half-hour savings in training time, assuming OSHA's estimates of other parameters remain unchanged, the total benefits of the final rule would increase by $285 million annually,[35] or by about 38 percent, while net benefits would also increase by $285 million annually, from $556 million to $841 million annually.

OSHA also examined the effect of a change in the discount rate on the annualized costs and benefits. Changing the discount rate from 7 percent, used in the base case, to 3 percent would have the effect of lowering the costs to $161 million per year and increasing the gross benefits to $839 million per year. The result, as shown in Table VI–14, would be to increase net benefits by

[32] For this sensitivity analysis, OSHA calculated only the impact on costs of an increase in the number of SDSs. However, in principle, each additional SDS would yield future benefits due to improved efficiencies in creating and revising SDSs under GHS. Although not shown in Table VI–8, this effect would increase benefits by $32 million annually, more than offsetting the $23 million annual cost increase.

[33] As noted in the earlier discussion on benefit, in Section VI.D of this preamble, comments on the proposed rule contained extensive qualitative support for the proposition that the revisions to the HCS rule will make training easier and therefore less time-consuming and less costly.

[34] Printing Industries of America testified at the OSHA public hearing held in Pittsburgh that training for an employee who would be responsible for working with hazardous materials is ''approximately an hour to an hour and a half'' and that training would be less time-consuming under the revised HCS and might be reduced ''possibly by a third simply because [the revised HCS will] be removing a number of types [of MSDS and labeling systems]'' (Document ID #0499, Tr. 96–7). This estimate would be consistent with a saving in training time of one-third to one-half of an hour relative to current training time of one to one and a half hours. OSHA chose the one-half-hour estimate because a representative training time for all the commenters would be at least an hour and a half (and arguably more like 3 hours). Furthermore, in its final economic analysis for the original hazard communication rule, OSHA estimated that the rule would require an average of 3 hours of training per employee (48 FR 53280, Nov. 25, 1983).

[35] This estimate uses the BLS turnover rate to arrive at the number of new employees per year per establishment and assumes from one to ten employees per training session, depending on establishment size. The cost savings due to simplified training take into account one half hour of managerial time to deliver the training plus one half hour of time for each of 17.5 million new employees a year to receive the training. The annualized cost savings of $285 million is equal to annual cost savings of $465.5 million multiplied by an annualization factor of 0.6130 to reflect the fact that these cost savings would not begin to be realized until five years after the effective date of the final rule.

$122 million per year, from $556 million to $678 million per year.

OSHA also considered the sensitivity of its findings that the final rule is economically feasible and does not have a significant economic impact on a substantial number of small entities. For example, even if all of the estimated annualized costs of compliance were to increase by 50 percent, these costs would still represent less than 0.005 percent of annual revenues and less than 0.1 percent of annual profit for the average establishment, small entity, or very small entity, and no small entity or very small entity would have costs in excess of 1 percent of revenues or 5 percent of profits.

In conclusion, the sensitivity analysis demonstrates that even with relatively large variations in the input parameters, there would not be any disproportionately large changes in the estimates of compliance cost or benefits. Further, even if there were a 50 percent increase in all of the compliance cost estimates, there would still be a relatively high confidence in OSHA's finding concerning economic feasibility, the certification that the standard will not have significant economic impacts on a substantial number of small entities, and the conclusion that the benefits of the final rule exceed the costs.

VII. OMB Review Under the Paperwork Reduction Act of 1995

The final rule revises existing Hazard Communication collection of information (paperwork) requirements that are currently approved by the Office of Management and Budget (OMB) under the Paperwork Reduction Act of 1995 (PRA–95), 44 U.S.C. 3501 *et seq.,* and OMB's regulations at 5 CFR part 1320. On October 30, 2009, the Department of Labor submitted Hazard Communication collection of information requirements identified in the NPRM to OMB for review in accordance with 44 U.S.C. 3507(d). In accordance with 44 U.S.C. 3506(c)(2), the proposed regulation solicited public comments on the revision of the Hazard Communication Standard's (HCS) Information Collection Request (ICR) (paperwork burden hour and cost analysis) for the proposal. OSHA received no public comments on the Hazard Communication Standard's ICR. On November 18, 2009, OMB filed a comment on the Hazard Communication Standard NPRM ICR in accordance with 44 U.S.C. 3507(d). OMB stated, ''This OMB action is not an approval to conduct or sponsor an information collection request under the Paperwork Reduction Act of 1995.'' The final Standard modifies existing information collection requirements that are currently approved under OMB Control Number 1218–0072. This ICR has been revised and submitted to OMB. OSHA will publish a separate notice in the **Federal Register** that will announce the result of OMB's reviews. The Department of Labor notes that a Federal agency cannot conduct or sponsor a collection of information unless OMB approves it under the PRA–95, and the agency displays a currently valid OMB control number. Also, notwithstanding any other provision of law, no employer shall be subject to penalty for failing to comply with a collection of information if the collection of information does not display a currently valid OMB control number.

The final rule standardizes the hazard communication requirements for hazardous chemical products used in U.S. workplaces, and thus provides employees with consistent hazard communication information. Hazard communication is currently addressed by many different international, national, and State authorities. These existing requirements are not always consistent and often contain different definitions of hazards and varying provisions for what information is required on labels and safety data sheets (SDSs). The final standard harmonizes the U.S. system with international norms and as a result would enhance worker safety and facilitate international trade. The final rule's modifications to the Hazard Communication Standard's collection of information requirements include: (1) Revised criteria for classification of chemical hazards; (2) revised labeling provisions that include requirements for use of standardized signal words, pictograms, hazard statements, and precautionary statements; (3) a specified format for SDSs; and (4) related revisions to definitions of terms used in the Standard and to requirements for employee training on labels and SDSs.

Paragraph (d), ''hazard classification,'' requires chemical manufacturers and importers to evaluate chemicals produced in their workplaces or imported by them to classify the chemicals' health and physical hazards in accordance with the Standard. For each chemical, the chemical manufacturer or importer must determine the hazard classes, and the category of each hazard class, that apply to the chemical being classified. Employers are not required to classify chemicals unless they choose not to rely on the classification performed by the chemical manufacturer or importer for the chemical. Chemical manufacturers, importers or employers classifying chemicals must identify and consider the full range of available scientific literature and other evidence concerning the potential hazards. There is no requirement to test the chemical to determine how to classify its hazards. Mandatory Appendix A to § 1910.1200 shall be consulted for classification of health hazards, and Mandatory Appendix B to § 1910.1200 shall be consulted for the classification of physical hazards.

For mixtures, chemical manufacturers, importers, or employers evaluating chemicals also must follow the procedures described in Appendixes A and B to § 1910.1200 to classify the hazards of the chemicals, including determinations regarding when mixtures of the classified chemicals are covered by the Standard. When classifying mixtures they produce or import, chemical manufacturers and importers of mixtures may rely on the information provided on current SDSs of the individual ingredients except where the chemical manufacturer or importer knows, or in the exercise of reasonable diligence should know, that the SDS misstates or omits information required by the provisions in the final HCS.

Pursuant to paragraph (e), employers are required to develop, implement, and maintain at each workplace a written hazard communication program which at least describes how the criteria specified in paragraphs (f), (g), and (h) of the standard on labels and other forms of warning, SDSs, and employee information and training will be met, and which also includes the following: (i) a list of the hazardous chemicals known to be present using a product identifier that is referenced on the appropriate SDS (the list may be compiled for the workplace as a whole or for individual work areas); and (ii) the methods the employer will use to inform employees of the hazards of non-routine tasks (for example, the cleaning of reactor vessels) and the hazards associated with chemicals contained in unlabeled pipes in their work areas. The final rule makes no changes to this requirement.

Paragraph (f) modifies existing label requirements by requiring more specific information. Paragraph (f)(1) requires chemical manufacturers, importers, or distributors to ensure that each shipped container of classified hazardous chemicals leaving the workplace is labeled, tagged, or marked with the following information:

(i) Product identifier;

(ii) Signal word;
(iii) Hazard statement(s);
(iv) Pictogram(s);
(v) Precautionary statement(s); and
(vi) Name, address, and telephone number of the chemical manufacturer,
importer, or other responsible party.

The chemical manufacturer, importer, or distributor must ensure that the information provided under (i) through (v) above must be in accordance with the mandatory Appendix C, *Allocation of Label Elements,* for each hazard class and associated hazard category for the hazardous chemical; prominently displayed; and in English (other languages may also be included if appropriate). In addition, the information in (ii) through (iv) must be located together on the label, tag, or mark.

For labels in the workplace, except as provided in paragraphs (f)(7) and (f)(8) of the Standard, employers must ensure that each container of hazardous chemicals in the workplace is labeled, tagged, or marked with either (i) the information specified under (f)(1)(i) through (v) for labels on shipped containers; or (ii) product identifier and words, pictures, symbols, or combination thereof, which provide at least general information regarding the hazards of the chemicals, and which, in conjunction with the other information immediately available to employees under the hazard communication program, will provide employees with the specific information regarding the physical and health hazards of the hazardous chemical.

OSHA has also updated the language for workplace signs and labels to incorporate the GHS hazard statement and the applicable precautionary statement(s), where required. Most OSHA substance-specific heath standards require hazard warning signs, usually for regulated areas, and the language required on the signs varies. With the GHS revision, these standards retain the requirements for specific warning language for specific signs; however, OSHA has modified the language to be compatible with GHS and consistent throughout the OSHA standards. The GHS classification process for a specific substance dictates the hazard warnings and the precautionary statements that will be required on the new GHS-compliant product labels. OSHA believes that having signs and labels in the same formats and containing identical warnings for the same health effects will make it far easier for employers and employees to quickly recognize the hazard and the degree of danger of a hazard, thus enhancing communication.

The final rule modifies the language requirements for signs and labels found in the Agency's health standards listed below in Table VII–1. Since the final rule provides specific language for signs and for labels on containers of contaminated clothing, waste and debris, the Agency is exempted from taking burden hours and costs for these provisions. (*See* 5 CFR 1320.2(c)(2) (''Controlling paperwork burden on the public'')). The Agency is taking burden hours and costs for employers to label, tag, or mark each container of hazardous chemicals with either (i) the information specified under (f)(1)(i) through (v) for labels on shipped containers; or (ii) the product identifier and words, pictures, symbols, or combination thereof, which provide at least general information regarding the hazards of the chemicals.

BILLING CODE 4510–26–C

Pursuant to paragraph (f)(11), chemical manufacturers, importers, distributors, or employers who become newly aware of any significant information regarding the hazards of a chemical shall revise the labels for the chemical within six months of becoming aware of the new information, and shall ensure that labels on containers of hazardous chemicals shipped after that time contain the new information. If the chemical is not currently produced or imported, the chemical manufacturer, importer, distributor, or employer shall add the information to the label before the chemical is shipped or introduced into the workplace again.

Paragraph (g)(2) requires the chemical manufacturer or importer preparing the SDS to ensure that it is in English (although the employer may maintain copies in other languages as well), and include the following section numbers and headings, and associated information under each heading, in the order listed (*See* Appendix D to § 1910.1200—Safety Data Sheets, for the specific content of each section of the safety data sheet).

Section 1, Identification;
Section 2, Hazard(s) identification;
Section 3, Composition/information on ingredients;
Section 4, First-aid measures;
Section 5, Fire-fighting measures;
Section 6, Accidental release measures;
Section 7, Handling and storage;
Section 8, Exposure controls/personal protection;
Section 9, Physical and chemical properties;
Section 10, Stability and reactivity;
Section 11, Toxicological information; and
Section 16, Other information, including date of preparation or last revision.

Although not required by the final rule, an employer may include the following sections to be consistent with the GHS:

Section 12, Ecological information;
Section 13, Disposal considerations;
Section 14, Transport information; and
Section 15, Regulatory information.

Paragraph (g)(5) requires the chemical manufacturer, importer or employer preparing the SDS to ensure that the information provided accurately reflects the scientific evidence used in making the hazard classification. If the chemical manufacturer, importer or employer preparing the SDS becomes newly aware of any significant information regarding the hazards of a chemical, or ways to protect against the hazards, this new information must be added to the SDS within three months. If the chemical is not currently being produced or imported, the chemical manufacturer or importer must add the information to the SDS before the chemical is introduced into the workplace again.

Paragraph (g)(11) requires that employers ensure the SDSs are readily available, upon request, to designated representatives, the Assistant Secretary, and the Director, in accordance with the requirements of 29 CFR 1910.1020(e).

OMB Control Number: 1218–0072.

Affected Public: Business or other for-profit.

Number of Respondents: 5,514,697.

Frequency: On Occasion.

Average Time per Response: The average time per response ranges from twelve seconds for employers to label portable in-plant containers to seven hours for employers to reclassify chemicals and revise SDSs and labels.

Estimated Total Burden Hours: 11.3 million hours.

Estimated Cost: $34.7 million.

VIII. Federalism and Consultation and Coordination With Indian Tribal Governments

The Agency reviewed this final rule according to the most recent Executive Order (''E.O.'') on Federalism (E.O. 13132, 64 FR 43255, August 10, 1999). This E.O. requires that Federal agencies, to the extent possible, refrain from limiting State policy or local

policymaking discretion, consult with States and local officials prior to taking any actions that restrict their policy options, and take such actions only where there is constitutional and statutory authority to do so and the problem is of national significance. The E.O. generally allows Federal agencies to preempt State law only where there is clear evidence of Congressional intent to allow it, or where the exercise of State authority would conflict with the exercise of Federal authority under a statute; in such cases, Federal agencies must limit preemption of State law to the extent possible.

In Section 18 of the Occupational Safety and Health Act (the OSH Act), Congress expressly provides that States may adopt, with Federal OSHA approval, a plan for the development and enforcement of occupational safety and health standards. States that obtain Federal approval for such plans are referred to as ''State Plan States'' (29 U.S.C. 667). Occupational safety and health standards developed by such State Plan States, among other things, must be at least as effective in providing safe and healthful employment and places of employment as Federal OSHA standards.

OSHA intends to closely scrutinize amendments to previously approved State hazard communication standards submitted under current or future State plans to ensure equal or greater effectiveness, including assurance that any additional requirements do not conflict with, or adversely affect, the effectiveness of the national application of OSHA's standard. OSHA must also determine in its review whether any State plan standard provisions that differ from the Federal provisions, when applicable to products distributed or used in interstate commerce, are ''required by compelling local conditions and do not unduly burden interstate commerce.'' OSH Act section 18(c), 29 U.S.C. 667(c).

This final rule complies with E.O. 13132. In States that do not have OSHA-approved State Plans, this rule limits State policy options in the same manner as all OSHA standards.

OSHA also reviewed this final rule in accordance with E.O. 13,175 on Consultation and Coordination with Indian Tribal Governments (65 FR 67,249 (Nov. 9, 2000)), and determined that it does not have ''tribal implications'' as defined in that order. The final rule does not have substantial direct effects on one or more Indian tribes, on the relationship between the Federal government and Indian tribes, or on the distribution of power and responsibilities between the Federal government and Indian tribes.

IX. State Plans

When federal OSHA promulgates a new standard or more stringent amendment to an existing standard, the 27 States or U.S. territories with their own OSHA-approved occupational safety and health plans must revise their standards to reflect the new standard or amendment, or show OSHA why there is no need for action, e.g., because an existing state standard covering this area is already ''at least as effective'' as the new federal standard or amendment. 29 CFR 1953.5(a). The state standard must be at least as effective as the final federal rule, must be applicable to both the private and public (state and local government employees) sectors, and must be completed within six months of the publication date of the final federal rule. When OSHA promulgates a new standard or a standards amendment which does not impose additional or more stringent requirements than an existing standard, states are not required to revise their standards, although OSHA may encourage them to do so.

The 27 States and U.S. territories with OSHA-approved occupational safety and health plans are: Alaska, Arizona, California, Hawaii, Indiana, Iowa, Kentucky, Maryland, Michigan, Minnesota, Nevada, New Mexico, North Carolina, Oregon, Puerto Rico, South Carolina, Tennessee, Utah, Vermont, Virginia, Washington, and Wyoming. Connecticut, Illinois, New Jersey, New York and the Virgin Islands have OSHA approved State Plans that apply to public-sector employees only.

This final rule modifies OSHA's hazard communication standard to conform to the United Nations' Globally Harmonized System of Classification and Labelling of Chemicals (GHS). It requires chemical manufacturers to use revised criteria for classification of chemical hazards, revised labeling provisions, and a specified format for safety data sheets. There are also revised requirements for employers to train their employees regarding labels and safety data sheets for hazardous chemicals. This GHS rule will also increase worker protection by improving the quality and consistency of information provided to employers and employees regarding chemical hazards and protective measures. Therefore, State Plan States must adopt comparable provisions within six months of publication of the final rule. Each State's existing requirements will continue to be in effect until it adopts the required revisions.

X. Unfunded Mandates

OSHA reviewed this final rule according to the Unfunded Mandates Reform Act of 1995 (''UMRA''; 2 U.S.C. 1501 *et seq.*) and Executive Order (''E.O.'') 12875 (58 FR 58093, Oct. 28, 1993).

Under Section 202 of the UMRA, an agency must prepare a written ''qualitative and quantitative assessment'' of the anticipated costs and benefits of any Federal regulation creating a mandate that ''may result in the expenditure by State, local, and tribal governments, in the aggregate, or by the private sector, of $100,000,000 or more'' in any one year. 2 U.S.C. 1532(a). As discussed in section VI of this preamble (''Final Economic and Voluntary Regulatory Flexibility Analysis''), the Agency estimates that this final rule will require private sector employers annualized expenditures of $201 million per year. However, OSHA's final rule does not place a mandate on State or local governments, for purposes of the UMRA, because OSHA cannot enforce its regulations or standards on State or local governments. (*See* 29 U.S.C. 652(5).) Under voluntary agreement with OSHA, some States enforce compliance with their State standards on public sector entities, and these agreements specify that these State standards must be equivalent to OSHA standards. The OSH Act also does not cover tribal governments in the performance of traditional governmental functions, though it does when tribal governments engage in commercial activity. However, this final rule does not require tribal governments to expend, in the aggregate, $100,000,000 or more in any one year for their commercial activities. Thus, although OSHA may include compliance costs for affected governmental entities in its analysis, this rulemaking did not trigger the requirements of UMRA based on its impact on State, local, or tribal governments.

Based on the analysis presented in the Final Economic Analysis (section VI above), OSHA has determined that this final rule will impose a Federal mandate on the private sector in excess of $100 million in expenditures in any one year, and is thus subject to the requirements under UMRA for review of private sector costs. The Final Economic Analysis in section VI, satisfies these requirements, and provides a written statement containing the qualitative and quantitative assessment of costs and benefits as is required under Section 202(a) of UMRA (2 U.S.C. 1532).

XI. Protecting Children From Environmental Health and Safety Risks

E.O.13045 requires that Federal agencies submitting covered regulatory actions to OMB's Office of Information and Regulatory Affairs (OIRA) for review pursuant to E.O.12866 must provide OIRA with (1) an evaluation of the environmental health or safety effects that the planned regulation may have on children, and (2) an explanation of why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the agency. E.O.13045 defines ''covered regulatory actions'' as rules that may (1) be economically significant under E.O.12866 (*i.e.,* a rulemaking that has an annual effect on the economy of $100 million or more, or would adversely effect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or tribal governments or communities), and (2) concern an environmental health risk or safety risk that an agency has reason to believe may disproportionately affect children. In this context, the term ''environmental health risks and safety risks'' means risks to health or safety that are attributable to products or substances that children are likely to come in contact with or ingest (*e.g.,* through air, food, water, soil, product use). This final rule is economically significant under E.O.12866 (*See* section VI of this preamble). However, after reviewing this final rule, OSHA has determined that the standard would not impose environmental health or safety risks to children as set forth in E.O.13045.

XII. Environmental Impacts

The Agency reviewed this final rule according to the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq.*), the regulations of the Council on Environmental Quality (40 CFR part 1500), and the Department of Labor's NEPA procedures (29 CFR part 11).

As a result of this review, OSHA has determined that this final rule will have no impact on air, water, or soil quality; plant or animal life; or the use of land or aspects of the external environment. Therefore, OSHA concludes that this final rule will have no significant environmental impacts.

XIII. Summary and Explanation of the Final Rule

This final rule is based on the public record developed during the rulemaking. As described in Section II, an advance notice of proposed rulemaking (ANPR) was published by OSHA on September 12, 2006 (71 FR 53617). The ANPR included a series of questions to solicit information on a number of specific topics. The responses from more than 100 commenters were used by the Agency to help prepare the required analyses for the proposed rulemaking, as well as to make determinations regarding the proposed text. The notice of proposed rulemaking (NPRM) was published by OSHA on September 29, 2009 (74 FR 50280). Public comments were received during a 90-day comment period that ended on December 29, 2009. Subsequently, public hearings were convened in March 2010 in Washington, DC, and Pittsburgh, PA, for the Agency to receive oral testimony from interested parties. Following completion of the hearings, participants were given an opportunity to provide additional information to OSHA during a post-hearing comment period, as well as submit briefs summarizing their views for the record. The public record upon which OSHA is basing the final standard includes all of the comments, testimony, and supporting information submitted by rulemaking participants, as well as by OSHA.

Support for the rulemaking. Many of those who responded to the ANPR expressed their support for adoption and implementation of the GHS. The supporters far outnumbered those who opposed or questioned adoption (*See, e.g.,* Document ID #0003, 0007, 0011, 0033, 0038, 0047, 0050, 0052, 0062, 0106, 0123, 0130, 0151, 0163, and 0171). The reasons presented for this support varied, but included the belief that adoption of the GHS will bring consistency and clarity to hazard communication (*e.g.,* Document ID #0038, 0046, 0059, and 0081); will help to ensure that employees have reliable, consistent, comprehensive, and comprehensible information (*e.g.,* Document ID #0030, 0037, and 0124); will help to enhance human health and the environment (improved worker safety) (*e.g.,* Document ID #0032, 0064, 0081, and 0128); and will reduce burdens associated with preparing multiple classifications and labels for the same product (*e.g.,* Document ID #0030, 0048, 0080, and 0123).

Support for implementation of the GHS by OSHA was expressed by both users and producers of chemicals who responded to the ANPR (*See, e.g.,* Document ID #0038, 0054, 0064, and 0124). While support for implementation of the GHS was widespread in the ANPR comments, these supporters also recognized the challenges associated with implementation. For example, it was noted by a number of commenters that there will be short-term costs associated with implementation, and they urged OSHA to take steps to minimize them by providing a reasonable time period for phase-in, coordinating with other agencies, and providing extensive outreach (*See, e.g.,* Document ID #0032, 0111, 0155, 0157, and 0162). Others were concerned that the GHS is not completely harmonized because it allows countries, and agencies within countries, to select from among a collection of building blocks when determining the scope of their requirements (*e.g.,* Document ID #0076).

In addition to those who supported implementation, but raised areas of concern regarding the way in which it is pursued, there were others who did not support implementation (Document ID #0004, 0065, 0068, and 0108). These commenters argued that it would be too burdensome (Document ID #0004); delegates power to an international body, which can only be accomplished through a treaty, if at all (Document ID #0065); would change the current hazard communication scheme and thus potentially impair safety (Document ID #0065); and should not be applied to pesticides because they are already heavily regulated (Document ID #0108).

In the NPRM, OSHA addressed each of these concerns and concluded that evidence, arguments, and accompanying analyses supported pursuing the modifications to the HCS. OSHA preliminarily determined that these modifications would enhance employee protection and facilitate compliance for all workplaces that produce or use hazardous chemicals.

While OSHA did not include questions regarding the support of stakeholders for adoption of the GHS, it was clear that a majority of those responding to the ANPR supported moving forward with the rulemaking. The arguments presented by those few who actively objected to adoption were addressed in the NPRM and the analyses for the rule, and were not found by OSHA to be persuasive. Other issues raised by supporters as concerns, or suggestions for addressing concerns, were also addressed in the proposed rule.

OSHA indicated in the NPRM (74 FR 50281, Sept. 30, 2009) that the Agency had made a ''preliminary determination that the proposed modifications to the HCS would increase the quality and consistency of information provided to employers and employees.'' OSHA also indicated that the ''standardized label elements would be more effective in communicating hazard information;

standardized headings and a consistent order of information would improve the utility of SDSs; and training would support and enhance the effectiveness of the new label and SDS requirements.'' Participants were asked if they agreed with this assessment, and also to provide information that reflected on the effectiveness of the proposed modifications in protecting employees from chemical hazards in the workplace.

Many participants responded, and the vast majority agreed with OSHA's preliminary determination that the proposed modifications would be effective in protecting employees, as well as the conclusions as to the reasons why it would be effective, and thus supported the rulemaking (*See, e.g.,* Document ID #0336, 0338, 0339, 0376, 0377, 0382, 0402, 0403, 0404, and 0412). These commenters reflected on a number of different aspects regarding effectiveness when indicating their support. For example, in comments provided on behalf of the American Iron and Steel Institute (AISI) and the American Coke and Coal Chemicals Institute (ACCCI), it was stated (Document ID #0360):

> AISI and ACCCI support OSHA's assessment that modifications to the Hazard Communication Standard (HCS) would increase the quality and consistency of information provided to employers and employees. Two improvements are expected with the changes OSHA has proposed:
>
> a. Standardized criteria to evaluate chemicals and communicate the hazards via Safety Data Sheets (SDSs) and labeling should assure consistent communication and lower the likelihood of miscommunication and misinterpretation.
>
> b. Standardized criteria to evaluate chemicals should facilitate training. With a single teaching format for SDSs and Labels, understanding, regardless of an employee's educational background, should be improved.

Comments of the Society of Chemical Manufacturers and Affiliates (SOCMA) express support, while highlighting some of the potential implementation challenges that will have to be addressed (Document ID #0402). SOCMA's comments are illustrative of those provided by other commenters who qualified their support by expressing issues that would have to be addressed in order for the benefits to occur *(See also, e.g.,* Document ID #0369):

> SOCMA members are generally very supportive of the implementation of GHS for workplace hazard communication in the United States, and for over the past forty years, we have spent millions of dollars and dedicated an insurmountable amount of time towards evaluating potential chemical hazards, communicating hazard information and protecting workers. The proposed rule may have a disproportionate economic impact on small business chemical manufacturers, particularly companies that are already struggling in these unstable economic times. A majority of these burdens can be mitigated, though, if the most affected entities are given adequate time to transition and proper compliance assistance is provided.
>
> * * * Once overcome though, the potential benefits of implementing GHS in the United States are highly anticipated by SOCMA members, some of which include: The harmonization of incompatibilities and inconsistencies in labeling and classification, more uniformity in both substance and format, the elimination of language and reading barriers through pictograms, and the facilitation of control banding.

OSHA addresses the suggestions of SOCMA and other commenters on ways to mitigate implementation issues in discussions of specific provisions below. The Agency believes it has taken the legitimate concerns of stakeholders into consideration when determining the final provisions of this rule.

The National Institute for Occupational Safety and Health (NIOSH) has extensive experience in another international effort to harmonize information on chemicals—development of International Chemical Safety Cards under the auspices of the World Health Organization (WHO) and the International Program on Chemical Safety (IPCS). In their comments, they highlighted the advantages of internationally-harmonized classification criteria (Document ID #0412):

> NIOSH recognizes OSHA's Hazard Communication Standard (HCS) as one of the most important U.S. regulations in occupational safety and health and concurs with OSHA on the need for a revised HCS. A significant advantage of the proposed standard is the detailed criteria for classification will improve accuracy and consistency in the information provided to employers and employees on chemical hazards and protective measures. Those criteria will reduce the likelihood of differing interpretations of the same data. In addition, the specified hazard categories will convey the severity of the effect, unlike the hazard classes in the current HCS.

Worker representatives also supported the proposed rulemaking. For example, comments on behalf of the United Steel, Paper and Forestry, Rubber, Manufacturing, Energy, Allied Industrial and Service Workers International Union (AFL/CIO.CLC), stated (Document ID #0403.2):

> The committees which designed the GHS agreed on an important principle early in the work: The final harmonized system should not weaken the protection afforded by any existing system. That in itself was a significant accomplishment. However, in the United States, adopting the GHS will go a step further—the revised, GHS-compliant Hazard Communication rule will greatly improve the comprehensibility of labels and safety data sheets, giving workers and employers—especially employers in small business—information they can more easily understand and use.

While stakeholder support for the rule was extensive, there were some stakeholders who did not support pursuing a final rule to modify the HCS, sought to exempt their constituents from its provisions, or supported a different approach. For example, the American Composite Manufacturers Association (ACMA) argued that the protections of the current rule are sufficient, and implementation of the revisions would be too burdensome for their industry (Document ID #0407). No data were provided to support these contentions. The North American Insulation Manufacturers Association (NAIMA) indicated they support harmonization, but argued that the proposed standard will not achieve global harmonization for a number of reasons, including conflicting domestic requirements (*See* discussion below), administrative hurdles to regularly revising the GHS to remain current with the international version, and obstacles to keeping the GHS current (Document ID #0411). And the National Propane Gas Association (NPGA) stated that only those who operate in an international market will benefit, and that does not include the propane industry (Document ID #0400). Similarly, the Intercontinental Chemical Corporation (ICC) argued that companies not involved in international trade should be allowed to continue complying with the existing standard, and that those who are involved can comply with the revised provisions (Document ID #0502).

OSHA does not find any of these arguments persuasive. With regard to NAIMA, OSHA indicated in the NPRM how it plans to maintain the necessary consistency with the GHS through the various rulemaking options available to the Agency, and that it continues to participate in the international GHS activities in order to be involved in maintenance of the system itself. We do not agree that these are insurmountable concerns that argue against adopting the provisions, or changing the approach in a significant way.

OSHA agrees with ACMA and ICC that the existing standard provides extensive protections to exposed employees. However, the analyses presented in support of the proposed and final rules demonstrate that these

protections could be improved by adopting the revised provisions. See Sections IV and VI of this document. In addition, the argument of NPGA that benefits only accrue to companies involved in international trade is not accurate. The improved protections of the rule due to standardization of classification criteria and harmonization of communication on labels and safety data sheets apply equally to employees of companies involved in international trade, and to those in companies that are not involved in such trade. Workers who use hazardous chemicals produced for the domestic market are entitled to the same level of protection as those who use chemicals produced for the international market, and any standard that treated them differently might well be inconsistent with the OSH Act. As indicated in the regulatory analyses for the proposed and final rules, the revisions are economically and technologically feasible for all businesses, including small businesses. See Section VI of this document.

Other general issues. Commenters also raised a number of other issues related to the rulemaking that were not directed to specific paragraphs of the HCS in responses to both the ANPR and the NPRM. Some respondents indicated that OSHA should limit changes to the HCS to those required to align with the GHS, thus keeping the framework of the existing HCS (*See, e.g.,* Document ID #0047, 0080, 0104, 0123, 0145, 0163, 0167, and 0170). For example, ORC Worldwide (Document ID #0123) stated in ANPR comments:

> * * * OSHA can help minimize the cost to businesses by only modifying those sections of the OSHA Hazard Communication Standard (HCS) that must be changed to be consistent with GHS. Therefore, we strongly support OSHA's stated intent to maintain the current scope, application, and interpretations of the HCS, and only modify those sections of the standard necessary for consistency with the GHS. Not only will this help minimize the implementation burden on industry, it should also serve to minimize confusion among employers and employees during the implementation period.

OSHA agreed with these commenters, and made every effort in the NPRM to maintain the framework of the current HCS in the proposed revisions. The modifications proposed were believed by OSHA to be those that were required to align the current HCS with the GHS, but did not address provisions of the current standard that are not addressed in the GHS. Thus, for example, the scope and application paragraph remained largely unchanged, as did the paragraph addressing trade secret protection. The primary modifications proposed in those paragraphs were changes in terminology required to ensure consistency.

A number of commenters addressed this issue in their NPRM comments and testimony as well. For example, Dow Chemical Corporation indicated (Document ID #0353) that OSHA should follow two overarching principles as it revises the HCS. The first is to ''implement the GHS with as little US customization as possible,'' and the second is to ''make only those changes to the HCS that are necessary to facilitate GHS implementation.'' (*See also, e.g.,* Document ID #0370.) Both of these principles were, in fact, followed by OSHA when preparing the NPRM.

Others commenters recognized this was OSHA's approach, and supported it. For example, the Defoamer Industry Trade Association (DITA) noted (Document ID #0367):

> DITA applauds the fact that OSHA did not modify the GHS definitions to a great degree. These definitions reflect a consensus scientific process for the review of the hazards that chemicals can present and the toxicology data that predicts the likelihood of hazard occurring. Accordingly, this should lead to a high level of harmonization on the classification of chemical substances between the EU and the US. A high degree of harmonization is desirable so that manufacturers do not need different SDSs that satisfy the requirements of different countries.

In the final rule, OSHA has continued to remain as consistent as possible with the provisions of the GHS. In general, OSHA has not changed the language of GHS provisions unless necessary to conform with the regulatory requirements of the HCS. Country-specific deviations are very limited, and are intended to ensure that the protections of the current rule are maintained in the final rule. This is consistent with the principle of the GHS developers that no country should have to reduce protections in order to harmonize. OSHA does not believe that any of the deviations in the final rule conflict in a substantive way with the GHS itself.

Many commenters to the ANPR also suggested that OSHA should coordinate implementation of the GHS with other Federal agencies. These included primarily EPA, DOT, and CPSC (*See, e.g.,* Document ID #0048, 0050, 0053, 0076, 0104, 0111, 0123, 0134, 0154, 0162, and 0170). For example, the Soap and Detergent Association (Document ID #0170) stated:

> SDA urges OSHA to coordinate implementation of revisions to the HCS related to the GHS with the Environmental Protection Agency (EPA), Department of Transportation (DOT), and the Consumer Product Safety Commission (CPSC), which all have announced their intentions to implement GHS provisions in their regulations. Workplace hazard communication occurs in a stage of the overall life cycle of chemicals and finished products. Coordination and synchronization of implementation timing could greatly improve the efficiency of implementation of the GHS by industry.

Others mentioned coordinating implementation with the Mine Safety and Health Administration (MSHA) (Document ID #0049, 0101, and 0111).

Similar comments were received in responses to the NPRM (*See, e.g.,* Document ID #0344, 0345, 0350, 0351, 0375, 0376, 0403, and 0411). OSHA agrees with these commenters that the U.S. government agencies should continue to coordinate their activities with regard to implementation of the GHS. In terms of adopting the GHS provisions, DOT has substantially aligned the criteria for physical hazards in their regulations with those of the GHS under the HM–215I rulemaking (71 FR 78596, Dec. 29, 2006). DOT and OSHA arguably have the greatest interface in covered chemical products, and thus adoption of this final rule will result in greater consistency between these two agencies. EPA and CPSC have not initiated rulemaking on the GHS. However, as will be discussed later in this preamble, EPA and OSHA have worked together to develop a common position on coverage of pesticides and chemicals covered by the hazard communication requirements of the Toxic Substances Control Act's (TSCA's) significant new use rules. Clearly, there is no way to coordinate timelines for adoption given that OSHA is at the final rule stage, and neither EPA nor CPSC has started a rulemaking process. As rulemaking develops in these Agencies, discussions will continue to take place in the interagency committee on this subject. With regard to MSHA, Department of Labor rulemaking activities are coordinated through Department officials, and MSHA has been apprised of OSHA's activities in order to determine what action may be appropriate for them to pursue in this area.

A number of commenters to the ANPR also argued that OSHA should coordinate implementation with major U.S. trading partners (*See, e.g.,* Document ID #0042, 0048, 0101, 0116, 0128, 0141, 0155, and 0170). Similarly, several argued that countries should limit modifications to the GHS that are country-specific, and that the UN process should be used to control such changes (Document ID #0018, 0042,

0134, 0154, 0163, 0164, and 0171). For example, the American Petroleum Institute (API) addressed these issues as follows (Document ID #0171):

API strongly recommends that OSHA ensure that timing and coordination of GHS implementation schedules are in line with those of other countries, allowing sufficient time for companies to organize and accomplish necessary work. In order to achieve international harmonization of hazard communication materials and to avoid undue burden on companies, OSHA must stay engaged with all other actors to encourage even and consistent implementation of GHS by individual countries. Further, API recommends that OSHA work closely with other government agencies and countries to ensure alignment to the UN endorsed version of the GHS. As the implementation of the GHS by countries deviates from the UN version of GHS, the perceived benefits of harmonization substantially decrease.

Similar comments were received by participants in the rulemaking after the NPRM was published. For example, 3M indicated (Document ID #0405):

3M agrees that the potential benefits identified in the proposed NPRM may be achieved through global implementation of GHS. However, 3M emphasizes that the potential benefits of GHS will depend on countries around the world aligning as closely as possible with the GHS. The potential benefits of GHS will be substantially undercut by country-specific differences or additions that would require companies to have multiple SDSs and labels for the same product.

Michele Sullivan, an independent consultant, recognized OSHA's approach as being appropriate, and argued for coordination among trading partners (Document ID #0382):

Consistent implementation among the major trading partners of the world is crucial to realize the benefits of the GHS system. For this reason, the alignment, insofar as possible, of all national and regional GHS systems with the UN GHS system is critical. In addition, any national or regional GHS implementation effort must retain enough flexibility to continually adapt the system as necessary to harmonize as closely as possible with the UN GHS system.

OSHA agrees with these commenters that coordination among trading partners would enhance harmonization and facilitate implementation. The Agency remains active in the UN process, participating in the Sub-committee of Experts on the GHS (UNSCEGHS), as well as the United Nations Institute for Training and Research (UNITAR) Programme Advisory Group. There is increased emphasis in the Sub-committee on implementation issues as well as coordination. OSHA is leading a correspondence group of interested members established by the Sub-committee that is reviewing practical classification and hazard communication issues, and proposing modifications to the Sub-committee to clarify such provisions when identified. There are also other correspondence groups that are addressing implementation issues as they are raised to the Sub-committee. OSHA tries to participate in all of this work in the Sub-committee to help ensure that any U.S.-identified issues are raised and addressed. Essentially all of the countries involved in implementation participate in the Sub-committee, so this is OSHA's best opportunity to coordinate with them.

The Agency has also had bilateral discussions with Canada, as well as the European Union (EU), on issues related to implementation. These discussions continue periodically to address mutual issues of concern.

Canada has not yet proposed modifications to their system to achieve harmonization, but they are planning to in the near future. The EU has adopted the GHS, and according to a press release on January 4, 2011, from the European Chemicals Agency (ECHA), recently reached a significant implementation milestone for its Classification, Labelling and Packaging (CLP) regulation. (*http://echa.europa.eu/news/pr/201101/pr_11_01_clp_deadline_20110104_en.asp*):

By 3 January 2011, ECHA received 3,114,835 notifications of 24,529 substances for the Classification and Labelling Inventory. By this deadline, industry had to notify the classification and labelling of all chemical substances that are hazardous or subject to registration under the REACH regulation and placed on the EU market.
* * *

The Classification, Labelling and Packaging regulation relates to chemical substances and mixtures. It introduces into the EU the criteria of the United Nations' Globally Harmonised System for classifying and labelling chemicals. One of the aims of the CLP regulation is to improve the protection of human health and the environment by providing criteria for defining when a substance or mixture displays properties that lead to its classification as hazardous.

CLP applies to manufacturers, importers, users or distributors of chemical substances or mixtures. They must classify, label and package any substance or mixture, regardless of its annual tonnage, in accordance with the Regulation.

The largest number of the notifications, over 800,000, came from Germany. Over 500,000 notifications were submitted from the United Kingdom and nearly 300,000 from France. All together over 6,600 companies notified at least one substance.

Canada and the EU are two of the major trading partners for the U.S. When OSHA prepared the NPRM, it examined the CLP to coordinate where possible on approaches to implementation. However, the primary principles followed by OSHA in developing this proposal were to ensure that the modifications maintain or enhance the protections of the current standard, and that the modifications are consistent with the negotiated provisions of the GHS.

One of the issues of concern regarding implementation by some other countries has been deviation from the GHS itself. Because GHS is intended to be globally implemented, efforts by countries to deviate in a collective manner from the GHS, rather than maintaining consistency, defeats the purpose and, consequently, lessens the benefits of the GHS. OSHA will continue to seek opportunities to ensure coordination of implementation and promote harmonization, both internationally and bilaterally.

It should also be noted that the GHS is a living document, and the UN actively reviews it and considers possible changes based on implementation experiences and other information. These changes are made on a two-year cycle, referred to as a biennium. The OSHA proposal and the final rule are based on Revision 3 of the GHS. Revision 3 was adopted by the UN Committee and Sub-Committee of Experts on the GHS in December 2008, and is available as a publication and on the UN Web site. In December 2010, the UN Committee and Sub-committee of Experts on the GHS adopted additional changes that will be issued as Revision 4.

It is expected that as the UNSCEGHS fulfills its mandate to ensure that the GHS is up-to-date and relevant, further changes will be adopted on a biennium basis. If the change(s) is substantive and controversial, OSHA will have to engage in notice-and-comment rulemaking in order to amend the HCS. However, for non-substantive or clarification changes, other rulemaking options are available that can be utilized to implement the changes more quickly than the full notice-and-comment rulemaking process.

Two possible means are the Standards' Improvement Process (SIPs) or a Direct Final Rule (DFR). Each of these options gives the public notice and opportunity to comment, but has the advantage of a faster process. Either method could be used to ensure that the HCS remains current with the GHS.

A number of NPRM participants commented that OSHA should establish a stakeholder process for input into U.S. government positions on issues raised at

the UN (*See, e.g.,* Document ID #0376, 0377, 0381, 0382, and 0411). OSHA is always open to receiving suggestions from stakeholders regarding issues raised in the UN process. The working papers are made publicly available on the UN Web site some 12 weeks before meetings. Public meetings are scheduled to receive input in some situations, and stakeholders may also contact the primary OSHA delegate directly to discuss any of the issues raised. Stakeholders can participate in the Sub-committee discussions directly as well through organizations that have recognized status in the Sub-committee. As already noted, changes to the OSHA HCS as a result of modifications to the GHS in the future will be subject to a public rulemaking process where all stakeholders have the opportunity to participate.

In the NPRM (74 FR 50288, Sept. 30, 2009), OSHA noted that one advantage of adopting a system with harmonized hazard statements is that it would facilitate the use of ''control banding'' in the U.S. Control banding is an approach to selecting control measures for workplace chemical exposures. Basically, the employer can, with the use of information readily available in the workplace, use the approach to determine the appropriate control measures for a chemical. The harmonized hazard statements are key to assessing the hazards, and the degree of severity of the hazards. In combination with data about physical and chemical characteristics, quantities used, and the types of processing, the employer can access recommended control measures. It is particularly helpful in situations with common operations (*e.g.,* bagging operations), and chemicals with well-known hazards that are not severe (*e.g.,* it would not generally be applied to a carcinogen—the control banding guidance would inform the employer that professional assistance must be acquired to address such a hazard). Control banding has been used successfully by small and medium-sized businesses that don't have extensive health and safety expertise in these types of situations.

There is considerable international interest in this approach, and there have been a number of research studies conducted to refine the approach and determine its applicability. Both OSHA and NIOSH have taken part in activities to further investigate its utility in the U.S. NIOSH has extensive information available on its Web site at *http://www.cdc.gov/niosh/topics/ctrlbanding/*. As they indicated in their comments (Document ID #0412):

> The use of control banding to provide guidance for chemical safety and health approaches in U.S. workplaces cannot be accomplished until harmonized hazard statements are readily available. Adoption of the GHS and its phrases would open up the possibility that control banding guidance can be used in the United States to help small- and medium-sized employers select and implement appropriate control measures [NIOSH 2009].

The American Society of Safety Engineers (Document ID #0336) is also a strong proponent of control banding. However, their position was that OSHA should have included control banding in the NPRM, and thus in the HCS:

> * * * ASSE believes OSHA should update the HCS to incorporate elements of control banding. Assuming that most elements of GHS will be adopted and a national database for safety data sheets (SDSs) and chemical classifications will be established to support the transition to GHS from current practice, building a system that would allow guided review of materials and processes such as control banding would be a relatively small additional step. We encourage OSHA to take that step now and avoid revisiting this issue when it becomes unavoidable as control banding grows in use internationally as well among leading employers in this nation.

While OSHA agrees with ASSE that control banding may be a very useful approach to controlling workplace exposures to chemicals, it does not agree that this rulemaking is the appropriate place to address this issue. As noted by both OSHA and NIOSH, adoption of the GHS will facilitate the use of control banding in the U.S. by making harmonized hazard statements readily available on labels and SDSs. This will allow the adaptation of the approach in a way that could not be readily accomplished with the current performance orientation of the HCS. However, it is generally viewed as a guidance approach where it is currently used, and not a mandatory requirement. Furthermore, control banding continues to be refined in terms of application, and is not harmonized. Adoption of it in the HCS would also not be consistent with the principles OSHA has followed in devising the NPRM, *i.e.,* to limit changes to those required to align with the GHS, and to be as consistent as possible with the GHS provisions. Therefore, while OSHA believes the utility of control banding should continue to be assessed and evaluated in the U.S., it is premature to consider the approach as a mandatory requirement and part of the revised HCS.

Outreach/compliance assistance. The ANPR included a series of questions to solicit input from the public on what outreach or compliance assistance materials would be appropriate and useful. OSHA received many comments in response to these questions, with a number of creative and interesting suggestions for outreach products. The Agency will use this input to develop an outreach plan and prepare materials for distribution when the rulemaking is completed. In addition, and as suggested by a number of ANPR commenters (*See, e.g.,* Document ID #0018, 0025, 0047, 0065, 0081, 0104, and 0154), OSHA will continue working with interested parties to examine projects that could be completed by them, or in coordination with them, that could be targeted to specific industries or interest groups.

OSHA solicited additional ideas for outreach or compliance assistance in the NPRM, and many commenters provided such information (*See, e.g.,* Document ID #0332, 0344, 0356, 0370, 0382, 0405, 0408, 0410, and 0414). There was a wide range of suggestions, including training programs, workshops, web resources, and enforcement tools addressing different aspects of the modified standard. OSHA has already developed some compliance assistance products—or updated products available for the existing standard—and will be developing and distributing these and others as resources are made available. There are also tools being developed internationally that will be available for employers undertaking compliance, such as training materials in preparation by the United Nations Institute for Training and Research (UNITAR). OSHA has provided support to this activity, and expects these materials will be made available on its Web site when completed. OSHA encourages trade associations, professional societies, and others to develop materials that are specific to certain interest groups or industries, thus providing a more focused compliance assistance approach than can be done by OSHA at the national level.

The final standard. The following is a description of the provisions of the final standard, along with a discussion of what was proposed and the information provided by rulemaking participants. As noted above (and supported by rulemaking participants), OSHA's approach has been to confine changes to the standard to those required to align it with the GHS. Therefore, provisions that do not require changes for that purpose have been left the way they are in the current HCS. While participants supported this approach in general, suggestions were made that involved changes to the current text in areas unaffected by the GHS. Since OSHA did not propose to

open these parts of the rule in the proposed rulemaking, and the analyses did not involve such changes, the Agency will not be adopting them in the final rule.

Similarly, as OSHA indicated in the NPRM, the Agency's approach was also to be as consistent as possible with the GHS itself. Editing was limited to what was required to make the provisions mandatory in the context of OSHA rulemaking, and using the regulatory language required for that purpose. Additionally, as described in the NPRM, OSHA did not propose adopting language from the GHS that was strictly provided for guidance purposes (such as the decision logics in the chapters in the GHS that describe the physical and health hazard criteria). There is no question that other changes could be made to the language to make it more readable, or to state it in American English. However, introducing different terminology also introduces the possibility that readers will believe that OSHA means something different than the GHS because we have used different language. Since this is not the intent, the Agency has avoided doing this.

Nevertheless, many such editorial changes were suggested. While OSHA has reviewed all of them, and adopted a few that seemed appropriate or necessary, in general the Agency did not engage in extensive editing of agreed text for fear of changing the meaning, or giving the impression that the meaning has changed. In particular, Dow Chemical submitted extensive suggested edits in both its initial comments on the NPRM and in post-hearing comments (Document ID #0353 and 0526). Most of these issues were not raised by any other participants. Given the large number of such editorial suggestions from Dow, OSHA does not discuss each one in this preamble, but simply notes where changes have been made to the text. OSHA, however, gave each of Dow's suggestions full consideration.

(a) Purpose. The HCS includes a paragraph that states the purpose of the rule. This stated purpose is two-fold. First, the paragraph indicates that the standard addresses assessment of the hazards of workplace chemicals, and the transmittal of that information to employers and employees. It also describes the contents of a comprehensive hazard communication program as being container labeling and other forms of warning, material safety data sheets, and employee training.

The second part of the paragraph addresses the preemption of State or local laws by this Federal standard. It indicates that OSHA is addressing comprehensively the issues described, and thus the standard preempts States, and political subdivisions of States, from addressing these issues except under the authority of a Federally-approved State plan under Section 18 of the OSH Act. While Section 18 applies to every occupational safety and health standard that OSHA promulgates, the HCS raises particular issues because of the nature of the provisions. It requires chemical manufacturers and importers to evaluate the hazards of the chemicals they produce or import, and to prepare labels and safety data sheets based on those evaluations to transmit hazard information and appropriate precautionary advice to users downstream. This is a unique but highly appropriate approach for an OSHA standard, as it recognizes that chemical manufacturers and importers are in the best position to assess the hazards of their products and develop appropriate information for labels and SDSs.

There is a national, indeed international, marketplace for industrial chemicals, and thus chemical manufacturers and importers affect commerce within the meaning of the OSH Act and therefore fall under OSHA's jurisdiction. If a State, or a political subdivision of a State, were to establish different requirements for labels and safety data sheets, such requirements would have an impact on chemical manufacturers and importers that are not located in that State. This is a burden that the HCS eliminates by establishing national requirements.

The proposed revisions to the HCS had essentially the same purposes, and thus the NPRM included only minor modifications to this paragraph. OSHA proposed to modify paragraph (a)(1) to change the language regarding the assessment of hazards to indicate that the hazards will be ''classified'' rather than simply assessed or evaluated. This is consistent with the approach in the GHS. In addition, OSHA proposed to modify this paragraph to clearly indicate that the standard is intended to be consistent with the GHS, Revision 3. That change is a reflection of the purpose of this rulemaking to harmonize the existing requirements with the provisions of the GHS, which is the international instrument that includes globally harmonized provisions on hazard communication. In addition, in this paragraph and succeeding paragraphs of the revised rule, the term ''material safety data sheet'' was modified to ''safety data sheet'' to reflect the terminology of the GHS.

The only modifications proposed to paragraph (a)(2) also addressed terminology, using ''classifying'' instead of ''evaluating'', and ''safety data sheet'' instead of ''material safety data sheet''.

There were a few comments that were related to the Purpose paragraph provisions. One comment suggested that the standard should be limited to a purpose of international communication so as not to trigger hazard assessments under other OSHA standards that address respiratory protection, personal protective equipment, or process safety management (Document ID #0049). There were several other comments that indicated that new assessments would have to be done for these standards (Document ID #0111, 0134, 0164, and 0178). Arguments were made that this would lead to extensive additional costs for new engineering controls, respirators, or other personal protective equipment.

As discussed above, there is no identified link to these other standards in the stated purpose of the HCS either currently or with the proposed modifications in the NPRM. While the current HCS and this final standard require the provision of information on recommended control measures, including respiratory protection, personal protective equipment, and engineering controls, there is no requirement for employers to implement the recommended controls. An employer should use all available information when designing an appropriate protective program, but a recommendation on a safety data sheet by itself would not trigger the need to implement new controls.

Furthermore, these comments seem to imply that there will be major changes in the classification of the hazards of chemicals as a result of implementation of the GHS provisions. Both the HCS and the GHS are based on identifying and communicating the inherent hazards of chemicals. Thus the biggest change for most chemicals under the final rule will be in categorizing the chemical's hazards. Under the current standard, for example, a chemical either is, or is not, a carcinogen. Under the revised HCS, if a chemical is a carcinogen, it would be categorized as a Category 1 or a Category 2 carcinogen. Such a change would provide additional information for the downstream user, but would not generally result in a need to change engineering controls or respiratory protection.

It is possible that a chemical may be classified under the final rule as having a hazard it did not have before, but OSHA believes that this is not likely to happen frequently given the broad coverage of the current rule. Furthermore, the physical and chemical characteristics of the chemical—which

affect the types of protection required—would not be changed as a result of this proposal. OSHA believes that these revisions would result in few, if any, changes in protective measures required under other OSHA standards.

Several commenters to the ANPR noted what they believed to be the continued need to address the preemption of State standards (*See, e.g.,* Document ID #0036, 0048, 0056, 0080, 0123, 0135, and 0178). In addition, commenters also noted that the impact of GHS adoption on State and local laws should be considered in the process (for example, California Proposition 65), and that differences between such laws and the revised HCS should be discouraged (Document ID #0015, 0038, 0042, and 0072).

It was also indicated that changes in State laws should be coordinated with the Federal changes to facilitate implementation (Document ID #0146). *See* Section VIII and IX of this preamble for a comprehensive discussion regarding Federalism and State plans.

There were a number of comments received in response to the NPRM that addressed the Purpose paragraph provisions. For example, the Styrene Information and Research Center (Document ID #0361) indicated that OSHA should revise paragraph (a)(1) to say that it is intended to be consistent with the GHS ''with some exceptions,'' since there are some deviations from the GHS. OSHA does not agree with this suggestion. The language proposed, and in the final rule, is accurate—it is consistent with the provisions of the GHS. The GHS is not a model regulation, and it is not intended that countries will adopt the actual text of the GHS. Furthermore, there is allowance for flexibility and differences where necessary to accommodate a country's specific needs. There was nothing in the NPRM that was inconsistent with the GHS, and neither is the final rule inconsistent.

Dow Chemical (Document ID #0353), argued that paragraph (a)(2) should state that OSHA is preempting personal injury suits alleging that labels provided inadequate warnings. The Industrial Minerals Association-North America (Document ID #0394) indicates that the new rule must make clear that it preempts state law tort claims alleging failure to warn. OSHA declines these invitations. As recently explained in the Solicitor of Labor's letter to Stephen Wodka, dated October 18, 2011, in general the HCS does not preempt state tort failure to warn lawsuits, and OSHA does not intend to change that position in the final rule. Indeed, the OSH Act's ''savings clause'' explicitly preserves, rather than preempts, State tort law. OSH Act § 4(b)(4), 29 U.S.C. 653(b)(4); *Lindsey* v. *Caterpiller, Inc.,* 480 F.3d 202, 209 (3d Cir. 2007); *Pedraza* v. *Shell Oil Co.,* 942 F.2d 48, 53–54 (1st Cir. 1991). While a limited preemption might be possible to the extent a state tort rule directly conflicted with the requirements of the standard, no commenter has provided any evidence of such a conflict. For example, the record contains no evidence that a manufacturer might be held liable under a State's tort law rules for complying with the GHS. However, to eliminate any confusion about the standard's preemptive effect, and to be consistent with the President's May 20, 2009 Memorandum on Preemption, OSHA has made two small changes to (a)(2) in the final rule, changing the words ''legal requirements'' to ''legislative or regulatory enactments'' in the provision's first sentence and eliminating the words ''through any court or agency'' in the last sentence.

Similarly, DuPont (Document ID #0329) says OSHA should convince States to voluntarily rescind their ''right-to-know'' laws, or make them consistent with the HCS final rule. And the National Paint and Coatings Association (NPCA) (Document ID #0328) believes that OSHA should not allow States to promulgate a standard that is different from the Federal rule. As indicated in paragraph (a)(2), States with OSHA-approved State Plans will have to adopt standards that are at least as effective as this final rule. (*See,* generally, 62 FR 31159, Jun. 6, 1997.) Those standards will be reviewed by Federal OSHA. Other States are preempted from covering these areas with regard to workplace protections. OSHA has no authority with regard to provisions that are intended to address non-workplace situations.

Therefore, OSHA has concluded that the changes it proposed to Paragraph (a) are appropriate, and those changes are being incorporated into the final rule. No other revisions are being made.

(b) Scope and application. The HCS is a generic standard that has very broad provisions in terms of chemicals addressed and workplaces covered. It also interfaces with a number of requirements of other Federal agencies that address labeling of chemical hazards. Paragraph (b) thus includes all of the practical modifications the Agency has developed to ensure that employers and employees understand how the standard is to be applied, and to accommodate various circumstances that potentially affect the application of the standard.

The provisions of paragraph (b)(2) in the HCS address the overall scope of the standard as applying to ''any chemical which is known to be present in the workplace in such a manner that employees may be exposed under normal conditions of use or in a foreseeable emergency.'' This provision addresses many questions that are raised about the application of the standard.

In general, OSHA does not expect significant changes in the chemicals covered by the HCS under the final rule as compared to the current standard. The scope of hazards covered by the GHS is very similar to what is covered by the current HCS. Additional chemicals may be considered to be acutely toxic due to the proposed adoption of Category 4 in acute toxicity, which would expand the criteria for inclusion from the current definition (*See* the discussion under ''Hazard classification''). However, these chemicals are already covered under the voluntary national industry consensus standard on precautionary labeling of industrial chemicals that many manufacturers follow in their labeling programs (ANSI Z400.1/Z129.1–2010, *Hazardous Chemicals—Hazard Evaluation and Safety Data Sheet and Precautionary Labeling Preparation),* as well as being covered in the requirements that apply to chemicals shipped to the EU. Thus many manufacturers are already classifying and labeling these chemicals as acute toxins. The final rule is also likely to cover fewer mixtures as acute toxins than the current rule given the hazard classification approach in the GHS that uses a calculation based on proportionality to determine whether a mixture is covered, rather than the strict percentage cut-off of 1% in the current HCS. Other definitions of health hazards would maintain the current broad HCS scope.

In addition to the overall scope statement, the final rule, like the current rule, provides for limited coverage in workplace situations that have special circumstances, including laboratories (paragraph (b)(3)) and work operations where employees only handle chemicals in closed containers (paragraph (b)(4)).

OSHA also addresses the interface with other Federal agency requirements by either exempting the products covered from additional OSHA labeling (such as pesticides required to be labeled by the EPA) (paragraph (b)(5)), or completely exempting the product (such as hazardous waste regulated by EPA) (paragraph (b)(6)). These accommodations help to ensure that

Federal requirements do not conflict or duplicate each other.

Under the GHS, such provisions are left under the purview of the ''competent authority.'' In developing the GHS, it was recognized that countries' regulatory authorities would need to have the discretion to address such national circumstances in ways that are suited to the regulatory perspective of the country. Thus authorities such as OSHA are free to make determinations about scope and application issues while still being harmonized with the primary provisions of the GHS.

OSHA reviewed the current provisions of paragraph (b), and determined that no significant changes were required to be consistent with the GHS. Several minor changes to revise terminology were retained from the proposal (*i.e.,* adopting the terms ''classifying'' and ''safety data sheets''), but OSHA is not modifying any of the remaining provisions of paragraph (b). The Agency is also deleting Appendix E of the current HCS, which was guidance for application of the standard, and thus is deleting the reference to it in paragraph (b)(1). The Sheet Metal and Air Conditioning Contractors National Association (SMACNA) (Document ID #0415) suggested in response to the NPRM that OSHA update Appendix E and continue to include it in the standard. OSHA will update Appendix E, and make it available as a compliance assistance product. It was always available as a pamphlet in any event, and has been very useful in helping small employers who are users of chemicals comply with the standard. And as noted above, new outreach and compliance assistance materials are being prepared as well.

Several commenters to the ANPR indicated that OSHA should adopt exemptions included by the European Union in its requirements. Specifically, these exemptions address non-isolated intermediates, chemicals involved in research and development, and waste (Document ID #0049, 0134, and 0164). In response to the NPRM, the Society of the Plastics Industry (SPI) (Document ID #0392) continued to argue that the EU exemptions should be adopted. All of these situations are already addressed in paragraph (b), and OSHA does not agree that it is appropriate or necessary to change them.

In terms of non-isolated intermediates, the overall scope provision in paragraph (b)(2) adequately addresses this situation. This was described in the preamble to the 1983 final rule (48 FR 53335, Nov. 25, 1983):

> That is, the term ''known'' means the employer need not analyze intermediate process streams, for example, to determine the presence or quantity of trace contaminants. However, where the employer knows of such contaminants, and they are hazardous, then they fall under the provisions of the standard.

With regard to chemicals involved in research and development, paragraph (b)(3) limits coverage in laboratories, and partially addresses this situation. Where there is no knowledge of the hazards of such chemicals, the HCS does not apply at all since there is no requirement to generate new hazard information. Where information is available, it must be provided to exposed employees, consistent with paragraph (b)(3) when it is in a laboratory situation. Therefore, it appears to OSHA that this situation is also adequately addressed under the current provisions. Hazardous waste as regulated by EPA is already exempted under paragraphs (b)(6)(i) and (ii).

The North American Metals Council (NAMC) (Document ID #0377) argued in response to the NPRM that OSHA should use the EU approach to exempt metals in their massive form, alloys, and other preparations that do not present a hazard. Provisions already exist in the current HCS, and are included in the final rule, that address these issues (*See, e.g.,* definition of article (paragraph (c)), special labeling provisions for solid metals (paragraph (f)(4))).

There were commenters who suggested that OSHA maintain current exemptions or limitations in the revised GHS, including the consumer product exemption (Document ID #0064), guidance on byproducts (Document ID #0064), the relative roles of manufacturers and employers (Document ID #0064), and the article exemption (Document ID #0160). OSHA agrees and all of these accommodations remain the same in the revised rule. The Agency is not changing those parts of the HCS that are not affected by the GHS.

There were also a few comments regarding the scope of the revised rule in terms of provisions of the GHS that affect the environment or transportation (*See, e.g.,* Document ID #0072 and 0179). OSHA does not have the authority to require information in these areas since they are not directed to the protection of employees under its jurisdiction. However, OSHA does not prohibit this type of information on labels or safety data sheets, and is aware that it is often included on labels and safety data sheets currently developed to comply with the HCS. OSHA expects that chemical manufacturers will continue to voluntarily include such data on their labels and safety data sheets to meet the requests of their domestic and international customers. Commenters to the NPRM continued to state that OSHA should allow environmental information although it is not required (Document ID #0344 and 0381). OSHA maintains the position proposed that manufacturers are free to provide additional information on labels and safety data sheets to address environmental concerns, as well as aspects of concern in other areas such as transportation. (74 FR 50387, Sept. 30, 2009)

Few comments were received on this paragraph in the NPRM. Dow Chemical (Document ID #0353) suggested that paragraph (b)(5)(iv) be updated to reflect the changed name of the Bureau of Alcohol, Tobacco, Firearms, and Explosives (the word ''Explosives'' has been added to their name). This has been done. In addition, two typographical errors in (b)(6)(ii) have been corrected.

The North American Insulation Manufacturers Association (NAIMA) (Document ID #0411) states that OSHA has given unwarranted exemption by ceding authority for products regulated by other agencies. In particular, NAIMA is concerned about coverage by CPSC, and indicates that CPSC addresses the fire hazards of cellulose insulation, but not the health hazards, in its label requirements. NAIMA argues that OSHA should not allow consumer product labels to supersede OSHA requirements.

OSHA considered this issue at length in previous amendments to the HCS (53 FR 29822, 29834–38, Aug. 8, 1988; 59 FR 6126, 6150–52, Feb. 9, 1994; *See also* 52 FR 31852, 31862–63, Aug. 24, 1987). After noting that CPSC labels often do not contain all hazard information relevant to worker exposures, OSHA concluded that:

> OSHA nevertheless decided to permit the CPSC labels to suffice so as not to disrupt the extensive labeling conducted in accordance with those rules. OSHA believed that this could be justified on the basis that some information is provided on the labels that would be useful to workers, and that the requirement for MSDSs would provide what information is necessary to supplement the labels. 48 FR 53289. This additional information is critical to ensuring that training can be properly conducted, and that adequate protective measures are used in the workplace.

(53 FR 29834, Aug. 8, 1988; *See also* 59 FR 6151, Feb. 9, 1994.) Thus, under the current HCS, SDSs and employee training are required where employee exposure to a consumer product exceeds

the range that ''could reasonably be experienced by consumers when used for the purpose intended.'' 29 CFR 1910.1200(b)(6)(ix). OSHA sees no need to revisit this issue now, and in any event it is outside the scope of this rulemaking, which is aimed at the changes necessary to bring the HCS in conformity with the GHS.

A few comments were received in response to the ANPR regarding EPA labels for pesticides, noting that signal words in these labels would change if GHS is adopted (Document ID #0178), and noting that the requirements for these labels are dictated by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), which also controls the SDS content (Document ID #0108). A commenter also argued that FIFRA pesticide labels are more useful because they are risk-based rather than hazard-based (Document ID #0108). These concerns were not related to the proposal which maintained the exemption for additional labels on containers that are labeled in accordance with EPA requirements. If EPA decides to adopt the GHS, then labels for pesticides would be consistent with OSHA labels on other types of products. With regard to SDSs, these are required by the HCS, not FIFRA, and therefore such SDSs must be consistent with GHS provisions as adopted in this final standard.

A number of additional comments, and oral testimony, were received in response to the NPRM from representatives of the pesticide industry regarding potential conflicts between OSHA and EPA requirements (*See, e.g.,* Document ID #0352, 0385, 0387, and 0468). OSHA does not require additional labels on pesticides that require labels under EPA requirements. However, OSHA does have SDS requirements that must still be applied, and have been applied since the HCS first went into effect. Pesticide industry representatives believe that the SDS requirements as aligned with the GHS would conflict with the EPA-approved labels because they may have different information on them for OSHA than what is included in the pesticide label. For example, EPA has three signal words for pesticides (danger, caution, and warning), while OSHA will have the two specified by the GHS (danger and warning). There are also other differences. For example, chronic health effects are rarely addressed on pesticide labels as the risk mitigation measures are intended to minimize the possibility of their occurrence. However, OSHA would require such effects to be included when appropriate. The commenters also argue that EPA ''labels'' include any information related to the product, and thus SDSs would be preempted by the EPA labeling requirements. Therefore, they argue that pesticides should be exempted from the HCS. For example, the American Chemistry Council's Biocides Panel says the reasons for exempting pesticides are as follows (Document ID #0385):

> The principal reasons for this are: (i) Requiring GHS compliant SDS's but not pesticide labels will result in significant confusion in workplaces in which pesticides are used; (ii) imposing GHS-based SDS's would be inconsistent with EPA's interpretation of FIFRA, which includes all material that may be shipped with a pesticide, including SDS's, as part of its definition of labeling; and (iii) applying GHS to pesticide SDS's will not provide any additional substantive information, as EPA's evaluation of pesticides before approving them for sale includes all aspects of potential occupational exposures.

OSHA considered exempting pesticides from the final rule. However, exempting pesticides would reduce protections for those workers under OSHA's jurisdiction. For example, OSHA's jurisdiction extends to employees in pesticide manufacture and formulation. While EPA approves the label on the final product shipped out of these facilities, and that label includes information needed when the products are used by applicators, EPA does not have hazard communication requirements for the protection of workers in production facilities. Such protection is covered by OSHA, and OSHA requires labels on containers that are not subject to EPA labeling, as well as SDSs and training. The workplace exposures of these workers are of great concern. The chemicals are generally designed to be biologically active, and the exposures can be quite different than they would be for applicators, for example, who may use them only on an intermittent basis.

In testimony during the public hearing, representatives from the ACC Biocides Panel and CropLife America, Inc., agreed that EPA does not cover workers in pesticide manufacturing or formulating facilities (*See* Document ID #0495 Tr. 248–250). An exemption from the HCS would provide reduced protection for these workers.

As a result of receiving these comments, and the concerns about removing current protections from the final rule, OSHA considered several options. OSHA considered allowing the SDS preparer to use the EPA classification in section 2 of the SDS to ensure consistency with the FIFRA label. However, in doing this the SDS would then be inconsistent with other chemicals in the production of pesticides. In the pesticide manufacturing workplace the pesticide chemical ''active'' ingredients would bear a FIFRA label but would have an OSHA SDS, however other chemicals in the workplace such the ''inactive'' ingredients or cleaning products might still be considered hazardous under the HCS would contain an OSHA label and an OSHA SDS. An added complication is that an identical chemical (for example, chlorine) could potentially be in a pesticide manufacturing workplace where in one situation it could contain a FIFRA label and another it could bear an OSHA style label depending on its end use (e.g., a disinfectant). Adding a different SDS would create additional confusion not only for the worker handling the chemicals but also the personnel in charge of chemical management as well. Therefore, OSHA and EPA met to discuss what would be an appropriate resolution. First, with regard to the argument that SDSs are part of labels, and therefore preempted, EPA has long had an interpretation that they will not apply their review requirements to SDSs (US EPA Pesticide Registration Notices 92–04). Based on our discussions, OSHA does not anticipate that this policy will change. Secondly, EPA has indicated that they are committed to working with OSHA to develop an approach that will provide both appropriate protection for employees, as well as the environment, through workable guidance for the pesticide industry. OSHA anticipates that EPA will provide guidance to their regulated community (such as through a Pesticide Registration Notice) on how to develop an OSHA GHS-compliant SDS that will not be in conflict with the pesticide label. Therefore, pesticides will continue to be covered in the same manner as has been done under the HCS since its inception, and the exemption requested by pesticides industry rulemaking participants for such products is not granted.

Although the OSHA ICR (OMB Control No. 1218–0072) that is currently pending review and approval by OMB addresses the information collection activities associated with preparing the entire SDS as prescribed by the OSHA final rule, the approach OSHA anticipates will be provided in the EPA guidance for pesticide registrants was not considered by OSHA at the proposed rule stage. While OSHA preliminarily believes it has taken sufficient time in its paperwork estimate to cover compliance with the anticipated EPA guidance, the public has not had the opportunity to comment

on the paperwork burdens created by that guidance. As such, EPA and OSHA are collaborating on a subsequent revision to OSHA's ICR to ensure that it addresses the activities in the EPA guidance. EPA intends to solicit public comment on an ICR revision that addresses the information collection activities and related burden estimates associated with the EPA guidance as part of its release of that guidance. After public comments are considered by both agencies, OSHA intends to ask OMB to revise its ICR approval, identified under OMB Control No. 1218–0072, to capture the information collection activities and burden adjustments, if any, related to EPA's guidance.

(c) Definitions. This paragraph in the HCS includes the terminology used with the corresponding definitions. Comprehension of the appropriate definitions is critical to understanding the provisions of the standard. In some cases, terms are defined somewhat differently than when used in other contexts, so familiarity with the standard's definitions is important.

In the proposed revisions, OSHA retained as many definitions as possible from the current HCS. Changes were proposed only when there was a new term used that needed to be defined, or there is a different definition in the GHS, and consistency with the international definition was needed for harmonization purposes. As with the preceding paragraphs, minor modifications were proposed to ensure terminology is appropriate—primarily the use of terms related to classification and safety data sheets. These modifications were retained in the final rule. There were relatively few comments submitted on the proposed revisions to the definitions, other than those referring to the new definition OSHA proposed to address ''unclassified hazards'' and the definition for ''pictogram'' that references a red border frame.

One important difference between the HCS and GHS in terminology involves the use of the term ''chemical.'' The HCS has used this term since it was originally promulgated, and defines it to include elements, chemical compounds, and mixtures of elements and/or compounds. It has been a convenient way to describe the coverage of the rule. The GHS, like some other international standards, uses the terms ''substance'' and ''mixture''. OSHA has decided to retain a definition of ''chemical'' in the revised standard, which minimizes the number of terminology changes that have to be made to the regulatory text, as well as providing a shorthand way to define the scope to include both individual substances and mixtures of substances. This term is used in the body of the regulatory text of the final standard, similar to its use in the current HCS. However, the modifications also include definitions for ''substance'' as well as ''mixture'' to align with the GHS, and both of these terms are used as well. In particular, in the appendixes that are adopting GHS language, the separate terms ''substance'' and ''mixture'' are used consistent with the GHS.

''Substance'' means ''chemical elements and their compounds in the natural state or obtained by any production process, including any additive necessary to preserve the stability of the product and any impurities deriving from the process used, but excluding any solvent which may be separated without affecting the stability of the substance or changing its composition.'' Dow Chemical (Document ID #0353) objected to this definition, and suggested that it should be ''chemical elements and compounds in their natural state or obtained by any production process.'' OSHA has concluded that it is appropriate to maintain the GHS language for this definition to help to ensure consistent application, and thus the revised rule includes the definition of substance that was proposed.

A ''mixture'' is defined as a ''combination or a solution composed of two or more substances in which they do not react.'' This is consistent with the GHS definition—and while slightly different than the definition in the current HCS, means the same thing. Dow Chemical (Document ID #0353) suggested that OSHA maintain part of its current definition in order to avoid inadvertently changing the scope of coverage by adding ''if the combination is not, in whole or in part, the result of a chemical reaction.'' OSHA does not believe that the scope is changed by the GHS definition, and has retained the GHS-consistent language that was proposed.

OSHA also proposed to maintain the term ''hazardous chemical'' in this revised standard as used in the current standard (a chemical which is a physical or health hazard), except to add the term ''classified'' to indicate how it is determined that it is a physical or health hazard. OSHA also proposed to include unclassified hazards in this definition, but, as will be described below, has chosen a different approach in the final rule. Instead, the definition of ''hazardous chemical'' in this final rule is ''any chemical which is classified as a physical hazard or a health hazard, a simple asphyxiant, combustible dust, pyrophoric gas, or hazard not otherwise classified.'' The term is used throughout the standard to indicate that the classification process is completed, and the chemical manufacturer has determined that the chemical poses a hazard. Most of the substantive requirements of the rule apply to hazardous chemicals.

Dow Chemical (Document ID #0353) indicated that OSHA should drop the use of the word ''substance'' altogether, and instead use the word ''chemical.'' As noted in the definition of ''chemical,'' however, it is to be used when a reference is to both substances and mixtures. Where a provision or statement refers only to a substance, or only to a mixture, those terms are used in lieu of ''chemical'' or ''hazardous chemical.'' These individual designations are used most commonly in the appendixes, particularly in the classification criteria. OSHA has maintained consistency in the criteria with the GHS insofar as is possible with regard to this terminology.

Another proposed modification to the definitions paragraph was to move the specific physical hazard definitions to an appendix. In the current HCS, health hazard definitions are addressed specifically in Appendix A, but the physical hazard definitions were included in paragraph (c). In the final standard, health hazard definitions continue to be addressed in Appendix A, but a new Appendix B addresses physical hazards. Both of these appendixes are discussed below under the summary and explanation of paragraph (d) ''Hazard Classification.''

As noted in Section III above, the physical hazard definitions in the GHS are drawn from the United Nations' Recommendations on the Transport of Dangerous Goods. Since DOT has already adopted this international approach, the GHS definitions are substantially harmonized with the U.S. requirements for labeling of dangerous goods in transport. All chemicals that are shipped in the U.S. have already been classified according to DOT's physical hazard definitions. This will reduce the burdens associated with classifying physical hazards under the revised HCS. The primary differences involve exceptions that make the definitions more applicable to workplace situations (for example, coverage of flammable liquids that are currently defined as combustible under the HCS). Modifying the HCS to align with the GHS thus serves the purpose of harmonizing many of these definitions domestically, and results in shippers only having to classify their chemicals once for most physical hazards.

OSHA also has updated the definition of the term ''classification'' to reflect the additional hazards in this final rule (simple asphyxiant, combustible dust, and pyrophoric gas). The definition for classification will now read: ''Classification means to identify the relevant data regarding the hazards of a chemical; review those data to ascertain the hazards associated with the chemical; and decide whether the chemical will be classified as hazardous according to the definition of hazardous chemical in this section. In addition, classification for health and physical hazards include the determination of the degree of hazard, where appropriate, by comparing the data with the criteria for health and physical hazards,'' Dow Chemical (Document ID #0353) suggested that the language be changed to read ''for health hazards and for physical hazards.'' OSHA does not find this to be a necessary revision, and has adopted the definition as proposed. This definition is very similar to the process of hazard determination that is currently in the HCS, with the exception of determining the degree of hazard where appropriate. This reflects the GHS approach of having categories for each class of hazard. Under the current HCS, there are some definitions that have categories in a hazard class (*e.g.,* acute toxicity, flammability), but other definitions are simply one category (*e.g.,* carcinogenicity). The additional breakdown in the GHS of classes into categories that reflect different severities or levels of effect will provide both employers and employees with more precise information to understand the hazards, to consider when evaluating workplace conditions to determine the risks in the workplace, and to respond to exposure incidents.

OSHA has also retained in the final rule the proposed definitions for ''hazard class'' and ''hazard category'' to further explain the approach of breaking down the hazardous effects into levels of severity. A ''hazard class'' is defined as ''the nature of the physical or health hazards, *e.g.,* flammable solid, carcinogen, oral acute toxicity.'' The definition of ''hazard category'' is ''the division of criteria within each hazard class, *e.g.,* oral acute toxicity and flammable liquids include four hazard categories. These categories compare hazard severity within a hazard class and should not be taken as a comparison of hazard categories generally.'' Both of these definitions are taken from the GHS. Dow Chemical (Document ID #0353) suggested that the last sentence of the definition of ''hazard category'' should be deleted or moved to Appendix A because it is ''non-definitional information.'' Given that it is included in the GHS definition, OSHA has adopted it in the final standard.

OSHA has retained the proposed definition of ''health hazard'' to reflect the specific hazards defined in the GHS. While the overall scope of what is covered is essentially the same as the current HCS, the hazards may be identified slightly differently. For example, the current HCS covers reproductive toxicity as a target organ effect, and includes all aspects of the effect under that hazard. The GHS has a separate definition for germ cell mutagenicity, which is considered part of reproductive toxicity in the current HCS. The definition of ''health hazard'' was thus proposed to be ''a chemical which is classified as posing one of the following hazardous effects: acute toxicity (any route of exposure); skin corrosion or irritation; serious eye damage or eye irritation; respiratory or skin sensitization; germ cell mutagenicity; carcinogenicity; reproductive toxicity; specific target organ toxicity (single or repeated exposure); or aspiration hazard. The criteria for determining whether a chemical is classified as a health hazard are detailed in Appendix A to § 1910.1200—Health Hazard Criteria.''

Both the American Chemistry Council (ACC) (Document ID #0393) and Dow Chemical (Document ID #0353) suggested that OSHA modify the phrase ''any route of exposure,'' which refers to ''acute toxicity.'' ACC suggested it list the three specific routes of exposure in the criteria, and Dow suggested that it include ''relevant'' to modify routes of exposures. OSHA does not believe either of these changes is necessary. The definition already uses the term ''classified'' to refer to each of the health hazards listed, and the acute toxicity criteria include three routes of exposure for classification. Dow further suggested that ''serious eye damage'' be modified to say ''by chemical action.'' Again, the classification process is for chemicals, and the definition already indicates that it is covered as a health hazard when classified. Similarly, Dow suggested that ''aspiration hazard'' be modified to say ''aspiration toxicity hazard.'' The proposed language is consistent with the GHS, and OSHA is maintaining it for harmonization purposes in the final standard.

A revised definition of ''physical hazard'' was proposed to reflect the physical hazards covered in the GHS. While these are similar to the coverage of the HCS, they are in some cases described differently. The definition proposed for ''physical hazard'' is ''a chemical that is classified as posing one of the following hazardous effects: Explosive; flammable (gases, aerosols, liquids, or solids); oxidizer (liquid, solid or gas); self-reactive; pyrophoric (liquid or solid); self-heating; organic peroxide; corrosive to metal; gas under pressure; or in contact with water, emits flammable gas. *See* Appendix B to § 1910.1200—Physical Hazard Criteria.'' This definition has been adopted in the final standard with one change. OSHA did not include pyrophoric gas in the definition in the proposal. There is no definition for pyrophoric gas in the GHS, which is covered under the current HCS, and OSHA inadvertently left it out in the proposed standard when the generic definition for pyrophorics was removed. This omission was pointed out by commenters (*e.g.,* Document ID #0382 and 0530). OSHA is therefore returning the pyrophoric gas definition from the current rule to paragraph (c), and making it specific to just gases since the current rule covers all physical states. Thus, pyrophoric gas is defined as ''a chemical in a gaseous state that will ignite spontaneously in air at a temperature of 130 degrees F (54.4 degrees C) or below.'' Label elements are provided in C.4.30. The signal word will be danger; the pictogram is the flame; and the hazard statement is ''Catches fire spontaneously if exposed to air.''

Procter & Gamble (Document ID #0381) noted that the definition for ''flashpoint'' was missing from the NPRM and suggested that it should be put back into the rule. However, the meaning of the term ''flashpoint'' is already addressed in the criteria for ''flammable liquid'' in Appendix B by specifying the test methods to determine it. OSHA has also included a definition for flashpoint in the criteria chapter, rather than in the definitions paragraph.

The definition of ''label'' in the GHS is slightly different than what is currently in the HCS, and OSHA proposed to modify the HCS to be consistent with the GHS. The proposed definition of ''label,'' which has been retained in the final rule, is ''an appropriate group of written, printed or graphic information elements concerning a hazardous chemical that is affixed to, printed on, or attached to the immediate container of a hazardous chemical, or to the outside packaging.'' The GHS label is more specific than what is required in the current HCS, and includes certain core information that must be presented. Thus, a definition for ''label elements'' was also proposed and adopted in the final rule as ''the specified pictogram, hazard statement,

signal word, and precautionary statement for each hazard class and category.'' ACC (Document ID #0393) noted that this definition is different from what is in the GHS. OSHA modified the definition by making it plural to reflect the way it is used in this section to refer to the OSHA-required label elements for each GHS label. The GHS definition in this case defines the singular term ''label element'' as ''one type of information that has been harmonized for use in a label, *e.g.,* pictogram, signal word.'' OSHA has listed all of the label elements, including precautionary statements since they are mandatory under the revised rule. OSHA believes its definition is consistent with the GHS but more appropriate for the revised rule, and has adopted it in this final standard.

''Safety data sheet (SDS)'' is defined in both the NPRM and the final rule as ''written or printed material concerning a hazardous chemical which is prepared in accordance with paragraph (g) of this section.''

Definitions for terms that describe information required to be provided on labels were also proposed to be added to the HCS and are included in the final rule. These terms include ''hazard statement,'' ''pictogram,'' ''precautionary statement,'' ''product identifier,'' and ''signal word.'' These new definitions will help to clarify the specific requirements for labels under the revised HCS, and are consistent with similar definitions in the GHS.

''Hazard statement'' is ''a statement assigned to a hazard class and category that describes the nature of the hazards of a chemical, including, where appropriate, the degree of hazard.'' This is essentially what is defined as a hazard warning under the current rule. An example of a hazard statement under the GHS is: ''Causes serious eye damage.'' These statements have been codified, meaning that numbers have been assigned to them. They are available in all of the official languages of the United Nations, and thus translation will not be a problem when shipping to countries using those languages. Having standardized statements is expected to facilitate translation into other languages as well. The definition for ''hazard statement'' is being adopted as proposed.

There were a few comments about specific hazard statements, such as an objection from the National Propane Gas Association (Document ID #0400) indicating the statement for flammable gas is ambiguous, and lacks substantiation and scientific credence. They object to labeling propane as ''extremely flammable,'' which is the required statement for Category 1 for flammability hazards. This objection was also raised in a comment to the ANPR (Document ID #0068). OSHA responded in the NPRM that it would not be making chemical-specific changes to hazard statements (74 FR 50399, Sept. 30, 2009). The point of having harmonized statements is that all chemicals with the same degree of hazard have the same statement. OSHA also indicated that some in the industry already use the ''extremely flammable'' terminology. NPGA responded that not everyone is familiar with it, or uses it. That is why OSHA is establishing a standardized approach, so everyone in an industry with a common product like propane uses the same language to convey the hazard. This consistency will help people understand what the hazards are, and simplify the process of conveying them since everyone will use the same approach. As noted previously, examples of where the hazard statement ''extremely flammable'' are currently being used for propane are readily found (*e.g.,* Document ID #0554). Therefore, OSHA does not agree with NPGA that the hazard statement is inappropriate or should be modified.

A few commenters suggested that where hazard statements include two hazards, separating them should be permitted when data indicate that only one is applicable to the product involved (for example, it causes infertility but not developmental hazards) (Document ID #0344, 0376, 0377, 0381, 0382, and 0393). OSHA agrees that such separation should be permitted. The following provision has been added to Appendix C.2.2.2: ''If the chemical manufacturer, importer, or responsible party can demonstrate that all or part of the hazard statement is inappropriate to a specific substance or mixture, the corresponding statement may be omitted from the label.''

Additionally, OSHA permits chemical manufacturers and importers to combine hazard statements where the information is related and the combination can shorten the text required on the label. Appendix C.2.2.1 states: ''Hazard statements may be combined where appropriate to reduce the information on the label and improve readability, as long as all of the hazards are conveyed as required.'' OSHA also allows additional hazard statements under supplementary information, as long as they are accurate and do not conflict with the required statements. ''Pictogram'' is defined as a ''composition that may include a symbol plus other graphic elements, such as a border, background pattern, or color, that is intended to convey specific information about the hazards of a chemical.'' This definition covers both pictograms in the transport sector, and those in other sectors covered by the GHS. The pictograms are required as part of the core information provided on a label to describe the hazards of a chemical. ACC (Document ID #0393) and Procter & Gamble (Document ID #0381) noted that the proposed definition of pictogram, which was retained in the final rule, is slightly different than what is in the GHS: ''a graphical composition that may include a symbol plus other graphic elements, such as a border, background pattern, or color, that is intended to convey specific information.'' OSHA added ''about the hazards of a chemical'' because that is the only type of information that will be conveyed by the pictograms in the HCS. The definition is being adopted as proposed.

The workplace pictograms proposed were a black symbol on a white background with a red diamond border frame. Some ANPR commenters noted that the frame should be permitted to be black for domestic shipments as allowed under the GHS (*See, e.g.,* Document ID #0032 and 0163). However, as described in Section IV of the proposed preamble, there are clear safety and health benefits associated with the use of the red frame in terms of recognition and comprehensibility. Thus OSHA proposed to allow only the red frame to be used, whether the shipment is domestic or international.

Many of the rulemaking participants recognized the communication benefits of the red border, and supported the proposed requirement for a red border frame for all shipments (*See, e.g.,* Document ID #0313, 0324, 0330, 0335, 0336, 0339, 0341, 0365, 0383, 0408, 0410, 0412, and 0456). For example, Product Safety Solutions (Document ID #0313) stated:

> OSHA requests comment on whether pictogram borders should be required to be in red or should be allowed to be printed in black. While the use of a red border may increase the cost of printing some labels, the use of color to draw attention to a potential hazard is a useful tool and is likely to enhance the communication of safety information. As products may also be exported to other countries, the use of the red border would be consistent with the establishment of a globally recognized hazard symbol. Imported products likewise, would have to contain the red symbol border and this would have to be made abundantly clear to Customs Agents and others responsible for monitoring the importation of chemical products.

However, others argued that black frames should be permitted on domestic shipments, and that the use of red borders is too costly and burdensome in terms of printing costs in particular (*See, e.g.,* Document ID #0328, 0338, 0344, 0352, 0370, 0376, 0389, 0399, 0405, and 0411). For example, ISSA (Document ID #0399) claims:

> If OSHA were to require only the red frame for pictograms, it would require those formulators that presently print single color labels to utilize different systems for producing labels of this nature, requiring a substantial capital investment which in turn will add greatly to the cost of transitioning to the revised HCS. OSHA must keep in mind, that small and medium sized formulators handle hundreds of products, each of which in turn are sold under multiple private labels. Thus a change in color requirements for labels generally will literally require a formulator to revise hundreds, if not thousands, of individual labels.
>
> Further, we believe the use of a black frame will not present a threat to worker health and safety. ISSA disagrees with OSHA's conclusion that a red frame would significantly enhance the communicative value of the label. In citing studies, OSHA does not take into account that the use of the new labels will be the subject of intensive employee training that will more than mitigate the use of a black frame over a red frame.

In the NPRM regulatory analyses, OSHA did not assess the specific costs associated with red versus black borders, but has done so in the analyses for the final rule. *See* Section VI. As noted by proponents of the black border option for domestic shipments, the costs of a red border are greater. However, OSHA's analysis shows that they are economically feasible. In addition, OSHA believes that it is likely additional, cheaper printing options will be developed to comply with this requirement in the final rule. The EU requires red frames for pictograms: ''Hazard pictograms shall be in the shape of a square set at a point. They shall have a black symbol on a white background with a red frame sufficiently wide to be clearly visible.'' (*http://europa.eu/legislation_summaries/internal_market/single_market_for_goods/chemical_products/ev0013_en.htm*) Application of this requirement in the twenty-seven (27) EU member states is expected to lead to new printing options for compliance.

OSHA believes that the increased comprehension that will be provided by the red border frame is compelling. The red color will clearly delineate the hazard symbols from the other information on the label, and the prominence will lead to increased attention and recognition of the hazards. The transport labels and placards that have been in use for many years have multiple colors in their pictograms, and yet compliance has been achieved. Plus most product labels have various colors related to their logos, brands, etc., so clearly it can be done.

There are also some logistical issues that would make compliance more difficult with two different colored frames. First, it is unlikely that it would always be known whether a product would be exported at the point of labeling it at the end of the manufacturing process. Many containers are simply shipped to distributors, and the original manufacturer does not know where they will be sent after that—thus raising the question of whether a manufacturer or importer would know when to apply a black versus a red frame. In addition, workers exposed to chemicals purchased from different sources might have different frames, requiring additional training to avoid potential confusion. The final rule remains as proposed, and requires pictograms to have a red frame, with a black symbol on a white background, for all shipped chemicals regardless of destination.

Several commenters (Document ID #0318, 0382, and 0393) also raised issues regarding whether pre-printed labels with blank red frames could be used. The manufacturer would simply add the symbols to the frames when printing the required label information. If a manufacturer or importer took this approach, a particular label might have one or more empty red diamonds in addition to any required pictograms. OSHA does not believe that this would be appropriate. Blank frames would still attract attention, but workers could be confused about what they mean and whether something is missing from the information. While blank frames could be marked to indicate they are intentionally left blank, they will still contribute to clutter on the label and distract from the primary messages (*See, e.g.,* Document ID #0284). Blank frames are not considered acceptable by DOT. (*See* 49 CFR 172.401, Prohibited labeling; PHMSA Interpretation 02–0088). OSHA does not believe this is a good alternative for compliance either, and the final rule prohibits blank frames on the label (Appendix C.2.3.1).

Under the GHS, a symbol is generally assigned to each hazard class and category. There are nine agreed symbols under the GHS to convey the health, physical and environmental hazards. Eight of these symbols were proposed for adoption in this rulemaking, the exception being the environmental symbol. Six of these symbols have been used for many years in the international transport requirements, so some employers and employees will already be familiar with them.

The symbols in the proposed rule are adopted in the final rule. Dow Chemical (Document ID #0353) noted that the pictograms are not entirely self-evident. While this may be true, the rule requires training workers so they will know what the symbols mean and how to respond.

It should be noted that in the NPRM, the pictogram for C.4.17 (oxidizing gases) was published with a ''flame'' symbol, rather than the ''flame over circle'' symbol that was appropriate, and was described. OSHA has corrected this error in the final rule, and has inserted the appropriate ''flame over circle'' symbol in Appendix C.4.17 for oxidizing gases.

The ''precautionary statement'' is ''a phrase that describes recommended measures that should be taken to minimize or prevent adverse effects resulting from exposure to a hazardous chemical, or improper storage or handling.'' The precautionary statements specified in Appendix C will be required on containers under the final rule. An example of a precautionary statement is: ''Wear protective gloves.'' The precautionary statements in the GHS are assigned to certain hazard classes and categories.

Precautionary statements are not required under the current HCS, although many chemical manufacturers include them on their labels for safe handling and use. These statements are codified under the GHS, meaning that numbers have been assigned to them. The precautionary statements in the GHS are not harmonized like the hazard statements are, and the regulatory authority is free to use the statements in the GHS annex or to use alternative statements when adopting the current version of the GHS. Using the GHS statements has the advantage of adopting statements that have undergone expert review by the UN Sub-committee, are assigned to the appropriate hazard class and category, and have been translated into six languages. Work continues on them in the Sub-committee to combine or edit the precautionary statements to reduce repetition and the complexity of the label. The precautionary statements may be considered harmonized in the future.

Other countries are already using them (*e.g.,* in Europe). Since OSHA did not previously require the use of precautionary statements, and had no such recommended statements to provide, the Agency decided to use those in the GHS as the mandatory

requirements. This will make it easier for compliance since chemical manufacturers and importers will not need to develop, maintain, and translate precautionary statements on their own. It will also help employees since they will be seeing the same language on labels regardless of the supplier of the chemical. Such standardization improves comprehension, and thus the effectiveness of the information transmitted under the standard.

While the definition of precautionary statement itself did not seem to raise questions with rulemaking participants, there were a number of comments on the proposal to make the GHS precautionary statements mandatory. Many commenters agreed with OSHA that the statements should be on the label, and should be mandatory (Document ID #0328, 0329, 0335, 0336, 0347, 0352, 0365, 0370, 0372, 0377, 0379, 0389, 0402, 0408, 0410, 0412, and 0456). Commenters mentioned increased comprehensibility, as well as available translations, as some of the reasons why they support this approach. It was also noted by a number of commenters that OSHA should permit additional precautionary statements to cover situations without an available statement in Appendix C (Document ID #0313, 0324, 0327, 0329, 0335, 0352, 0365, 0370, 0376, and 0402). Others supported making them mandatory when they are harmonized in the GHS (Document ID #0351 and 0405). And at least one participant argued that precautionary statements should not appear on labels, just SDSs (Document ID #0338).

Other commenters did not support the mandatory approach, and thought that manufacturers should be able to continue to use their own precautionary statements (Document ID #0321, 0330, 0344, 0353, 0363, 0376, 0381, 0382, 0393, and 0399). It was also suggested that the UN needs to provide further guidance on when precautionary statements can be combined or omitted (Document ID #0328, 0370, and 0376), or that the number of phrases appearing on a label should be limited (Document ID #0329 and 0405).

In the final standard, OSHA has maintained the proposed provision to require the precautionary statements in the GHS to be used on labels. As noted previously, the use of prescribed precautionary statements is consistent with the other label elements, and provides the significant benefits of improved communication of information through increased comprehensibility and familiarity. In terms of flexibility, chemical manufacturers and importers are free to put additional precautionary statements on the label from other sources in the supplementary information area. As long as the information provided is accurate, and does not conflict with the required information, this is permitted.

OSHA will also permit the statements to be combined as appropriate, and states in Appendix C.2.4.6: ''Precautionary statements may be combined or consolidated to save label space and improve readability. For example, ''Keep away from heat, sparks and open flame,'' ''Store in a well-ventilated place,'' and ''Keep cool'' can be combined to read ''Keep away from heat, sparks and open flame and store in a cool, well-ventilated place.''

In addition, where there are concerns, supported by evidence, about the applicability of a statement to a particular product, the chemical manufacturer or importer may revise the statements as appropriate for the situation. Appendix C.2.4.8 states: ''If the chemical manufacturer, importer, or responsible party can demonstrate that a precautionary statement is inappropriate to a specific substance or mixture, the precautionary statement may be omitted from the label.''

Thus, the final rule adopts the precautionary statements, which are taken from the GHS. However, it allows the use of additional statements where necessary, as long as they are accurate, do not conflict, and are placed in supplementary information. Additionally, chemical manufacturers and importers can use their judgment to combine related statements to shorten the amount of information on a label, as well as omit any statements that can be demonstrated to be inapplicable to the particular chemical involved. OSHA believes this approach maximizes the comprehensibility of the precautionary statements, as well as simplifies compliance for employers. Nevertheless, there are allowances for unique situations, and thus assurances that the information will be accurate.

It was suggested that the precautionary statements should be written in plain language (Document ID #0321). There were some specific changes to particular statements that were suggested (such as a statement regarding fighting fires near explosives, Document ID #0353). OSHA is not going to modify any of the statements as published in the GHS in terms of technical information. These have been reviewed by many experts. Changes should only be made to them through the UN Sub-committee process at this point, as they are close to being harmonized.

However, OSHA has made a few minor changes to precautionary statements in this final rule to address clarity and related issues. These changes were adopted by the Sub-committee of Experts on the GHS at its December 2010 meeting, and are expected to be included in Revision 4 of the GHS. Most changes simply amend the precautionary statement to clarify its meaning by making the statement more concise, or stating it in plain language. Others either provide added flexibility in applying the precautionary statement, or provide instructions for the classifier on the conditions relating to use of the precautionary statement. Examples of each type are presented below.

Examples of precautionary statements for physical hazards that were clarified in the final rule are presented below:

Precautionary statement in proposed rule	Precautionary statement in final rule
Keep away from any possible contact with water.	Do not allow contact with water.
In case of fire: Use * * * for extinction.	In case of fire: Use * * * to extinguish.

An example of a precautionary statement providing instructions for the classifier on the conditions relating to use of the precautionary statement is provided below for the health hazard class Skin corrosion/irritation, Category 1A to 1C (for the illustration, the instructions for use are provided in italics). In this example, note that the precautionary statement was clarified and the conditions relating to use of the precautionary statement were added.

Precautionary statement in proposed rule	Precautionary statement in final rule
Immediately call a poison center/or doctor/physician.	Immediately call a poison center/ doctor/ * * * *Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice.*

The final example of the precautionary statement changes is provided below for instructions for the classifier on the conditions relating to use of the precautionary statement. In certain situations, text in a precautionary statement may not be appropriate. To address this issue, a new paragraph C.2.4.5 has been added to explain the use of text provided in square brackets ([ ]). Paragraph C.2.4.5 states: ''Where square brackets ([ ]) appear around text in a precautionary

statement, this indicates that the text in square brackets is not appropriate in every case and should be used only in certain circumstances. In these cases, conditions for use explaining when the text should be used are provided. For example, one precautionary statement states: ''[In case of inadequate ventilation] wear respiratory protection.'' This statement is given with the condition for use: ''text in square brackets may be used if additional information is provided with the chemical at the point of use that explains what type of ventilation would be adequate for safe use.'' This means that, if additional information is provided with the chemical explaining what type of ventilation would be adequate for safe use, the text in square brackets should be used and the statement would read: ''In case of inadequate ventilation, wear respiratory protection.'' However, if the chemical is supplied without such ventilation information, the text in square brackets should not be used, and the precautionary statement should read: ''Wear respiratory protection.''

OSHA has included these non-substantive, minor changes approved by the UN Sub-committee, because they make the statements more readable, allow added flexibility, and are consistent with the latest version of the GHS.

Container labels will also be required to include a ''product identifier.'' The proposed definition for this term, which was retained in the final rule with a clarifying change (discussed below), was ''the name or number used for a hazardous chemical on a label and in the SDS. It provides a unique means by which the user can identify the chemical. The product identifier used shall permit cross references to be made among the required list of hazardous chemicals, the label, and the SDS.'' In other words, the product identifier is essentially the same as the ''identity'' under the current HCS. The GHS allows competent authorities for workplace requirements to choose not to require specific chemical identities of ingredients to be listed on the label, as long as they are on the SDS. This is the approach OSHA currently uses in the HCS, and it has been effective. OSHA will continue to require chemical identities only on SDSs, and has proposed a definition for ''product identifier'' that is consistent with the current definition for ''identity'' (which has been deleted from the final rule) to maintain this approach. ACC (Document ID #0393) and Procter & Gamble (Document ID #0381) suggested that OSHA should clarify what the ''required list of hazardous chemicals'' refers to in the definition. This terminology has been in the HCS since the original standard was published in 1983, and refers to the only list of chemicals required by the HCS, which is in the written hazard communication program. Therefore, OSHA has modified the language in the final rule to read: ''among the list of hazardous chemicals required in the written hazard communication program, the label and the SDS.''

Another new concept in the NPRM for HCS labels is inclusion of a ''signal word'' to bring attention to the hazardous effects, as well as to contribute to the recognition of the severity of the hazard. Signal words have been used for many years in the United States on consumer and pesticide labels. The proposed definition is ''a word used to indicate the relative level of severity of hazard and alert the reader to a potential hazard on the label. The signal words used in this section are 'danger' and 'warning.' 'Danger' is used for the more severe hazards, while 'warning' is used for the less severe.'' OSHA received no objections to the proposed definition of ''signal word'' and it is being carried through to the final rule.

OSHA proposed to add a definition to the HCS for ''unclassified'' hazards. As has been noted, the current HCS is performance-oriented, and takes a very broad approach to defining hazards covered by the rule. The GHS is similarly broad in approach, but includes very specific definitions of criteria to apply when determining whether a chemical poses a physical or health hazard. This specification approach has significant benefits associated with it, including providing more guidance to help ensure a consistent approach to determining hazards. It also allows more information to be developed that provides an indication of the severity of effect.

OSHA proposed to add a definition to the HCS for ''unclassified'' hazards. As has been noted, the current HCS is performance-oriented, and takes a very broad approach to defining hazards covered by the rule. The GHS is similarly broad in approach, but includes very specific definitions of criteria to apply when determining whether a chemical poses a physical or health hazard. This specification approach has significant benefits associated with it, including providing more guidance to help ensure a consistent approach to determining hazards. It also allows more information to be developed that provides an indication of the severity of effect.

In the ANPR, OSHA asked for comment on whether the GHS criteria are sufficient to cover the hazards present in the workplace. While the Agency believed the scope of coverage is similar between the two approaches, OSHA wanted to be sure that the new approach is as comprehensive as the existing standard. In the NPRM (74 FR 50390, Sept. 30, 2009), OSHA noted two hazards of concern—combustible dust and simple asphyxiants. Both of these are mentioned in the GHS in the SDS annex as examples of hazards not classified that should be addressed on the SDS.

It is possible that there are other hazards that may not yet be specifically defined. Rulemaking participants have mentioned several (*e.g.,* static accumulators) (Document ID #0382 and 0402). The addition of the definition for unclassified hazards was intended to address these situations. Where a classifier has identified evidence of a hazard, but the evidence does not meet the currently specified criteria for hazards covered by the rule, the definition for unclassified hazards captures those effects to ensure that the final rule is appropriately protective, and covers all of the hazards covered by the current rule. During the negotiations for the GHS, U.S. industry representatives often raised the issue of ensuring that they could provide additional hazard information in order to satisfy product liability laws in the U.S. This was the rationale for allowing such information to be included on labels under supplementary information, and on SDSs under Section 2. OSHA believed that addition of the proposed definition of ''unclassified hazards,'' and specific recognition of the need to provide information when such effects arise, would help U.S. industry address its product liability concerns as well as protect exposed workers (74 FR 50390, Sept. 30, 2009).

OSHA proposed to require the chemicals posing unclassified hazards to be treated as hazardous chemicals under the rule. The Agency anticipated that this information would appear in Section 2 of the SDS (Hazard Identification)—the GHS already identifies this as the appropriate place in its guidance on the contents of SDSs (A4.3.2.3, *Other hazards which do not result in classification*), and proposed Appendix D included the requirement to list unclassified hazards. In terms of labeling, there are no specified label elements in the GHS for chemicals that pose unclassified hazards. OSHA proposed to require that the label for such hazards must name the chemical, and describe the hazardous effects

under supplementary information on the label, as well as provide any appropriate precautionary information. OSHA also expected that such hazards would be addressed in worker training programs.

It is important to understand that the Agency anticipated that there would be relatively few situations where there would be scientific evidence or data indicating an effect that is not currently classified, and merely wanted to ensure that this information is captured and conveyed to employers and employees. OSHA also indicated that it would be appropriate to establish a feedback mechanism, where classifiers could inform OSHA of situations where the current criteria are insufficient, and the Agency can then suggest to the United Nations that appropriate criteria be developed and added to the GHS. This is consistent with the overall approach to hazard classification in the GHS that OSHA proposed to adopt—that specific criteria be provided to help ensure that classification is appropriate, and information transmittal is consistent from company to company. Therefore, the use of the definition of unclassified hazard was to be a temporary situation for these hazards, ensuring information is provided until such time as the criteria are added to the rule.

There were many comments received regarding the NPRM definition and concept of ''unclassified hazards.'' A number of participants agreed with OSHA that there is a need to cover some hazardous effects that have not yet been spelled out in the GHS with criteria (Document ID #0313, 0327, 0347, 0363, 0365, 0366, 0367, 0410, and 0412). Others suggested that it was an appropriate interim step, while working with the UN to get criteria added to the GHS (Document ID #0329, 0330, 0335, 0339, 0352, 0370, 0376, 0383, 0405, and 0414). Some argued that these hazardous effects should have specific criteria so employers would know with certainty what is covered (Document ID #0327, 0361, 0366, 0377, and 0392).

With regard to the actual definition, some thought it was too broad and ambiguous (Document ID #0344, 0379, 0381, and 0399). The U.S. Chamber of Commerce (Document ID #0397) argued that the definition should be withdrawn, or substantially revised, and that OSHA was exceeding its authority. There were other commenters who thought the effects should be called ''hazards not otherwise classified'' or ''additional hazards'' rather than ''unclassified hazards.'' *See, e.g.,* Document ID #0328, 0344, 0363, 0370, 0376, 0393, and 0405. It was also suggested that the approach should only cover those hazards currently covered by the HCS (Document ID #0338).

OSHA has considered all of these comments, and the need to provide sufficient protection for exposed employees, in devising an approach for the final rule. First, OSHA agrees with commenters that using the term ''hazards not otherwise classified'' is a better designation. Secondly, OSHA has revised the language to clarify the intent and address what was perceived as ambiguity. The definition in the final rule, which replaces and amends the proposed definition of ''unclassified hazard,'' now reads: '''Hazard not otherwise classified (HNOC) means an adverse physical or health effect identified through evaluation of scientific evidence during the classification process that does not meet the specified criteria for the physical or health hazard classes addressed in this section. This does not extend coverage to adverse physical and health effects for which there is a hazard class addressed in this section, but the effect either falls below the cut-off value/concentration limit of the hazard class or is under a GHS hazard category that has not been adopted by OSHA *(e.g.,* acute toxicity Category 5).''

Additionally, and importantly, OSHA has deleted proposed paragraph (f)(2), which specified information to include on labels for the HNOC chemicals. Given that there are no harmonized label elements available for these effects, it appears that this could be confusing to both the label preparers and the users of the chemicals. However, provision of an SDS for HNOC chemicals is required under the final rule, and information regarding their hazards is to be included in Section 2.

The U.S. Chamber of Commerce objected to the inclusion of ''unclassified hazards'' in the final rule because, in its view, the proposed definition is ''broad,'' ''expansive,'' and will ''impose new requirements on employers without undertaking all of the steps in a full OSHA rulemaking'' (Document ID #0397). OSHA appreciates the concerns and has carefully considered (and in some respects revised) the provision with those concerns in mind. OSHA does not intend to impose new requirements, or to bypass rulemaking, but includes the definition to continue the longstanding requirements that such hazards be disclosed. As finalized and clarified, the relevant provision does not expand on those requirements or add new burdens; on the contrary, it preserves requirements in the current rule. The following discussion is designed to clarify these points.

As noted above, the final rule retains the proposed requirement, using the term ''hazard not otherwise classified'' (HNOC) instead of unclassified hazard. In essence, this definition requires classifiers who find ''scientific evidence'' that a chemical can cause death, illness, or injury to workers in a way not currently covered by the GHS classification criteria to disclose that fact on the SDS. This is meant to be a modest and narrow requirement. It is triggered only when the classifier has objective, scientific evidence of the hazard. OSHA believes that there are likely to be few such hazards outside those covered by the specific criteria in the final rule, which are the product of over thirty years of international experience in hazard communication.

It is important to understand that the HNOC definition essentially preserves (and does not expand) the scope of the current rule, which is not as tightly bound to specific criteria as the GHS. The HNOC definition should be interpreted and understood with this preservative goal in mind. For example, under the current rule, ''health hazard'' means a chemical for which there is at least one statistically significant scientific study showing that ''acute or chronic health effects may occur to exposed employees.'' Indeed, while mandatory Appendix A of the current standard lists criteria for specific health effects, it also notes that these criteria are not intended to be an exclusive categorization scheme, but rather any available scientific data on the chemical must be evaluated to determine whether the chemical presents a health hazard. Likewise, though the current definition of physical hazard is tied to a specific list of effects, some of these can also be quite broad. For example, under the current rule, ''flammable solid'' includes a material ''which can be ignited readily and when ignited burns so vigorously and persistently as to create serious hazard.''

The essential point is that the HNOC definition is designed so as to prevent the final rule from being less protective than the current standard by picking up any hazards that might fall within the definitions of the current rule, but might fall outside the GHS hazard classes. As discussed above, it is OSHA's intent that the HNOC classification would be an interim measure, used until harmonized criteria for a hazard can be adopted at the UN Sub-committee level, and subsequently incorporated into the HCS through rulemaking.

If the provision is understood in light of the foregoing points, this rulemaking is all the OSH Act and the Administrative Procedures Act (APA)

requires of OSHA before adopting the HNOC requirement. By preserving the requirements equivalent to those in the current rule, all the final rule does is to require chemical manufacturers and importers with reliable information that exposure to their chemical can cause illness, injury or death to an employee to disclose that fact on an SDS. OSHA has the authority to regulate hazard communication on a general level; indeed it must if it is to provide comprehensive worker protection in this area. *See National Ass'n of Manuf.* v. *OSHA,* 485 F.3d 1201, 1204 (D.C. Cir. 2007); *Associated Bldrs & Contrs. Inc.* v. *Brock,* 862 F.2d 63, 68 (3d Cir. 1988). Stakeholders have had a chance to comment on the HNOC requirement, and this rulemaking proceeding satisfies OSHA's statutory obligations.

With regard to the three hazards specifically mentioned during the rulemaking (pyrophoric gases, simply asphyxiants, and combustible dust), OSHA is handling them as follows in the final rule.

OSHA inadvertently removed the definition of pyrophoric gases from the proposal when it removed the generic definition for pyrophorics. The American Chemistry Council (ACC) correctly pointed out that excluding the pyrophoric gases, even though there is no corresponding definition in GHS, would mean that they would not be labeled or classified appropriately (Document ID #0393). OSHA agrees and has included the definition of pyrophoric gas in the current HCS in this final rule. Pyrophoric gases must therefore be addressed both on container labels and SDSs, and in worker training programs. Therefore, OSHA has retained the definition for pyrophoric gases from the current HCS and has added pyrophoric gases to the definition of ''hazardous chemical''. Label elements are provided in C.4.30. The signal word will be danger; the pictogram is the flame; and the hazard statement is ''Catches fire spontaneously if exposed to air.''

For the two examples of effects not addressed in the GHS that were raised in the proposal (simple asphyxiants and combustible dust), OSHA is addressing them specifically in the final rule rather than covering them under the HNOC definition. Using comments in the record, and commonly applied voluntary industry consensus standards, the Agency has designated chemicals with these properties under the definition of ''hazardous chemical.'' The chemicals posing such effects must therefore be both labeled where appropriate, and addressed on SDSs and in training. In addition, OSHA has added C.4.30 to Appendix C to provide the label elements for OSHA defined hazards.

With regard to simple asphyxiants, OSHA had indicated in Issue #8 (74 FR 50282, Sept. 30, 2009) that it believed it might be more appropriate to simply add a definition of this effect to the final rule rather than covering it under the ''unclassified hazard'' approach. A definition was proposed as follows:

> ''Simple asphyxiants'' are substances that displace oxygen in the ambient atmosphere, and can thus cause oxygen deprivation in exposed workers that leads to unconsciousness and death. They are of particular concern in confined spaces. Examples of asphyxiants include: nitrogen, helium, argon, propane, neon, carbon dioxide, and methane.

OSHA also solicited comments on proposed specific label elements. No symbol would be required, but the signal word ''warning'' would be used, with the hazard statement ''may be harmful if inhaled.'' In addition, a precautionary statement such as the following would be required: ''May displace oxygen in breathing air and lead to suffocation and death, particularly in confined spaces.''

A number of commenters agreed with the definition and the approach (Document ID #0339, 0347, 0351, 0365, 0366, 0370, 0405, 0408, and 0456). Others had specific comments on what was proposed, such as arguing for simplification of the language (Document ID #0414); proposing to replace the definition with the NFPA 704 definition of ''simple asphyxiant'' (Document ID #0330); suggesting a reference to ''suffocation'' (Document ID #0329 and 0335), or indicating that the hazard statement is really a precautionary measure, or vice versa (Document ID #0376, 0382, 0393, and 0405). Procter & Gamble suggested it should not be covered since it is not an inherent toxicity (Document ID #0381).

OSHA disagrees with Procter & Gamble's argument. Chemicals with certain properties can displace oxygen and cause asphyxiation. Not every chemical has those properties, so the asphyxiation hazard is inherent and chemical-dependent. Moreover, OSHA has provided longstanding interpretations that indicate simple asphyxiants are covered under the current HCS (*e.g.,* OSHA interpretation, March 4, 1993) and therefore industries working with these substances have provided labels and SDSs on simple asphyxiants in accordance with HCS requirements.

OSHA believes that coverage of simple asphyxiants is very important to the HCS. Such substances result in fatalities in the workplace, particularly in confined spaces, and need to be warned about effectively. The definition has been revised based on the comments received, and included in paragraph (c): '' 'Simple asphyxiant means a substance or mixture that displaces oxygen in the ambient atmosphere, and can thus cause oxygen deprivation in those who are exposed, leading to unconsciousness and death.'' Label elements are provided for simple asphyxiants in Appendix C.4.30. Simple asphyxiants will require the signal word ''warning'' and the hazard statement ''may displace oxygen and cause rapid suffocation.'' In addition, OSHA has added ''simple asphyxiant'' to the definition of ''hazardous chemical.'' Thus all of the provisions of the rule that apply to hazardous chemicals will apply to simple asphyxiants as well.

OSHA will continue to work with the UN to add this hazard to the GHS. (The U.S. has raised this issue in the UN Sub-committee, but it has not yet been resolved. Some of the Sub-committee members share the view that it should not be covered since, according to them, it is not an inherent hazard.) We will evaluate the need for additional rulemaking to change the definition and label elements if the UN incorporates simple asphyxiants into the GHS.

For combustible dust, OSHA has also already provided considerable guidance on the nature and definition of combustible dust in a variety of materials, including OSHA's *Hazard Communication Guidance for Combustible Dusts, OSHA* (3371–08 2009), and its Combustible Dust National Emphasis Program Directive CPL 03–00–008. As described in the preamble to the NPRM (74 FR 50395, Sept. 30, 2009), this was an issue that many ANPR commenters had provided information on, and is clearly a concern in the workplace. There have been a number of workplace incidents involving combustible dust, and the U.S. Chemical Safety and Health Investigation Board highlighted the need to address this specifically in the HCS (Document ID #0110):

> The CSB therefore recommends that OSHA amend the HCS to explicitly address the fire and explosion hazards of combustible dusts, and those materials that could reasonably be expected to produce combustible dusts, among the substances covered by the standard, and also that the Agency require inclusion of dust fires and explosions among the physical hazards that must be addressed in Material Safety Data Sheets. The CSB also requests that OSHA advocate similar changes to the GHS through appropriate international mechanisms.

OSHA has introduced this issue to the UN Sub-committee as well, and is leading a correspondence group on it. However, one of the problems in pursuing this approach is that some countries' systems are limited to supply chain requirements, and do not cover hazard communication issues that arise in the workplace as a result of processing. OSHA's rule does cover such workplace hazards, and requires the provision of information to downstream customers when known processing approaches will result in a hazard. Therefore, discussions continue, but the Sub-committee will not resolve this for at least two years.

In light of the important nature of the issue, a number of public comments, and the need to provide clarity sooner than the UN Sub-committee will complete its work, OSHA is including combustible dust in the definition of ''hazardous chemical'' in this final rule. We have noted that many commenters agreed that there was a need to provide hazard communication on combustible dust, as has been required by OSHA under the current rule. But there were also suggestions that criteria and greater clarity were needed in order to avoid confusion. A few commenters argued that OSHA should not cover combustible dust since it is not an intrinsic hazard of a product (*See, e.g.,* Document ID#0393). However, OSHA believes that similar to the situation with simple asphyxiants, all dusts in the workplace are not combustible, and processing of them does not always result in combustible atmospheres. Consistent with Executive Order 13563 and its emphasis on reducing uncertainty, OSHA agrees with commenters noted above that employers need certainty to properly cover it.

It is true that a separate rulemaking is ongoing on this topic in OSHA, and some commenters suggested that the combustible dust issue should therefore not be addressed in this rulemaking. Such an approach would, however, eliminate safeguards that have long been in place (since 1983). Similar to the situation with simple asphyxiants, OSHA has provided longstanding interpretations that indicate combustible dusts are covered under the current HCS (*e.g.,* OSHA interpretation, January 16, 1986). Specifically, under OSHA's existing Hazard Communication Standard, combustible dust is addressed under the broad definition as both a flammable solid and an explosive hazard. Therefore, not addressing combustible dust in this rulemaking would fail to meet the requirements—which are central to the existing standard—that chemical manufacturers and importers provide information on hazardous chemicals.

While OSHA is currently in the preliminary stages of developing a proposed rule to address combustible dust, the new standard is not expected to be completed for some time. It is also important to note that there is a clear distinction between coverage under the HCS, and potential provisions promulgated under a specific rulemaking for combustible dust. The rulemaking on combustible dust is a much broader approach to the issue, and will likely establish methods to control and address such dusts in the workplace. The HCS is an information transmittal standard. Provision of information to downstream employers is critical now, as it can alert them to the need to have a protective program. This is a fundamental purpose of the HCS—to provide employers and employees with information about hazards so they can take steps to protect their employees and themselves. A failure to continue to address the combustible dust issue in the HCS at this time would eliminate current protections. Therefore, the Agency is clarifying its position that it will continue to regard combustible dust as a serious hazard for which chemical manufacturers and importers must provide information to downstream employers.

The Agency is not adding a definition for combustible dust to the final rule given ongoing activities in the specific rulemaking, as well as in the UN Sub-committee. However, guidance is being provided through existing documents, including the Combustible Dust National Emphasis Program Directive CPL 03–00–008. This directive includes an operative definition, as well as provides information about current responsibilities in this area. In addition, there are a number of voluntary industry consensus standards (particularly those of the NFPA) that address combustible dust, and were noted by commenters as providing further guidance in this area. (*See, e.g.,* Document ID #0379 and 0530). Chemical manufacturers and importers must be aware of the hazards of their products, both in the shipped form, and under normal conditions of use or foreseeable emergencies in downstream workplaces, in order to comply with the HCS. Information about these hazards is required to be transmitted through labels and SDSs as specified in the standard. The protection of workers in downstream workplaces depends on the provision of accurate information to their employers.

Label elements are also provided for combustible dust in C.4.30 requiring, when appropriate, the signal word ''warning'' and the hazard statement ''May form combustible dust concentrations in air'' (similar to ANSI Z400.1/Z129.1—2010 statements).

Concerns were raised by commenters that labels with a signal word and hazard statement may not be appropriate in some situations, because the combustible dust is created through processing downstream, and the product may not present a hazard in its shipped form. (*See, e.g.,* Document ID #0050 and 0353.) Dow (Document ID #0353) pointed out: ''Over-warning would dilute the message.''

OSHA has already addressed a similar situation under paragraph (f)(4) of the final standard, which addresses solid metal, solid wood, plastic, and shipments of whole grain that present no hazard in shipping, but which are used in such a way in downstream operations that employees can be exposed to hazards. In this situation, the downstream employer needs label information about the hazards to protect employees, but OSHA determined that such label information does not need to accompany the product. Therefore, paragraph (f)(4) allows the chemical manufacturer or importer to transmit the label to the customer at the time of the initial shipment, but the label does not need to be included with subsequent shipments unless it changes. This provides the needed information to the downstream users on the potential hazards in the workplace, while acknowledging that the solid metal or other materials do not present the same hazards that are produced when these materials are processed under normal conditions of use.

Many products that are a combustible dust hazard when processed are similar in nature, and therefore paragraph (f)(4) would apply. A shipment of grain, for example, does not present a combustible dust hazard in the shipped form. But when processed downstream in a plant, such hazards are a concern, and the employer needs the label information to properly address the hazard in the workplace. Since this is a normal condition of use for the grain, the chemical manufacturer or importer must provide the information at the time of the initial shipment, and in the future if there is new information regarding the hazards or protective measures. An SDS must always be provided.

In other situations where the material is shipped in a dust form that is potentially combustible without further processing, the chemical manufacturer or importer must have appropriate labels on the containers when shipped under the requirements of paragraph (f)(1). If the chemical manufacturer

labels the product for combustible dust, the label must use the required labeling elements in C.4.30.

Combustible dust has been added to the definition for hazardous chemical, and thus all of the provisions of the standard as amended by the final rule that apply to hazardous chemicals will also apply to combustible dusts, including safety data sheets and worker training. Employers with workplaces where combustible dusts are generated must comply with the workplace labeling requirements in paragraph (f)(6).

As with simple asphyxiants, OSHA will continue to encourage the UN Sub-committee to deal with combustible dusts and develop criteria to be adopted by countries such as ours where workplace exposures are a key part of the hazard communication system.

(d) Hazard Classification

Hazard determination under the current standard. Under the current HCS, chemical manufacturers and importers are required to evaluate the scientific data available regarding each chemical they produce or import, and determine whether the chemical is hazardous within the meaning of the standard. This requires a thorough search of the scientific literature on both the health and physical hazards that the chemical may pose. The identified information must be evaluated within the parameters established in the standard to determine whether the chemical is considered to pose a hazard. Paragraph (d), Hazard determination, provides the regulatory approach for evaluation. This approach is to be implemented using the definitions provided in paragraph (c) as well as in Appendix A, which provides further elaboration on the nature and breadth of health hazards covered. Appendix B provides additional requirements for identifying and evaluating data regarding hazards. Both of these appendixes are mandatory.

In order to ensure the broadest dissemination of information, and to reduce the number of situations where conflicting determinations may be made for the same chemical by different suppliers, the current HCS considers one study, conducted according to established scientific principles and producing a statistically significant result consistent with the definitions of hazard in the standard, to be sufficient for a finding of health hazard under the rule. *See* 29 CFR 1910.1200(d)(2) and Appendix B. This approach was the broadest among those systems that were used as the basis for the development of the GHS.

Most of the definitions under the current HCS simply lead to a conclusion that the chemical involved poses that hazard or it does not. For example, a chemical might be found to be a carcinogen under the rule based on one study indicating that it poses a carcinogenic effect. The current standard does not generally address the degree of severity of the hazardous effect in most of the definitions—so a chemical is either a carcinogen, or it is not. However, while a one-study determination leads to providing information about that hazardous effect on a safety data sheet, it may not lead to a hazard warning on a label. The current HCS requires such warnings to be ''appropriate,'' and there are situations where the data do not support warning about the hazard on the label because of other negative studies or information. *See* 29 CFR 1910.1200 (f)(1)(ii). Thus, there is consideration of the weight of evidence when deciding what to include on a label. Chemical manufacturers and importers may also review the weight of evidence in preparing SDSs, and are permitted to discuss negative evidence and other constraints when reporting the information. Under the current standard, OSHA expects the hazard evaluation process to go beyond simply identifying one study, and include a complete evaluation of all of the information available when determining what information to transmit to users of the chemical.

This hazard evaluation process is consistent with product stewardship processes that have evolved in the chemical industry. (*See, e.g.,* the Responsible Care® program implemented by chemical manufacturers.) Under such processes, chemical manufacturers develop and maintain thorough knowledge of their chemicals. This knowledge is critical to the safe handling and use of the chemicals in their own facilities, as well as in their customers' facilities. It is also critical to handling product liability concerns for their materials.

The current HCS requires chemical manufacturers to remain vigilant regarding new information about their chemicals, and to add significant new information about hazards or protective measures to their hazard communication documents within three months of learning about them. *See* 29 CFR 1910.1200(f)(11), (g)(5). This has always been seen by OSHA as a more rigorous, but essential, requirement than some other countries' provisions, which only require these documents to be reviewed every few years. It should be noted that OSHA has not been enforcing the current requirement to change labels within three months of getting new information. This stay on enforcement began some years ago when the standard was first promulgated, and involved concerns about existing stockpiles of chemicals and other related information. The stay does not apply to safety data sheets. OSHA proposed to reinstate the requirement and lift the stay, making the updating period consistent with that required for safety data sheets (*See* the discussion below on labels).

At the time the HCS was promulgated, the standard's provisions and approach were quite novel, and there were concerns that chemical manufacturers and importers would need more guidance regarding what chemicals to consider hazardous. Thus OSHA included provisions in the hazard determination paragraph that established certain chemicals as being hazardous. Chemical manufacturers and importers still had to complete a hazard evaluation and determination of what hazards were posed, but for these designated chemicals, there was no decision to be made as to whether they were hazardous or not. These chemicals were considered to be a ''floor'' of chemicals covered by the rule, and included those for which OSHA has permissible exposure limits in 29 CFR Part 1910, as well as those for which the American Conference of Governmental Industrial Hygienists (ACGIH) has recommended Threshold Limit Values (TLVs). In addition, given that carcinogenicity was the most controversial and difficult health effect to address, OSHA indicated that, at a minimum, chemicals found to be carcinogenic in the National Toxicology Program's biennial Report on Carcinogens (RoC), or in monographs published by the International Agency for Research on Cancer, were to be considered to be carcinogens in addition to those regulated by OSHA as carcinogens.

The current HCS also includes provisions regarding hazard determinations for mixtures. 29 CFR 1910.1200(d)(5). Where such mixtures have been tested to determine their hazardous effects, the data on the mixture as a whole are used. Where testing has not been done, OSHA promulgated an approach based on the percentage of a hazardous chemical in a mixture to determine if the mixture is hazardous. Therefore, if a mixture contains one percent (by weight or volume) or more of a chemical determined to present a health hazard, the mixture is assumed to have the same effect. The one exception is

carcinogens—a mixture is considered to be carcinogenic if it contains 0.1% or more of a chemical found to be carcinogenic.

In all cases, a mixture will still be considered to be hazardous if there is evidence that it poses a health risk when the hazardous chemical is present in concentrations below the cut-offs. This was included to ensure that chemicals that can have effects at very low concentrations, such as sensitizers, will be adequately addressed.

For physical hazards, the evaluator must determine based on whatever objective evidence is available whether the hazardous effect is still possible in smaller concentrations. This recognizes that, for physical effects, such a determination may be made based on factors such as dilution, and there are readily available means to make an appropriate assessment.

The approach in the current HCS is considered to be a self-classification system. In other words, the chemical manufacturer or importer reviews the available information, and makes the determination as to whether the product presents a potential hazardous effect. This is different than some other systems where the regulatory authority makes the determination, and publishes a list of hazardous chemicals that must be used by the chemical manufacturer or importer.

The hazard determination is to be completed based on available information. The current HCS does not require testing of chemicals to produce information where it is not available.

The hazard determination approach in the current HCS recognizes that information about chemicals changes, new chemicals are introduced, others cease to be used—in other words, the world of chemicals in the workplace changes constantly, and the standard is designed to ensure that employees receive the most up-to-date information available regarding the chemicals to which they are currently being exposed.

Employers who simply use chemicals, rather than producing or importing them, are permitted to rely on the information received from their suppliers. 29 CFR 1910.1200(d)(1). This downstream flow of information recognizes that the chemical manufacturers and importers have access to information about the chemicals they sell that is not available to those who only use them. It also reduces duplication of effort by focusing the hazard determination process at the source, rather than having everyone who uses a chemical trying to complete such a process.

The current HCS requires chemical manufacturers and importers to maintain a copy of the procedures they follow to make hazard determinations. 29 CFR 1910.1200(d)(6). If OSHA finds errors in a label or SDS, the chemical manufacturer or importer that prepared the document will be held responsible—not the employer using the chemical.

The hazard determination procedures in the current HCS, including the definitions and Appendixes A and B, have been in place since the standard was promulgated in 1983.

Hazard classification under the GHS. The challenge in negotiating an international approach was to create a system that did not require frequent changes yet remained current and protective, incorporating the best parts of the approaches in the existing systems. The GHS embodies an approach that is very similar to the current HCS in scope and concept, but builds in additional details and parameters to help to ensure consistency worldwide. Like the HCS, the GHS approach is based on a downstream flow of information from suppliers to users; self-classification; use of available information with no new testing; and a broad approach to definitions of hazard. The GHS has further refined the approach to include addressing the degree of severity of the hazardous effects by assigning categories of hazard within hazard classes; providing detailed scientific approaches to evaluating the available data to help ensure that multiple evaluators produce similar results when classifying hazards; and allowing a broader use of available data by establishing principles where data can be extrapolated in situations regarding mixtures. OSHA believes that these additional provisions in the GHS enhance employee protection in addition to the benefits of having an internationally harmonized approach when preparing labels and SDSs.

To accommodate these refinements, and improve protection for employees exposed to chemicals in the U.S., the final rule modifies the current HCS as follows. First, paragraph (d) is re-named ''hazard classification'' rather than the current ''hazard determination.'' This re-naming is consistent with the approach and terminology used in the GHS.

Similarly, final paragraph (d)(1), like the proposal, modifies the current HCS to indicate that chemical manufacturers and importers are required to classify the chemicals' health and physical hazards in accordance with this section. For each chemical, the chemical manufacturer or importer must determine the hazard classes, and the category of each class, that apply to the chemical being classified.

Final paragraph (d)(1) allows employers to rely on information received from suppliers (*i.e.,* chemical manufacturers or importers). In the final rule, OSHA made two minor changes to the proposed text. Instead of saying that chemical manufacturers would be required to classify ''their'' physical and health hazards, OSHA has replaced ''their'' with ''the chemicals'' for clarification purposes. In addition, OSHA has added the phrase ''where appropriate'' to add clarity that not all hazard classes have more than one category. The final paragraph (d)(1) now reads as set forth in the regulatory text of this final rule.

Final paragraph (d)(2), which is identical to the proposal, similarly modifies the current HCS's terminology regarding classification. However, the final paragraph also includes modifications to address the evaluation process and the role of testing. The paragraph specifically states that evaluation of the hazards of chemicals requires the evaluator to ''identify and consider the full range of available scientific literature and other evidence concerning the potential hazards.'' This is consistent with the current HCS, but re-emphasizes the responsibility to fully characterize the hazard of the chemicals. To clarify that available evidence is to be used, final paragraph (d)(2) specifically states that there is no requirement to test a chemical to classify its hazards under the modified provisions—just as there is no such requirement under the current HCS. Dow Chemical Company (Document ID #0353) suggested that OSHA revert to the current text of paragraph (d)(2), which simply referred to Appendix B for the parameters of the hazard determination. This would not be appropriate since Appendix B no longer exists in its current form. But OSHA does not believe that what is written in paragraph (d)(2) is inconsistent with what is currently required in Appendix B. It is not intended to mean (and does not say) that an evaluator must identify every ''shred'' of information as Dow has indicated in its comment, but rather that the evaluator cannot, for example, only review acute toxicity data and consider that a complete evaluation. The extent of the literature search must be what the reasonably prudent classifier would do to assure themselves that evidence for the range of hazards covered by the rule has been identified, and a thorough evaluation has been done of the potential effects. That is

what is required today under the current HCS.

On the other hand, the Styrene Information and Research Center (SIRC) (Document ID #0361) commented on the same paragraph as follows:

> SIRC supports hazard classification for carcinogenicity and other endpoints based on a comprehensive assessment of the ''full range of available scientific literature and other evidence concerning the potential hazards,'' within a best available science framework. This approach should provide optimum precision assessing potential hazards and a sound basis for maintaining a safe and healthy workplace.

Final paragraph (d)(2) refers to Appendixes A and B for further information on classification as in the current standard. However, the Appendixes have been completely changed from the current text. New Appendix A includes the criteria for classification of health hazards, and new Appendix B includes the criteria for classification of physical hazards. These mandatory appendixes have to be used for the hazard classification process under the revised standard. The Appendixes have been adopted in the final rule, with some changes as described below.

Reference to these appendixes is also included in final paragraph (d)(3), which addresses mixtures. Final paragraph (d)(3)(i), like the proposal, states that chemical manufacturers and importers must follow the procedures in Appendixes A and B to classify hazards for mixtures as well as for individual chemicals. Proposed paragraph (d)(3)(ii) stated that the chemical manufacturer or importer ''shall be responsible for the accuracy of the classification even when relying on the classifications for individual ingredients received from the ingredient manufacturers or importers on the safety data sheets.'' SIRC expressed reservations about this proposed paragraph (Document ID #0494 Tr. 128–29; *See also* Document ID #0361). In commenting on this provision, SIRC said it was uncertain whether this provision meant that a classifier could rely on the classifications found in SDSs from the ingredient supplier, or whether the classifier was required to ensure that the supplier's classification was correct. It was OSHA's intent in the proposal to clarify that generally classifiers may rely on the classifications found on the SDSs received from suppliers. The final rule revises (d)(3)(ii) to state that when chemical manufacturers and importers are classifying mixtures, they may rely on the information provided on current safety data sheets of the individual ingredients, except where the chemical manufacturer or importer knows, or in the exercise of reasonable diligence should know, that the safety data sheet misstates or omits required information.

In reconsidering the language proposed, OSHA wanted to ensure that chemical manufacturers and importers know that, in most cases, they can continue to rely on their suppliers' SDS information for ingredients they will be using in formulations. However, where they know information is incomplete or wrong, they have some responsibility for ensuring they have the correct information before using it for their own evaluations.

During implementation of the current HCS, OSHA allowed formulators of chemicals to develop an SDS by simply providing the SDSs for all the ingredients rather than compiling a specific SDS for the product. OSHA does not believe that this practice of providing the SDSs for all the ingredients is widely pursued, but it will not be permitted under the final rule. The revisions to the approach to classifying mixtures do not lend themselves to such a practice. Hazard classification requires consideration and application of bridging principles based on the constituents, as well as the application of a formula when there are multiple ingredients with acute toxicity. These approaches require the evaluator to determine a classification for the mixture as a whole. In addition, this practice places more of a burden on the user of the product to sort out the relevant information for protection of their employees. The formulator is in a better position to assess the information and provide what is needed to their customers.

Under the current HCS, paragraph (d)(6) requires chemical manufacturers, importers, or employers performing hazard determinations to keep a copy of the procedures they follow in the hazard determination process. This provision has been deleted in the final rule because the hazard classification procedures have been specified, and thus all evaluators are following the same process.

Final paragraph (d) is thus much shorter and less detailed than paragraph (d) in the existing standard. This is largely due to the approach in the GHS to include the details regarding classification in hazard-specific discussions that address both the individual substance and that substance in mixtures. Given the volume of these criteria, it appeared to OSHA that presenting the relevant information in mandatory appendixes was a more efficient way to describe the criteria than including it all in the primary text of the standard. This is particularly true for those many employers reading the standard who do not have to perform hazard classification—the revisions only apply to chemical manufacturers and importers, unless an employer chooses not to rely on information received from them.

The GHS criteria. A number of commenters expressed their general support for the GHS criteria, and agreed that the criteria will result in thorough, harmonized hazard evaluations (*See, e.g.,* Document ID #0329, 0330, 0335, 0339, 0370, 0375, and 0389). In adopting the GHS approach, the final rule deletes from the hazard classification requirements the ''floor'' of hazardous chemicals described above—established lists of chemicals that are considered hazardous under the HCS in all situations. In addition, OSHA deleted the across-the-board ''one study'' rule described above, wherein one good scientific study established that a substance is a hazard. However, the one-study approach is still included in some of the criteria in the GHS, and thus in the revised OSHA rule.

With the detailed criteria, and the weight of evidence approach in the GHS, OSHA indicated in the NPRM that it appeared to no longer be necessary to have such a floor or the one study rule. Many commenters agreed with OSHA (*See, e.g.,* Document ID #0313, 0327, 0328, 0336, 0338, 0339, 0344, 0351, 0361, 0363, 0365, 0367, 0370, 0371, 0375, 0376, 0377, 0379, 0381, 0382, 0383, 0393, 0399, 0405, 0408, and 0410). For example, the Alliance of Hazardous Materials Professionals (Document ID #0327) indicated:

> Elimination of the ''floor'' definition of hazardous (as consistent with the GHS) would require producers and users to more closely examine the properties of the materials they produce or handle. While this would increase the effort necessary to determine that some substances are hazardous, it would also force a more careful examination of the underlying reasons that the substance is hazardous.

There were few comments that questioned taking the floor out of the requirements given the detailed nature of the criteria to evaluate hazards. It was noted that the lack of a floor may result in some inconsistencies in evaluations (Document ID #0352). There were also some concerns about removing IARC and NTP as sources to evaluate chemicals (Document ID #0321). Conversely, others supported elimination of these resources because inclusion violated the Data Quality Act (Document ID #0417)—a conclusion that OSHA does not believe is accurate. Evaluation of carcinogens will be

addressed further below. OSHA has not included a ''floor'' of hazardous chemicals in the final standard.

As OSHA indicated in the proposed rule (74 FR 50282, Sept. 30, 2009), the Agency planned to adopt all of the health and physical hazard classes in the GHS, but not all of the hazard categories. In keeping with its intent to maintain the scope of coverage of the existing rule to the extent possible, as well as to be as consistent as possible with the scope of the European implementation of the GHS, OSHA did not propose to adopt Acute Toxicity, Category 5; Skin Corrosion/Irritation, Category 3; and Aspiration Hazard, Category 2.

Many commenters agreed that the categories selected in the proposal were appropriate (*See, e.g.,* Document ID #0313, 0327, 0329, 0330, 0338, 0344, 0351, 0353, 0365, 0367, 0370, 0376, 0377, 0379, 0381, 0382, 0383, 0393, 0399, 0402, 0408, and 0410), although there were some who thought all hazard categories should be adopted to be completely consistent with the GHS (*See, e.g.,* Document ID #0328, 0335, 0336, and 0339). There were other comments that supported streamlining the document by omitting the guidance portions of the GHS (Document ID #0328, 0399, and 0408); stated that the goal should be harmonization with trading partners, so if they exclude categories, OSHA should exclude them too (Document ID #0335 and 0389); or indicated that OSHA should accept labels and SDSs that include the excluded hazard categories (Document ID #0328, 0379, and 0405). OSHA indicated in the NPRM (74 FR 50383, Sept. 30, 2009) that additional information could be included on labels and SDSs in any event, and that is the position in the final rule as well. *(See* (g)(2); Appendix C.3.)

While the decision logics for the health and physical hazard criteria were omitted from the regulatory text, OSHA indicated that it would consider publishing them as guidance. Commenters agreed with this concept (*See, e.g.,* Document ID #0344, 0351, 0370, 0381, 0410, and 0453). It was further suggested that the diagrams be made simple so all workers can understand them (Document ID #0336). The decision logics are already part of the GHS, and are graphic representations of the process of determining each type of hazard. As such, they are tools for preparers of labels and SDSs, rather than for exposed workers. Another comment was that public comment should be sought on the decision logics before publishing them (Document ID #0379). Given that they are already part of the agreed text of the GHS, and are guidance, OSHA will make them readily available on the Agency's Web page.

There were also comments that OSHA should publish guidance on its interpretation of criteria application, and indicate whether it agrees or disagrees with interpretations published by other countries (Document ID #0382). OSHA is considering many different types of guidance documents, but has not made final decisions in this regard.

Background on Appendices A and B

The text of Appendixes A and B is the bulk of what was proposed to be adopted essentially verbatim from the GHS. While some of the provisions of the GHS have been adopted into the final rule with OSHA-developed language that is specific to the regulatory system of the U.S., OSHA has strived in these appendixes to retain the text of the GHS intact. In order to understand the context of this language, and OSHA's approach to its inclusion, a brief history of its development is necessary.

Most people think of the labels and SDSs as the products of the GHS that are harmonized since they are the system's ''output'' that are seen most frequently. But harmonization of these documents cannot occur unless the underlying criteria are harmonized, and countries adopting them implement them similarly. The health hazard criteria were developed in the Organization for Economic Cooperation and Development (OECD)—an organization of 34 countries that ''provides a forum in which governments can work together to share experiences and seek solutions to common problems.'' *See www.oecd.org.* One of the areas in which the OECD has long been actively involved is chemicals. As such, the OECD provides a forum for countries' experts to discuss and resolve issues of mutual concern. In addition, the OECD works with business, through the Business and Industry Advisory Committee, and with labor, through the Trade Union Advisory Committee. Perhaps its most visible contribution in the area of chemicals is test guidelines to assess the hazards of chemicals. These test guidelines address many different health effects; are considered to be scientifically robust, validated test methods; and are widely used around the world.

It was this expertise and recognition that led to the OECD being the ''focal point'' for development of the health hazard criteria. The OECD also uses a process of consensus to develop their documents, requiring agreement from all countries to move forward rather than a simple majority vote. Working on a consensus basis is much more difficult to accomplish, but is advantageous in other ways since it helps to ensure that the concerns of all parties are taken into consideration, and thus are more likely to remain consistent with the results.

A disadvantage is that the text must satisfy all parties, and thus it is not always written in the clearest fashion. The text was also reviewed further when it was submitted to the UN Sub-committee, and additional editing was done to address concerns. Therefore, it is fair to say that it was written by expert committees, and reflects the involvement of many different people and ideas.

The criteria in Appendix B, unlike those in Appendix A, were not developed ''from scratch,'' but were based on the harmonized criteria developed to classify the physical hazards of chemicals involved in transport by the UN Sub-committee of Experts on the Transport of Dangerous Goods (TDG). The TDG Sub-committee includes many subject experts in areas such as explosives and flammability. The TDG Sub-committee and the International Labor Organization (ILO) were jointly tasked to review the TDG criteria for application to other sectors such as the workplace. This review not only took advantage of the UN and ILO expertise, but also created a system that is harmonized with transport in terms of criteria.

When OSHA developed the proposed rule, it considered editing the text of the criteria for purposes of improving the language. However, the trade-off is inconsistency with the GHS, and the potential for people to believe that OSHA means something different because the text has been revised. Thus, as noted in the NPRM (74 FR 50392, Sept. 30, 2009), OSHA chose to take the approach of adopting the language as stated in the GHS. Editing of the criteria focused on what needed to be changed for purposes of putting it into mandatory regulatory language, including deleting what was clearly identified as guidance.

Therefore, while we have reviewed every suggestion that was made to the text of the Appendixes, our general approach was not to make changes unless they were truly necessary. Editorial changes for purposes of clarification are more appropriately made through the UN Sub-committee process, and OSHA participates actively in that activity, and chairs the primary correspondence group. Those changes that were suggested that OSHA believes have merit in terms of clarifying

provisions will be worked through this correspondence group so the UN Sub-committee can make the changes. Then OSHA will adopt them into the revised standard through rulemaking processes discussed elsewhere in this preamble. To avoid giving this same response repeatedly, OSHA will not be individually addressing the many suggestions for clarifications in this preamble.

In general, there were very few substantive technical comments provided on the approaches in the criteria, and OSHA assumes that reflects the fact that the criteria were developed by technical experts from countries and stakeholder organizations. There were some suggestions received that certain parts of Appendix A be withdrawn so OSHA can consult with toxicologists (Document ID #0353). Numerous toxicologists and other health professionals from the U.S., as well as many other countries, have been involved in the development and review of the text in Appendix A, and it has been subject to extensive scientific and policy discourse. Furthermore, this rulemaking was also the opportunity for others who have not been involved to provide input. If OSHA had received significant comments on the technical aspects of the criteria that indicated a systemic concern about the criteria, it may have been cause for reconsideration. But most of the comments that were received were more reflective of differences on policy positions than truly technical issues. Therefore, there are relatively few changes to Appendixes A and B as a result of record input. These changes are discussed below.

As described in the NPRM and this document, in Appendixes A and B OSHA has maintained its general approach (supported by stakeholders) of: (a) Limiting changes to the HCS to those that are required to align with the GHS; and (b) remaining as consistent with the GHS as possible within the need to use appropriate regulatory language and maintain or enhance current protections. OSHA has also remained mindful of the approaches of its trading partners, although it notes that some proponents of that principle were quite inconsistent themselves when using this particular argument. Therefore, while this argument was used to support choosing higher cut-offs for mixtures, for example, some of these same commenters also suggested not covering hazard classes or categories that are both covered by the EU and currently addressed by OSHA (*See, e.g.,* Document ID #0344, 0381, and 0393). These comments are addressed below.

Appendix A, Health Hazards. Proposed Appendix A began with an introduction that includes material related to principles of classification taken from Chapter 1 of the GHS. These address both weight of the evidence, and the approach to mixtures. In A.0.3.2, the proposed text referred to both positive and negative results being ''assembled together.'' Dow (Document ID #0353) expressed concern about the implications of the word ''assembled.'' In the final rule, OSHA has revised this language throughout the chapter to say ''shall be considered together.'' Dow also commented that in the discussion regarding acceptable data in A.0.2.2 and A.0.2.3, the text should refer to ''valid'' methods, rather than ''validated.'' OSHA does not agree that this change is warranted. To be ''valid'' data, the methods used to produce the data must be validated. In order to clarify the discussion, OSHA has revised the text by adding two sentences from the GHS to A.0.2.3 as follows:

> Any test that determines hazardous properties, which is conducted according to recognized scientific principles, can be used for purposes of a hazard determination for health hazards. Test conditions need to be standardized so that the results are reproducible with a given substance, and the standardized test yields 'valid' data for defining the hazard class of concern.

As mentioned below in the discussion on mixtures, OSHA has also revised Appendix A to use ''cut-offs/concentration limits'' everywhere one of these terms was formerly used in order to be consistent, and make clear the terms are interchangeable.

The remainder of Appendix A is taken from Chapter 3 of the GHS on Health Hazards. OSHA has included the specific discussions of all of the health hazards covered by the HCS in proposed Appendix A, extracted from Chapter 3 of the GHS. OSHA removed the decision logics that are in the GHS from the criteria, and is considering including them in a guidance document to be made available at the time the final rule is published. As discussed above, stakeholders generally supported this approach. The hazard communication portions of the criteria chapters have also been removed since all of this information is already available in Appendix C and would thus be duplicative. In addition, edits have been made where OSHA is not adopting all of the categories of a particular hazard class.

The chapters on Skin Corrosion/Irritation (Chapter A.2) and Serious Eye Damage/Irritation (Chapter A.3) have been modified more extensively than the other chapters on health hazards in the GHS. In these chapters, the GHS leads the evaluator to conduct additional testing on the chemical when information is not available. While the GHS does not require such testing, the criteria for these effects imply that it should be conducted to complete an evaluation. The HCS is based solely on available information, and no testing is ever required. Therefore, OSHA has modified these chapters to eliminate any references to additional testing and limit the evaluation to what is known based on available information. It should be noted that the UNSCEGHS has initiated work to edit these chapters and make them easier to follow. OSHA will continue to participate in this activity.

Coverage of Mixtures

The coverage of mixtures in terms of health hazards is addressed in two places in the revised rule. First, general principles that apply to multiple effects are addressed in the introductory part of Appendix A in Chapter A.0, ''General Classification Considerations.'' Second, each hazard class discussion includes the criteria for classifying a substance or a mixture. Unlike the current HCS, which defines across-the-board percentage cut-offs for all health hazard classes, the GHS employs a tiered approach to classification. Like the HCS, classification would be based on test data for a mixture as a whole for most hazard classes where it is available. However, where it is not available, but there are data on ingredients and similar mixtures, the GHS allows extrapolation or bridging of data to classify a mixture. This allows greater use of available data before resorting to a percentage cut-off or similar approach. Where such data are not available, the criteria address how to classify mixtures based on cut-offs specific to that hazard. In the case of acute toxicity, this includes calculations based on the acute toxicity of each ingredient in the mixture.

The tiered scheme is somewhat different for certain hazard classes. As described, usually the evaluation is based first on test data available on the complete mixture, followed by the applicable bridging principles and, lastly, cut-offs/concentration limits or additivity. The criteria for Germ Cell Mutagenicity, Carcinogenicity, and Reproductive Toxicity take a different approach by considering the cut-off levels as the primary tier and allowing the classification to be modified on a case-by-case basis based on available test data for the mixture as a whole. This approach is related to the sensitivity of available test methods to detect these types of effects at small

concentrations in the mixture as a whole.

The approach to mixture classification may result in some mixtures that are currently considered to pose a particular hazard not being so classified under the GHS. OSHA believes that the protections of the GHS approach are appropriate, and that these changes will not result in an inappropriate reduction in protection. For example, if there is a mixture that is comprised of 1% of an acutely toxic material, regardless of the severity of that effect, and 99% water, the current HCS would require that mixture to be considered acutely toxic. Under the GHS, it is unlikely to be considered as such. Based on the dilution effect of the water, the acute toxicity is no longer a concern. Thus the bridging principles under the GHS allow for a more accurate assessment of the potential harm of the mixture, whereas the strict cut-off approach under the current HCS may provide hazard information in cases where the exposure is minimal and the occurrence of an adverse effect is unlikely. In the example described, the presence of the water in the mixture as used by the workers reduces the potential for exposure to the hazardous ingredient to such a small amount that no effect is expected to result. The GHS approach is not as simple to apply as the current HCS, but the resulting approximation of the hazards of the mixture will be more accurate.

The GHS uses both the term ''cut-off'' (which is what is used in the current HCS), and ''concentration limit'' (which is used in the EU requirements). The terms are used interchangeably and often appear together (*i.e.,* cut-offs/concentration limits). Several commenters indicated that OSHA should define these terms (Document ID #0344, 0381, and 0393). There are no definitions in the GHS since the terms are self-evident when viewed in the context of how they are used. OSHA does not believe that definitions are needed for these terms. However, Appendix A has been reviewed to make sure the terms are both used consistently throughout the Appendix. The GHS was also reviewed, and it appears the terms are not necessarily used consistently in that text.

Several commenters indicated that language in A.0.5.1.1(a), in the bridging principle that addresses dilution, was inappropriately changed from ''may'' to ''shall'' in the NPRM (*See, e.g.,* Document ID #0344, 0381, 0382, and 0393). OSHA changed the language to track the mandatory nature of the provision when present in a standard versus a non-mandatory recommendation such as the GHS. Therefore, the language remains as ''shall'' in the final rule.

In another part of the bridging principles, the term ''commercial product'' is used in the GHS, and was thus used by OSHA in the NPRM (A.0.5.1.2). Commenters asked that this term be defined (Document ID #0344 and 0381). OSHA reviewed the text, and has changed the term to ''mixture'' instead of ''commercial product''. This is accurate, and the term is already defined.

There are several hazard classes in the GHS that give competent authorities such as OSHA a choice of cut-offs/concentration limits to apply when classifying a mixture containing ingredients that pose these effects (*e.g.,* reproductive toxicity, sensitization, target organ effects). The reason the GHS includes a choice of cut-offs to trigger label disclosure is that countries involved in the negotiations on mixtures had different views on the issue that could not be resolved. All countries agreed to use the lower of the two cut-offs for SDSs, so information will be provided consistently for those documents in all cases. But for labels, some countries had what were described as ''downstream consequences'' that were linked to label disclosures, and therefore did not want to adopt the lower level and trigger those consequences (*e.g.,* banning the use of the chemical for consumer products).

In North America, Canada and the U.S. do not have such consequences linked to label statements, and their requirements are based on giving workers the right-to-know about the hazards and identities of the chemicals in their workplaces. Additionally, Canada has the lower cut-offs in most cases in their current requirements, and OSHA already has the 0.1% cut-off for carcinogenicity. Adoption of the lower cut-offs for both labels and SDSs was supported by both Canada and the U.S. from the outset.

As has been described, OSHA has used consistent cut-offs for purposes of hazard determination for mixtures since the HCS was promulgated in 1983. OSHA described the proposal as follows in the 1983 final rule preamble (48 FR 53290, Nov. 25, 1983):

> The rationale of the proposal was that when the hazard of a mixture is unknown, all hazardous ingredients should be indicated on the material safety data sheet. The user would then have the most complete information available to predict the potential hazards of the mixture. The one percent exclusion was included to absolve the employer from having to evaluate and list chemicals in small quantities, which are not likely to result in substantial exposures.

In the 1982 proposal, the one percent cut-off would have applied to all health and physical hazards. As a result of the comments submitted to the record, OSHA took a different approach to physical hazards in the final rule (no percentage cut-off applies to physical hazards), and also lowered the cut-off for carcinogenicity to 0.1 percent. In addition, a provision that required inclusion of chemicals below these cut-offs in certain situations was also part of the 1983 final rule.

In proposing the one percent cut-off, OSHA noted that ''there was no scientifically correct delineation, but that the one percent cut-off is apparently considered reasonable by a number of parties'' (47 FR 12102, Mar. 19, 1982). OSHA's intent was ''to absolve the employer from having to evaluate and list chemicals present in mixtures in small quantities, which are not likely to result in substantial exposures'' (48 FR 53290, Nov. 25, 1983). These cut-offs were practical accommodations, had been used in other regulatory settings (*See, e.g.,* 29 CFR 1910.1003(a)(2), 13 Carcinogens), and in the 1983 final rule were accompanied by a provision that also covered those situations where the cut-offs were too high for protection purposes. Science regarding potential health hazards in the workplace does not provide evidence that would allow the Agency to draw a bright line to indicate specific concentrations of a chemical in a mixture are, or are not, a potential hazard to workers. Therefore, the establishment of such cut-off levels is a policy decision based on scientific considerations, as well as concerns regarding practicality and utility, but not on studies that can be linked to a particular level for each type of health effect.

That being said, however, the scientific knowledge about these health effects has increased significantly since the HCS was first adopted, as has the concern about their occurrence in the work force. At that time, carcinogenicity was the primary concern in terms of chronic and/or significant health effects, and this concern was reflected in the lower cut-off value adopted by OSHA for that effect. Most of OSHA's substance-specific rulemakings were done for the purpose of addressing carcinogenicity. Now, however, there is more evidence that raises significant concerns about other types of effects.

Sensitization is a key example. Respiratory sensitization leads to asthma, and substantial evidence has

developed over the last few decades showing this effect is of increasing concern. For example, a study by Frazier *et al.* (2001, Document ID #0587) notes that the incidence of occupational asthma has increased by 50% over the last two decades, and that population-based surveys have reported that 5% to 21% of asthma cases are caused or exacerbated by occupational exposure. The authors extrapolated this to the estimated 12 million adults who have asthma in the U.S., and concluded that this suggested that between 500,000 and 2.5 million Americans had occupational asthma. This study was published in 2001, and the numbers are likely to be larger today. The study also examined SDSs for chemicals containing toluene diisocyanate, a known respiratory sensitizer, and found only half the SDSs noted asthma as a potential health effect, and one in four noted neither asthma nor respiratory sensitization effects. Other studies have also examined the increasing concerns about occupational asthma (Document ID #0588, 0591, 0592, and 0593).

Further, the most recent science shows that respiratory and skin sensitization can be caused at very low concentrations. A 2006 paper by Arts *et al.* summarizes human and animal studies on skin and respiratory sensitizers, and finds that sensitization effects often result from exposures to chemicals at concentrations below 1% in studied populations (Document ID #0593). Likewise, the World Health Organization's report, ''Skin Sensitization in Chemical Risk Assessment,'' also reports positive results for skin sensitization well below the 1% cut-off used by the current HCS (Document ID #0586). Moreover, once an individual is sensitized, a response can be triggered at even lower levels than those required initially to induce sensitization (Document ID #0585 and 0593). OSHA has often used sensitizers as an example of why SDS preparers need to consider whether information should be provided below the 1% cut-off. For example, in OSHA's compliance directive for the HCS (CPL 02–02–038), the following guidance is given:

> If the components of a mixture could be released in concentrations which would exceed an OSHA PEL, an ACGIH TLV, or could present a health risk to employees, information on these components must be included on the MSDS regardless if their final concentration in the mixture is less than 1% (or 0.1% for carcinogens). For instance, TDI is a sensitizer at very small concentrations and despite its low concentration in a mixture, can be offgassed in quantities which may present a health risk that must be noted on the MSDS.

But sensitization is not the only effect of concern. Reproductive toxicity is a serious hazard that includes both fertility and effects on the offspring. Recent research concerning endocrine disruptors suggests that these chemicals can have adverse reproductive effects at very low levels (Document ID #0583, 0584, and 626). Likewise, occupational disease mortality and morbidity statistics indicate a number of cases related to target organ effects as well (Document ID #0291, *e.g.,* heart disease and renal effects).

OSHA proposed to use the most protective of the GHS concentration limits for these hazard classes. For sensitizers and reproductive toxins, the final rule requires information to be provided on labels and safety data sheets at concentrations above 0.1%. Other countries may choose to only provide the information on SDSs when the concentration is higher. However, as indicated, these particular health effects are among the most significant to employees, and OSHA believes the provision of information on labels will help both employers and employees ensure that appropriate protective measures are followed. (On the other hand, it should be noted that OSHA was persuaded that the current 1% cut-off may be too conservative for many acute toxins and Category 3 Single Target Organ Toxicants, and the final rule is likely to result in fewer mixtures being covered for these effects than under the current approach.)

In addition to concerns regarding protection for these health effects, there is also a concern about the communication difficulties of having different hazard information on a label versus a safety data sheet. As indicated, the GHS negotiators agreed that all countries would use the lower levels in the criteria for providing information on SDSs. Using a different cut-off for labels would create a situation where there may be hazards on the SDS that do not appear on a label. This inconsistency makes training more difficult, and creates confusion for downstream employers as well when they are deciding about appropriate protective measures. Under the current rule, the mixture cut-offs apply to both the label and the SDS. Several commenters indicated that OSHA should provide guidance indicating specific threshold cut-offs (Document ID #0344, 0381, and 0399). The table below indicates what the cut-offs are for different health hazards. These commenters also suggested OSHA provide guidance on opting out of the cut-offs if data override the threshold. This is already addressed in A.0.4.3.2 (if the classifier has information that the hazard of an ingredient will be evident (*i.e.,* it presents a health risk) below the specified cut-off/concentration limit, the mixture containing that ingredient shall be classified accordingly). A.0.4.3.3 also allows the cut-off/concentration limit to be higher in exceptional cases. The evaluator must have conclusive data demonstrating that the hazard of an ingredient will not present a health risk. OSHA anticipates that the criteria of A.0.4.3.3 would rarely permit this approach to be used.

TABLE XIII–1

Hazard class	Label cut-offs	SDS cut-offs
Respiratory/Skin sensitization	≥0.1%	≥0.1%
Germ cell mutagenicity (Category 1)	≥0.1%	≥0.1%
Germ cell mutagenicity (Category 2)	≥1.0%	≥1.0%
Carcinogenicity	≥0.1%	≥0.1%
Reproductive toxicity	≥0.1%	≥0.1%
Specific target organ toxicity (single exposure)	≥1.0%	≥1.0%
Specific target organ toxicity (repeated exposure)	≥1.0%	≥1.0%
Specific target organ toxicity Category 3	>20%	>20%

During the hearing, worker representatives were asked to comment on whether consistency between the information on the label and the SDS was important for worker protection. They all indicated that it was important. For example, Mr. Platner, who represented the Building and Construction Trades Department of the

AFL–CIO stated (Document ID #0494 Tr. 25):

> Oh, absolutely. An example of a sensitizer that's very common is isocyanate components or polyurethane spray foams or coatings. They're potent sensitizers, and that information very rarely gets to the label. It's usually appropriately in the MSDS, but it rarely makes it to the label.

Similarly, Mr. Kojola of the AFL–CIO, commented (Document ID #0494 Tr. 33):

> Oh, absolutely. What it does is it provides a consistent message that workers are getting both in labels and on safety data sheets. And I think it enhanced the ability to, for example, translate that information into other languages, so I think that alone is a major step forward in enhancing worker protection.

Some commenters argued that OSHA should adopt the higher cut-off levels where given a choice by the GHS (Document ID #0344, 0361, 0367, 0371, 0376, 0381, 0392, and 0393). They questioned whether there was a scientific justification for the lower levels, and suggested that the U.S. should harmonize with the EU approach.

As OSHA described above, there are two primary reasons for the lower levels. First, OSHA believes it is important for effective communication to have the same hazards on the label and SDS to as great a degree as possible. Labels are in an employee's work area, and thus provide the most immediate source of information. While SDSs must be available, they are longer and more complicated, and workers are less likely to review them on a regular basis. For downstream employers, it is also important to maintain consistency and reduce confusion where possible by having the information on hazards the same on the label and SDS.

Secondly, as discussed above, increased knowledge of these health effects in the scientific literature, as well as studies indicating that they are often not reported when they should be, or the information is lacking, has led OSHA to the conclusion that communication at the lower levels is appropriate and necessary for worker protection. It is particularly critical in the area of sensitizers since the incidence of occupational asthma is increasing, and sensitization can occur at lower levels as it progresses. But with the advent of information on effects like those of endocrine disruptors, and the increased awareness of the possible effects of low levels of exposure, it is necessary for all of these effects.

As for the argument regarding consistency with the EU, OSHA has sought to be consistent where possible. However, the EU has a different regulatory structure for dealing with these effects downstream, and what is appropriate for their classification and labeling system is not necessarily appropriate for ours in the U.S. (*See, e.g., http://ec.europa.eu/environment/chemicals/dansub/pdfs/30_atp.pdf:* ''Under Directive 76/769/EEC on the restrictions of certain dangerous substances and preparations, the Commission is, in principle, obliged (within six months of the publication of the classification) to propose a ban on their placing on the market and use by consumers as substances or in preparations (above specified concentrations).'')

There are relatively few chemicals for which there are data indicating the types of effects of concern with regard to these lower cut-offs (*e.g.,* sensitizers), and fewer still that would fall into the range between the lower and higher cut-offs (*e.g.,* between 0.1% and 0.3% for reproductive toxicity). Furthermore, as suggested in one comment, disclosing at different levels on labels versus SDSs may actually create a product liability issue under U.S. law that would argue against taking such an approach (Document ID # 0353). While product liability is not one of the issues that influenced OSHA's decision-making, it may be important to these commenters in the future.

The American Chemistry Council asked during the hearing why OSHA adopted the cut-off levels 25 years ago if the Agency thought they weren't protective, or whether there is information to indicate that they have not been protective (Document ID # 0494 Tr. 174). In response to questions from OSHA as to what the scientific basis would be for communicating a hazard on an SDS and not a label, they responded (Document ID # 0494 Tr. 177): ''A scientific basis? Well, most of these are obligatory regulatory cut-offs for mixtures. There really is not much scientific basis for any of the mixture cut-offs.'' In other words, ACC concedes that there is also no scientific basis for the higher cut-offs it advocates—rather the EU cut-offs are simply policy choices made by a different authority with a distinct regulatory structure. As described previously, OSHA believes there is evidence that these cut-offs are no longer sufficiently protective in light of additional information developed since the HCS was adopted in 1983. Furthermore, having inconsistencies in information on a label versus a safety data sheet impacts the effectiveness of the communication to workers and downstream employers. The cut-offs/concentration levels in the final rule are the same as proposed, and are the lower levels of those the GHS allows countries to choose from when implementing.

The Styrene Information and Research Center (SIRC) argues that OSHA may not lower the mixture cut-off thresholds for sensitizers and reproductive toxicants without establishing that a significant risk exists at that lower threshold (Document ID #0361, 0467, and 0642). OSHA disagrees.

As discussed in Section V, Pertinent Legal Authority, OSHA has found that inadequate hazard communication creates a significant risk and that the final rule will reduce that risk. Contrary to what the SIRC says, OSHA need not support each requirement in a standard with its own significant risk finding. *Public Citizen Health Research Group* v. *Tyson,* 796 F.2d 1479, 1502 n. 16 (D.C. Cir. 1986). Indeed, when the Supreme Court first construed the OSH Act as imposing a significant risk requirement, it spoke in terms of the Agency making findings about unsafe *workplaces,* not individual hazards. *Benzene,* 448 U.S. at 642 (''before promulgating any standard, the Secretary must make a finding that the workplaces in question are not safe [and] * * * a workplace can hardly be considered 'unsafe' unless it threatens the workers with a significant risk of harm''). *See* also, for example, *id.* (framing the ''significant risk'' requirement as requiring OSHA ''to make a threshold finding that a place of employment is unsafe—in the sense that significant risks are present and can be eliminated or lessened by a change in practices.''); *Texas Indep. Ginners Ass'n* v. *Marshall,* 630 F.2d 398, 400 (5th Cir. 1980) (''The Supreme Court recently ruled that the Act requires OSHA to provide substantial evidence that a significant risk of harm arises from a workplace or employment.''). Moreover, courts have held that the OSH Act does not require the disaggregation of significant risk analyses along other lines. *See,* for example, *Lockout/Tagout II,* 37 F.3d at 670 (upholding OSHA's decision not to conduct individual significant risk analyses for various affected industries); *American Dental Ass'n* v. *Martin,* 984 F.2d 823, 827 (7th Cir. 1993) (OSHA is not required to evaluate risk ''workplace by workplace''); *Associated Builders and Contractors, Inc.* v. *Brock,* 862 F.2d 63, 68 (3d Cir. 1988) (''the significant risk requirement must of necessity be satisfied by a general finding concerning all potentially covered industries'').

Indeed, a contrary rule would impose an unworkable burden on OSHA. As the Third Circuit held *Associated Builders and Contractors, Inc.* v. *Brock,* 862 F.2d 63 (3rd Cir. 1988), stating:

The holdings in *USWA I* and *USWA II* sustained a general significant risk finding. Assuming, however, that those opinions were construed as leaving open the significant risk issue, as presently presented, the outcome would be no different. This rulemaking proceeding produced a performance-oriented information disclosure standard covering thousands of chemical substances used in numerous industries. For such a standard the significant risk requirement must of necessity be satisfied by a general finding concerning all potentially covered industries. A requirement that the Secretary assess risk to workers and need for disclosure with respect to each substance in each industry would effectively cripple OSHA's performance of the duty imposed on it by 29 U.S.C. § 655(b)(5); a duty to protect all employees, to the maximum extent feasible.

Id. at 68. Thus, OSHA need not make the sort of significant risk finding suggested by SIRC.

Rather, once OSHA makes a general significant risk finding in support of a standard, the next question is whether a particular standard's requirements are reasonably related to the purpose of the standard as a whole. *Asbestos Information Ass'n/N. Am.* v. *Reich,* 117 F.3d 891, 894 (5th Cir. 1997); *Forging Indust. Ass'n* v. *Secretary of Labor,* 773 F.2d 1436, 1447 (4th Cir. 1985); *United Steelworkers of Am., AFL–CIO–CLC* v. *Marshall,* 647 F. 2d 1189, 1237–38 (D.C. Cir. 1980). The use of a threshold to govern when the standard applies is reasonably related to the purposes of hazard communication. It limits communication to those situations in which a chemical is present in sufficient quantities that workers might experience substantial exposures to its hazards. Hazard communication can be undermined just as much by overcommunication of risks as by undercommunication. An avalanche of information about less significant hazards on a label or SDS could obscure important information on substantial hazards faced by the worker. Thresholds also save manufacturers and importers the burden of evaluating and listing chemicals present in only small quantities and not likely to result in substantial exposures (48 FR 53280, 53290 (Nov. 25, 1983). And as noted above, OSHA has provided a justification for the lower levels challenged by the Styrene Institute and Research Center: chemicals presenting these hazards may be especially hazardous at low levels, and the potential effects are of high concern.

In addition, SIRC seems to challenge only the reduction of the threshold for disclosure on labels, not the identical reduction of the threshold for disclosing the hazard on SDS for these hazards. Under the final rule, the same information for sensitizers and reproductive toxicants must appear on both the label and the SDS, avoiding the potential for confusion. The reproductive toxicant and sensitizer cut-offs are reasonably related to the purposes of the Hazard Communication Standard.

The courts have upheld similar requirements even in the absence of a significant risk finding, provided the requirements were reasonable. In *National Cottonseed Products Ass'n* v. *Brock,* 825 F.2d 482, 487 (D.C. Cir. 1987), the court upheld medical monitoring for cottonseed workers where OSHA found no significant risk. OSHA had eliminated the PEL but imposed the monitoring as a ''backstop'' to the ''no significant risk'' determination, and the court upheld the monitoring requirement because the ''evidence indicates that there is a real possibility of significant health risks'' where no PEL was imposed. Likewise, in *National Mining Ass'n* v. *MSHA,* 116 F.3d 520, 527–28 (D.C. Cir. 1997), the court upheld MSHA's decision to require oxygen at a 19.5% level, even though the evidence only showed that adverse worker effects were experienced at a lower level of 18%. The proper minimum oxygen level was ''a technical decision entrusted to the expertise of the agency,'' which was ''entitled to 'err' on the side of overprotection.'' *Id.* at 528. And in *Public Citizen,* the court upheld a requirement to post signs to warn employees of the hazards presented by ethylene oxide exposures without a separate significant risk determination, noting that signs and labels were specifically contemplated by section 6(b)(7) of the OSH Act and a ''reasonably necessary and appropriate'' part of a standard. 796 F.2d at 1502 n.16.

As explained in the Pertinent Legal Authorities section, the mixture cut-off levels are part of the HCS's general approach of providing prophylaxis against the exposure to significant risks, similar to the medical monitoring requirement in *National Cottonseed,* the higher oxygen level requirement in *National Mining Ass'n,* and the sign requirement of *Public Citizen.* The mixture cut-off thresholds are supported by substantial evidence, as discussed above and, therefore, authorized by the Act.

A related issue is the cut-off in Category 3 of Specific Target Organ Toxicity, both in Single Exposure and Repeat Exposure. Under the GHS, a cut-off/concentration limit of 20% is suggested as guidance. It is an additive cut-off, meaning that the percentages of the ingredients that meet the definition for Category 3 would be added together and compared to the cut-off. Consistent with other revisions to the GHS language that are appropriate for a mandatory standard versus a non-mandatory recommendation, OSHA proposed to make the 20% cut-off mandatory, but requested comment on it. (74 FR 50282, Sept. 30, 2009; see also A.8.3.4.5 and A.9.3.4.4.) A limit that is not mandatory will be difficult for chemical manufacturers to know how to comply with, and it will also be difficult for OSHA to enforce. Furthermore, OSHA views this provision as relaxing the current requirement, which is a cut-off of one percent for each of the ingredients in the mixture that are in and of themselves hazardous. However, consistent with A.0.4.3.2, if the classifier has information that the hazard will be evident below the specified concentration limit, the mixture is to be classified accordingly. Therefore, where the 20% is too high, the classifier will nevertheless be required to classify it appropriately below that level.

There were a number of commenters who supported making the 20% level mandatory, suggesting that it was reasonable for the U.S., promoted consistency, and that the level could be lower if data warrant (*See, e.g.,* Document ID #0313, 0324, 0327, 0329, 0330, 0338, 0339, 0353, 0365, 0381, 0410, and 0412). Others did not agree (Document ID #0323, 0328, 0344, 0376, 0379, 0382, 0393, 0399, and 0405). Some of these commenters suggested that OSHA should provide data to support making it mandatory. The GHS is drafted in voluntary terms, but the HCS is a mandatory standard, meaning that all of its provisions are mandatory as well. OSHA is unaware of specific data one way or the other on the question, but notes that this is a significant relaxation of the applicable cut-off under the current rule. Given the minor hazard presented by these chemicals, OSHA believes the 20% cut-off is appropriate to guard against overwarning. Because no alternatives were presented (other than making the provision voluntary, which is not an acceptable solution), OSHA has included the mandatory requirement in the final rule. Again, as noted above, chemical manufacturers or importers are still required to classify mixtures at lower concentrations if they have evidence that it presents a hazard, so OSHA does not believe the final rule is less protective.

Acute toxicity. In Appendix A, Chapter A.1 (''Acute Toxicity''), OSHA proposed to adopt GHS Categories 1 through 4, but not 5. The current

coverage of the HCS is greater than Category 3 of the GHS, but does not include all of Category 4. If OSHA were to adopt only three categories, it would reduce protections with regard to acute toxicity. Adopting Category 4 expands coverage somewhat. However, chemicals meeting the definition of Category 4 are already covered under the national consensus standard on labeling that many chemical manufacturers already follow (ANSI Z129). In addition, the EU covered them under their previous classification, packaging, and labeling of dangerous substances (*Directive 67/548/EEC*) and preparations (*Directive 1999/45/EC*) directives, and their adopted GHS provisions. These countries comprise the largest trading partner in chemicals for the U.S. Thus, many manufacturers are already classifying their chemicals as acutely toxic to comply with European requirements.

Adopting Category 5 would not only expand coverage significantly, it would lead to inconsistency with Europe and with the current national consensus standard. OSHA also believes that exposures of this magnitude are not likely to be encountered in the occupational setting, and that such coverage would be excessive.

Since OSHA raised this issue for comment in the ANPR, a number of respondents specifically addressed acute toxicity. The responses varied, although a number supported the approach proposed to cover through Category 4 (Document ID #0021, 0046, 0047, 0077, 0104, 0123, 0135, 0145, 0155, 0163, and 0171). For example, Dow (Document ID #0047) stated:

> Dow believes that OSHA should adopt all health hazard criteria and categories, except Acute Toxicity Category 5. While this category may be useful for characterizing consumer products, its use with the substances characterized under the HCS would be confusing and unnecessary. Dow understands that the EU and Australia have both chosen not to include Acute Toxicity Category 5 in their implementation of the GHS and that Canada is currently considering doing the same. Dow believes that the U.S. should be consistent with these other major trading partners by not including this category when it adopts the GHS.

Others suggested that OSHA propose to adopt Categories 1 through 3 (Document ID #0034, 0128, and 0141). Some argued that all categories should be adopted to ensure harmonization (*See, e.g.,* Document ID #0018, 0036, 0050, 0078, 0106, and 0116).

OSHA believes that coverage provided by Categories 1 through 4 is appropriately protective for the workplace, and leads to the greatest harmonization with workplace authorities in other countries. With regard to coverage provided by Category 5, OSHA does not preclude inclusion of information on Category 5 on the label or the SDS. Thus chemical manufacturers or importers who wish to have one label that suffices for the workplace and the consumer sector, for example, could do that and still be in compliance with the HCS. As noted earlier, commenters on the NPRM supported the categories chosen by OSHA, except for a few who thought OSHA should adopt all categories in the GHS to promote complete harmonization. However, OSHA believes that this concern is addressed by permitting such categories to be addressed on labels and SDSs with no penalty.

OSHA did not propose to adopt Category 5. The final standard does not adopt Category 5, nor include it in Table A.1.1, which describes the criteria for acute toxicity. However, calculations for the acute toxicity of mixtures that are comprised of one or more ingredients that fall into Category 5 must include the acute toxicity estimate for the Category 5 ingredients. Proposed Paragraph A.1.3.6.1(a) indicated that the calculation of the acute toxicity of mixtures would ''[i]nclude ingredients with a known acute toxicity, which fall into any of the acute toxicity categories.'' This is consistent with the GHS (Subparagraph 3.1.3.6.1(a)).

As discussed in the Proposal, OSHA believes that the exclusion of Category 5 from the criteria Table A.1.1 may lead to classifiers overlooking substances falling into this category in the mixture calculation, which could result in a higher (less protective) classification. This could also mean a lack of harmonization within the U.S. if other Federal agencies adopt Category 5, potentially requiring inclusion of these data in the calculation. To avoid this situation, OSHA has clarified the text for the mixture calculation to ensure that the ingredients that would be classified as Category 5, and thus would not be classified under the HCS, are included in the mixture calculation. Paragraph A.1.3.6.1(a) has been modified to indicate the calculation must ''[i]nclude ingredients with a known acute toxicity, which fall into any of the acute toxicity categories, or which have an oral or dermal LD_{50} greater than 2000 but less than or equal to 5000 mg/kg body weight (or the equivalent dose for inhalation);''.

OSHA has modified the text of Note (d) to Table A.1.1 to help clarify the requirements. This was done in response to a comment from Dow (Document ID #0526), which stated that they were ''confused about the table,'' and that OSHA should revisit the table and the definitions to properly harmonize the provisions.

Several commenters noted that there were errors in Table A.1.2 in the NPRM (Document ID #0376, 0393, and 0405). The errors have been corrected in the final rule.

One commenter stated that the criteria seem to assume that acute lethality data are available in all situations, and they are not (Document ID # 0321). As with all other health hazard criteria in the standard, the HCS does not require data to be generated to comply with the standard. And the final rule recognizes that many chemicals have not been tested to ascertain their hazards. For example, the formula used to calculate the acute toxicity of a mixture makes an adjustment for ingredients whose acute toxicity is unknown. In addition, the fact that a mixture contains an ingredient of unknown toxicity must be indicated on the label and SDS. This is important because in some mixtures the unknown percentage could be significant, and therefore the estimation of toxicity for the mixture has less credibility than in a situation where the majority of the ingredients have data available.

It was also suggested that the formula used for acute toxicity be displayed in a way that is more commonly used for such equations (Document ID #0641). OSHA agrees that it could be displayed in a different way, but wanted to ensure it appeared the same in the regulatory text as it appears in the GHS. However, in guidance for application of the final rule, OSHA will include the formula in the alternative format as well to assist in understanding it.

The Styrene Information and Research Center (SIRC) challenged the proposal's requirement to disclose the concentration of ingredients in a mixture whose acute toxicity was unknown (Document ID #0361). It argued that ''[i]t is unclear how that requirement would pass a significant risk test'' and that ''[i]t seems unlikely to make the user more cautious.'' However, the record shows the contrary. Both workers and union representatives testified at the public hearing on this rulemaking that workers would be more cautious when dealing with chemicals of unknown toxicity and would look for substitutes where possible (Document ID #0494). Further, Cathy Cole, President of the American Industrial Hygiene Association, testified that industrial hygienists use the fact that a chemical's acute toxicity is unknown when they perform qualitative risk

assessments. She testified (Document ID #0496 Tr. 425):

> [W]e would take that information and use it to weigh it against all the other information within that mixture. If there's an unknown, then we would most likely provide a safety factor as we did our risk assessment * * *. If there's a mixture that has a number of unknowns, then we would treat that very carefully and we would have a high risk ranking for it.

The final rule's hazard classification scheme for mixtures presenting acute toxicity hazards treats unknown toxicity in a similar way. When testing data on the mixture as a whole are not available, the acute toxicity of the mixture is determined by assuming that the nontoxic ingredients dilute the toxicity of the acutely toxic ingredients. (*See* A.1.3.6.2.) However, where the acute toxicity of a particular ingredient is not known, the final rule excludes it from the toxicity calculation. (A.1.3.6.2.4.) In effect, this means that ingredients with unknown toxicity are assumed not to dilute the toxicity of the known acute toxicants. This approach reflects the same cautious treatment of ingredients having unknown acute toxicity that the witnesses testified to, as discussed above. In addition, it is necessary to disclose the concentration of ingredients with unknown toxicity because downstream users need that information to classify any products they make with the mixture.

OSHA has also made two minor, clarifying changes to paragraph A.1.3.6.2.4 that are consistent with changes that were approved by the UN Sub-committee in December. The word ''relevant'' has been added in front of ''ingredient,'' and the word ''total'' was deleted before ''percentage.'' Therefore, A.1.3.6.2.4 in the final rule requires that if the total concentration of the relevant ingredient(s) with unknown acute toxicity is ≤10% then the following formula must be used:

$$\frac{100}{\text{ATEmix}} = \sum_{n} \frac{\text{Ci}}{\text{ATE}_{i}}$$

However, if the total concentration of the relevant ingredient(s) with unknown acute toxicity is >10%, the formula presented above is corrected to adjust for the percentage of the unknown ingredient(s) as follows:

$$\frac{100 - \left(\sum C_{unknown} \text{ if} > 10\%\right)}{ATE_{mix}} = \sum_{n} \frac{Ci}{ATE_{i}}$$

The above discussion shows that SIRC's concerns about the unknown toxicity requirement are unfounded. Employers use the fact that a chemical's acute toxicity is unknown in determining how chemicals should be handled. As such, the disclosure requirement is reasonably related to the purpose of hazard communication and, therefore, within OSHA's authority. In addition, by providing the worker with information about the limits of the known information, the requirement provides the sort of prophylactic function that has been upheld even in situations where the Agency has not made a significant risk finding. The unknown toxicity requirement is consistent with the OSH Act.

Another commenter suggested the trade secret provisions should apply to the requirement for disclosing the concentration of ingredients with unknown toxicity (Document ID #0353). The revised rule (and the GHS) do not suggest that the names of the components be disclosed—simply the aggregate percentage of the total composition that has unknown acute toxicity. So if there are three ingredients in a mixture that have no acute toxicity data available, and they comprise 20% of the mixture, the label and SDS must indicate that 20% of the mixture has unknown acute toxicity. The names of the chemicals do not have to be disclosed, and neither does the number of chemicals involved. Therefore, there should be no trade secret issue.

Skin corrosion/irritation. OSHA proposed to adopt Categories 1 and 2, but not Category 3, for skin corrosion/irritation. Category 3 covers more than the criteria for this hazardous effect under the current HCS. In addition, the irritant effects covered by Category 3 are very minor and transient, and of limited applicability in the workplace setting. The Agency received several ANPR comments supporting such an approach (Document ID #0034, 0077, 0128, 0145, and 0171). This approach is also consistent with the European Union.

As OSHA noted in the preamble to the NPRM (74 FR 50392–93, Sept. 30, 2009), significant editing was done to the GHS text for this health hazard. The criteria in the GHS lead the evaluator to conduct additional testing when information is not available. While the GHS does not require testing, the criteria imply that it should be done to complete an evaluation. This implication is not acceptable under the HCS, which is based solely on available evidence.

As noted in the NPRM discussion, work had already been initiated in the UN Sub-committee to modify the chapter on skin corrosion/irritation to address inconsistencies and clarify provisions. That work has proceeded since the NPRM, and is on the work program for the next two years as well. OSHA has made modifications to the HCS criteria to reflect discussions in the Sub-committee, and clarify areas of concern. In particular, Chapter A.2 of Appendix A, ''Skin Corrosion/Irritation,'' was reorganized in the final rule so that text and figures are consistent. Paragraph A.2.1's title was changed to ''Definitions and general considerations.'' Paragraph A.2.1.2 was added to introduce a tiered approach to follow when classifying for skin corrosion/irritation. Paragraph A.2.2, ''Classification criteria for substances using test data,'' has been modified to reflect that it covers animal test data. In Paragraph A.2.3, ''Irritation,'' the factors used to determine the corrosion/irritation potential of a substance were deleted, and the text was reorganized to follow the tiered approach to classify substances using other data elements. Figure A.2.1 was updated to make it consistent with the text, and to show the tiered evaluation scheme instead of a testing scheme. Comments had been received that indicated this figure was confusing (Document ID #0344 and 0381). Another commenter noted that the criteria are provided without indicating how they were derived (Document ID #0321). The criteria were developed by a group of experts in the OECD and were derived from the existing criteria of the countries involved. They do not specify a test method because the GHS is test method neutral, but the OECD testing guidelines are generally agreed to provide the type of information needed for classification under the GHS.

There were also several comments that pH criteria are not appropriate to use in some situations (for example, the pH of the ingredients in a mixture may not predict the pH of the mixture) (Document ID #0321, 0335, and 0381). The criteria recognize that test data for these effects provide better information

to base a classification on, but pH information can be of assistance when such data are not available.

OSHA believes the edits and changes make the chapter less confusing and clarify that testing is not required to achieve compliance. The basic provisions and approach remain the same as the GHS. The Agency is participating in the continuing work of the UN Sub-committee on this topic, and will revise the HCS if any additional clarifications are made in the criteria for these hazards that will help classifiers follow the provisions.

Serious eye damage/irritation. Proposed Appendix A, Chapter A.3 (''Serious Eye Damage/Eye Irritation''), did not include the criteria for Category 2B of eye irritation, but addressed the label elements for the category in Appendix C. A number of commenters indicated that OSHA should include the criteria for Category 2B (Document IDs #0344, 0351, 0367, 0371, 0381, and 0393), clarify coverage of Category 2B (Document ID #0376 and 0382), or exclude it (Document ID #0405). The omission of the criteria was an oversight, and OSHA has added the criteria for Category 2B to the final rule.

The text for GHS Chapter 3.3, ''Serious Eye Damage/Eye Irritation,'' posed similar issues to those described above for skin corrosion/irritation. The criteria in the GHS implied that testing might be needed to complete classification in the absence of data. This is required by neither the GHS nor the HCS. OSHA made a number of modifications to the parallel text in Appendix A, Chapter A.3, of the HCS proposal to address the perception that testing might be required when it is not. And the UN Sub-committee is also reviewing this chapter for purposes of clarifying the requirements.

As with the skin chapter, in the final rule OSHA has reorganized Chapter A.3 so that the text and figures are consistent, and so that it is clear that what must be followed is a tiered approach. The title of A.3.1 was modified to indicate it covers definitions and general considerations, and paragraph A.3.1.2 was added to introduce the tiered approach for classification. Paragraph A.3.2 (''Classification criteria for substances using animal test data'') was modified to indicate it addresses animal data. Table A.3.1 was modified to indicate that Category 1 corresponds to Serious Eye Damage and not to eye irritants, and Table A.3.2 adds the criteria for Category 2B. In A.3.3 (''Classification criteria for substances using other data elements''), the classification criteria for substances were reorganized using other data elements to make it consistent with Figure A.3.1, and to show the tiered evaluation strategy for classification. Figure A.3.1 was updated to make it consistent with the text. And Table A.3.3 now has a note to indicate that a mixture may be classified as Category 2B in cases when all relevant ingredients are classified as Category 2B. As with skin corrosion/irritation, OSHA will continue to monitor work in the UN Sub-committee to clarify these criteria, and will modify the rule to update the chapter as necessary if changes are made.

One additional issue was raised concerning the coverage of the GHS criteria for eye irritation in comparison to current criteria used by CPSC and EPA. The National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) (Document ID #0384) suggests that the GHS criteria are not as protective as the current criteria used by CPSC and EPA. OSHA uses the CPSC criteria in the current HCS, but does not use EPA criteria. NICEATM did an analysis of a group of chemicals to determine what their classifications would be under the different criteria, and concluded that at least 14 of 149 chemicals it reviewed (17%) would not be classified under the GHS criteria, but would have been under current HCS criteria.

OSHA asked a consulting toxicologist familiar with the GHS criteria to review the comment and the analysis, and the results of his review have been entered into the public record (Document ID #0576, 0577, and 0578). The results of this review show that all of the 14 chemicals are differently classified because they present transitory effects that resolve in 72 hours or less; the difference in classification results from the way each method accumulates transitory positive results across test animals. While there may be some differences in conclusions made under the differing criteria, the differences are less pronounced when variance in transient effects is considered (as it is under the criteria as proposed). This is explained as follows in the toxicologist's report:

> In order to compensate for this difference in approaches, OSHA has proposed to also adopt the GHS concept of ''pronounced variability''. Under this concept, for those chemicals where there is pronounced variability among animal responses, such information may be taken into account in determining the classification. As discussed specifically under OSHA's proposed criteria for Classification and Categorization of Skin Corrosion/Irritation, but only mentioned in passing under Serious Eye Damage/Eye Irritation, this notion would allow for classification in cases where there are very definite, positive irritant effects related to chemical exposure in a single animal, but the overall data set does not support classification. In cases where the response is borderline but persistent or severe but transient, the Assessor would likely classify a substance as irritating. It is noted that there are at least two chemicals among those under examination where ''pronounced variability'' would likely cause the Assessor to classify them as irritants (see data for ethyl thioglycolate and glycidyl methacrylate; fomesafen, 2,2-dimethyl-3-pentanol, and cellosolve acetate might also be classified as irritants under this concept).

The final rule retains the pronounced variability language at A.2.2.2.2 and A.3.2.3. The toxicologist also noted that:

> Finally, a quick search of secondary and tertiary sources available on-line indicates that 12 of the 14 chemicals in question would be classified as hazardous materials under both the current and proposed classification criteria. Those that would not be classified are N,N-dimethylguanidine sulfate (sub-EU classification eye and skin irritation responses; not a sensitizer; no other data found); and tetraaminopyrimidine sulfate (not an acute or chronic toxicant; identified as non-irritating by EU Scientific Committee on Cosmetic Products and Non-Food Products intended for Consumers (SCCNFP)).

Therefore, although the chemical may not be addressed as an eye irritant, it would still be considered a health hazard under the GHS—and the HCS—and thus have information available about its effects on labels and SDSs.

While OSHA appreciates the concerns raised by NICEATM, the criteria are being finalized as proposed, other than the modifications made for clarification purposes. It appears that the pronounced variability considerations will address some of the concerns raised, and that the primary remaining differences involve transient effects of relatively low concern. Both CPSC and EPA were involved in the development of the criteria in the GHS, and were aware of the differences between their existing systems and the agreed harmonized criteria. In harmonizing between the existing systems, the criteria selected were between what currently exists in the U.S. and in the EU. The classification criteria in each existing system is not a bright line determined by science, but rather a scientifically influenced policy determination, and as discussed elsewhere, an inevitable part of adopting harmonized criteria is that a few borderline chemicals might be dropped. No other stakeholders have raised the issue of whether the criteria are protective enough. OSHA is proceeding with the final rule because it believes that in this situation,

maintaining harmonization with the GHS is ultimately more important for worker health. This situation will continue to be monitored as implementation takes place to ensure that it is appropriate.

Respiratory or skin sensitization. The final rule makes only minor changes to the proposed text of Appendix A, Chapter A.4, ''Respiratory or Skin Sensitization.'' The footnotes have been re-numbered since they were out of sequence in the NPRM. And the term EC3 has been explained in a footnote to Tables A.4.3 and A.4.4 (estimated concentration of test chemical required to induce a stimulation index of 3 in the local lymph node assay).

The GHS criteria for respiratory and skin sensitizers have one category for each type of sensitization, but also give the option of dividing that one category into two sub-categories, which involves a differentiation in the type of evidence available. In the NPRM, OSHA proposed to adopt the sub-categories for classification. One commenter strongly supported adopting sub-categories for these sensitizers (Document ID #0381), while another did not support it because the EU has not adopted sub-categories (Document ID #0376). OSHA is adopting the sub-categories as proposed. However, the Agency recognizes that there are situations where data are not available to place the chemical into one of the sub-categories. The GHS itself addresses this in 3.4.2.1.1.1 (respiratory sensitization), and 3.4.2.2.1.1 (skin sensitization). Therefore, under the revised HCS, simply classifying the chemical as Category 1 will be sufficient in cases where data are insufficient to assign a subcategory. The American Chemistry Council (Document ID #0393) suggested that more guidance is needed to differentiate potential and severe sensitizers for placement into the sub-categories. OSHA believes that this type of guidance should be developed through the Sub-committee process, rather than by countries independently developing guidance for application. The Agency will consider requesting the Sub-committee to develop such guidance.

Germ cell mutagenicity. The comments on this health hazard centered on whether or not it should be included in Appendix A. Procter & Gamble (Document ID #0381) and the American Chemistry Council (Document ID #0393) argued that it should not be included. The Soap and Detergent Association (Document ID #0344) also argued for exclusion, but said if it is included, only Category 1A should be covered. Ecolab (Document ID #0351) also argued that only Category 1A should be covered. These commenters argued that it is already covered by reproductive toxicity and carcinogenicity, and adding a separate hazard class would create a training burden.

OSHA disagrees. First, while the current HCS does not define mutagenicity as a separate health hazard, it is covered by the reproductive toxin definition. Under the GHS, mutagenicity is not covered by reproductive toxicity, and OSHA's failure to adopt the mutagenicity category would render the final less protective than the current HCS. The hazard class will have to be adopted to maintain coverage. Secondly, though mutagenicity data are used to predict carcinogenicity, the mutagenicity hazard is not covered by the carcinogenicity criteria. Furthermore, little additional burden for training can be claimed for what is already covered under reproductive toxicity in the current HCS.

All of these commenters argue that the HCS should be as consistent with the EU as possible. The EU has already adopted these criteria, so excluding them would not be consistent with the EU. OSHA is maintaining the hazard class as part of the HCS, and including both categories. It is OSHA's understanding that at present there are no chemicals that meet the criteria for Category 1A, so currently this has no burden associated with it—although there may be minimal burdens if new data in the future place chemicals in this category. (*See, e.g.,* Annex VI to the EU's former directive on classification and labeling, which states: ''To place a substance in category 1, positive evidence from human mutation epidemiology studies will be needed. Examples of such substances are not known to date. It is recognized that it is extremely difficult to obtain reliable information from studies on the incidence of mutations in human populations, or on possible increases in their frequencies.'') Chemicals in Category 2 are frequently used already in discussions of potential carcinogenicity, since mutagenicity test results are used to predict carcinogenicity. Thus, there is little burden associated with adopting that category either. Therefore, OSHA has retained Appendix A, Chapter A.5, ''Germ Cell Mutagenicity.''

OSHA included a new heading in A.5.4 entitled ''Examples of scientifically validated test methods.'' In the interest of maintaining current protections, as well as being consistent with implementation in the EU, germ cell mutagenicity is adopted in the final rule as proposed.

Carcinogenicity. The primary change to the carcinogenicity hazard class as proposed in Appendix A, Chapter A.6, ''Carcinogenicity,'' is the addition of A.6.4, ''Classification of carcinogenicity.'' In the current HCS, carcinogenicity was determined in part by consulting the National Toxicology Program's biennial Report on Carcinogens (RoC), or the International Agency for Research on Cancer's monographs. In addition, chemicals that are regulated by OSHA based on their carcinogenicity (*i.e.,* there is a substance-specific standard addressing the chemical, and the chemical poses a risk of carcinogenicity), are always covered by the HCS. The IARC and NTP documents are prepared based on the evaluation of data by experts convened by these organizations. A number of commenters suggested that this should still be permitted under the GHS-aligned criteria. For example, the United Steelworkers argued (Document ID #0403):

> The current Hazard Communication standard includes a reference to several lists of chemicals automatically presumed to be hazardous, such as the lists of carcinogens published by the National Toxicology Program (NTP) and the International Agency for Research on Cancer (IARC). The proposal removes references to such lists, in favor of a more detailed and complicated classification system. While that classification system is required by the GHS, the lists provide useful guidance and should not be removed altogether.
>
> We suggest the following compromise: OSHA should state in the regulatory text that a classifier may presume that the presence of a chemical on one or more of those lists is sufficient to classify the chemical as hazardous with respect to the hazard covered by the list. (OSHA should also state that the inverse is not true: The absence from a list does not indicate the lack of a hazard.) This does not mean that the classifier is required to classify a chemical as hazardous based solely on the list, only that he or she is free to do so. OSHA should also indicate in the preamble that the Agency will use the lists as guidance in enforcement, and that a classifier who ignores the lists should be prepared to show why his or her judgment is better than the judgment of, for example, NTP or IARC.

Similarly, Morganite Industries, Inc. and Morgan Technical Ceramics, stated (Document ID #0321):

> For example, IARC, NTP and other qualified organizations assess carcinogenicity and come to published conclusions. We do not understand why the proposed Hazard Communication Standard establishes procedures for chemical suppliers to conduct such assessments, seemingly asking them to conduct their own evaluations in the manner

of similar to these expert agencies. That makes no sense to us. Why not just refer to the conclusions published by these agencies? That would shorten and simplify the regulation, it would eliminate large parts of the difficult language and it would eliminate regulatory requirements that are in fact infeasible for most preparers of MSDS to comply with.

OSHA agrees with these commenters that allowing evaluators to rely on IARC and NTP could make classification easier for them, as well as lead to greater consistency. Therefore, A.6.4.1 has been added to the criteria in the final rule to indicate that classifiers may treat these sources as establishing that a chemical is a carcinogen without applying the criteria themselves. And A.6.4.2 reiterates that OSHA-regulated carcinogens are covered under the HCS.

In order to facilitate the use of IARC and NTP determinations as sources for purposes of classification, non-mandatory Appendix F has been significantly modified. In the NPRM, Appendix F was simply a verbatim quote of guidance from IARC on determining carcinogenicity. In the final rule, Appendix F has been updated to reflect the latest version of that IARC text, but also includes additional guidance on how to use IARC and NTP to make carcinogenicity classifications. The inclusion of this guidance should make classification easier for chemicals addressed by these sources, and should also provide parameters for the type of weight-of-evidence decisions that are appropriate under the GHS-aligned criteria.

The following table is included in Part D of Appendix F, and may be used to perform hazard classifications for carcinogenicity under the HCS. It relates the approximated GHS hazard categories for carcinogenicity to the classifications provided by IARC and NTP, as described in Parts B and C of Appendix F:

TABLE XIII–2

Approximate equivalences among carcinogen classification schemes

IARC	GHS	NTP RoC
Group 1	Category 1A	Known.
Group 2A	Category 1B	Reasonably Anticipated (See Note 1).
Group 2B	Category 2.	

Note 1:
1. Limited evidence of carcinogenicity from studies in humans (corresponding to IARC 2A/GHS 1B);
2. Sufficient evidence of carcinogenicity from studies in experimental animals (again, essentially corresponding to IARC 2A/GHS 1B);
3. Less than sufficient evidence of carcinogenicity in humans or laboratory animals; however:
a. The agent, substance, or mixture belongs to a well-defined, structurally-related class of substances whose members are listed in a previous RoC as either ''Known'' or ''Reasonably Anticipated'' to be a human carcinogen, or
b. There is convincing relevant information that the agent acts through mechanisms indicating it would likely cause cancer in humans.

While the criteria for carcinogenicity (as well as other health effects) are largely based on weight of evidence evaluations, there are also provisions in the GHS for countries that want to ensure that all potential carcinogens are adequately captured by the criteria. Thus paragraph 3.6.2.6 of the GHS chapter on carcinogenicity states:

* * * For inclusion into Safety Data Sheets, positive results in any carcinogenicity study performed according to good scientific principles with statistically significant results may be considered.

OSHA chose to include this requirement in Figure A.6.1 of Appendix A in the NPRM under Category 2, suspected human carcinogen. Specifically, the statement read:

Positive results in any carcinogenicity study performed according to good scientific principles with statistically significant results qualifies for referencing the chemical as, at the least a Category 2 carcinogen.

The Styrene Information and Research Council (SIRC) (Document ID #0361) argues that the ''one positive study'' criterion is inconsistent with the weight of evidence approach. In fact, it is not part of the weight of evidence approach, but rather reflects the Agency's decision to ensure that the current level of protection in terms of identifying potential carcinogens in the workplace is maintained in the HCS as permitted by the GHS provisions.

SIRC also indicated that it is not clear what is meant by ''referencing'' the chemical as, at the least, a Category 2 carcinogen. OSHA agrees that the inclusion of this language in Figure A.6.1 is not as clear as it could be in terms of what is required. In the final rule, OSHA has separated this requirement from Category 2, and added a new heading of ''Other considerations'' to the table. The text for the ''Other considerations'' is: ''Where the weight of evidence for the carcinogenicity of a substance does not meet the above criteria, any positive study conducted in accordance with established scientific principles, and which reports statistically significant findings regarding the carcinogenic potential of the substance, must be noted on the safety data sheet.'' Categories 1 and 2 will remain based on weight of evidence, but the data that meet the definition of ''other considerations'' must also be provided on the SDS for the chemical. This will maintain the protections of the current rule and provide information to downstream users so they can determine the appropriate protective measures to be taken in these situations.

In paragraph A.6.3.2 of the NPRM, OSHA included the mixture approach in GHS paragraph 3.6.3.1 regarding use of test data as a whole to characterize the carcinogenic potential of a mixture:

A mixture may be classified based on the available test data for the mixture as a whole. In such cases, the test results for the mixture as a whole must be shown to be conclusive taking into account dose and other factors such as duration, observations and analysis (*e.g.,* statistical analysis, test sensitivity) of carcinogenicity test systems.

SIRC (Document ID #0361) similarly took issue with this provision:

Again, the use of the word ''conclusive'' appears to be an inappropriate attempt to apply the European Precautionary Principle to this issue. It is inconsistent with the fundamental principle that hazard communication is to be based on the application of expert judgment to known information and not require chemical testing (either explicitly or as an inevitable practical requirement to avoid unacceptable economic consequences). The word ''conclusive'' should be replaced with the word ''adequate'' or ''persuasive.''

The provision in A.6.3.2 recognizes that it is difficult to accurately characterize the carcinogenicity of a mixture with an ingredient that is clearly carcinogenic. It requires skilled, expert judgment, and test results on the mixture as a whole may be misleading. Therefore, the

experts who developed the carcinogenicity criteria believed that given the critical nature of this effect and the known limitations of assessing carcinogenic potential in a mixture, it was appropriate to allow testing of the mixture as a whole to supersede an evaluation based on the carcinogenic potential of a known ingredient only when the data allow a sufficient level of confidence about the mixture's hazards. OSHA agrees with the findings of these experts, and does not believe that the word ''conclusive'' needs to be replaced. This provision remains the same in the final rule. It also does not require or imply that any testing of chemicals be performed. It is actually rather unusual to have mixtures tested for any types of effects, so it is expected that this provision will not be applied frequently. If a test is performed voluntarily with the purpose of avoiding characterization of a mixture as a carcinogen, it is very important that the test provide conclusive evidence before depriving downstream users of information that ingredients in the mixture present a carcinogenicity hazard.

In addition to the technical considerations, SIRC (Document ID #0361) (as well as SPI, Document ID #0392), repeatedly suggests that the precautionary principle, or European approaches, are the genesis of various provisions. First, OSHA does not agree that the precautionary principle had any part in the GHS, or the HCS, provisions. The HCS is an information transmittal standard, not a standard that requires the implementation of controls or other risk management approaches. The precautionary principle generally applies to competent authorities, and allows them to regulate or establish controls in situations where complete information is not available about the situation. That certainly does not apply to this provision in the HCS, which requires definitive data before allowing a chemical manufacturer or importer to designate a mixture as not being carcinogenic, although it contains an ingredient that clearly has a carcinogenic potential. The HCS is a standard that is intended to provide information to users of chemicals so they can make their own determinations as to what controls are needed to prevent adverse health effects or the effects of physical hazards. The better information they have about the chemicals in their workplaces, the more likely they will be able to make their own risk assessments, and choose appropriate risk management measures. The provisions of the HCS—as well as the GHS—are designed to ensure that such information is available to users.

The criteria proposed are adopted in the final standard, with the addition of the paragraphs referring to NTP, IARC, and OSHA-regulated substances, and supplemented by the revised non-mandatory Appendix F.

Reproductive toxicity. This hazard class, described in Appendix A, Chapter A.7, was proposed to have two hazard categories (Category 1, which is subdivided into two sub-categories based on human evidence, and Category 2, which also includes evidence from animal studies). In addition, it requires consideration of effects on or via lactation. Several commenters argued that OSHA should not adopt effects on or via lactation (Document ID #0344, 0351, and 0381). The rationale provided is that there is no standard assessment method. However, the criteria already recognize that there is no standard assessment method, and provide the types of information that can be used to assess whether a chemical poses this effect. While such information may not be available for many chemicals, there are certain types of products that may have such information available, and it is information that needs to be provided to exposed workers. Therefore, OSHA is maintaining effects on or via lactation in the final rule. In addition, this maintains consistency with the EU approach.

The only change OSHA has made in the final rule is to change ''should'' to ''shall'' in A.7.2.5.4, since it is mandatory in the HCS. Otherwise, the criteria are adopted as proposed in the text of the final rule.

Specific target organ toxicity single exposure (STOT–SE). This hazard class, described in Appendix A, Chapter A.8, was proposed to have three categories. The first two categories deal with differences in the type of evidence available to assess the effect, while the third addresses transient target organ effects, such as narcotic effects and respiratory irritation. Several commenters indicated that Category 3 could be adopted without adopting Category 2 (Document ID #0344, 0351, 0381, and 0393). Procter & Gamble (P&G) (Document ID #0381) argues that Category 2 should not be adopted:

> There are also a significant difficulty and potential unintended outcome that weigh against applying Category 2. Animal studies may be done for a variety of purposes, some of which are not relevant to consumer product uses, and the interpretations of animal data from these types of studies often yield conclusions not relevant to consumer products. Using the outcomes from animal studies for classification into Category 2, especially studies at exposures near the point of morbidity, requires an unusual level of expertise that many classifiers would not possess. In addition, classification into Category 2 relies on interpretation of the phrase ''relevant to human health,'' which would involve an additional expertise. Therefore, Category 2 should not be adopted.

There are a number of difficulties with this argument. First, this section addresses protection of workers exposed to chemicals, and not the assessment of consumer products and exposures. Many consumer products are not covered by the HCS, although provisions in the scope and application cover those products where they are used in the workplace in a manner different than consumers would use them, or with a more extensive duration and frequency of use.

In devising the Category 1/Category 2 approach to classifying specific target organ toxicity after single (and repeated) exposure, the framers of the STOT–SE (and STOT–Repeated Exposure) criteria sought to establish a means by which the chemical manufacturers and importers could communicate to the worker information as to both the nature and the severity of adverse systemic and target organ effects. The final rule provides detailed criteria to clarify what would be considered an ''adverse'' effect (*See* A.8.2.1.7.3*),* and it also provides specific examples of effects (''changes'') that might be seen in animal studies, yet would not be considered to be ''adverse'' (A.8.2.1.8).

Using these criteria and examples, classifiers will be able to consider whether a change was, as required by Category 2, ''of *relevance for human health.''* In specific cases when an evaluated change was deemed not to be relevant, the classifier is allowed to discount specific toxicological study findings that are not relevant to human hazard assessment and not classify. OSHA believes that classification under Category 2 will be no more difficult than other hazards under the rule, and that no ''special additional experience'' will be needed to classify for Category 2, as suggested by P&G.

Additionally, the GHS-based STOT criteria proposed for adoption by OSHA sought to introduce the concept of dose response to the communication of specific target organ toxicity hazards. Such a concept has long been part of the assessment of acute toxicity hazards, but has been missing from the communication of many other health hazard endpoints. Adoption of both Categories 1 and 2, as proposed, allows the chemical manufacturer/importer of a chemical to convey to the worker additional information as to the

characterization of the specific target organ hazard by providing some general measure of whether an effect (change) might be expected at low (presumably occupationally relevant) exposure, or whether it would be seen only in cases of unusually high exposure (*e.g.,* catastrophic loss of safety controls).

P&G also suggests that Category 2 is inconsistent with paragraph 3.8.1.3 of the GHS in that ''it does not rely primarily on human data * * *.'' However, while GHS 3.8.1.3 (A.8.1.3 in the final rule) does say that human data will be the ''primary source for classification,'' it also specifically states that classification in this hazard class may also be made on reliable evidence ''in experimental animals, toxicologically significant changes * * *.'' Thus, P&G's contention is not accurate. In addition, animal data are used or referred to throughout the criteria in the GHS for health hazards, and the use of such data to predict effects in exposed humans is a standard toxicological approach.

In addition to its appropriateness for protection of workers, Category 2 has been adopted by the EU, and adopting it in the final rule will thus maintain consistency with the EU as well.

Aspiration hazard. OSHA did not propose to adopt Category 2 for aspiration hazards covered by the GHS. This category appeared to be more appropriate for the consumer sector than the workplace. OSHA does not specifically address aspiration hazards in the current HCS although the Agency believes the more relevant and serious Category 1 aspiration hazards are captured under the broad scope of the rule. Several ANPR commenters agreed that Category 2 should not be covered in the HCS (Document ID #0034, 0077, 0128, 0145, and 0171), and the EU does not include it in their requirements. Others suggested that aspiration should not be covered at all since it is not relevant to the occupational setting (Document ID #0102, 0104, and 0163).

Several commenters on the NPRM also argued that aspiration hazard should be completely excluded from the revised HCS (*See, e.g.,* Document ID #0373, 0393, 0398, 0486, and 0528). In addition, one comment suggested that the criteria could be interpreted as applying to drowning, and is overbroad (Document ID #0353).

The primary proponent for complete exclusion of aspiration as a hazard in the revised GHS was the Hydrocarbon Solvents Panel (the Panel) of the American Chemistry Council. In their post-hearing comments, the Panel summarized their position as follows (Document ID #0528):

> (1) OSHA should not adopt the Aspiration Toxicity class under the GHS because, as demonstrated by data submitted to the record, aspiration as a route of exposure is not common in the industrial setting, and is not a significant cause of occupationally related severe or fatal poisonings.
>
> (2) Should OSHA include Aspiration Toxicity as one of the Health Hazard classes, the Panel urged that OSHA not require the Health Hazard Symbol be used as part of the pictogram because it does not accurately symbolize the nature of the hazard represented by the aspiration route of entry, and could be potentially misleading.
>
> (3) Should OSHA include Aspiration Toxicity and a symbol, the Exclamation Mark symbol is more appropriate for the Aspiration Hazard Pictogram. Of the existing symbols in the proposed rule, the Exclamation Mark symbol is more representative of an actual aspiration episode. The Exclamation Mark would be a better choice to connote the hazard endpoints and response necessary in an aspiration event, due to the immediate need for intervention in an aspiration episode.
>
> (4) If OSHA is unwilling to adopt the Exclamation Mark symbol for Aspiration Toxicity, we request that OSHA forward the concern to the UNSCEGHS for its consideration.

With regard to the Panel's first point, OSHA agrees that this route of exposure is not frequently found in the occupational setting. But that is different than saying it does not occur, or should not be a concern. NIOSH has submitted a number of studies and reports to the record that document concerns about aspiration (Document ID #0523 and 0524), and address occupational exposures as well (Document ID #0523). For example:

> *Amoruso et al.* [2008] reported that aspiration of mineral spirits into the lungs may produce serious damage leading to bronchopneumonia that may be fatal within 24 h[ours] * * *.
>
> *Rodriguez et al.* [1991] reported a case incident where deaths in 3 crude oil tanker workers were reported as attributed to pulmonary aspiration as evidenced by histopathology studies. The hypothesized mechanism of deaths included the contributing factors of asphyxia by toxic gases leading to loss of consciousness, traumatic injury and aspiration.

A number of other cases are described in the NIOSH comment. The Panel itself noted two aspiration fatalities in the period from 2003 to 2007, one of which was related to a corrosion inhibitor, and the other to sodium bisulfate (Document ID #0486, 0494 Tr. 212). Moreover, the Panel's chair testified that her company includes aspiration hazard warnings on all of its products (Document ID #494 Tr. 214–15). Therefore, it is clear to OSHA that there are legitimate concerns about aspiration in terms of both occupational injuries and fatalities, and that aspiration hazards need to be included in the scope of the HCS. Thus, OSHA included Chapter A.10, ''Aspiration Hazard,'' in Appendix A in the proposed rule and has retained it in the final rule.

With regard to the symbol, the application of the more severe health hazard symbol to a Category 1 hazard category is consistent with how the symbols are applied to all of the health hazards. Adopting the exclamation mark in the U.S. for aspiration Category 1 would make the HCS inconsistent with other countries' rules regarding aspiration hazard, which would present difficulties for countries exporting to the U.S., and potentially create inconsistencies in what workers see on labels and SDSs. This would not be an effective communication approach to aspiration hazards. Therefore, OSHA does not agree that the exclamation mark should be permitted for Category 1 aspiration hazards. In terms of presenting it to the UN Sub-committee as an issue, OSHA will take that suggestion under advisement. However, industry stakeholders are free to make this suggestion to the Sub-committee themselves through submission of a paper.

With regard to the contention that drowning in water could conceivably be read as being covered by the aspiration hazard criteria, OSHA assures stakeholders that drowning in water is not covered and that the HCS will not be interpreted as addressing drowning in water as an effect covered by the rule.

Aspiration Hazard, Category 1, is included in the final rule as proposed.

Appendix B, Physical Hazards. Appendix B includes the criteria for the physical hazards proposed to be covered by the HCS to be consistent with the GHS. The current HCS covers these hazards, but the definitions, while similar, are not the same as those included in the GHS. The GHS based its physical hazard criteria on those incorporated into the United Nations' Recommendations on the Transport of Dangerous Goods. In the U.S., the Department of Transportation (DOT) has already harmonized its definitions with the UN, and thus, with few exceptions, the GHS. While OSHA's initial physical hazard definitions were consistent with the DOT definitions at the time the current HCS was promulgated, DOT's harmonization with the international requirements resulted in the two agencies having different definitions. Thus the U.S. has not been domestically harmonized for some years. Adopting the same definitions in this rulemaking as DOT has in this rulemaking will have

the additional benefit of accomplishing substantial domestic harmonization.

As with Appendix A and the health hazard criteria, OSHA edited Chapter 2 of the GHS (''Physical Hazards'') to shorten the discussions and focus only on the criteria in the proposed revisions. Decision logics and hazard communication information are not included. As with health hazards, OSHA tried to maintain the current scope of the HCS for physical hazards in the proposal, as well as being as consistent as possible with trading partners, particularly the European Union. One exception may be flammable gases, where it appears that more flammable gases will be covered by OSHA adopting Category 2 than are currently covered by the HCS. OSHA is adopting all of the physical hazards in the GHS.

The one deviation from the approach adopted by the European Union is in the proposed adoption of Categories 1 through 4 for flammable liquids. The European system only addresses Categories 1 through 3. The current HCS covers flammable liquids in Category 4, and exclusion of this category would result in reduced protection, which OSHA does not believe is appropriate. Thus Category 4 is included in the revised HCS.

One edit that should be noted occurs in the criteria for explosives. The GHS criteria currently use the term ''article'' in a manner that is inconsistent with that term as used in the workplace in the U.S. OSHA has changed the term to ''item'' in these criteria. This modification was supported by stakeholders (*See, e.g.,* Document ID #0362).

While OSHA believes that harmonizing with DOT provides significant benefits, there were some concerns regarding this approach that arose in reviewing the physical hazard criteria. These concerns involved the test methods referred to in the GHS criteria, which are based on issues related to the packaging and volume in transportation. Packaging is obviously a major concern in transport, and is used to address or mitigate the risk of conveying certain types of chemicals. These chemicals may or may not be present in the workplace in the same size or type of packaging and the relevance of these factors in the test methods are questionable in terms of workplace exposures. OSHA invited comment on these factors, including comments on the appropriateness of the criteria (including the test methods and references to packaging or volume) when applied to the workplace, and any suggestions that interested parties have to address these issues. Of particular interest were criteria for self-reactive chemicals, organic peroxides, self-heating chemicals, and explosives. Commenters indicated that the criteria could be applied to the workplace (*See, e.g.,* Document ID #0330, 0336, 0383, and 0405). Others specifically noted that OSHA should maintain consistency with DOT (*See, e.g.,* Document ID #0338, 0344, 0351, 0376, 0379, 0381, and 0392). For example, the Industry Minerals Association—North America stated (Document ID #0379):

> The classification, labeling, handling and storage of chemicals related to transport concerns should remain aligned with the principles of HCS. OSHA should seek where possible to reduce incompatibilities between HCS criteria and US DOT transportation requirements.

Accordingly, OSHA has decided to carry through these requirements to the final rule as proposed. OSHA is satisfied that, in this respect, the criteria proposed are appropriate.

The Society of the Plastics Industry, Inc. (SPI) (Document ID #0392) contends that the requirements will not be possible to implement for organic peroxides:

> The GHS would require that the SDS for organic peroxide include:
> (1) Recommended use of the chemical and restrictions on use;
> (2) Precautions for safe handling;
> (3) Conditions for safe storage, including any incompatibilities, and
> (4) Appropriate engineering controls.
> Compliance with these requirements, which include principles from the EU regulation for the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH), presents a particular concern for organic peroxide producers following transportation and initial storage in the DOT-regulated transport container. As written, compliance would present unreasonable difficulties and appears to be infeasible for suppliers of these chemicals. Customers are likely to handle and use these materials under significantly different conditions once they remove the organic peroxides from the packages in which they were transported.

SPI further recommends that OSHA require ''that labels and SDSs include a generic statement of fact indicating that changes in risk and hazard can occur when these self-reactive materials are moved from normal transport and storage conditions into process settings, and that they may require assessments by specialists.'' SPI also suggests that OSHA should be harmonizing with DOT in this area.

SPI indicates that these requirements for information on SDSs originate with REACH requirements in Europe. In fact, OSHA has always required such information on SDSs (with the exception of intended use of the chemical, and restrictions on use), and these requirements preceded REACH by many years—as did the negotiated text of the GHS. In § 1910.1200 (g)(2)(viii) and (ix) of the HCS promulgated in 1983, the preparer of the MSDS is required to provide any generally applicable precautions for safe handling and use, and any generally applicable control measures such as engineering controls, which are known to the chemical manufacturer, importer or employer. OSHA also notes that the manual supplied and written by SPI: ''SAFETY AND HANDLING OF ORGANIC PEROXIDES: A Guide'' (dated August 1999), recommends that downstream users consult labels and MSDSs for handling information (Document ID #0392). OSHA does not agree that the SDS requirements in the NPRM, and the final rule, are infeasible or even substantially different than what has been required by OSHA since 1983. The Agency does not agree that the suggested statement should be required by OSHA regarding organic peroxides. Chemical manufacturers and importers of organic peroxides are free to provide whatever advice they deem appropriate in the supplementary information part of the label, or on the SDS, to guide downstream users for appropriate handling, as long as the advice does not conflict with the required hazard communication information.

With regard to harmonizing with DOT, the criteria in the final rule are the criteria that DOT adopted from the UN Transport recommendations. Therefore, OSHA is harmonizing with DOT through this rulemaking.

One commenter indicated that there was concern that criteria based on transport classification may confuse workplace application, and guidance would be needed (Document ID #0339):

> Concerns have been expressed that the criteria developed for transport concerns, as stated in the GHS, express very specific constraints, or ''worse case scenarios'', which can be confusing to suppliers and users of chemicals who are reading the Safety Data Sheets (SDSs)/labels, etc., without benefit of the context. PRR believes this is an area in which OSHA could develop informational materials to help chemical suppliers and users understand the rationale behind physical hazard classifications.

OSHA will keep this suggestion in mind as guidance materials are developed.

Only minor editorial revisions have been made to Appendix B after reviewing all of the comments received. While a great number of changes were suggested by one commenter (Document ID #0353), most have not been adopted, consistent with the discussion above on

the background for Appendixes A and B. This approach is to maintain consistency with the GHS and DOT, as well as the EU.

The modifications made in the final rule include changing metric references to units used in the U.S., and modifying references to documents incorporated by reference to make them consistent with OSHA's requirements for such references. There are no technical changes to the criteria. Therefore, Appendix B in the final rule is substantially the same as proposed.

Classification Database

One interesting comment that was submitted by a number of respondents to the ANPR involved development of a classification database (Document ID #0047, 0050, 0053, 0054, 0038, 0155, 0160, and 0165). Opinions as to who would develop and maintain such a database varied (OSHA, U.S. industry, and an international body were all mentioned). It appears that the European Union will be making such a database available for compliance with its requirements, as have Japan, Taiwan, South Korea, and New Zealand. Concerns have been raised by stakeholders that classifications in these databases are different for the same chemical. OSHA invited additional comment on this issue in the NPRM (74 FR 50284, Sept. 30, 2009), and received a number of responses.

Many supported the concept of having such a database (Document ID #0328, 0329, 0330, 0335, 0336, 0339, 0341, 0352, 0365, 0366, 0379, 0383, 0389, 0408, 0410, and 0453). There were also various comments about how a database might be done. Some thought OSHA should do the classifications and maintain them online, or that the classifications should be considered ''official'' (Document ID #0330, 0341, and 0453). Others were concerned about the Agency's ability to develop and maintain a database (Document ID #0339), or said it should only be done if resources were provided to maintain it (Document ID #0365). Alternatively, resources could be provided for classifiers to help improve the quality of their classifications (Document ID #0365).

Others suggested that NIOSH could be tasked with developing and maintaining the database (Document ID #0341 and 0408). NIOSH commented that funding is not currently available, and that OSHA may wish to partner with the EU database efforts (Document ID #0412). Additionally, NIOSH and another commenter (Document ID #0383) suggested alternatives to developing a database using existing information such as the Department of Homeland Security's database; using International Chemical Safety Cards that currently cover 1,650 substances and are translated into many languages; or adding GHS classifications to the National Library of Medicine, including its Hazardous Substances Data Bank. NIOSH is also updating its Pocket Guide to include GHS classifications.

Another suggestion was to have the UN develop a database so there is a globally harmonized list, and the Department of Labor could help support it (Document ID #0328 and 0335). The National Fire Protection Association (NFPA) (Document ID #0366) suggested that its database of 2,500 chemicals could be useful in the transition. Other commenters suggested that suppliers can provide classifications to a central repository (Document ID #0352, 0408, and 0410), but one commenter warned that if left to manufacturers, there would be differences that would have to be resolved downstream (Document ID #0328). Another comment raised a concern that, while a common database might be useful, it could also interfere with weight-of-evidence determinations (Document ID #0379). However, such a database could prove useful for substances, which would provide the basis for mixture classifications (Document ID #0335).

Other commenters did not support having a classification database (Document ID #0324, 0344, 0351, 0370, and 0377), or indicated that if OSHA were to develop a classification list, it should be non-binding guidance, and include stakeholder input and global accessibility (Document ID #0344, 0381, 0393, and 0405). Others were concerned that a common database would create another unharmonized list of classifications compared to lists in other countries (Document ID #0344), and that manufacturers should have the responsibility for classification (Document ID #0324 and 0405). Also, a company could have valid data that contradicts a classification assigned in a database, and should be allowed to use its own information (Document ID #0351). There was also a concern that such a list might impede progress by not using the best available data (Document ID #0377). Another commenter argued that the database would need to be internationally developed and maintained to be useful, which would result in the elimination of national or regional lists (Document ID #0376).

OSHA is very interested in whether an international database of classifications could be developed and maintained. It is not likely to be feasible for OSHA to develop and maintain a U.S.-based database, which, as some have noted, would be less useful than an internationally harmonized approach that preempts countries and regions from developing their own approaches. The subject has been raised and discussed in the UN Sub-committee, and a correspondence group has been established to explore the issue further. OSHA has volunteered to lead that group and to help form a consensus position in the Sub-committee on options to address this issue. In the meantime, some of the suggested sources can provide extensive information to assist businesses with GHS classifications, particularly small businesses with fewer technical resources. The International Chemical Safety Cards—which are linked on both OSHA and NIOSH Web pages—are one such resource. The OECD has also established a global chemical portal that includes extensive information on chemicals (*www.oecd.org/ehs/eChemPortal*).

(e) Written hazard communication program. The GHS does not include provisions for a written hazard communication program. Thus the provisions of this paragraph are not directly affected by implementation of the GHS. The only changes proposed align terminology *(i.e.,* the proposal uses the term ''safety data sheet'' rather than ''material safety data sheet'').

The written hazard communication program requirements in paragraph (e) are intended to ensure that hazard communication in a given workplace is coordinated and comprehensive. An employer's program must include a list of the hazardous chemicals known to be present in the workplace (paragraph (e)(1)(i)). This list is basically an inventory of the chemicals the employer must have safety data sheets for, and must be available to employees so they, too, can determine what chemicals should be included under the hazard communication programs in their workplace. The list can be maintained by work area or for the workplace as a whole, and must be kept by an ''identity'' of the chemicals (which will be the ''product identifier'' under the final rule). In other words, the inventory can be common names or product names, rather than individual chemical ingredients of each product by specific chemical identity or chemical name.

The employer's hazard communication program must also include how the standard's requirements for labels, SDSs, and training will be met (paragraph (e)(1)); how the hazards of non-routine tasks will be addressed (paragraph (e)(1)(ii)); and how hazard communication will be

handled in a multi-employer workplace situation (paragraph (e)(2)). OSHA has provided guidance over the years on completing a written program, and there are many sample programs in circulation. The program need not be lengthy or complicated, but it should have enough detail to provide the reader with a blueprint of the workplace-specific program.

Several comments to the ANPR were received from the Small Business Administration (SBA) and others that suggested there would be significant burdens associated with revising the written program as a result of implementing the GHS (*See, e.g.,* Document ID #0022, 0027, 0111, and 0164). Revising the chemical inventory was cited by these commenters as one aspect that was likely to be burdensome. Since the chemical inventory is basically a list of the products an employer has in the workplace that are considered hazardous, the only way this list would change as a result of implementing the GHS would be if something that was not hazardous before is now, or vice versa. OSHA believes that this is not a significant concern for three reasons. First, it would be unusual for a chemical to only have one hazardous effect associated with it so that the overall determination of hazard would be affected by a change in classification in one hazard class. Second, because HCS currently covers hazardous chemicals, unless the chemical is new, it is highly probable that it is already covered. Third, as discussed above in relation to paragraph (b) (Scope and application), OSHA does not believe that the scope of hazards covered by the final rule is substantially different than the current HCS.

The most likely differences resulting from re-classification under the final rule are that a chemical would be placed in a category under a hazard class that does not currently include categories. It may also be possible that a chemical may fall into a different category where there are already defined categories (such as flammability). Neither of these differences would necessitate a change in the inventory.

With regard to other changes in an employer's program, it does not appear likely there would be many, if any at all. Written hazard communication programs usually include provisions such as who in the organization is responsible for implementing different parts of the program, or the type of in-plant labeling system used. The final HCS will not affect those provisions. OSHA does not believe that extensive revisions would have to be made to written programs, including the inventory, under the final rule.

OSHA did not propose any substantive modifications to the written hazard communication program, and it does not anticipate any significant new burdens associated with revising the program as a result of other modifications in the final rule.

While the written hazard communication program was mentioned several times in relation to the costs of compliance, or the burdens on small businesses, it was generally not discussed in a substantive way by rulemaking participants. The Building and Construction Trades Department of the AFL–CIO (Document ID #0359) expressed concerns about the challenges associated with implementation of the HCS on multi-employer worksites, a subject that is addressed in the written hazard communication program requirements. They suggested that the controlling employer on a site coordinate hazard communication activities. This is not a subject related to adopting the GHS, and no changes are being made to the rule to address it. The written program must address how the exchange of information will be accomplished, and that will continue under the final rule.

(f) Labels and other forms of warning. The HCS is designed to provide information through three different media: labels or other forms of immediate warning; safety data sheets; and training. Labels are attached to the container of chemicals, and thus provide the information that employees have the most ready access to in the workplace. Given that they are attached to containers, they are by necessity somewhat limited in the amount of information they can present. The labels provide a snapshot or brief summary of the more detailed information provided to employees in training programs, or available to them on safety data sheets. They are not intended to be a complete or detailed source of information on the chemical.

In the current HCS, the requirements for labels are performance-oriented. At the time the standard was promulgated, there were many different types of labels in use. A common label format used by industry was that provided by the ANSI Z129, Hazardous Industrial Chemicals—Precautionary Labeling standard. Employers following this format at the time provided a number of different types of information on the chemicals involved. However, there were two areas where employers were inconsistent or did not necessarily provide what was needed when following the national consensus standard. The first was provision of an identity on the label that could lead a chemical user to the specific chemical identities for the hazardous ingredients. It was common practice to provide a trade name for a product, but not the names of ingredients, on either the label or the safety data sheet. The second was provision of specific information on the hazards involved, such as the target organ affected.

The current HCS label provisions focus on this typically missing information. On shipped containers, chemical manufacturers or importers are required to include an identity, and appropriate hazard warnings, as well as their name and address or that of a responsible party. The term ''identity'' is defined in the current HCS definitions (paragraph (c)) as ''any chemical or common name which is indicated on the material safety data sheet (MSDS) for the chemical. The identity used shall permit cross-references to be made among the required list of hazardous chemicals, the label and the MSDS.'' The hazard warning is to provide specific information about the health or physical hazards posed by the chemical. The term is defined as ''any words, pictures, symbols, or combination thereof appearing on a label or other appropriate form of warning which convey the specific physical and health hazard(s), including target organ effects, of the chemical(s) in the container(s). (*See* the definitions for 'physical hazard' and 'health hazard' to determine the hazards which must be covered.)''

The current HCS similarly requires identity and appropriate hazard warnings for in-plant containers. OSHA has taken a flexible approach to in-plant labeling, allowing a wide variety of systems to be used as long as all of the required information is readily available to employees when they are in their work areas. Thus the current standard allows employers to continue to use systems such as the Hazardous Materials Information System (HMIS) and the National Fire Protection Association (NFPA) labeling systems that use numerical rankings of hazard.

The labeling provisions of the current HCS exemplify the overall performance orientation of the rule. They establish the basic information requirements for chemical manufacturers and importers, but do not specify a format, or any particular label elements to be used. As a result, labels are often quite different when the same chemical is addressed by different suppliers, creating the potential for employee confusion. While many manufacturers follow the ANSI national consensus standard, others do

not. Large manufacturers have frequently developed their own libraries or repositories of standard phrases, with decision logics for when to apply them to convey a hazard or a precaution. Therefore, not only does this approach lead to labels that are different, it also results in a large duplication of effort by chemical manufacturers developing their own systems.

This performance-oriented approach also did not lend itself to harmonization. Other countries often use more specific approaches, including assignment of standard phrases to certain hazardous effects, symbols, and other label elements. It was clear that the performance orientation of HCS, with its many acceptable varieties of labels, could not be standardized through agreement on content to achieve harmonization.

Given that a more specified approach would also lead to consistency among manufacturers, as well as helping to ensure the same message is received by all exposed employees, OSHA agreed to negotiate a harmonized approach that was more specific than the current standard. This was also agreed to by stakeholder representatives involved in the negotiations. Thus once a chemical is classified as to its hazard classes and corresponding categories, the GHS specifies exactly what information is to appear on a label for that chemical. As described in Part IV of this preamble, OSHA believes that these specific labeling requirements will be more protective of employee health and safety than the current performance-oriented standard.

The NPRM proposed more modifications for paragraph (f) than most of the other paragraphs of the existing standard. It changed the title of paragraph (f)(1) to indicate it addresses labels on shipped containers. OSHA also proposed adding a number of new types of information to the label: Product identifier, signal word, hazard statement(s), pictogram(s), precautionary statement(s), and the name, address, and telephone number of the chemical manufacturer, importer, or other responsible party. One commenter (Document ID #0520) proposed a different format for the requirements in paragraph (f). While OSHA appreciates the suggestion, the format followed by OSHA is dictated to a large extent by document drafting requirements of the **Federal Register**, and remains the same in the final rule. Commenters suggested that OSHA add the words ''where specified'' to paragraph (f)(1) because there are a few hazard categories that do not require all of the elements listed (for example, there may be no symbol required for the category (Document ID #0344, 0381, 0381, and 0393)). However, this concern is addressed in paragraph (f)(2), which states that the information has to be consistent with Appendix C. Therefore, the change has not been made. There was also a suggestion that the language in (f)(1) conflicts with the definition of label (Document ID #0353). OSHA reviewed both the paragraph language and the definition, and does not agree. Therefore, this change has not been made.

The final rule requires that labels on shipped containers contain much more information than required by the current standard. However, much of this additional information has already been included by manufacturers, particularly when following the ANSI standard for precautionary labeling. In addition, the OSHA requirements are intended to be the minimum information to be provided by manufacturers and importers. Under the GHS, as well as the current HCS and the final rule, chemical manufacturers and importers are free to provide additional information regarding the hazardous chemical and precautions for safe handling and use. The GHS and the final rule refer to this as supplemental information. Several commenters requested that this be permitted (Document ID #0132 and 0145). As has already been discussed above with regard to the definitions for hazard statements and precautionary statements, such additional information is permitted in Appendix C of the rule as long as it is accurate and does not conflict with the required label elements. Paragraph (f)(1) is adopted in the final rule as proposed except to provide clarity in light of OSHA deleting the requirement for labeling for hazards not otherwise classified. OSHA has modified paragraph (f)(1) to explicitly state that hazards not otherwise classified do not have to be addressed on container labels. Paragraph (f)(1) in this final rule now requires that chemical manufacturers, importers, or distributors ensure that each container of hazardous chemical leaving the workplace is labeled, tagged, or marked. Hazards not otherwise classified do not have to be addressed on the container. The paragraph also includes the information that the chemical manufacturer or importer must provide on the label, tag, or mark.

Paragraph (f)(2) of the proposal addressed labeling for unclassified hazards. As noted in the discussion on definitions, this has been changed to Hazards Not Otherwise Classified in the final rule. In addition to the change in the definition, OSHA has removed the proposed requirement for labeling unclassified hazards. Since there are no label elements in the rule to address these hazards, the Agency decided to cover them in a more limited fashion, and removed the requirement for labeling them from the final rule. Hazards not otherwise classified will still be addressed on the SDS.

Paragraph (f)(3) in the proposal elaborated the label requirements by stating that the required information would be taken from new Appendix C of the standard on Allocation of Label Elements, which incorporates the GHS labeling requirements. This Appendix specifies the signal word, hazard statement, pictogram, and precautionary statements for each hazard class and category. It also includes a few basic rules about preparing labels that address precedence of hazards and other topics. Thus once a hazard classification is completed, the chemical manufacturer or importer can refer to Appendix C to determine what information must be included on the label. Since paragraph (f)(2) of the proposal has been deleted from the final standard, paragraph (f)(3) of the proposal is now paragraph (f)(2) in the final rule. Each of the subsequent paragraph numbers have changed accordingly. New paragraph (f)(2) also requires that the label be prominently displayed, and in English (although other languages may also be included).

New paragraph (f)(3) requires the harmonized information to be located together on the label, tag, or mark. This paragraph has been adopted in the final standard as it was proposed.

The rest of paragraph (f) in the current standard remained largely the same in the proposed modified text, although conforming changes to terminology were made throughout the paragraph. The current standard's accommodation for labels associated with solid metal was maintained in the revised text, although OSHA has added a heading of ''Solid materials'' to it. The provision regarding conflicts with the requirements of DOT has also been maintained. In fact, since transport rules have been harmonized with the other sectors under the GHS, the possibility of a conflict in information is less likely when the HCS is consistent with the international approach. Two ANPR commenters specifically noted that OSHA should avoid conflict with DOT (Document ID #0064 and 0066). This is already addressed in paragraph (f)(5) in the final standard. NPRM commenters further noted that the exterior package should be for displaying DOT labels, rather than for OSHA labels (Document ID #0345). In general, this would be

true, although there are some cases where the single container serves as both the shipping container and the workplace container, such as drums. In these situations, there are rules in the GHS regarding which pictograms take precedence and the ways in which to display the information. These rules are set forth in Appendix C of the final standard.

The American Trucking Association (ATA) also raised the issue as to whether a GHS-compliant label might lead to a carrier's violation under DOT based on the carrier's ''constructive knowledge'' that a shipment contains a hazardous material (Document ID #0345). ATA suggested that OSHA and DOT need to work together to address this issue. OSHA contacted DOT and was told that this issue is addressed in 49 CFR 172.401, Prohibited Labeling. Specifically, GHS labels are exempted under 49 CFR 172.401(c)(5).

Under proposed paragraph (f)(7) (paragraph (f)(6) in the final rule), OSHA addressed workplace labeling. As noted previously, the current standard provides employers with flexibility regarding the type of system to be used in their workplaces. Some ANPR comments suggested that OSHA maintain this flexibility in the proposed standard (*See, e.g.,* Document ID #0047, 0145, and 0157). OSHA agrees, and the final rule retains the flexibility by indicating that the employer can choose to label workplace containers either with the same label that would be on shipped containers for the chemical under the revised rule, or with label alternatives that meet the requirements for the standard. It should be noted that while alternatives are permitted for workplace containers, the information supplied must be consistent with the revised HCS. Hazard classifications must be revised as necessary to conform with the final rule, and the other information provided must be revised accordingly to ensure the appropriate message is conveyed. Final paragraph (f)(7) remains the same as proposed.

OSHA did not propose to modify the remaining paragraphs on labels in the current HCS, including those that deal with alternatives to affixing labels to stationary containers; labeling of portable containers where the materials are transferred from a labeled container, used within a work shift, and under the control of the employee who performs the transfer; ensuring that all containers in the workplace have a label; a requirement for workplace labels to be in English and prominently displayed, while allowing the information to be in other languages as well; and the requirement for updating label information when there is new and significant information regarding the hazards of a chemical.

The only one of these provisions that received significant comment was the one regarding updating of label information within three months of receiving new and significant information regarding the hazards of a chemical. This provision ((f)(11) in the final rule) has been in the HCS since the 1994 revisions, but an administrative stay was placed on it shortly after it was promulgated in response to manufacturers' concerns. That administrative stay was never reconsidered or removed by OSHA, so the provision was not enforced. OSHA noted in the NPRM (74 FR 50283, Sept. 30, 2009) its intent to lift the stay, and requested comment and input on whether the time frame is appropriate. It should also be noted that an administrative stay is a tool available to OSHA to cease enforcement for reasons the Agency finds appropriate. It is not, as some appeared to assume, something that is adjudicated by an outside body, nor does it involve publication or documentation based on any type of record. It is usually a short-term solution to a problem that can be resolved through discussions with affected parties.

The current HCS requires that SDSs be updated within three months of learning of significant new hazard information, and that requirement has been enforced since the standard first went into effect in 1983. 29 CFR 1910.1200(g)(5). It is important to ensure that labels are similarly updated in a timely fashion, particularly since they provide the most immediate information in the workplace.

It appears that some commenters thought this provision was the effective date for updating the labels with the new GHS-aligned provisions (Document ID #0400, 0502, and 0513). This is not the case. Paragraph (j) of the final rule gives a much longer time period to implement the new GHS label requirements. Paragraph (f)(11), by contrast, addresses situations when a label must be changed because there is new and significant information about the hazards of the chemical. For example, there may be new studies that indicate an ingredient of the product is a potential carcinogen. This happens infrequently, so it is not anticipated that this provision would apply in many cases.

The key concern of commenters is what to do about stockpiles of chemicals that are already labeled. As noted by one commenter (Document ID #0370), new technology is available that links labels and SDSs, making new label generation more efficient. Stockpiles and distribution are now managed through computer programs that were not widely available in 1983. These programs can affect the amount of product kept in stockpiles, as well as the distribution of products in the supply chain, and thus the ability to deal with this updating issue. Consequently, a number of participants agreed that three months was an acceptable time frame (Document ID #0330, 0335, 0336, 0339, 0349, 0351, 0370, 0383, 0408, and 0410). Other commenters suggested that it was reasonable to allow sales to continue of products that are already labeled (Document ID #0313, 0323, 0327, 0328, 0329, 0344, 0351, 0361, 0375, 0377, 0381, 0399, and 0410). For example, Ecolab (Document ID #0351) stated:

> Ecolab agrees that three months for labels to be updated with significant changes to the hazards is acceptable. However, it would also be reasonable to allow the sell-through of product that is already produced and labeled. By three months, we agree new production of that product should occur with the significant new information, as long as existing date-coded inventory can be sold without modification. * * *

Others thought the administrative stay should be continued (Document ID #0353 and 0405). Of those who suggested alternative time frames, a number thought twelve months would be appropriate (Document ID #0328, 0352, 0372, 0376, 0382, 0399, 0402, and 0405). Others indicated three months was not enough (Document ID #0379); updating at some time interval is needed (Document ID #0365); six months would be the minimum (Document ID #0324, 0344, and 0361); or a range of six or seven to twelve months would be appropriate (Document ID #0411).

The North American Insulation Manufacturers Association (NAIMA) detailed some of the factors that influence the ability of a manufacturer to update a label: (1) Identification of the products whose labels need to be changed; (2) drafting new label language, which might require redesign of the packaging; (3) the ability to obtain new label or packing stock for printing; (4) the availability of printers to print the new material within the required time; (5) and transportation time for stock to the printer, from the printer to the manufacturer, and from the manufacturer through the supply chain (Document ID #411). NAIMA argues that many of these factors may be beyond the control of the manufacturer.

OSHA will not maintain the stay. It is necessary that labels be updated to

ensure that users have the appropriate information in a timely manner. OSHA is also not convinced that any difficulties in updating labels justify a full year's delay in providing significant new information. However, OSHA is persuaded that, in some cases at least, it may be difficult to update labels within three months. Thus, final paragraph (f)(11) allows six months to begin labeling shipped containers with the new information. As noted above, there are few situations where this provision will come into play. It is not related to every modification of the label, just those that are significant with regard to hazard information. Six months should be long enough to revise labels, and allow for the depletion of already labeled product. While some commenters discussed the need for global compliance associated with different labels (Document ID #0376), OSHA is only requiring domestic compliance within this time frame. Therefore, the provision is adopted in the final rule with a six-month time period for updating product labels when there is new and significant information about the hazards.

One commenter suggested that OSHA add a new requirement that importers, distributors, and employers inform the chemical manufacturer in writing, within three months, when they become aware of significant information about the hazards of a chemical (unless they have already received this information from the chemical manufacturer) (Document ID #0520). The HCS has always been designed on the premise that the chemical manufacturer is in the best position to know what information is available about the chemicals produced. This information is then to be disseminated downstream to distributors and users of the chemical. This suggestion would create a very extensive new burden on parties in the distribution chain who are not responsible for the chemical or the information regarding it as required under the GHS. It is not consistent with the approach in the rule, and is not the most effective and efficient way to identify and distribute information. Therefore, OSHA rejects this suggestion. However, downstream users are free to inform manufacturers of new hazards of which they learn, and OSHA encourages the sharing of such information.

A few commenters on the ANPR also argued that a small package exemption, or some type of prioritization of information on small packages, should be permitted (Document ID #0043, 0046, and 0080). The current HCS does not have such an exemption or limitation, but the Agency has allowed practical accommodations in enforcement policies for those situations where an issue has occurred. (*See, e.g., CPL 02–02–038*'' *Inspection Procedures for the Hazard Communication Standard:* ''CSHOs must consider alternate labeling provisions (for example, tags or markings) for containers which are of unusual shape or proportion and do not easily accommodate a legible label.'')

In Revision 3 of the GHS, some provisions regarding small package labels have been included (1.4.10.5.4.4, Labelling of small packagings). The competent authority is given the discretion to implement changes that allow label preparers to reduce the required information to accommodate a small package size. OSHA did not propose to adopt such a provision, and has retained its current approach regarding small packages in the final rule. Very small packages are less frequent in the workplace than in consumer settings, and it is difficult to argue that employees should get less information just because of the size of the package. The practical accommodation approach OSHA has been utilizing addresses those situations where there is a valid issue, and ensures that workers receive all of the required information.

Following the NPRM, further comments were received on the issue of labeling small packages. Some suggested that OSHA should provide clear guidance for small containers, including perhaps a suggested priority for the label information (Document ID #0313, 0327, and 0339). Others thought the manufacturer should be permitted to pick the most important hazard and precautionary statements to include on small packages (Document ID #0405), or that OSHA should use the GHS guidance on the issue (Document ID #0342). Particular problems were noted, such as labeling small containers for reference standards (Document ID #0342). Phylmar Regulatory Roundtable testified during the hearing, and suggested that OSHA should either establish a priority for information on a small package label, or clarify what is meant by practical accommodations (Document ID #0497 Tr. 113).

The guidance in the GHS (1.4.10.5.4.4) basically allows countries to introduce a consideration of risk by determining that small quantities of the chemical are not a concern, or that information may be omitted because of the small volume. This approach is not consistent with the HCS, or with the concept of right-to-know. It is also unacceptable to OSHA to allow manufacturers to decide which information is the most important. Essentially, all of the suggested solutions result in less information being available to exposed employees than other employees would receive when exposed to the same chemical packaged in a larger container.

The concept of practical accommodations is difficult to define, since it entails a judgment by OSHA staff when confronted with the details of a specific situation. The point, however, is to find a way to provide the required information in every situation, and not to start with the premise that the solution is to omit such information. Ensuring that workers receive the required information may be accomplished in ways other than simply attaching it directly to each small container. OSHA will examine the situation to make sure that the information is associated with the proper containers, and that it is complete. OSHA is not adopting any regulatory requirements for small packages, but will consider whether any additional guidance is needed as the standard is implemented.

While the GHS specifies the information to be placed on a label, it does not provide a specific format for placement, which is similar to current HCS requirements. At least one commenter noted that the GHS does not specify a location or size of core information on a shipment (Document ID #0066). OSHA believes that the performance-oriented approach of paragraphs (f)(3) and (f)(10) is preferable. The Agency will allow accommodations to be made as long as the information is located together, and is prominently displayed as required.

A number of commenters endorsed the overall approach or specific parts of the label requirements. Comments included adopting the GHS labels (Document ID #0324 and 0339), supporting the flexibility of the in-plant labeling (Document ID #0392), and the use of signal words (Document ID #0321). Others wanted to ensure that hazards are conveyed accurately to all levels of education in the work force (Document ID #0331); supported allowing other languages on labels (Document ID #0381); suggested OSHA should allow flexibility of format and placement of required label elements (Document ID #0405); and suggested that OSHA should follow Revision 3 of the GHS for label requirements (Document ID #0382). OSHA believes that the final standard incorporates all of these concepts.

Appendix C details how the specified label elements apply to each hazard class and hazard category. OSHA has made some modifications to the

introductory text to Appendix C regarding the combination of hazard and precautionary statements, and these modifications were discussed under paragraph (c), Definitions. Comments received regarding red border frames for pictograms, and making the precautionary statements mandatory, are also discussed above in the explanation of paragraph (c), Definitions. Also, as discussed in the explanation of that paragraph, OSHA has added definitions to the final standard for simple asphyxiant and pyrophoric gas. The Agency has also added a new section to Appendix C to provide the label elements for these hazards (C.4.30, Label Elements for OSHA Defined Hazards).

In C.2.1, ''Precedence of hazard information,'' addressing precedence of symbols, OSHA indicated that where the skull and crossbones is on a label, the exclamation point should not be included for acute toxicity. In the GHS, the statement simply says the exclamation point should not be included where the skull and crossbones is on the label. This is followed in the GHS by two other statements about not using the exclamation point for specific hazards when there is already a symbol for the more severe category of the same hazard. OSHA received a comment that the phrase ''where it is used for acute toxicity'' should be deleted since it is not in the GHS (Document ID #0393). OSHA believes that this phrase is appropriate for clarity and parallel construction with the other provisions of the paragraph. The skull and crossbones symbol only addresses acute toxicity, and does not convey other types of effects.

One commenter indicated that paragraph C.2.3.3 should not be mandatory (Document ID #0335). The paragraph indicates that when there is a DOT pictogram for a hazard on a label, an additional GHS pictogram for the same hazard must not appear. The reason it is mandatory is that having two different pictograms addressing the same hazard may lead to confusion for people handling the chemical.

OSHA also indicated that it was proposing to exclude ammunition and ammunition components under Division 1.4S from having the exploding bomb symbol and precautionary statements normally used for explosives (74 FR 50283, Sept. 30, 2009). This proposed exclusion was based on discussions during OSHA's rulemaking to update the explosives standard, and the issue of ammunition being sold in retail establishments. The Agency asked for input on whether the exclusion of the symbol was sufficiently protective, and whether any adjustments needed to be made. Several people thought the symbol should be included on ammunition and components since they are explosive (Document ID #0313, 0327, and 0328). However, others thought it was appropriate to treat ammunition and components differently, and that the exploding bomb does not represent the hazards of ammunition (Document ID #0330, 0336, 0338, 0370, and 0376). OSHA agrees with these commenters that the exploding bomb does not represent the hazards of ammunition, implying that there is a mass explosion hazard when handling these items, although that is not the case. Therefore, the Agency is maintaining the proposed provisions in the final standard, and will not be requiring a symbol or precautionary statements for ammunition and ammunition components.

A question was raised by the National Propane Gas Association (Document ID #0400) regarding signal words for propane if both simple asphyxiant and flammability hazards are covered since they have different signal words (warning and danger, respectively). Appendix C explains the precedence rules for signal words. Only one is ever required on a label. If one of the hazards warrants a ''danger'' signal word, then that will be the only one required on the label.

A few comments were also received about the interface of the new OSHA label requirements with the requirements of other agencies. For example, it was noted that it would be difficult to use one label to comply with both OSHA and CPSC (Document ID #0405), and that EPA and CPSC should accept GHS labels until they adopt the system themselves (Document ID #0328). OSHA does not have authority to determine the policies of other agencies with regard to accepting the new GHS-aligned labels. Another commenter noted that fireworks are regulated by other agencies, and therefore additional requirements are burdensome (Document ID #0355). The new OSHA requirements will be essentially harmonized with DOT's requirements, which will facilitate compliance with both agencies. Lastly, it was noted that OSHA should coordinate label implementation with Canada's Workplace Hazardous Material Information System (WHMIS) (Document ID #0461). As was noted earlier, OSHA does have bilateral discussions with Canada on implementation issues—however, Canada has not yet adopted the GHS or initiated implementation by regulation.

(g) Safety data sheets. The proposed revisions to this paragraph were confined primarily to paragraph (g)(2), other than conforming terminology regarding classification and SDSs. Paragraph (g)(2) of the current HCS indicates what information must be included on an SDS. It does not specify a format for presentation, or an order of information. Chemical manufacturers and importers have been free to use whatever format they choose, as long as the information is provided.

While this performance orientation was supported by chemical manufacturers when the standard was originally promulgated, it was largely based on the positions of those who were already providing SDSs and did not want to change their format. As the scope of the standard was expanded to cover other industries, it became clear that SDS users preferred a uniform order of information or a format. In particular, stakeholders such as emergency responders were concerned that information not being located in the same place on every SDS could create an increased risk in situations where the information was needed quickly.

Several years after the HCS was adopted, the chemical manufacturers themselves responded to these concerns by developing a national voluntary industry consensus standard that included a 16-section SDS (ANSI Z400, Hazardous Industrial Chemicals—Material Safety Data Sheets—Preparation). This consensus standard establishes the titles of each section and the order of presentation. It addresses concerns raised by also putting information of most use to those exposed in the beginning of the SDS, with the more technical data required by health and safety professionals in later sections. ANSI Z400 also responded to comments indicating that the SDS should be essentially ''one stop shopping'' in terms of information on a chemical, and should include other information such as how it is regulated by other Federal agencies, including transport requirements and environmental information by having sections for each of those categories of information.

In 1990, OSHA published a Request for Information (RFI) that addressed the issues of comprehensibility of labels and SDSs (55 FR 20580, May 17, 1990). Nearly 600 comments were received, and the majority of respondents sought an order of information or format for SDSs. Since the international harmonization process had begun at that point, OSHA thought it would be useful to wait until a globally harmonized SDS was available before changing the

requirements. However, through interpretation, OSHA has made clear for many years that the ANSI format is acceptable, as long as the SDS includes the required information (*See* CPL 02–02–038, ''Inspection Procedures for the Hazard Communication Standard'' (Mar. 20, 1998), the compliance directive for the HCS). As explained in Section IV of this preamble, OSHA believes that the implementation of a standardized SDS format will enhance hazard communication and be more protective of employee health than the current performance-oriented standard.

The 16-section format continued to be recognized in different countries and organizations over the years, including an International Labour Organization (ILO) recommendation on chemical safety, the European SDS requirements, and an International Standards Organization standard on SDSs. When the GHS was developed, it was decided that this 16-section format was already a *de facto* international approach, so it was adapted to be part of the GHS. One small change was made to reverse sections 2 and 3 so that hazard information comes before the chemical names of ingredients. This change has subsequently been adopted by ANSI and other groups to be consistent with the GHS.

Since the 16-section SDS was initiated in the U.S. by industry, many companies have been using it. This adoption by industry will reduce the impact of the harmonized GHS requirements. Others who continued to use different formats will need to change their SDSs to conform. There is already software available to assist in developing SDSs in the 16-section format, and it is expected that more tools will be available as the dates for SDS compliance approach.

OSHA proposed to modify paragraph (g)(2) to establish the section numbers and title headings of the sections of the SDS to be consistent with the GHS. Furthermore, a new Appendix D was proposed to be added to the standard to address safety data sheets, and it indicates what information must be included in each section.

As OSHA indicated in the ANPR and the NPRM, sections 12 through 15 of the SDS require information on subjects that are outside the Agency's jurisdiction (*See* the list of sections below). OSHA will not be making these sections mandatory for inclusion, nor will any enforcement activity be directed to these sections. However, inclusion of the sections in an SDS is not precluded, and they have been included in the text of the revised standard so people will be aware that a fully GHS-compliant SDS will have to address those areas in addition to the ones mandated by OSHA.

The revised SDS would require the following sections:

Section 1. Identification.
Section 2. Hazard(s) identification.
Section 3. Composition/Information on ingredients.
Section 4. First-aid measures.
Section 5. Fire-fighting measures.
Section 6. Accidental release measures.
Section 7. Handling and storage.
Section 8. Exposure controls/personal protection.
Section 9. Physical and chemical properties.
Section 10. Stability and reactivity.
Section 11. Toxicological information.
Section 16. Other information, including date of preparation of the last revision.

A note in the revised text addresses the other sections that are not mandatory for OSHA:

Section 12. Ecological information.
Section 13. Disposal considerations.
Section 14. Transport information.
Section 15. Regulatory information.

The remainder of the paragraph on SDSs remains the same as the current HCS. The final rule, like the proposal, retains the current HCS design, ensuring the downstream flow of information from the chemical manufacturer or importer to the distributor and ultimately the employer. Other provisions (completion of all sections of the SDS; provisions for complex mixtures; the requirement for information to be accurate and reflect the scientific evidence; the need to update the SDS when new and significant information is available; maintenance of SDSs so they are accessible to employees; accommodations for situations where employees travel between workplaces during a work shift; and access for OSHA and NIOSH) remain in this final standard as they are in the current standard, although they have been re-numbered.

As was the case with labels, relatively few comments were submitted in response to the ANPR or the NPRM on the specific provisions for SDSs. The final provisions are generally consistent with the current HCS, with the exception of the standardized approach described above that OSHA proposed and adopted in the final rule.

The only text changes that were made to the provisions that follow (g)(2) in the standard were to revise the terminology to be consistent with the new approach. However, there were some editorial suggestions for other changes (Document ID #0353). Consistent with OSHA's stated intent to not change anything that does not require change to align with the GHS, these suggestions have not been implemented in the final rule.

A number of rulemaking participants stated that they support the standardization of SDSs, and some noted that standardization would facilitate training (Document ID #0307, 0321, 0322, 0349, 0456, and 0463). It was suggested that OSHA update (g)(8) to (g)(10) to indicate that electronic distribution is acceptable (Document ID #0376 and 0395). It is already stated in (g)(8) that electronic access is acceptable for employees (although OSHA has removed ''microfiche'' from this provision since that technology is outdated and rarely used and in any event is captured under the broader term ''other alternatives,'' which is retained in the final rule). Electronic distribution is not precluded, although the employer on the receiving end of the information must be able to access it in that form. The general issue of electronic distribution and access is addressed in the compliance directive for the standard (CPL 02–02.038), and is based on recommendations made by the National Advisory Committee on Occupational Safety and Health (NACOSH). As explained in the directive, electronic distribution is permitted, but the appropriateness of its implementation will be judged as follows:

> MSDSs must be readily accessible and there must be no barriers to employee access during the work shift. The Agency interprets the term ''readily accessible'' to mean immediate access to MSDSs. The employer has flexibility to determine how this will be accomplished. The use of electronic means such as computers with printers, microfiche machines, the Internet, CD–ROMS, fax machines, etc., is acceptable. Employers using electronic means to supply MSDSs to their employees must ensure that reliable devices are readily accessible in the workplace at all times; that workers are trained in the use of these devices, including specific software; that there is an adequate back-up system for rapid access to MSDSs in the event of an emergency, including power outages, equipment, and on-line access delays; and that the system is part of the overall hazard communication program of the workplace. Additionally, employees must be able to access hard copies of the MSDSs, and in the event of medical emergencies, employers must be able to immediately provide copies of MSDSs to medical personnel. Mere transmission of the requested information orally via telephone is not acceptable.
>
> Employers may use off-site MSDS management services to meet the requirements of the HCS only if MSDSs are readily available to employees, either as hard copies in the workplace or through electronic means and as long as the provisions outlined

in the previous paragraph are ensured. Despite the use of an MSDS management service, the employer maintains primary responsibility for the hazard communication program, including receipt and use of the information to develop and implement a site-specific hazard communication program under paragraph (e) of the HCS.

When immediate access to paper or hard copy MSDSs does not exist, CSHOs should evaluate the performance of the employer's system by requesting a specific MSDS. Ultimately, the evaluation of an adequate system will rely on the professional judgment of the CSHO. Factors that may be appropriate to consider when determining if MSDSs are readily accessible include:

(1) Are the sheets or alternative methods maintained at a location and under conditions where employees can access them during each work shift, when they are in their work areas?

(2) If an electronic system is used for MSDS access (computer, fax, etc.) do employees know how to operate and obtain information from the system? (CSHOs should request an employee to retrieve MSDSs using the electronic system.)

(3) Was there an emergency/accident where immediate access was critical?

(4) How quickly did the employer respond to the employee's request?

Employees must have immediate access to MSDSs and be able to get information when they need it in order for an employer to be in compliance.

On multi-employer job sites, employers who produce, use or store hazardous chemicals in such a way that other employers' employees are exposed or potentially exposed, must communicate to other employers how the means of access to MSDSs will be accomplished.

Various suggestions were made for improvements to SDSs. For example, it was suggested that the SDS be limited to five pages (Document ID #0415); that a one-page, eighth-grade reading level summary of its contents should be provided (Document ID #0306); and that SDSs be written in plain and simple language (Document ID #0347). OSHA agrees that SDS preparers should try to ensure the SDSs are written clearly, and preparers should consider the audience in determining how the information may be best communicated. As originally designed by ANSI, the sections in the beginning of the SDS are intended to be written in plain language, with fewer technical terms where possible. This information should be of immediate use in emergency situations, and addresses information that exposed workers are most likely to need (summary of hazards for example). But many of the remaining sections of the SDS require technical information, and they are intended to be of use primarily to professionals designing protective measures or providing services such as medical surveillance to exposed employees. These sections need to retain their technical terminology in order to be useful to the professionals for these purposes. It is difficult to regulate those aspects of preparing documents that are intended to convey technical information, and no specific requirements of this type have been included in the final standard.

There was also a comment that the Superfund Amendments and Reauthorization Act (SARA) refers to material safety data sheets (*See 42 U.S.C. 11022),* and that changing the name to safety data sheets would violate the Paperwork Reduction Act (PRA)(Document ID #0350). Changing the references to the data sheet does not violate PRA or SARA. As is clear from the foregoing discussion, MSDSs under the current standard and SDSs under the final rule both serve the same function and communicate the same types of information. OSHA believes that an SDS under the final rule should be treated as an MSDS under SARA, but if the regulated community needs additional clarity, it can ask EPA to issue an interpretation to ensure there are no compliance issues. Similarly, because the change of the regulatory term from material safety data sheet to safety data sheet does not, by itself, create a paperwork burden, there are no PRA implications.

One commenter suggested that OSHA add to the SDS the date the chemical was produced, where chemical testing occurred to determine SDS data, and the manufacturer's Web site (Document ID #0346). OSHA rejects this suggestion, noting that the final rule does not require adding information to the SDS that would make it significantly different from the GHS harmonized information requirements. Furthermore, it would not be practical to require either the date the chemical was produced (which would result in a costly requirement to revise SDSs for every day the chemical was produced), or where chemical testing occurred (which may not be known, given that such information is obtained from many different sources, and studies do not frequently indicate where the testing occurred). However, suppliers are free to provide this information on their Web sites, and often do.

In the NPRM, OSHA noted that mixture safety data sheets could no longer be prepared by attaching multiple SDSs for the ingredients, but rather would have to be an SDS for the mixture as a whole (74 FR 50392, Sept. 30, 2009). One commenter (Document ID #0334) thought the multiple SDSs practice should continue to be allowed, particularly to minimize burdens for small businesses. OSHA believes that this approach is not in compliance with the GHS-aligned requirements. It also does not provide the best information for those downstream, including small business users.

New mandatory Appendix D, ''Safety Data Sheets,'' provides additional requirements for the information to be included under each section heading. The sub-headings used to indicate the additional information were lettered (*e.g.,* (a) product identifier used on the label, (b) Other means of identification, and so forth). Questions were raised as to whether the letters identifying each subheading were considered mandatory (Document ID #0382, 0376, and 0393). Apparently, the EU requires the subheadings to be numbered. OSHA does not consider the letters to be mandatory, but the information each subheading identifies is required to be included. A similar comment indicated that the format of Section 9, Physical and chemical properties should be clarified (Document ID #0339). No particular format is required. Appendix D simply requires that information responsive to that heading and its subheadings must be included. If applicable information is not available, the SDS must state so.

Another commenter indicated concern that Appendix D does not refer to ANSI Z400.1 or Annex 4 of the GHS (Document ID #0336). OSHA does not believe that reference to either of these documents is necessary since Appendix D is self-contained. As Appendix D is mandatory, those documents would have to be incorporated by reference to be referred to, and that is not necessary for purposes of compliance with the standard. However, both ANSI Z400.1 and Annex 4 would be useful references for SDS preparers since they provide additional guidance for completing an SDS.

In the final rule, a small modification has been made to the introduction to Appendix D to indicate that a subheading ''within a section'' needs to be marked when no relevant information is available. Also, OSHA has added column identifiers of ''heading'' and ''sub-heading'' to clarify what is being referred to by that terminology.

Additional comments were received on specific sections of the SDS. For example, in section 1, ''Identification,'' the American Chemistry Council wanted clarification of subheading (c), ''Recommended use of the chemical and restrictions on use'' (Document ID #0393). As explained in Annex 4 of the GHS, A4.3.1.3, the SDS preparer should ''provide the recommended or intended use of the substance or mixture,

including a brief description of what it actually does, *e.g.,* flame retardant, anti-oxidant, etc. Restrictions on use should, as far as possible, be stated including non-statutory recommendations by the supplier.'' Section 1 is adopted in the final rule as proposed.

On Section 2 of the SDS, ''Hazard identification,'' the Soap and Detergent Association argued that the requirement for precautionary statements in subheading (b) should not be included because they are not mandatory in the GHS (Document ID #0344). However, the GHS requires that precautionary statements appear on a label (1.4.10.5.2(c)), and Annex 4 (A.4.3.2.2) indicates that the GHS label elements, including precautionary statements, should be included in Section 2 of the SDS. As has already been discussed, OSHA is adopting the GHS precautionary statements, so they are mandatory for purposes of complying with this standard.

Other commenters questioned what was meant by ''unknown toxicity'' in Section 2, subheading (d) (Document ID #0367 and 0371). This term refers to the criteria for determining the acute toxicity of a mixture where there are ingredients that have no available acute toxicity data. In this case, the percentage of ingredients that have no data to consider in the calculations must be indicated in Section 2. In the final rule, OSHA has slightly modified sub-heading (d) to clarify this reference.

In addition to this clarification, two other changes have been made in Section 2. First, references to paragraphs (d) and (f) said ''paragraph (d)[(f)] of this section,'' which is the normal regulatory reference since the entire standard is called a ''section'' of the Code of Federal Regulations. However, since parts of the SDS under the ''Headings'' column are also referred to as sections, it was confusing. Section 2 now refers to the section number of the standard, 1910.1200. This change is tracked in other parts of Appendix D as well. Second, subheading (c) has been revised to refer to hazards not otherwise classified, rather than unclassified hazards, consistent with modifications to the regulatory text.

In Section 3, ''Composition/information on ingredients,'' commenters indicated that OSHA had left out a phrase that appears in the GHS with regard to identification of ingredients in a mixture (Document ID #0344 and 0393). This was an oversight, and OSHA has added the language ''and are present above their concentration limits/cut-off levels'' into Section 3. To ensure consistency with the classification criteria, OSHA has also clarified that ingredients that present a health risk below the cut-off/concentration limits would also need to be disclosed in section 3 of the SDS. It was also suggested that where the SDS discloses only the range of concentrations, the narrowest range possible should be permitted (Document ID #0395). Neither the GHS provisions for information on SDSs, nor the guidance for completing them, address specific limits for concentration limits. Under the current rule, concentrations of chemicals in a mixture are not required to be disclosed at all. OSHA agrees with the commenter that when SDS preparers use ranges rather than a specific percentage composition, the range must be limited in terms of the percentage concentration variation, and the variation in concentration must have no effect on the hazard of the mixture.

In order to help ensure that use of concentration ranges is understood, OSHA has added the term ''concentration'' in parentheses after the ''exact percentage'' terminology used in paragraph (i)(1) regarding trade secret protection. Similarly, the term ''exact percentage'' has been added in parentheses after ''concentration'' in Section 3 requirements for the SDS. These terms refer to situations where the mixture has a set formula, and the amount of a substance in the mixture is consistent from batch-to-batch. OSHA recognizes that there are some very small variances in this situation that have no impact on the hazard of the overall mixture. ''Exact percentage'' is the terminology used in the GHS guidance for preparation of SDSs, but these small variations or tolerances are expected and acceptable when reporting the anticipated percentage based on the formula.

Concentration ranges, rather than concentrations, may be used in other situations. For example, the final standard includes the longstanding provision that addresses the use of a single SDS for complex mixtures in paragraph (g)(4). Under this provision, where complex mixtures have similar hazards and contents (the ingredients are essentially the same, but the specific composition varies from mixture to mixture), one SDS may be used for all of these similar mixtures. Petroleum streams would be an example of a type of complex mixture to which this provision applies. In this situation, concentration ranges may be used for the ingredients that vary from stream to stream.

A chemical manufacturer or importer may also have a line of products that are very similar, but can be varied slightly in composition to meet the needs of customers. For example, toner colors may be changed by varying the amount of pigment. The variances are small, and the hazard remains the same. In these situations, concentration ranges may be used for multiple, similar products.

Trade secret status may be claimed for exact percentage composition but not for concentration ranges. Where a trade secret claim is made for exact percentage, the chemical manufacturer or importer may choose to provide a concentration range to assist downstream users in providing appropriate protections and, at the same time, potentially eliminating requests from users for disclosure of the trade secret in accordance with § 1910.1200. However, Section 3 must indicate that a trade secret claim is being made and information has been withheld.

Section 8 addresses exposure controls and personal protection. Some commenters noted that the information provided should have more detail than what was proposed in Appendix D, such as requiring information on specific PPE materials that provide protection (Document ID #0359 and 0456). OSHA agrees that SDS preparers should provide the most specific information available for the material so that the appropriate protective measures can be implemented. Annex 4 of the GHS, guidance for preparing the SDS, addresses the specific type of information on personal protective equipment that should be provided in Section 8 of the SDS in paragraph A4.3.8.3. OSHA will be making additional guidance available when the rule is implemented.

Section 8 also addresses inclusion of occupational exposure limits (OELs) on the SDS. Comments were received on inclusion of exposure limits on SDSs in response to the ANPR, and a number of different opinions were expressed, particularly regarding TLVs being required. Many ANPR commenters argued that TLVs should be included on the SDSs, as is currently required under the HCS (*See, e.g.,* Document ID #0042, 0179, 0021, 0038, 0124, and 0149). Others suggested they should not be required (*See, e.g.,* Document ID #0036, 0058, 0064, 0129, 0151, and 0163). A number of commenters suggested other types of occupational exposure limits that should be included on SDSs, such as levels from other countries, those recommended by NIOSH, and those recommended by the American Industrial Hygiene Association (*See, e.g.,* Document ID #0018, 0024, 0109, 0147, and 0171).

In the NPRM, OSHA proposed to maintain the requirement to include its mandatory permissible exposure limits

(PELs) on the SDSs, and to specify, as in the existing HCS, that manufacturers should include ''any other exposure limit used or recommended by the chemical manufacturer, importer, or employer preparing the safety data sheet.'' This would allow inclusion of any of the different types of occupational exposure limits commenters recommended for inclusion where the SDS preparer deems it appropriate. It also helps to minimize differences between the U.S. and other countries by not providing (except for PELs) a list of U.S.-specific occupational exposure limits that must be included, yet provides protection for employees by allowing inclusion of various recommendations that will help employers design appropriate protective measures. OSHA requested comment on this approach, and received many opinions from rulemaking participants.

First, many people agreed that the PEL should be on the SDS (although some acknowledged that they are out-of-date) (*See, e.g.,* Document ID #0328, 0330, 0332, 0336, 0338, 0339, 0340, 0341, 0344, 0349, 0351, 0352, 0354, 0357, 0359, 0375, 0379, 0382, 0399, 0412, and 0414). For example, the American Foundry Society (Document ID #0375) supported including the PEL, but thought other limits should only be included at the discretion of the SDS preparer:

> Our industry generally supports the requirement to include OSHA PELs, but not require the other recommended limits on SDSs. In particular, the American Conference of Industrial Hygienists (ACGIH)_TLVs, while able to provide useful information often lack credibility. As the result of a sometimes flawed development process, the TLVs can be misleading and their use can reduce clarity of communication. For certain materials, some manufacturers may choose to include TLVs on an SDS, or include other non-mandatory exposure values, including their own recommendations, but this should not be mandatory. The relevance of such other non-mandatory guidelines should be determined by the manufacturer who can best explain the meaning, context and limitations of such values.

Others specifically supported the approach proposed (*See, e.g.,* Document ID #0351, 0366, 0370, 0376, 0381, 0383, 0393, 0408, and 0411). Clariant Corporation (Document ID #0383) indicated they would support the proposed text, as well as a non-mandatory appendix listing other exposure limits:

> Clariant supports the recommendation to ''include other occupational exposure limits used or recommended''. Clariant would also support a non-mandatory appendix to the HCS to include reference to the TLVs and other occupational exposure limits such as the AIHA WEELs. Many companies already include other occupational exposure limits on their SDS. In most cases, those other limits are more up-to-date than the OSHA PELs.

The American Industrial Hygiene Association (AIHA) also suggested inclusion of a non-mandatory appendix listing other exposure limits such as the TLVs and WEELs (Document ID #0365).

Many commenters supported mandatory disclosure of applicable TLVs on the SDS in Section 8 (*See, e.g.,* Document ID #0313, 0315, 0317, 0319, 0323, 0327, 0328, 0330, 0332, 0336, 0340, 0347, 0349, 0353, 0354, 0357, 0359, 0401, 0403, 0410, 0412, 0413, 0414, 0463, and 0464). Others argued that inclusion of the TLVs would be inappropriate because such inclusion does not meet the Information (or Data) Quality Act, the development process is flawed, or they are non-governmental (*See, e.g.,* Document ID #0325, 0375, 0379, 0408, and 0409).

For example, the Center for Regulatory Effectiveness argued that OSHA's decision to require the disclosure of ACGIH TLVs on SDSs is inconsistent with the requirements of the Information Quality Act, Public Law 106–554, § 1(a)(3), Title V, § 515, 114 Stat. 2763 (2000). That act required OMB and DOL to issue guidelines ''ensuring and maximizing the quality, objectivity, utility, and integrity of information * * * disseminated by the agency.'' 44 U.S.C. 3516, note, at (b)(2)(A). Both OMB and DOL have issued such guidelines, and in addition OMB issued the ''Peer Review Bulletin,'' citing the authority of the Information Quality Act. OMB, *Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by Federal Agencies,* 67 FR 8452 (Feb. 22, 2002) (hereafter ''OMB Guidelines''); DOL, *Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by the Department of Labor* (Oct. 1, 2002), found at *http://www.dol.gov/cio/programs/infoguidelines/informationqualitytext.htm* (hereafter ''DOL Guidelines''); OMB, *Final Information Quality Bulletin for Peer Review,* 70 FR 2664 (Jan. 14, 2005) (hereafter ''Peer Review Bulletin''). Each of these guidelines specifies certain steps an agency should take when engaged in the ''dissemination'' of ''information.'' OSHA does not believe that it is disseminating ''information,'' as defined by these documents, in requiring disclosure of TLVs on SDSs.

All three documents except from the definition of information ''opinions, where the agency's presentation makes it clear that what is being offered is someone's opinion rather than fact or the agency's views.'' (OMB Guidelines V.5; DOL Guidelines at 5, 13–14; Peer Review Bulletin I.5.) OSHA understands this to mean that the guidelines do not apply unless the public could reasonably understand the information being disseminated as the official view of the agency. This understanding is supported by a number of statements by OMB and DOL. In the preamble to the Peer Review Bulletin, for example, OMB states that ''[a]n information product is not covered by the Bulletin unless it represents an official view of one or more departments or agencies of the federal government.'' 70 FR at 2667/2. Likewise, DOL's guidelines do not apply to information ''clearly represented as opinion and not an official agency or Departmental representation.'' DOL Guidelines at 3. Hyperlinks on an agency's Web site to information on non-governmental Web sites are not an agency dissemination of information, nor is a private researcher's publication and communication of the results of a government-funded study, where an appropriate disclaimer appears. OMB Guidelines V.5; 67 FR 8454/1; DOL Guidelines at 5, 13–14.

Users of hazardous chemicals could not reasonably think that ACGIH TLVs listed on an SDS are OSHA's dissemination of information as to the correct or feasible level of exposure to the chemical. As explained on the ACGIH Web site, TLVs are the ACGIH's statements of ''scientific opinion'' (Document ID #0529). The SDS is prepared by the manufacturer and represents the manufacturer's understanding of the hazards of the chemical, the appropriate conditions of use, and the necessary protective measures to be employed. It is hard to see, in that context, how a user of the SDS could understand that the TLVs listed on the SDS represent information disseminated by OSHA. The TLV will be identified as such on the SDS. Indeed, in the many cases where there is an applicable OSHA PEL, the PEL will also be listed in addition to the TLV.

Further, if TLVs are ''information'' for purposes of the IQA, then so too is everything in the SDS. If that were true, it would render the approach of the HCS unworkable because it would require OSHA to review and approve every manufacturer's label and SDS. OSHA does not believe Congress intended such a result in enacting the IQA.

The Center for Regulatory Effectiveness and the AFL–CIO's Building and Construction Trades Department suggested that OSHA could

require SDS preparers to add a statement to the SDS saying that the TLV does not represent OSHA's view of a safe level (Document ID #0325 and 0644). OSHA has decided against such an approach. First, as explained above, OSHA does not believe that a reasonable SDS user would understand the TLV to be OSHA's official representation. Second, such a disclaimer could cause confusion, creating the incorrect impression that the remainder of the information on the SDS does represent OSHA's official representation about the hazards of the chemical in question.

There are other reasons the IQA guidelines do not apply here. The OMB and DOL guidelines only apply to information ''first disseminated after October 1, 2002'' (OMB Guidelines III.4; DOL Guidelines at 2), and OSHA has required TLVs to be disclosed on MSDSs since 1983. Moreover, the guidelines are ''not intended to impose any binding requirements on DOL or the public or * * * to provide any right to judicial review'' (DOL Guidelines at 2). Rather, ''information quality [is] an important management objective.'' (*Id.*) Courts have accordingly rejected private attempts to force agency compliance with the data quality guidelines. *See, e.g., Salt Institute* v. *Leavitt,* 440 F.3d 156, 159 (4th Cir. 2006) (IQA ''does not create a legal right to access to information or to correctness''); *Single Stick, Inc.* v. *Johanns,* 601 F. Supp. 2d 307, 316 (D.D.C. 2009) (same), *aff'd in relevant part on other grounds sub nom Prime Time Int'l Co.* v. *Vilsack,* 599 F.3d 678, 686 (D.C. Cir. 2010). Likewise, the Peer Review Bulletin is ''intended to improve the internal management of the executive branch, and is not intended to, and does not, create any right or benefit, substantive or procedural'' enforceable against the federal government (Peer Review Bulletin XII). OSHA finds that the DOL and OMB Guidelines and the Peer Review Bulletin do not require the Agency to take the additional step of analysis before requiring the disclosure of TLVs on safety data sheets.

At least one commenter suggested that requiring disclosure of the TLV would violate the Administrative Procedure Act's notice and comment requirements, to the extent that the SDSs were required to disclose TLVs that the ACGIH might adopt after the final rule is published (Document ID #0361). That contention was rejected in *National Ass'n of Manufacturers* v. *OSHA,* 485 F.3d 1201, 1204 (D.C. Cir. 2007), where the court held that the hazard communication standard does not prescribe particular chemicals for which hazard communications are required, but rather a system by which manufacturers and the ACGIH evaluate and communicate chemical hazards. This system is not changed when the ACGIH modifies a TLV, and therefore no new notice and comment is required. *Id.* Nor is OSHA impermissibly delegating its authority to the ACGIH by requiring that TLVs be listed, as argued by the National Association of Home Builders (Document ID #0372). The Third Circuit rejected that argument in a challenge to the current standard, which also required that manufacturers and importers perform hazard determinations for all chemicals for which the ACGIH had published TLVs. *Associated Builders and Contractors* v. *Brock,* 862 F.2d 63, 68 (3d Cir. 1988). The final rule's requirement to list nonbinding TLVs is an *a fortiori* case.

Finally, a number of commenters expressed concerns about the procedures ACGIH uses in adopting TLVs (Document ID #0083, 0084, 0361, 0371, 0372, and 0529). Typical of these is the comment from the Independent Lubricant Manufacturers Association:

> TLVs are developed by way of ACGIH committees that operate in secret with *anonymous* authors. Though the opportunity to provide written comments exists, there is no ''appeal'' process to challenge, question or even engage in a professional discourse with the people responsible for developing and finalizing the TLVs. ILMA believes that because the TLV development process is closed, TLVs have compromised scientific value and limited utility in addressing occupational health and safety matters. Indeed, this non-consensus process can generate defective decisions that have the potential to compromise the health and safety of the very workers the TLVs are designed to help. In addition to issues of transparency and fairness, TLVs are developed without any regard to the economic and technical feasibility of its recommendations or the availability of acceptable methods to determine compliance.

(Document ID #0371 (emphasis in original)). Other commenters also objected to the fact that the ACGIH provides no public hearing, that the extent of review ACGIH committees devote to TLV recommendations before adopting them is unclear, and that TLVs are not ''consensus standards'' within the meaning of the OSH Act (Document ID #0372 and 0529).

As explained on its Web site, ACGIH TLVs ''represent conditions under which ACGIH believes that nearly all workers may be repeatedly exposed without adverse health effects. They are not fine lines between safe and dangerous exposures'' (Document ID #0529). TLVs are to be used by industrial hygienists in determining safe exposures in workplace, according to the ACGIH, but ''are only one of multiple factors to be considered in evaluating specific workplace situations and conditions.'' (*Id.*)

The record evidence shows that the ACGIH uses a reliable and open method to develop TLVs with ample opportunity for public input. ACGIH TLVs are set by the Threshold Limit Value Chemical Substances Committee (Document ID #0536). Members of this committee are chosen for their expertise in industrial hygiene, occupational medicine, epidemiology, toxicology, or related fields such as statistics or chemistry, and members are selected to maintain a balance between these specialties. (*Id.*) Membership preference is given, among other things, to those with 10 or more years experience and advanced degrees within their field. (*Id.*) A majority of committee members must be ''Regular'' ACGIH members, that is, those occupational hygiene, occupational health, environmental health, or safety professionals whose primary employment is with a government agency or an educational institution. (*Id.; See also http://www.acgih.org/Members/memdescrip.htm.*)

The ACGIH has a conflict of interest policy, requiring that members disclose, both orally and in writing, ''potential, real, or perceived conflict[s] of interest'' with respect to a substance under consideration (Document ID #0536). The Committee chair is required to conduct a conflict of interest presentation annually, and Sub-committee chairs will typically inquire at the beginning of meetings as to whether members' conflict status has changed. (*Id.*) Where conflicts arise, the steps to be taken—such as recusal, abstention, or disclosure—are decided based on the nature of the conflict involved. (*Id.*)

Once the relevant ACGIH sub-committee decides to consider a new TLV, it is included on an ''Under Study'' list that the ACGIH publishes each February 1. (*Id.*) Each July 31, that list is updated to indicate the substances for which the ACGIH anticipates issuing a ''Notice of Intended Change'' in the coming year. (*Id.*) An author is assigned to prepare a draft ''documentation'' supporting a proposed new TLV; the author or ACGIH staff must conduct a full literature search on the substance; and only published, peer-reviewed data may be relied upon in the documentation. (*Id.*) The ACGIH has detailed guidelines governing the content of documentations and the method of conducting literature searches. (*Id.*) Once the draft documentation is approved by a sub-

committee (by consensus) and the full TLV committee, ACGIH issues a public Notice of Intended Change and makes the draft documentation available to the public for at least a year to submit comments. (*Id.*)

The author and the sub-committee review the public comments received, and the draft documentation is amended if necessary. (*Id.*) Once the sub-committee reaches consensus, the draft documentation is forwarded to the full committee with a proposal to (1) retain the current TLV and publish the draft documentation for comment for an additional year; (2) change the TLV but publish the draft documentation for comment for an additional year; (3) adopt the proposed TLV and draft documentation; or (4) withdraw the proposal. (*Id.*) The proposal is then voted on by the full committee, and then the committee's recommendation is sent to the ACGIH board of directors for ''ratification.'' (*Id.*) Generally ACGIH does not hold meetings with interested parties during this process, but its rules allow for public discussion of the evidence on a chemical's hazard at ACGIH-sponsored symposia, and allows for meetings where new evidence has been developed and is ''essential to the Committee's deliberations.'' (*Id.*)

NIOSH, the Kentucky Labor Cabinet, the American Industrial Hygiene Association, the American Society of Safety Engineers, the Alliance of Hazardous Materials Professionals, and several occupational safety and health consulting firms support the TLV requirement, stating that ACGIH TLVs are useful in developing health and safety programs and are widely used in industry (Document ID #0313, 0323, 0327, 0336, 0354, 0365, 0410, 0412, 0496, and 0521). A number of manufacturers and manufacturer associations also support the TLV requirement (Document ID #0328, 0330, 0332, 0353, 0413, and 495). The International Chemical Safety Cards, prepared under the auspices of the UN, list TLVs (Document ID #0497). TLVs are currently required to be disclosed under the HCS, and witnesses testified that failure to include TLVs on SDSs in the final rule would render the standard less protective of worker health because TLVs are more up to date and cover more substances than OSHA's PELs (Document ID #494 Tr. 28–29, 94; Document ID #496 Tr. 368, 382).

Based on this record, OSHA finds that commenters' objections to TLVs are without merit. TLVs are set through an open process with ample opportunity for public input through the comment and symposium process; the fact that the ACGIH does not hold public hearings on proposed TLVs does not undermine the fairness of the process. While OSHA agrees that TLVs do not address feasibility concerns, it finds that TLVs are useful information for employers and employees to use in evaluating the hazards presented by chemicals used in their workplaces. OSHA finds that the record does not support the contention that TLVs have ''compromised scientific value'' because of the process used by the ACGIH. Each TLV is supported by a documentation explaining the evidence and assumptions on which it relies; these documentations are subjected to public comment and approved at several levels within the organization. It is certainly possible that a manufacturer or importer might disagree with the scientific judgments embodied in a TLV, but the final rule allows them to set forth their own recommendations about an appropriate exposure level on the SDS. Based on the ACGIH's procedures and the evidence of TLV use by industry, occupational safety and health professionals, and NIOSH, OSHA reaffirms its position that, in general, TLVs provide useful information that should be disclosed to employers and employees using hazardous chemicals.

Some commenters supported requiring other limits to be on the SDS in addition to the TLVs, such as the NIOSH Recommended Exposure Limits (RELs); the AIHA Workplace Environmental Exposure Limits (WEELs); and the German maximum allowable concentrations (MAKs) (*See, e.g.,* Document ID #0323, 0330, 0336, 0340, 0349, 0354, 0357, 0359, 0401, 0410, 0412, and 0414). NIOSH recommended broad inclusion of available occupational exposure limits (Document ID #0412):

> Providing occupational exposure limits (OELs) helps workers and employers understand the relationship between exposure concentration and adverse health effects. NIOSH supports the requirement of including PELs on the SDSs and further suggests that OSHA consider adding additional exposure limits, whenever available, such as NIOSH recommended exposure limits (RELs), American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Values (TLVs), American Industrial Hygiene Association (AIHA) Workplace Environmental Exposure Limits (WEELs), and German maximum allowable concentrations (MAKs) * * *.

There were a number of other comments on the issue of exposure limits in Section 8 of the SDSs, such as asking for an explanation of ''any other exposure limit used or recommended'' by the SDS preparer (Document ID #0329, 0351, 0382, 0381, and 0393), including whether this means exposure limits from other countries. There was also a suggestion to delete ''used or'' from the requirement (Document ID #0339). This language is in the current HCS, and is intended to include any exposure limits developed by the producer to protect their own employees, as well as other exposure limits commonly available such as the TLV or REL. It may also include exposure limits from other countries, but there is no intent to require that every known exposure limit in the world be provided. OSHA does not agree that it is appropriate to delete ''used or'' since companies often have exposure limits to protect their own employees, and this information can help their customers to determine what is needed to protect downstream employees as well. Others thought inclusion of exposure limits in addition to the PELs would confuse small businesses (Document ID #0372), or be detrimental to harmonization (Document ID #0464).

The AFL–CIO summarized their view of the record on this issue, as well as that of other worker representatives, in their post-hearing brief (Document ID #0645):

> We believe that OSHA needs to issue a final rule that restores the requirement to list the TLV on the SDS and strong record evidence supports our position. There is broad support for this position, covering a wide range of organizations including NIOSH (Ex. 0412.1) unions (AFL–CIO, Ex. 340.1; Building and Construction Trades Department, Ex. 0359.1; and the Steelworkers, Ex. 0403.2); safety and health professional associations (American Society of Safety Engineers, Ex. 0336.1); employers and their representatives (Dow Chemical Company, Ex. 03353.1); Patton Boggs, Ex. 0413.1); and individual experts (Adam Finkel, Ex. 0401.1; Harry Ettinger, Ex. 0319.1).

In Section 8 of the SDS in the final rule, OSHA has included the language used in the current rule to describe what exposure limits are to be addressed: ''OSHA permissible exposure limit (PEL), American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value (TLV), and any other exposure limit used or recommended by the chemical manufacturer, importer, or employer preparing the safety data sheet, where available.''

As noted in the NPRM, OSHA took the reference to TLVs out of Section 8 of the SDS in the interest of limiting country-specific deviations from the GHS. However, based on many comments in the record, OSHA has concluded that the TLVs provide useful information for those designing

protection programs for employees exposed to the chemicals involved, and are already widely used and applied for that purpose in American workplaces, as well as around the world. Referencing TLVs on the SDSs does not make them mandatory or establish them as control guidelines. It simply provides additional information that can help employers determine the proper levels of protections in their workplaces.

With regard to the recommendations for other exposure limits to be included on the SDS, OSHA agrees that referring to those exposure limits could also be useful, and would encourage SDS preparers to include them where available. However, the Agency is still concerned about including additional country-specific deviations, especially for limits that are less available than the TLVs. Providing too many different exposure limits may also be confusing to employers. Publication of a non-mandatory appendix would require OSHA to continually update it, as these different lists are prepared by various organizations. Since the Code of Federal Regulations is only updated annually, the Appendix would always be out-of-date. We do not believe this would be helpful in the long term, and that resources would be better put to other purposes than updating a non-mandatory appendix.

In the NPRM, OSHA did not propose to continue to require specific mention of IARC, NTP, and OSHA as sources of determinations regarding carcinogenicity. The requirement to consider these sources definitive in terms of a carcinogen determination was not included in the NPRM since it was not part of the GHS approach. However, as was discussed above, OSHA has modified Appendix F to allow classifiers to use these sources when assessing carcinogenicity, rather than applying the criteria to the data themselves. In order to facilitate this, OSHA has provided a table in Appendix F that aligns the GHS criteria with those of IARC and NTP. In addition, OSHA has decided to retain the requirement to include this information on the SDS in Section 11. This information will be of use to classifiers, as well as to employers and employees, when ascertaining potential hazards and determining appropriate control measures. This was supported by some commenters (*See, e.g.,* Document ID #0321, 0335, and 0403), while others argued that the determinations of such organizations should not be included because of issues with their process of making determinations (*See, e.g.,* Document ID #0379, 0417, and 0529). OSHA believes that this information from organizations that are recognized as expert in the field of carcinogenicity will continue to be helpful to both classifiers and users of chemicals, and does not agree with the commenters who argue about the process followed to make such determinations. The arguments were similar to those discussed above regarding inclusion of TLVs on SDSs, and OSHA's response to such arguments apply here as well. OSHA finds that both IARC and NTP use reliable procedures and criteria in making their determinations.

OSHA indicated in the NPRM that Sections 12 through 15 of the SDS were not going to be mandatory since they involved information that is outside OSHA's jurisdiction. With regard to Section 12 on environmental effects, some commenters expressed concern about the lack of harmonization with trading partners on environmental issues, or suggested that OSHA should work with EPA on this issue (*See, e.g.,* Document ID #0351 and 0377). OSHA and EPA have discussed this issue, and EPA's Office of Chemical Safety and Pollution Prevention will be updating applicable Toxic Substances Control Act (TSCA) regulations consistent with modifications made in this **Federal Register** Notice. Dates will be published in the Unified Regulatory Agenda (*www.reginfo.gov*). As noted previously, OSHA encourages SDS preparers to complete Section 12, as well as Sections 13 through 15, so as to have an SDS that is compatible with other international requirements, as well as ensuring customers have complete information.

Similarly, comment was received suggesting that Section 14 on transport information should be required, and producers should indicate whether the product is, or is not, covered by DOT's Hazardous Material Regulations (Document ID #0345). While OSHA does not have authority to require this to be included in Section 14, we certainly agree that it would be useful information for users of the chemical, and encourage producers to complete Section 14.

In the final rule, non-mandatory Section 15 of the SDS is intended to provide other regulatory information. OSHA raised as an issue for comment whether this section should be made mandatory by requiring regulatory information on OSHA's substance-specific standards be included in it. Employers can, of course, voluntarily list information about other OSHA standards (Document ID #0376), but voluntarily provided information is not subject to enforcement. Many of the respondents commented that Section 15 should not be made mandatory (*See, e.g.,* Document ID #0324, 0335, 0344, 0352, 0353, 0355, 0370, 0372, 0376, 0377, 0379, 0381, 0385, 0393, 0399, 0402, 0405, and 0408). Some questioned whether information about substance-specific standards would be useful to users of the SDS (*See, e.g.,* Document ID #0329, 0335, 0372, and 0405). Others thought that OSHA should require the substance-specific standards to be indicated, and that Section 15 should thus be mandatory (*See, e.g.,* Document ID #0328, 0330, 0336, 0338, 0339, 0340, 0347, 0349, 0351, 0354, 0357, 0365, 0383, 0389, 0403, 0410, 0414, and 0453).

While OSHA agrees that there is merit in including the substance-specific standards in Section 15 to inform chemical users of their existence and applicability, it is difficult to make completion of Section 15 mandatory since there is likely to be considerable other information in the section that would not be enforceable by OSHA. Having a section that includes both mandatory and non-mandatory information is potentially confusing to the regulated community. Additionally, the PELs will already be indicated in Section 8, and will thus inform the user when there is a substance-specific standard of concern. Therefore, while OSHA encourages additional information in Section 15, it remains non-mandatory in the final rule.

One suggestion received for Section 16 indicated that the preparer should identify the exact changes made to the SDS when revising it so the user can determine if re-training is needed (Document ID #0469). Presumably, the user would review the changes to decide whether re-training is needed. However, the success of such an approach would depend on how often the chemical is purchased, and a new SDS is received. If the chemical has not been purchased for a while, and a new SDS only indicates what changes have been made since the last update, the user could have missed versions of the SDS in the interim, and thus would not know all of the changes that had been made since the last SDS was received. In addition, adding such a requirement would make the OSHA provisions internationally inconsistent.

(h) Employee information and training. The GHS does not include harmonized training requirements, but does recognize the important role that training plays in hazard communication. For example, 1.1.3.1.3 of the GHS states:

> In the workplace, it is expected that all of the GHS elements will be adopted, including labels that have the harmonized core information under the GHS, and safety data

sheets. It is also anticipated that this will be supplemented by employee training to help ensure effective communication.

OSHA agrees that training is key to ensuring effective hazard communication. Under the current HCS, training is used to explain the label and SDS systems used in a workplace, and to address the hazards of chemicals and protective measures. While the written information provided is clearly important, training is an opportunity to explain the data and helps to ensure that the messages are being received accurately so they can be acted on appropriately. (*See* Section IV of this preamble.)

The training provisions in the HCS do not need to be modified to be consistent with the GHS since it does not include such requirements. However, OSHA proposed small revisions to track terminology used in other paragraphs, as well as to clarify the requirement to train on the details of the hazard communication program in (h)(3)(iv). While training on the program has always been required in the HCS, OSHA believed that modifying the text slightly would convey the need to address both the labels that will arrive on shipped containers, as well as any workplace-specific system that the employer uses. In addition, the training on SDSs must include the order of information. The final rule requires that training include the details of the hazard communication program developed by the employer, including an explanation of the labels received on shipped containers and the workplace labeling system used by their employer; the safety data sheets, including the order of information and how employees can obtain and use the appropriate hazard information.

OSHA proposed that employers train or re-train employees regarding the new labels and safety data sheets within two years after the rule is promulgated. The Agency believes that the training needs to be completed by the time employees begin to see labels and safety data sheets with the new information on them, rather than waiting until after the transition has been completed.

Some commenters to the ANPR noted that training would be required to ensure employees understand, in particular, the symbols and pictograms that will be used on labels. Some argued that the burden would be substantial given that all training would have to be revised, and the time and resources required would be significant (*See, e.g.,* Document ID #0153 and 0178). However, many agreed that having a standardized approach to labels and SDSs will make training easier in the future than training under the current rule where chemical manufacturers and importers can use whatever formats they choose (*See, e.g.,* Document ID #0030, 0042, 0072, and 0077).

Marshfield Clinic (Document ID #0028) noted that communication of information about chemicals and other hazardous substances:

> * * * is one of the more difficult to get across to workers. It is very appreciated that OSHA is revisiting this. Standardization will greatly assist in giving workers a better understanding of the hazards they may encounter when working with chemicals and other hazardous substances.

Similarly, Alcoa (Document ID #0042) suggested: ''A standardized format will simplify hazard communication training and the use of pictograms will alleviate some of the problems presented by poor language skills.''

There were a few commenters who argued that the standardized approach either would not simplify training, or they did not know if it would (*See, e.g.,* Document ID #0065 and 0078). Another noted that the current approach is fine for companies that are domestic only (Document ID #0026).

The majority of the comments made on the training provisions suggested additions to the existing requirements to further specify what is expected, and to improve the training. These comments were submitted primarily by worker representatives, or by the National Institute of Environmental Health Sciences (NIEHS) (*See, e.g.,* Document ID #0340, 0347, 0349, 0357, and 0403). For example, the Communication Workers of America (CWA) (Document ID #0349) suggested:

> * * * Given the significance of education and training, OSHA should develop a mandatory appendix to the Proposed Rule that sets forth the elements (including an evaluative component) of an acceptable education and training program.

As noted above, OSHA agrees with these commenters that effective training is a key part of hazard communication. While the GHS does not include such requirements, the developers also recognized the importance of including training in national programs, and encouraged countries to do that. In addition, the United Nations Institute for Training and Research (UNITAR), which is the international focal point for capacity building on the GHS, is developing training courses to be made available to developing countries, in particular to assist them in adopting the GHS.

As described, OSHA proposed a slight modification to ensure that employers are aware that they need to train specifically on the new label elements and SDS format. This modification is in the final rule, and the training on these aspects is to be completed prior to other provisions going into full effect. OSHA does not agree that other changes should be made to the training provisions of the HCS at this time. As also indicated in this document, the changes to the HCS being promulgated are focused on what is necessary to comply with the GHS. Since the GHS does not have any training requirements, the modification proposed and adopted by OSHA is what is necessary to ensure appropriate compliance with the revised standard, and does not introduce any new approaches or requirements.

OSHA is planning to provide additional guidance to help ensure appropriate training is conducted when complying with the revised HCS. A draft Model Training Program was posted for comment on OSHA's Web page some years ago. It includes many of the concepts addressed in the comments received, but was never finalized. While it was designed to provide an array of tools from which employers could choose what they needed based on their workplaces (lesson plans and slides), there were comments received at the time that it was too long for small employers. OSHA believes that the model program includes important information about conducting appropriate training (which was also the view of other commenters on the program). It is being revised and updated to be consistent with the revised rule, and will be made available on OSHA's Web page. A shorter guidance document for small employers is also being developed.

In addition to these training-specific tools, OSHA has other tools under development that could be used in training (*e.g.,* a quick card with the new symbols). These too will help to address some of the issues that have been raised.

Based on the above reasons, the final rule adopts the training provisions in the proposal. OSHA will address other comments provided through guidance and compliance assistance materials, rather than through further revisions to the rule.

OSHA has made minor changes to the training provisions to reflect the new definition of hazardous chemical in the final rule. In (h)(1), OSHA is replacing the phrase ''new physical or health hazard'' with the broader term ''chemical hazard.'' Final paragraph (h)(1) requires that employers provide employees with effective information and training on hazardous chemicals in their work area at the time of their initial assignment, and whenever a new chemical hazard the employees have not

previously been trained about is introduced into their work area. Information and training may be designed to cover categories of hazards (e.g., flammability, carcinogenicity) or specific chemicals. Chemical-specific information must always be available through labels and safety data sheets.

Similarly in paragraph (h)(3)(ii), OSHA is replacing the phrase ''The physical and health hazards'' with all of the hazards identified as well as the hazards not otherwise classified. Final paragraph (h)(3)(ii) requires that the training include the physical, health, simple asphyxiation, combustible dust, and pyrophoric gas hazards, as well as hazards not otherwise classified, of the chemicals in the work area. This change was necessary because the final rule covers simple asphyxiants, pyrophoric gas, combustible dust, and hazards not otherwise classified, in addition to what falls under the new definitions for physical and health hazards. The modification to paragraph (h)(3)(ii) requires employers to train employees on all of the chemical hazards in the workplace, rather than only physical and health hazards as defined in the final rule.

(i) Trade secrets. The current HCS includes provisions that define what can be considered trade secret information under the rule, as well as delineate the conditions under which this information must be disclosed to ensure the safety and health of exposed employees. These provisions were a significant focus of the original rulemaking on the HCS, and reflect the common law of the United States on this topic. In the years since the rule has been in effect, however, this issue has not been as important. Overall, since these provisions were promulgated, it appears that fewer claims of trade secrecy have been made, and fewer requests for trade secret disclosure have been received, than were anticipated during the original rulemaking process.

The negotiations for development of the GHS recognized at the outset that trade secrets—generally referred to internationally as confidential business information—would be an issue of concern. Guiding principles included the following (*See* 1.1.1.6(j) of the GHS):

> In relation to chemical hazard communication, the safety and health of workers, consumers and the public in general, as well as the protection of the environment, should be ensured while protecting confidential business information, as prescribed by the competent authorities.

As the issue was considered further, it was recognized that laws regarding confidential business information were very much country-specific, and had a broader context than rules for classification and labeling. Such laws could not be modified or harmonized through the process of harmonizing classification and labeling. Thus it was determined that the GHS would recognize the importance of trade secrets, and provide principles for countries to follow when adopting the GHS. These principles are consistent with the approach already incorporated into the HCS.

The type of information that can be considered confidential or trade secret is limited to the names of chemicals and their concentrations in mixtures. Under the current HCS, OSHA did not require that concentrations in mixtures be disclosed, and thus limited trade secret claims to specific chemical identities. This was the primary difference between the current rule and the proposed revisions to the HCS. To be consistent with GHS, OSHA proposed to add percentage composition information to the SDS. This introduces the possibility that trade secret claims will be made for this type of information, as well as specific chemical identities. Thus the proposal revised the text of the current rule to add consideration of percentage composition everywhere specific chemical identity is addressed in the provisions.

The GHS further suggests that SDSs indicate when information has been withheld as confidential; that the information be disclosed to the competent authority upon request and under condition of confidentiality; that the information must be disclosed in a medical emergency, with mechanisms to protect it while ensuring timely disclosure; that the information be disclosed in non-emergency situations, also under conditions of protecting confidentiality; and that the competent authority have procedures to deal with challenges to this process. All of these principles have already been included in the trade secret provisions of the HCS, and are maintained in the final rule as previously promulgated. The proposed revisions simply conformed terminology, and added text regarding percentage composition being subject to the same provisions as specific chemical identity.

Very few comments on trade secrets or confidential business information were received in response to the ANPR. It was suggested that protection of confidential business information should be an implementation principle for the GHS modifications to HCS (Document ID #0072 and 0179), and that the current trade secret position should be retained (Document ID #0049). There was also a comment that indicated that full disclosure of all ingredients should be required on the SDS unless the employer provides a justification to the Agency showing that a particular ingredient is a trade secret, and demonstrating that the economic damage of disclosure exceeds the damage associated with the potential health effects to exposed employees (Document ID #0044). In addition, the National Paints and Coatings Association (NPCA) argued that the approaches to protection of confidential business information need to be harmonized (Document ID #0050). As NPCA stated, different approaches may lead to development of different SDSs for various authorities.

As noted above, laws regarding confidential business information are generally not specific to classification and labeling requirements, but rather reflect an overall approach of a country. It was not possible to change such laws through the harmonization of classification and labeling, and thus the limit of the agreement was to establish the principles already described. Those principles are consistent with law in the United States, and do not require any modifications to the current HCS approach to be consistent with the GHS.

There were a few comments on the trade secret provisions proposed. Some expressed their support for maintaining the current approach, with the small revisions to conform to the GHS (Document ID #0353, 0367, and 0371). Several indicated that the trade secret provisions should be extended to labels because the name of unclassified hazards was proposed to be included on labels, and when there is an ingredient of unknown toxicity, this must be indicated as well. For example, the American Petroleum Institute (Document ID #0376) indicated:

> Under certain conditions both the SDS and label can require text such as: *x percent of the mixture consists of ingredient(s) of unknown toxicity.* This statement may apply to an ingredient of a mixture whose percentage of composition is a trade secret. In such a case the trade secret provisions only apply when this statement is on the SDS. The current trade secret provisions do not apply to labels. Since the percentage composition of an ingredient can be required on labels as well as SDSs, the trade secret provisions should also apply to labels. (Footnote omitted; *See also* Document ID #0344, 0381, 0382, and 0393.)

With regard to the inclusion of the name of unclassified hazards on a label, this requirement has been deleted from the final rule. Therefore, listing unclassified hazards on the label no longer raises a trade secret concern. It should be noted that there was never a

requirement proposed for the ''specific chemical identity'' to be on the label for unclassified hazards, so even if the provision had been included in the final rule, it still would not have been analogous to the specific chemical identity required on an SDS.

With regard to the statement regarding unknown toxicity, OSHA does not find that this statement merits a change to allow the trade secret provisions to apply to labels. It is noted in paragraph A.1.3.6.2.3 that, where there is one or more ingredient of unknown toxicity in a mixture of other ingredients known to be acutely toxic, the calculation for predicting the acute toxicity cannot be completely accurate. Therefore, as suggested in the GHS, OSHA has indicated that a statement must be on the label and SDS indicating that a percentage of the mixture has unknown acute toxicity. There is no requirement to relate that general statement to specific ingredients, and specific chemical identities are not required on the label. Therefore, no trade secret information is required to be disclosed, and protection of the information under the trade secret provisions is not necessary.

There were also comments that OSHA should allow for flexibility in terms for indicating information is being withheld as a trade secret, such as ''confidential,'' ''confidential business information,'' or ''proprietary'' (Document ID #0376 and 0393). OSHA has never indicated specific terminology for claiming that information is subject to the trade secret provisions of the HCS, and would accept language such as ''confidential,'' ''confidential business information,'' or ''proprietary'' when indicating on an SDS that information is being withheld. This has never been an issue in OSHA enforcement of the HCS.

As implementation moves forward in different countries and regions, conformance to the GHS principles should lead to increased harmonization of approaches. This is an area that should be monitored to determine if further action can be defined and implemented. OSHA does not believe it would be prudent to implement changes in the approach to trade secret protection and disclosure before that time. Therefore, the final maintains the proposed language for the trade secret provisions.

(j) Effective dates. OSHA proposed to require training on the new labels and SDSs two years after publication, and all other provisions within three years. During the three-year transition period, employers would be required to be in compliance with either the existing HCS or the modified GHS, or both. OSHA recognized that hazard communication programs will go through a period of time where labels and safety data sheets under both standards will be present in the workplace. It was indicated that this would be considered acceptable, and employers would not be required to maintain two sets of labels or safety data sheets for compliance purposes. However, given the longstanding requirements for a hazard communication program, there must be no time during the transition period when hazard communication is not in effect in the workplace, and information is not available under either the existing requirements or the new final standard for exposed employees.

It should be noted that due to requirements of the **Federal Register**, a revision date of October 1, 2009, was entered into the proposed language to indicate the version to be used as the existing HCS standard. This confused some commenters (*See, e.g.,* Document ID #0376). There were no actual revisions introduced as of that date, and it is irrelevant to this final rule.

Many comments were received in response to the ANPR on the issue of phasing in the requirements of the GHS, as well as on current practices and time frames required for various activities. There was a wide variety of opinions, as well as a number of factors that commenters suggested should be considered in establishing effective dates.

OSHA specifically requested input on the possibility of phasing in requirements based on the size of the business. While a few commenters supported this approach (*See, e.g.,* Document ID #0022, 0144, 0146, and 0151), many more indicated that this would not be appropriate (*See, e.g.,* Document ID #0018, 0033, 0107, 0116, 0123, 0147, 0154, and 0171). One reason given was that the supply chain may involve large businesses purchasing from small businesses, and thus the large businesses would need information from the small businesses in order to comply themselves (Document ID #0080 and 0123).

There were also those who thought the phasing should be coordinated with other trading partners, particularly the European Union (Document ID #0024, 0072, 0080, 0081, 0163, 0171, and 0179). The European phasing is taking place over a long period of time because of the REACH requirements for chemicals that are going into effect and not necessarily because of the amount of time needed just for compliance with GHS. Another suggestion that had support from commenters was to phase in substances first, and then cover mixtures, or to have a three-step phase-in that includes intermediates before mixtures (*See, e.g.,* Document ID #0021, 0024, 0034, 0036, 0122, 0141, and 0154).

There were also suggestions for a specific number of years, or a range of years, for phase-in. Some of these suggested less than 3 years (*See, e.g.,* Document ID #0019, 0028, and 0064). A number suggested 3 to 5 years, or in some cases, 6 years (*See, e.g.,* Document ID #0015, 0032, 0038, 0111, 0125, and 0163). And there were some commenters who suggested anywhere from 7 to 13 years for full compliance (*See, e.g.,* Document ID #0018, 0050, 0077, 0078, 0116, 0129, 0141, and 0164).

OSHA decided on the three-year proposal based on a consideration of the widely diverse viewpoints expressed, as well as information provided by commenters about stockpiles and other issues. It is clear that activities have already begun by a number of vendors of software programs for hazard classification and labeling to convert to the GHS, and make programs available for companies to use to comply with requirements around the world as countries adopt the GHS.

Stakeholders provided many comments, as well as testimony, on the proposed effective dates. As with the record submitted in response to the ANPR described above, the opinions ranged over a wide variety of effective date options.

As noted, OSHA proposed that employers provide training regarding the new labels and safety data sheets two years after publication of the final rule. The intent of this training is to ensure that when employees begin to see such labels and SDSs in their workplaces, they understand how to use them and access the information effectively. Given the number of chemicals imported into American workplaces, as well as the number of employers who are already beginning to change over to the new formats, OSHA believes it is important to have this introductory training done before all of the labels and SDSs will be changed. It is not possible to pick a time frame that would ensure that such training is done before employees see any of these documents, but two years is a reasonable period of time and helps to ensure that employees will be trained before the new formats become the standard practice.

This training is not required to address the specific hazards of the chemicals, or the protective measures. Employees will have already been trained on hazards and protective

measures under the existing hazard communication requirements, but they will not have had training on the new label elements (*e.g.,* pictograms and signal words) and SDS format, nor have learned how this information is to be used in their workplaces. Completion of such training in two years will help to ensure they can use the new documents effectively when they begin to arrive in their workplaces.

Some commenters thought two years would not be enough time, or who appeared to misunderstand what training was to be done by this date (*See, e.g.,* Document ID #0330, 0344, 0351, 0361, 0390, 0397, and 0399). For example, the American Society of Safety Engineers and Industrial Health and Safety consultants indicated that the training should be completed within one year of the final rule (Document ID #0336 and 0410). But the majority of those who commented agreed that two years was an appropriate time period in which to complete the training on the new label and SDS formats (*See, e.g.,* Document ID #0324, 0329, 0335, 0338, 0346, 0370, and 0405).

The three-year time frame for compliance with all other requirements generated significant comment. Many commenters supported this time frame as being appropriate and feasible (*See, e.g.,* Document ID #0313, 0322, 0324, 0327, 0329, 0335, 0339, 0376, 0390, 0395, and 0405). Others indicated that three years would not be adequate (*See, e.g.,* Document ID #0342, 0371, 0399, and 0402). There were also comments that suggested additional time should be provided to distributors to ensure they have the information from suppliers to provide it downstream. For example, the National Association of Chemical Distributors (Document ID #0341) stated:

> OSHA should consider an additional 18-month phase in period for chemical distributors after the 3-year implementation date expires. This would allow for a more effective GHS while reducing any potential negative economic impact on small chemical distributors. NACD members have expressed concern that a three-year transition time for the entire value chain (suppliers, distributors, customers) presents the possibility of a bottleneck in the supply of chemicals * * *

Many commenters indicated that the time frame should be longer and tiered, with either substances first, and then mixtures, or a three-tiered system with substances, intermediate mixtures, and complex mixtures. The latter approach has been used by the EU. (*See, e.g.,* Document ID #0328, 0341, 0352, 0363, 0367, 0392, 0393, and 0400.) For example, comments on behalf of the Soap and Detergent Association and the Consumer Specialty Products Association indicated (Document ID #0344):

> Therefore, SDA and CPSA support either a sequenced approach of substance suppliers first and formulators last, or a longer overall timeframe in order to minimize the impact of undertaking this significant effort to reclassify substances and mixtures, develop revised labeling, while allowing time to deplete inventories of labels and products with a current label. Any consideration of business size for a phase-in approach would be unacceptable as businesses large and small use each other's products in their end-use products; each one may rely on the upstream supplier for information in hazard classification.

While the Agency wants to provide sufficient time for compliance, there is also a concern about the effect on employees of dealing with multiple systems during a transition period. While some time period when the currently required labels and SDSs, and the new GHS labels and SDSs, will co-exist in workplaces is inevitable, hazard communication during this transition period will be confusing and less effective. It is therefore important to minimize the effects of the transition on the effectiveness of hazard communication by ensuring that it is completed in a timely fashion, while allowing adequate time for an orderly changeover.

Requiring the phasing in of substances first, and then mixtures, clearly has some persuasive logic as an approach. However, the supply chain is not always orderly and logical. It cannot be assumed, for example, that no mixtures can be completed until all substances are done. Mixtures that are comprised of substances that are widely available, and their hazards are well known, do not need an extensive time period to complete. Some mixtures are comprised of other mixtures rather than substances, and producers of such mixtures will need information on the component mixtures before they can comply. If manufacturers of mixtures wait until the end of an extensive time period to complete their work, their customers might not meet the compliance dates. These types of issues are generally addressed by the market, and the needs of a manufacturer's customers, and cannot be individually addressed in a phasing-in period.

OSHA is also mindful of the fact that the initial HCS had a two-year phase-in period for completion and distribution of all labels and SDSs, and an additional six months for all other provisions of the rule to be completed. There was no tiered approach to substances and mixtures. In that situation, the requirements for labels and safety data sheets were completely new, and yet timely compliance was achieved by most employers. Where there were situations that needed special consideration (such as an employer not receiving the required information from suppliers), the Agency made adjustments through enforcement policies. It should also be noted that this took place nearly thirty years ago, and pre-dated many of the resources available today that can facilitate compliance—such as access to extensive information online.

As was the case in the comments to the ANPR, a number of NPRM participants referenced the timeline for compliance with European CLP requirements (*See, e.g.,* Document ID #0328, 0361, 0367, 0377, and 0392). When discussing this issue in the NPRM, OSHA noted that the dates selected for CLP compliance were influenced significantly by compliance dates for REACH, rather than providing an indication of how long compliance should take in the absence of such competing responsibilities (74 FR 50403, Sept. 30, 2009).

That being said, however, nearly two years have elapsed since the NPRM was published, and the EU requirements for notifications regarding classification of substances are now in effect. In January 2011, the European Chemicals Agency (ECHA) indicated that it had received over three million such classifications (*See* discussion earlier in the Summary and Explanation). These substance classifications are being made available in a public database. The availability of this information clearly facilitates compliance with this revised HCS. While chemical manufacturers and importers must review the information if they are using classifications performed by someone else, many of the classifications were being submitted by U.S. companies, and thus they are already substantially in compliance with the new U.S. requirements as well.

Taking into consideration all of the information received from the public during the comment periods and in hearing testimony, as well as the results of the economic analysis which examines the effects of different compliance dates on the overall costs of compliance, the following effective dates have been included in the final rule. Rather than specifying a time frame related to the publication date of the final rule, OSHA is establishing dates certain for these activities to be completed. The following table summarizes the requirements in the final rule:

TABLE XIII–3—EFFECTIVE DATES AND REQUIREMENTS

Effective completion date	Requirement(s)	Who
December 1, 2013	Train employees on the new label elements and SDS format.	Employers.
June 1, 2015	Compliance with all modified provisions of this final rule, except:	Chemical manufacturers, importers, distributors and employers.
December 1, 2015	The Distributor shall not ship containers labeled by the chemical manufacturer or importer unless it is a GHS label.	
June 1, 2016	Update alternative workplace labeling and hazard communication program as necessary, and provide additional employee training for newly identified physical or health hazards.	Employers.
Transition Period 5/25/12 to the effective completion dates noted above.	May comply with either 29 CFR 1910.1200 (this final standard), or the current standard, or both.	Chemical manufacturers, importers, distributors, and employers.

First, final paragraph (j)(1) requires training regarding the new label and SDS formats to be completed by all covered employers by December 1, 2013. OSHA has concluded that it is necessary and appropriate to complete this training prior to all of the new labels and SDSs being completed and received in workplaces so that employees know how to access and use the information appropriately. Most of those who commented on this issue agreed with that position, and with the timing proposed. Those who didn't may have misunderstood exactly what training is being required, but we have clarified that in this document.

Secondly, OSHA has not found the arguments regarding phasing in based on whether the product is a substance or a mixture to be convincing. There are many variations in the supply chain that impact the logic of this approach. In addition, given the current situation where substance classifications for the GHS have already had to be completed for both the EU countries, as well as other countries such as Japan, many suppliers involved in international trade have already had to complete substance evaluations. For those who have not, there is extensive information available as a result of these classifications having been done for the purpose of compliance with other authorities' requirements. Thus little time should be necessary to complete this part of the work.

Final paragraph (j)(2) requires compliance with all of the provisions for preparation of new labels and safety data sheets by June 1, 2015. This compliance date is consistent with the EU requirements for classification of mixtures. It also provides almost a year more time for compliance than was proposed. Thus it addresses a number of the suggestions received, but is still a reasonable time frame in terms of employee protections. There are two exceptions to this date. First, final paragraph (j)(2)(i) gives distributors an additional six months to distribute containers received from chemical manufacturers and importers with the new labels and SDSs in order to accommodate those they receive very close to the compliance date. Accordingly, by December 1, 2015, all their distributed containers must be appropriately labeled, and have the new SDS. Second, final paragraph (j)(2)(ii) gives employers until June 1, 2016, to make sure that their workplace labels and training programs reflect any new information received as a result of the final rule.

As was proposed, final paragraph (j)(3) states that employers will be considered to be in compliance with the HCS during the transition period as long as they are complying with either the existing HCS as of October 1, 2011, or this revised HCS.

Employers are encouraged to work with their suppliers to ensure they get the information they need by the dates they need it. While the final rule gives distributors and employers extra time to ensure they have the information before they have to be in compliance with all requirements, coordination will still be key to ensure everything is done on time. For example, mixture formulators need to make sure their suppliers are aware of their need to receive substance classifications as soon as possible. Employers would be best served to start evaluating their workplaces long before the year after suppliers must be in compliance to assess what they will need to do to bring their programs in line with the new requirements. As with the original rule, OSHA will handle individual problems through enforcement policies that recognize difficult issues or situations that impede compliance. Nevertheless, given the long time frame involved, and recognition of different players in the supply chain of the needs of others, OSHA expects that these situations will be minimal.

Summary and Explanation of Requirements in OSHA Standards Affected by the GHS Modifications to HCS

General Explanation

In this final standard, OSHA has modified its current standards in General Industry (29 CFR Part 1910), Construction (29 CFR Part 1926), and Maritime (Shipyards, Marine Terminals, and Longshoring (29 CFR Parts 1915, 1917, and 1918, respectively)) that contain hazard classification and communication provisions so that they will be internally consistent and aligned with the GHS modifications to the HCS. OSHA proposed to do so on the basis of the strong support in the record of comments on the ANPR. The majority of commenters who addressed the impact of the GHS on other OSHA standards recommended the Agency review all its standards and update them for consistency with GHS (71 FR 53617, Sept. 12, 2006) (Document ID #0031, 0038, 0046, 0050, 0054, 0072, 0077, 0107, 0116, 0145, 0147, 0154, 0155, 0163, 0165, 0171, and 0179). OSHA did so, and this rule contains the updates to the requirements in OSHA standards affected by the GHS modifications to HCS. Commenters also urged OSHA to complete these revisions in one rulemaking (Document ID #0079, 0123, 0137, 0154, and 0157). The comments on the proposed standard and testimony at the hearing also strongly supported modifying these standards for consistency with the GHS (Document ID #0313, 0327, 0328, 0329, 0336, 0338, 0352, 0359, 0365, 0370, 0372, 0405, 0408, 0410, 0412, and 494 Tr. 91, 162). Of the commenters who specifically addressed adopting GHS provisions on physical hazards, many urged the

Agency to conform the OSHA standards to the GHS in order to minimize discrepancies and ensure consistency (Document ID #0012, 0018, 0050, 0072, 0104, 0105, 0139, 0140, and 0144). One commenter, 3M, noted that adoption of the GHS physical hazard criteria (without changing OSHA standards) would ''create unacceptable inconsistencies between OSHA standards'' (Document ID #0128).

Several other commenters to the ANPR pointed out some of the difficulties with adoption of the GHS physical hazards criteria in OSHA standards (Document ID #0031, 0034, 0038, 0077, 0145, and 0166). BASF was concerned that modifying OSHA standards to conform to the GHS will cause them to deviate from the national consensus standards they were based on (Document ID #077). In addition, some ANPR commenters recommended that OSHA limit changes only to standards that directly refer to the HCS (Document ID #0047, 0064, 0077, 0104, and 0115). OSHA acknowledged these concerns when developing the NPRM.

OSHA's NPRM reflected the advantages of harmonizing OSHA's standards, but also took into account the places where harmonization might be too difficult at this time because it would substantially change the scope of coverage of a current standard or make OSHA's standards incompatible with other widely accepted standards (74 FR 50280, Sept. 30, 2009). OSHA proposed modifying requirements in primarily the substance-specific health standards and in physical hazards definitions and terminology for the purposes of internal consistency and compatibility with the GHS-modified Hazard Communication Standard (HCS).

Building and Trades Construction Department of AFL–CIO (BTCD) and Northrup Grumman Shipbuilding, in response to the NPRM, requested that OSHA again review the standards, and the Agency has done so (Document ID #0359 and 0395). OSHA reviewed all its standards, the comments, and the entire record and has decided to maintain the modifications to the substance-specific standards as proposed, except for some minor changes that are explained below.

Substance-Specific Health Standards

In the NPRM, OSHA updated the substance-specific health standards in General Industry, Construction, and Maritime, whether they specifically referenced HCS or contained their own hazard communication requirements. OSHA proposed to modify these standards as follows:

- Revise the provisions covering workplace signs to require warning statements that are consistent with the GHS modifications to HCS;
- Revise all standards to reference the modified HCS for labels, safety data sheets, and training, and identify the hazards that need to be addressed;
- Maintain the requirement to avoid creating dust currently in some substance-specific health standards for which GHS modifications contain no equivalent statements at this time;
- Maintain or specify language for contaminated clothing and debris;
- Update definitions in § 1910.1450, Occupational Exposure to Hazardous Chemicals in Laboratories, to maintain compatibility with the modified HCS; and
- Change the name Material Safety Data Sheets to Safety Data Sheets and require information on them to be compliant with GHS in content, format, and order.

Workplace Warning Language on Signs and Labels

OSHA proposed to update the language for workplace signs and labels to incorporate the GHS hazard statement and the applicable precautionary statement(s), where required. Most OSHA substance-specific heath standards require hazard warning signs, usually for regulated areas, and the language required on the signs varies greatly (*e.g.,* Asbestos, 4-Nitrobiphenyl, 13 Carcinogens, Vinyl Chloride, Inorganic Arsenic, Cadmium, Benzene, Coke Oven Emissions, Cotton Dust, DBCP, Acrylonitrile, Formaldehyde, Methylenedianiline, 1,3-Butadiene, Methylene Chloride, and Lead). With the GHS revision, these standards retain the requirements for specific warning language for specific signs; however, OSHA proposed to modify the language to be compatible with GHS and consistent throughout the OSHA standards. Labels for products, mixtures, and raw materials are included in the GHS-modified HCS and are required to be compliant with it. Labels required by the current standards for contaminated clothing, PPE, and waste and debris, which are not addressed in the GHS, are retained, but their language has been changed to be as reflective of GHS terminology as possible.

The vast majority of persons and entities who commented on the issue in response to the NPRM supported OSHA's harmonization of the signage and labeling currently required in its substance-specific standards with the modifications to HCS (Document ID #0313, 0315, 0327, 0328, 0329, 0330, 0336, 0338, 0344, 0365, 0370, 0372, 0376, 0381, 0382, 0383, 0405, 0408, and 0410). NIOSH pointed out that the consistent language on signs, labels, and SDSs would avoid confusion and allow for easy translation into other languages (Document ID #0414). AIHA, in supporting the modification of language for signs and labels, noted that the action was consistent with GHS and the goal of harmonization. They envisioned clearer warnings, improved comprehension, and better self-protection by workers (Document ID #0365). Companies such as Ecolab, Product Safety Solutions, DuPont Company, Phylmar Group, Stericycle, Procter & Gamble, Clariant Corporation, 3M, Industrial Health and Safety Consultants, and Wacker Chemical specifically addressed the issue of affected standards and stressed that aligning the standards with GHS would bring needed consistency and aid employee understanding (Document ID #0313, 0329, 0335, 0338, 0339, 0351, 0381, 0383, 0405, and 0410). Lawrence R. Klein of DuPont (Document ID #0329) commented that:

> * * * hazard communication regardless of whether * * * general chemicals or substance specific chemicals regulated under other OSHA standards, will prove to be beneficial for industry. Through adequate training * * * and consistent, easily comprehensible hazard and precautionary statements, via workplace signs or chemical labels, the safety and protection of employees will be enhanced.

Ameren added that the language proposed for the substance-specific standards accurately conveyed the hazards (Document ID #0330). Associations that addressed this issue also provided strong support. ORC, ASSE, NAHB, API, Alliance of Hazardous Materials Professionals, National Paint and Coatings Association, Soap and Detergent Association, ACC, and AISI agreed with OSHA that modifying the standards will provide consistency and aid in employee understanding (Document ID #0327, 0328, 0336, 0344, 0370, 0376, 0393, and 0408). Many commenters followed up with testimony at the informal public hearings. NIOSH testified that there would be better identification of what was a hazard and the nature of the hazard (Document ID #0494 Tr. 50). BCTD AFL–CIO testified that the specific format and vocabulary for labels would facilitate hazard communication across a range of English literacy, as one in four construction workers speaks a language other than English, and two in three entering workers speak Spanish. They said that the signs, symbols, and phrases will make it easier for employees to work safely with hazardous products

(Document ID #0497 Tr. 7, 16, 33–34, 62, 66). ORC Worldwide testified their companies have significant global operations and so support concurrent harmonization of hazardous communication components (Document ID #0497 Tr. 88, 91, 99). SIRC generally supported the principles of the GHS update (Document ID #0494 Tr. 118). ASSE agreed that it is important for consistency to have the same language on the label, SDS, and regulated area sign (Document ID #0496 Tr. p. 362). In speaking about all labeling requirements, USSW (Document ID #0499 Tr. 136–37) testified:

> It's imperative that the information on the labels is consistent from product to product. Incorporating the GHS labeling system with pictograms and single-word hazard statements will assist workers to quickly recognize hazards.

AIHA summed up the support from commenters and testifiers by declaring that the GHS modifications will improve quality and consistency of hazard communication information (Document ID #0496 Tr. 415).

Several commenters to the NPRM, while supporting the modifications, raised potential problems with warnings for substance-specific health standards' labels and regulated area signs. Northrop Grumman agreed with the wording of the regulated area signs and that it would enhance employee information, although there was concern that this was a change in OSHA's policy of allowing supplemental language on labels and signs that would enhance the information (Document ID #0395). OSHA has not changed its policy on regulated area signs with this rulemaking and will continue to allow supplemental language on labels and signs. ASSE suggested that, under the proposal, the term ''Cancer Agent'' would be retained in the thirteen identified carcinogens standard, though the ASSE did not believe the problems caused by this inconsistency would be significant (Document ID #0336). OSHA notes that all cancer warnings, including ''Cancer Agent'' and ''Cancer Suspect Agent,'' have been changed to ''May Cause Cancer,'' so there is no inconsistency. NAHB addressed the issue of the cancer warning in a comment to the ANPR, positing that the different signal words (''Danger'' versus ''Warning'') and different hazard statements (''May Cause Cancer'' versus ''Suspected of Causing Cancer'') may create confusion (Document ID #0065). Like other commenters, NIEHS supported consistency, but thought ''May Cause Cancer'' may not be strong enough, and recommended ''Causes Cancer'' be retained. The International Chemical Workers Union Council agreed that ''May Cause Cancer'' was not strong enough; they preferred ''Causes Cancer'' because it was a more definite statement about the health hazard. They were concerned that some workers might not see the warning as a clear indication of the material causing cancer and act accordingly (Document ID #0456). Dr. Michelle Sullivan also supported consistency among SDSs, labels, and in-plant warning signs, but cautioned that training would be needed especially on ''May Cause Cancer'' (Document ID #0382). OSHA agrees that training will be needed and that appropriately trained workers who see the phrase ''May Cause Cancer'' will be well warned and benefit from the use of a consistent hazard statement for all carcinogens.

The current substance-specific health standards that are regulated as carcinogens have varying hazard statements on signs and labels, as, for example, from ''Cancer Hazard'' for inorganic arsenic (29 CFR 1910.1018) to ''Cancer-Suspect Agent'' for vinyl chloride (29 CFR 1910.1017) to ''May Cause Cancer'' for methylenedianiline (MDA) (29 CFR 1910.1050). As stated in the preamble to the proposed standard, these warnings appeared to suggest gradations of cancer hazards, but they were not intended that way. The standards were promulgated over many years, and the differences in the warning language reflect the language widely used for each cancer warning at the time of promulgation, not the degree of hazard (74 FR 50405, Sept. 30, 2009). This inconsistency has long been a problem, especially in workplaces where two or more OSHA-regulated carcinogens are used. The final rule's revision to the substance-specific health standards will solve the problem of different warning statements by standardizing the carcinogen warning language to ''May Cause Cancer'' for each standard. This will lead to clearer and more timely recognition of the hazard and, with training, better understanding of the potential for developing cancer.

OSHA understands the points made by commenters who argued for another warning for cancer that might appear stronger, but any other warning would not be consistent with GHS and thus workers would not benefit from the global consistency of a single hazard statement for carcinogenicity. Moreover, OSHA believes that, with training, workers will understand the seriousness of the warning and benefit from seeing only one warning on carcinogens in the workplace. OSHA has concluded that the signal words and hazard statements, including ''May Cause Cancer,'' in its substance-specific health standards will provide better hazard information to employers, and has carried through the changes proposed in the NPRM to the final rule.

See Table XIII–4 for a comparison of the signs' final language to that currently required.

BILLING CODE 4510–26–P

Table XIII-4. Regulated Area Signs in Substance-Specific Health Standards

Standard	Substance	Original signs	Final Changes
1910.1001 1915.1001	Asbestos Regulated areas Where the use of respirators and protected clothing is required	DANGER ASBESTOS CANCER AND LUNG DISEASE HAZARD AUTHORIZED PERSONNEL ONLY RESPIRATORS AND PROTECTIVE CLOTHING ARE REQUIRED IN THIS AREA	DANGER ASBESTOS MAY CAUSE CANCER CAUSES DAMAGE TO LUNGS AUTHORIZED PERSONNEL ONLY WEAR RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING IN THIS AREA
1910.1003	4-Nitrobiphenyl: Regulated areas Regulated areas covered by paragraph (C) (5)	CANCER-SUSPECT AGENT AUTHORIZED PERSONNEL ONLY CANCER-SUSPECT AGENT EXPOSED IN THIS AREA IMPERVIOUS SUIT INCLUDING GLOVES, BOOTS, AND AIR-SUPPLIED HOOD REQUIRED AT ALL TIMES AUTHORIZED PERSONNEL ONLY	DANGER (CHEMICAL IDENTIFICATION*) MAY CAUSE CANCER AUTHORIZED PERSONNEL ONLY DANGER (CHEMICAL IDENTIFICATION) MAY CAUSE CANCER WEAR AIR-SUPPLIED HOODS, IMPERVIOUS SUITS, AND PROTECTIVE EQUIPMENT IN THIS AREA AUTHORIZED PERSONNEL ONLY *(Use this template for all 13 carcinogens)
1910.1004	alpha-Naphthylamine:		See 1910.1003
1910.1005	Methyl chloromethyl ether:		See 1910.1003
1910.1006	3,3'-Dichlorobenzidine (and its salts):		See 1910.1003

BILLING CODE 4510–26–C

OSHA's proposal to change the signage requirements in the substance-specific standards was nearly universally supported by commenters. Product Safety Solutions, AHMP, National Paint and Coatings Association, Ameren, Wacker Chemical Corp, ASSE, Stericycle, Phylmar Regulatory Roundtable, Soap and Detergent Association/Consumer Specialty Products Association, Ecolab, Inc., AIHA, ORC Worldwide, National Association of Homebuilders, API, Procter & Gamble Company, Dr. Michelle Sullivan, Clariant Corporation, American Chemical Council, 3M, AISI (American Coke and Coal Chemicals Institute), Industrial Health and Safety Consultants, and NIOSH, in their comments to the NPRM, specifically supported the harmonization of signage required in the substance-specific standards (Document ID #0313, 0327, 0328, 0330, 0335, 0336, 0338, 0339, 0344, 0351, 0365, 0370, 0372, 0376, 0381, 0382, 0383, 0393, 0405, 0408, 0410, and 0412). USSE, agreeing with the commenters above, testified that having the same wording on regulated-areas signs would be helpful to workers as they move around and it is better for them to see the same information they have been trained on (Document ID #0499 Tr. 165).

Commenters raised several signage issues. Dow Chemical advocated the elimination of signs in substance-specific health standards, arguing that there was no need for signs since the chemical will be labeled and workers can also refer to an SDS (Document ID #0353). OSHA disagrees. The substance-specific standards' sign requirements cover regulated areas of facilities that are by definition high-exposure or potentially high-exposure areas. They are among the most dangerous areas in a facility, which is why OSHA requires signs. Moreover, contrary to what Dow assumes, product labels may not always be available in these circumstances. Thus, OSHA disagrees with Dow Chemical and believes the signs convey crucial information about the chemical hazard in a regulated area and that the signs benefit not only the well-trained worker but also other workers who might be near, or inadvertently enter, the regulated area.

The Battery Council International (Document ID #0390) had suggestions for language on regulated area signs for the lead standard, 29 CFR 1910.1025. First, they requested that OSHA change the language from ''Causes Damage to the Central Nervous System'' to ''May Cause Damage to the Central Nervous System,'' since nerve damage may or may not occur depending on whether or not the facility has taken proper precautions. However, as discussed above, OSHA has updated the signs to be consistent with GHS labeling to ensure that the worker is receiving the same message and this would provide better identification of the hazard. Therefore, OSHA has retained the proposed language for lead regulated area signs in the final.

The Battery Council International also requested that OSHA retain the original language § 1910.1025(m)(2) so that it would be clear that other signage may also be used in places where required (Document ID #0390). For example, it reported that California has such a signage requirement under Proposition 65. OSHA agrees that, in some very specific cases, other warnings may be necessary for lead. Thus, the current requirement that, ''The employer may use signs required by other statutes, regulations or ordinances in addition to, or in combination with, signs required by this paragraph,'' has been retained in the final rule for the lead standard at § 1910.1025(m)(2)(iv).

OSHA concludes that the proposed changes, which are as close as possible to the GHS terminology, are essential in order to make the warnings on signs consistent with each other, as well as labels, to the extent possible. These consistent warning signs will provide the best hazard communication in the relevant workplace regulated areas. The proposed changes to the signage requirements of the substance-specific standards have been carried through to the final rule.

Hazard Communication, Classification and Labels

OSHA's current substance-specific standards are inconsistent in that some have their own communication of hazards requirements, while other standards reference the HCS, and still other standards have no requirements for labels and safety data sheets in their sections. Although these latter standards are missing requirements, they still are covered by HCS. Similarly for labels, while most substance-specific standards require labels on containers of raw materials, mixtures, and products, some specify specific language while others reference the HCS. As proposed, and as carried forward in this final rule, OSHA has standardized the language for hazard communication and has removed the requirements for specific language labels from the ''Communications of hazards'' paragraphs of the substance-specific standards. The new paragraph in each substance-specific standard uses the following model format:

Hazard Communication—General.

(i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (29 CFR 1910.1200) for [chemical name].

(ii) In classifying the hazards of [chemical name] at least the following hazards are to be addressed: [hazard information].

(iii) Employers shall include [chemical name] in the hazard communication program established to comply with the HCS. Employers shall ensure that each employee has access to labels on containers of [chemical name] and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph [Training paragraph] of this section.

By adding this paragraph in each substance-specific health standard, OSHA achieves consistency across standards and with GHS principles. Some commenters indicated that the chemicals covered by the substance-specific standards should not be classified any differently than any other chemical in regard to the health hazards included on a label or SDS (*See, e.g.,* Document ID #0365). That was OSHA's intent. OSHA has clarified the regulatory language to minimize confusion. The final rule, like the proposal, requires compliance with the HCS in each substance-specific standard.

OSHA believes that requiring standards to reference HCS will ensure consistency with the GHS revisions and across the standards and consistency when the specific chemical is part of a mixture. Removal of the current specific warning language was essential for adoption of the GHS language. Retention of these provisions in the standards would result in the untenable situation of two potentially conflicting requirements, only one of which (the reference to HCS) would be in accord with the GHS-modified HCS. Moreover, as OSHA noted in the preamble to the proposed standard, the hazard statements specified for the chemical in the standard might not be correct when the chemical is part of a mixture. As for the current standards that simply referenced HCS, employers could choose any language and format that conveyed the necessary information. This approach is no longer allowed because, as OSHA has found in adopting the GHS approach, consistency in labeling is key to effective communication of hazards. The vast majority of commenters agreed. For example, AHMP noted that eliminating language inconsistent with established hazard statements will facilitate hazard communication and should not result in lower protection (Document ID #0327). Others, including NIOSH, DuPont,

Ameren, ASSE, Ecolab, Inc., AIHA, ORC Worldwide, NAHB, API, Procter & Gamble, Dr. Michelle Sullivan, ACC, 3M, AISI, Industrial Health and Safety Consultants, and American Coke and Coal Chemicals Institute, agreed (Document ID #0329, 0330, 0336, 0351, 0365, 0370, 0372, 0376, 0381, 0382, 0393, 0405, 0408, 0410, and 0412). Commenters noted that for the benefits of consistency to accrue, harmonization is essential (Document ID #0313, 0315, 0327, 0328, 0329, 0330, 0335, 0336, 0338, 0344, 0365, 0370, 0372, 0376, 0381, 0382, 0383, 0393, 0405, 0408, and 0410). NIEHS Worker Education and Training Program agreed, testifying that consistency of labels and safety data sheets is important to help employees recognize hazards and be able to deal with them effectively (Document ID #0497 Tr. 104). Phylmar Regulatory said that standardized label elements will be more effective in communicating hazard information (Document ID #0497 Tr. 108–109). AIHA testified that standardized labels will make hazard identification easier and the pictograms will be useful in workplaces where English language reading is limited (Document ID #0496 Tr. 415). USSW affirmed that one hazard communication system would be best (Document ID #0499 Tr. 178). OSHA believes all these commenters provide important and compelling reasons for the labels required by the substance-specific standards to be consistent with the GHS modifications to HCS.

For classification purposes, OSHA proposed to provide guidance on the potential health outcomes that must be addressed when classifying a substance by setting forth the health end-points (outcomes) for each substance-specific health standard. The Agency did not attempt to formally classify each substance; rather, OSHA provided a proposed list of health effects to assist the classifier in determining what must be considered for inclusion on the new labels. The GHS classification process for a specific substance dictates the actual hazard warnings and precautionary statements that are required on the new GHS-compliant labels and SDSs. In determining the hazards to include for each substance-specific health standard, the Agency's primary sources on health effects were the information gained in its own rulemakings and subsequent experience, the NIOSH Pocket Guide to Chemical Hazards (2005), and the International Chemical Safety Cards (ICSCs). The ICSCs are an undertaking of the International Programme on Chemical Safety (IPCS) (a joint activity of three cooperating International Organizations, namely, the United Nations Environment Programme (UNEP), the International Labour Office (ILO), and the World Health Organization (WHO)) and are peer reviewed by a group of internationally recognized experts (Document ID #0412.2). As a secondary source, OSHA also considered the European Union's (EU) ''Proposal for a Regulation of the European Parliament and of the Council on Classification, Labeling and Packaging of Substances and Mixtures, and amending Directive 67/548/EEC and Regulation (EC) No 1907/2006.'' From these sources, OSHA developed hazard endpoints to be considered for hazard classification in the substance-specific health standards based on either of two criteria: (1) The health hazard was the basis for the original rulemaking; or (2) the health hazard was asserted by OSHA, NIOSH, or IPCS, and confirmed by a second source. For example, acrylonitrile (AN) (§ 1910.1045) was regulated by OSHA based on its carcinogenicity. Skin sensitization was acknowledged by OSHA, IPCS, and EU; skin irritation by OSHA, NIOSH, and EU; respiratory tract irritation by IPCS and EU; eye irritation by OSHA, NIOSH, and IPCS; liver effects and central nervous system effects by IPCS and NIOSH; acute toxicity by OSHA, IPCS, and EU; and flammability by IPCS, NIOSH, and EU. Because all these effects met the criteria for inclusion, skin sensitization, skin irritation, respiratory irritation, eye irritation, liver effects, central nervous system effects, acute toxicity, and flammability were listed as potential hazards in the acrylonitrile standard.

OSHA's approach, including its choice of sources for health effects, was generally supported by many commenters to the proposal (Document ID #0329, 0339, 0351, 0370, and 0376). However, some, including NIOSH, AIHA, ASSE, Ameren, Stericycle, Wacker Chemical Corporation, and 3M Corporation, wanted OSHA to add other sources (Document ID #0233, 0330, 0338, 0365, 0405, and 0412). NIOSH suggested OSHA look at OECD SIDS, ESIS, NOAA, NLM, NLM–TOXSEEK, NLM–TOXNET, IPCS, CCOHS, and GESTIS (Document ID #0412). AIHA commented that substance-specific health standards should be classified the same as other chemicals and that other references such as ATSDR Toxicological Profiles, IRIS Toxicological Reviews, WHC Monographs, CICADS, OECD SIDS, and Patty's Toxicology should be used (Document ID #0365). Wacker Chemical Corporation recommended IARC be included and that one recognized body's determination of a hazard should be sufficient (Document ID #0335). ASSE urged inclusion of ACGIH documentation of TLVs and RELs and precautions developed by manufacturers from testing and epidemiological studies. ASSE submitted a long list of sources including NSC's Fundamentals of Industrial Hygiene, The Industrial Environment—Its Evaluation and Control, Patty's Industrial Hygiene and Toxicology, Casarett & Doull's Toxicology, The Dose Makes the Poison, Quick Selection Guide to Chemical Protective Clothing, U.S. DHHS Seventh Annual Report on Carcinogens, AIHA Engineering Field Reference Manual, and 17 others (Document ID #0336). AIHA urged OSHA to have the hazards for the substance-specific standards considered, but not be mandatory. It recommended additional references such as ATSDR Toxicological Profiles, IRIS Toxicological Reviews, EHC Monographs, CICADS, OECD SIDS, and Patty's Toxicology (Document ID #0365). Ameren would have OSHA add ACHIS and AIHA sources (Document ID #0330). Stericycle advocated adding Industrial Chemical Safety Cards, European Commission, and ACGIH as secondary sources (Document ID #0338). Still others, such as ASSE, API, AHMP, Product Safety Solutions, National Paint and Coatings Association, and Industrial Minerals Association—North America, deemed OSHA's choice of sources inadequate (Document ID #0313, 0327, 0328, 0338, 0376, and 0379). USSW (Document ID #0403) found lists such as IARC's and NTP's useful, but wanted OSHA to state in the regulatory text that a chemical on one or more of these lists was sufficient to classify it as hazardous (although the absence of a chemical on a list does not mean it is not hazardous). It also wanted OSHA to use lists in enforcement.

Commenters also raised other issues in this regard. API believed OSHA should just reference the GHS criteria, while ASSE wanted OSHA to use other authoritative references (Document ID #0336 and 0376). Both AHMP and Product Safety Solutions were concerned the NIOSH Pocket Guide and International Chemical Safety Cards had not been subject to rulemaking and could be overly conservative, even though they felt these sources could be used as information, but not as precedent if significant contradictory information is presented (Document ID #0313 and 0327). National Paint and Coatings Association commented that the substance-specific standards' health

hazards should remain as published and only new information should be subject to the two-reference rule (Document ID #0328). Still other commenters, including DuPont Company, Soap and Detergent Association and Consumer Specialty Products Association, Procter & Gamble, and Dr. Michelle Sullivan, expressed concern about whether the sources OSHA was using were to be current or updated, as newer editions become available (Document ID #0329, 0344, 0381, and 0382).

OSHA believes these comments reflect a misunderstanding of what OSHA proposed for its substance-specific health standards and how the sources were used to yield health effects to be considered in classifying all health hazards but not to perform a formal classification. (*See* 74 FR at 50411, Sept. 30, 2009, for the preamble explanation). The substance-specific health standards are unique in that they were all the subject of rulemaking, enabling the Agency to collect extensive information on sources and on health effects. That collection of information, coupled with the Agency's own expertise, enabled the Agency to confidently select sources for these regulated chemicals that would provide adequate information to classifiers. OSHA disagrees with commenters who suggested its chosen sources were inadequate. Some commenters recommended other sources. OSHA believes that these other sources can be useful in classifying hazards, and can certainly be used by classifiers in evaluating the hazards related to chemicals regulated by the substance-specific standards. At issue here, though, is the method OSHA has determined to use for selecting a list of hazard endpoints that, at a minimum, must be considered to provide accurate warnings on labels for its substance-specific standards. OSHA has concluded that the method it used in the proposal is scientifically sound and appropriate.

In complying with the HCS, as discussed above, classifiers must take into account available scientific information about the hazards of the chemical being classified, which could include information found in the other sources noted by the commenters. The manufacturer, distributor, or importer must still classify and categorize each regulated chemical (in the substance-specific health standards) in compliance with the GHS-modified HCS and its appendices. The lists of endpoints for each substance-specific standard are the minimum that must be considered. The manufacturer or importer has leeway to use additional primary studies and sources to evaluate the substance-specific chemical and is free to add health effects' endpoints as appropriate according to the studies or sources. As discussed previously in this section, the HCS generally uses a weight-of-evidence approach in classifying health hazards. Therefore, a superior source or significant and compelling contradictory information to a particular source usually must be weighed with the total body of evidence.

IMA–NA suggested that OSHA's methodology for determining the list of health effects to be considered by classifiers does not meet the requirements of the Information Quality Act (Document ID #0233). OSHA disagrees. That statute, and the guidelines published under it (discussed in more detail above), require that agencies take steps to ensure the ''quality, objectivity, utility, and integrity'' of information they disseminate. Similar to its response to the concern regarding TLVs, discussed above, OSHA does not believe that it is disseminating information for purposes of the IQA when it merely requires that manufacturers and importers consider specific health effects listed for each substance-specific standard in classifying the chemical under the HCS. However, even if it were disseminating information in the final rule, OSHA believes that it has complied with the applicable requirements of the IQA. OSHA has fully described the methods by which it determined the listed health effects for each substance, relied only on respected health compilations prepared by governmental agencies or subject to peer review, and subjected its analysis to notice and comment in this rulemaking. This adequately assures the quality, objectivity, utility, and integrity of any dissemination of information involved in these provisions of the final rule.

OSHA received no comments on the particular hazards proposed for each substance-specific health standard, and retained them in the final rule. The endpoints for each substance-specific standard are listed in Table XIII–5, ''Health Effects Determined for the Substance-Specific Standards.''

TABLE XIII–5—HEALTH EFFECTS DETERMINED FOR THE SUBSTANCE-SPECIFIC STANDARDS

Standard No.	Substance	Health effects
1910.1001, 1915.1001, 1926.1101.	Asbestos	Cancer and lung effects.
1910.1003	4-Nitrobiphenyl	Cancer.
1910.1003	Alpha-Naphthylamine	Cancer; skin irritation; and acute toxicity effects.
1910.1003	Methyl chloromethyl ether	Cancer; skin, eye, and respiratory effects; acute toxicity effects; and flammability.
1910.1003	3,3′-Dichlorobenzidine (and its salts)	Cancer and skin sensitization.
1910.1003	Bis-Chloromethyl ether	Cancer; skin, eye, and respiratory tract effects; acute toxicity effects; and flammability.
1910.1003	Beta-Naphthylamine	Cancer and acute toxicity effects.
1910.1003	Benzidine	Cancer and acute toxicity effects.
1910.1003	4-Aminodiphenyl	Cancer.
1910.1003	Ethyleneimine	Cancer; mutagenicity; skin and eye effects; liver effects; kidney effects; acute toxicity effects; and flammability.
1910.1003	Beta-Propiolactone	Cancer; skin irritation; eye effects; and acute toxicity effects.
1910.1003	2-Acetylaminofluorene	Cancer.
1910.1003	4-Dimethylaminoazo-benzene	Cancer; skin effects; and respiratory tract irritation.
1910.1003	N-Nitrosodimethylamine	Cancer; liver effects; and acute toxicity effects.
1910.1017	Vinyl chloride	Cancer; central nervous system effects; liver effects; blood effects; and flammability.
1910.1018	Inorganic arsenic	Cancer; liver effects; skin effects; respiratory irritation; nervous system effects; and acute toxicity effects.

TABLE XIII–5—HEALTH EFFECTS DETERMINED FOR THE SUBSTANCE-SPECIFIC STANDARDS—Continued

Standard No.	Substance	Health effects
1910.1025, 1926.62	Lead	Reproductive/developmental toxicity; central nervous system effects; kidney effects; blood effects; and acute toxicity effects.
1910.1026, 1915.1026, 1926.1126.	Chromium VI	Cancer; skin sensitization; and eye irritation.
1910.1027, 1926.1127	Cadmium	Cancer; lung effects; kidney effects; and acute toxicity effects.
1910.1028	Benzene	Cancer; central nervous system effects; blood effects; aspiration; skin, eye, and respiratory tract irritation; and flammability.
1910.1029	Coke oven emissions	Cancer.
1910.1043	Cotton Dust	Lung effects.
1910.1044	1,2-dibromo-3-chloropropane (DBCP)	Cancer; reproductive effects; liver effects; kidney effects; central nervous system effects; skin, eye, and respiratory tract irritation; and acute toxicity effects.
1910.1045	Acrylonitrile (AN)	Cancer; central nervous system effects; liver effects; skin sensitization; skin, respiratory, and eye irritation; acute toxicity effects; and flammability.
1910.1047	Ethylene oxide (EtO)	Cancer; reproductive effects; mutagenicity; central nervous system; skin sensitization; skin, eye, and respiratory tract irritation; acute toxicity effects; and flammability.
1910.1048	Formaldehyde	Cancer; skin and respiratory sensitization; eye, skin, and respiratory track irritation; acute toxicity effects; and flammability.
1910.1050, 1926.62	Methylenedianiline (MDA)	Cancer; liver effects; and skin sensitization.
1910.1051	1,3 Butadiene (BD)	Cancer; eye and respiratory tract irritation; center nervous system effects; and flammability.
1910.1052	Methylene chloride	Cancer; cardiac effects; central nervous system effects; liver effects; and skin and eye irritation.

The NPRM retained specific language for labels in the substance-specific health standards for containers of contaminated clothing or waste and debris to ensure that protection gained from communicating these hazards to the downstream recipients of the materials would not be lessened. The proposal, however, updated the language to be consistent with the GHS. The labeling requirements in these standards are part of broad protections, resulting from PELs and ancillary provisions such as exposure monitoring, personal protective equipment, and medical surveillance. These requirements for labeling containers of contaminated clothing, PPE, and waste and debris have been an integral part of the standards since their promulgation. To simply conform the labeling requirements for these kinds of containers to the GHS-modified HCS rule would not offer the extra protection currently provided in these standards; because of the variation in the quantity of chemicals in the containers of contaminated clothing, PPE, and waste and debris, the chemical concentration may be lower than the specified cut-off values/concentration limits. In such a case, if OSHA only relied on the GHS-modified HCS labeling requirement, labeling for these containers may not be triggered and protections would be lessened.

Commenters agreed that specific language for labels on containers of contaminated clothing and waste and debris should be maintained. For example, Ameren and 3M Corporation commented that maintaining specific language for labels on contaminated clothing and waste/debris containers for the substance-specific health standards will provide adequate warnings to all (Document ID #0330 and 0405). AIHA, in supporting the specific labels, noted that the workplace-contaminated materials are not hazardous chemicals in commerce; thus, these special labels are not inconsistent with GHS. Further, AIHA said that because recipients of these containers are accustomed to specific warnings, a change, such as elimination of the specific warning language because it might not be required by GHS, might be perceived as a change in hazard (Document ID #0365). The Battery Council International urged OSHA not to eliminate the label language requiring the disposal of lead-contaminated waste water in accordance with applicable local, state, or federal regulations in § 1910.1025(m)(2) for contaminated clothing. OSHA agrees that this information is important and is not inconsistent with GHS labeling. Therefore, OSHA has retained this language for the labels for contaminated clothing and equipment in the final rule. AISI and Industrial Health and Safety Consultants urged OSHA to require that the language on containers of contaminated clothing and waste/debris be in accord with the GHS guidelines. Such harmonization would maintain consistency with other labeling and minimize confusion of downstream handlers (Document ID #0408). In addition, Industrial Health and Safety Consultants felt that containers of contaminated clothing and waste/debris should be classified according to the HCS and the specific language on the label should be eliminated (Document ID #0410). As discussed below, OSHA does not agree. Industrial Health and Safety Consultants also suggested that OSHA require HCS classification and labeling of contaminated waste clothing and waste for all chemicals (Document ID #0410). OSHA did not propose such extensive new requirements for containers of chemically contaminated clothing and waste and debris. These requirements were not part of HCS and would be a significant addition to the final rule.

OSHA agrees with the commenters who advocate retaining the warnings and harmonizing these labels for contaminated clothing and waste and

debris containers, and did so to the extent possible. (*See* 74 FR 50434–50439, Sept. 30, 2009). However, classifying containers of chemically contaminated clothing and waste and debris consistent with GHS would be an impossible task, as substances found on contaminated clothing and waste and debris often occur in unknown, varying, and frequently small quantities. In order to ensure and maintain protection for employees in workplaces that receive these containers, labeling of the hazards with specific language is essential. The warnings, like all other warnings, are most effective when they are consistent with each other and, to the extent possible, with the GHS language. This consistency was achieved with the proposed language. Therefore, the proposed language for the substance-specific standards remains unchanged and is finalized in this rulemaking.

OSHA is adding two warnings to the Cadmium standard, which were left out of one paragraph of the proposal, through an error. In the NPRM, OSHA proposed that the warning labels for waste, scrap, or debris be required to include ''Danger''; ''Contains Cadmium''; and ''May Cause Cancer'' in paragraph 1910.1027(m)(3)(ii). The warnings ''Causes Damage to Lungs and Kidneys'' and ''Avoid Creating Dust'' were inadvertently left out of this paragraph. (The NPRM properly included these two warnings in paragraph 1910.1027(i)(2)(iv) for bags and containers of contaminated protective clothing and equipment.) OSHA is correcting this error by adding these warnings in this final standard, making the Cadmium standard consistent with the other substance-specific standards and, to the extent possible, with GHS.

In addition, for labels of bags or containers of contaminated clothing and equipment, OSHA has determined precautionary statements that address creating dust in the current substance-specific health standards must be retained even though there is no GHS equivalent. At this time, a work group formed under the UN Sub-Committee of Experts for the GHS (UN Sub-committee) is working to finalize issues related to hazard and precautionary statements. OSHA has recommended to the UN Sub-committee to adopt the phrase ''avoid creating dust'' as a precautionary statement, if this statement is adopted as a precautionary statement, then this statement will be consistent with the GHS. However, if the UN Sub-committee does not adopt such a statement, OSHA intends to continue to require the dust statements in those paragraphs for labels of bags and containers of contaminated clothing and equipment since OSHA has concluded that removing these statements would be a lessening of protection. An example of requirements for those statements can be found in OSHA's Cadmium standard, § 1910.1027(i), (k), and (m). OSHA also inadvertently removed the term ''Avoid Creating Dust'' from the Asbestos labeling requirements in § 1910.1001(j) and § 1926.1101(l) of the proposal. As discussed above, OSHA believes that this is a unique statement and should be retained. OSHA is correcting this error by reinstating this phrase in the asbestos labeling requirements in § 1910.1001(j) and § 1926.1101(l).

Occupational Exposure To Hazardous Chemicals in Laboratories: Definitions

OSHA proposed to modify most of paragraph (b), Definitions, in § 1910.1450, Occupational Exposure to Hazardous Chemicals in Laboratories (the laboratory standard), in order to maintain compatibility with HCS. In particular, OSHA removed the definitions of Combustible liquid, Compressed gas, Explosive, Flammable, Flashpoint, Organic peroxide, Oxidizer, Unstable (reactive), and Water-reactive from paragraph (b). In addition, in the NPRM, OSHA revised the definitions of Hazardous chemical, Physical hazard, and Reproductive toxins in paragraph (b) and added definitions for Health hazard and Mutagen in paragraph (b). By these modifications to § 1910.1450, the proposal sought to ensure that the definitions to the GHS-modified HCS also apply to the laboratory standard (§ 1910.1450). The modification is consistent with the goal of this rulemaking and the original intent of the laboratory standard. OSHA explained in the preamble to the laboratory standard the importance of having the HCS and the laboratory standard both use the same definitions for hazardous chemicals:

> The term ''hazardous chemical'' used in this final rule relies on the definition of ''health hazard'' found in the OSHA Hazard Communication Standard. As discussed in the scope and application section above, commenters urged OSHA to maintain consistency in terms between the Hazard Communication Standard and this final standard since laboratories are subject to both regulations.
>
> (55 FR 3315, Jan. 31, 1990).

Ameren agreed with OSHA that ''combustible liquid'' should be removed from paragraph (b) (Document ID #0330). However, the company recommended that OSHA replace the term with specific flashpoint criteria. OSHA disagrees that a definition for combustible liquid with specific flashpoint criteria differing from GHS-modified HCS should be contained in the laboratory standard. OSHA's intention is to harmonize the laboratory standard with the GHS-modified HCS. The final HCS rule contains definitions of flammable liquids with flashpoint criteria in Appendix B, and these flashpoint criteria include what are currently the combustible liquid classes. The laboratory standard does not contain specific requirements for physical hazards, including flammable or combustible liquids. Rather, this program standard contains requirements for such things as a chemical hygiene plan, employee exposure determination, training, medical consultation and examinations, and recordkeeping. Thus, OSHA does not see a need for including separate flashpoint criteria for flammable or combustible liquids and believes that reference to the flammable liquid categories in HCS is appropriate for § 1910.1450.

OSHA proposed to maintain the current definition of ''select carcinogens'' in the laboratory standard since the original purpose of the standard was to deviate from the HCS definition and narrow the scope of the standard. As noted in the preamble to the final rule for the laboratory standard, the scope was set for ''select carcinogens'' based on the small, often minute, quantities of substances handled. OSHA stated its reasons for this deviation in that preamble, and those reasons remain persuasive:

> This final rule, however, modifies the carcinogen definition and the obligatory action so that special provisions must be explicitly considered by the employer, but need only be implemented when the employer deems them appropriate on the basis of the specific conditions existing in his/her laboratory. Moreover, the term, ''carcinogen'' has been replaced by ''select carcinogen'' which covers a narrower range of substances * * *
>
> (55 FR 3315, Jan. 31, 1990).

OSHA has thus incorporated in the final rule its proposed changes to the definitions in the laboratory standard.

Appendices

OSHA reviewed the appendices to each of its substance-specific health standards and made the following minor changes necessary to align the appendices with their GHS-harmonized standards.

The language in Appendix B, ''Employee Standard Summary,'' chapter XI, ''Signs,'' in both the general industry and the construction standards for lead (§ 1910.1025 and § 1926.62, respectively) has been made consistent

with the language in their regulatory texts.

In Asbestos § 1910.1001, Appendix F, ''Work Practices and Engineering Controls for Automotive Brake and Clutch Inspection, Disassembly, Repair and Assembly (Mandatory),'' a reference to paragraph (j)(4) of the standard has been redesignated as paragraph (j)(5) to be consistent with the changes in the regulatory text for § 1910.1001. No changes were made to the construction Asbestos standard § 1926.1101, as none were needed.

Safety Data Sheets

OSHA has changed the term ''material safety data sheets'' when it appears to ''safety data sheets'' in both the substance-specific health standards and their appendices. As discussed above, this change reflects the GHS terminology.

Compliance Dates for Substance-Specific Health Standards

OSHA proposed to require implementation of all but one of the revisions to the HCS in three years following completion or promulgation of the final rule. Training was proposed to be required in two years. OSHA noted that during the transition period, an employer could be in compliance with either the current HCS or the revised HCS (the final rule), but there could not be a lapse in compliance. For the final standard, OSHA has decided to align implementation of GHS with the final implementation of GHS in the EU for labeling and SDSs. A full explanation of the information and comments and the Agency's reasoning is set out above in this section.

The proposed changes to the substance-specific health standards required compliance with the HCS, thus incorporating the proposed compliance dates for the revised HCS. One commenter suggested that the proposed sign and label updates be done in accordance with the facility's normal replacement schedule (Document ID #0376). OSHA finds that this is too indefinite a period, because it essentially leaves the compliance date in the hands of each employer. OSHA has concluded that the administration of HCS programs by employers and the communication and comprehension of the hazards by employees will be most effective if the requirement for completion of changes for the substance-specific health standards is the same as for all other chemicals. In a sense, this is just another example of the consistency that was approved by so many of the commenters and hearing witnesses.

Thus, the final rule keeps the compliance dates for the new substance-specific health standard requirements in line with those for the revisions to the HCS. Employers must be using new labels for contaminated clothing and waste and debris by June 1, 2015, the date by which manufacturers and importers must comply with the labeling and SDS requirements of the revised HCS. Employers must post the new signs by June 1, 2016, the same date by which employers must also update their hazard communication plans for any new hazard information they receive as a result of the final rule. In the meantime, as with the revised HCS, employers must comply with either the old or new labeling and signage requirements. Provisions to this effect are inserted for each substance-specific standard in this final rule.

Safety Standards

OSHA proposed modifying safety standards that either directly reference the HCS or provide information pertinent to the SDSs, in particular regarding the storage and handling of chemicals. As noted above, many commenters supported standardizing physical hazard criteria across all applicable OSHA standards (Document ID #0034, 0104, 0105, 0155, 0170, 0171, 0313, 0324, 0327, 0328, 0329, 0336, 0338, 0359, 0365, 0376, 0382, 0395, 0405, 0408, 0410, and 0494 Tr. 91, 162). For example, the Compressed Gas Association (CGA) (Document ID #0324) stated:

> CGA agrees with the harmonization to GHS to align the definitions of the physical hazards to the requirements of the GHS categories in safety standards for general industry, construction, and maritime standards, which either directly reference the Hazard Communication Standard * * * or provide information pertinent to the SDS.

However, some other commenters, and even some who supported applying physical hazard criteria across all standards, raised concerns about storage and handling requirements; degree of impact; potential effects on the scope of the Process Safety Management of Highly Hazardous Chemicals (PSM) standard; and potential conflicts with widely accepted consensus standards (Document ID #0038, 0077, 0104, 0163, 0329, 0335, 0336, 0339, 0366, 0370, 0381, 0383, 0393, 0399, 0414, 0500, 0514, 0530, 0643, 0494 Tr. 91, 162, and 0497 Tr. 81–84).

OSHA agrees with the commenters who supported standardizing physical hazard criteria and is doing so except in some standards, such as OSHA's electrical standards, where conflicts with referenced consensus standards make harmonization inappropriate at this time. OSHA proposed to:

- Incorporate the current HCS definitions of flammable liquid and gas into PSM and health hazard into Hazardous Waste Operations and Emergency Response (HAZWOPER) standards;
- Modify the Welding standard (§ 1910.252) requirements on labeling welding consumables to be consistent with GHS modifications to HCS;
- Amend paragraphs on flammable and combustible liquids to conform categories, terminology, flashpoints (FP), and boiling points to the GHS modifications to HCS;
- Incorporate the modified-HCS definition of flammable aerosols into the Flammable and Combustible Liquids standard, § 1910.106. (In § 1910.106, OSHA is also correcting a rounding error in the conversion from 12 feet to meters. The change is from 3.648 meters to 3.658 meters); and
- Update the acceptable methods for determining flashpoints; but
- Leave unchanged electrical standards in Subpart S for general industry and Subpart K for construction, and explosive standards for general industry (§ 1910.109) and for construction (§ 1926.914).

Commenters overwhelmingly supported ensuring consistency in OSHA standards, while maintaining scope of coverage. (Document ID # 0049, 0050, 0077, 0105, 0123, 0145, 0163, 0170, 0313, 0324, 0327, 0328, 0351, 0359, 0365, 0376, and 0494 Tr. 91, 162). Organization Resource Counselors (ORC) (Document ID # 0494 Tr. 91) testified:

> ORC supports concurrent harmonization of hazard definitions in most OSHA standards. ORC agrees with OSHA's proposal to harmonize hazardous communication components across most other OSHA standards in this rulemaking. ORC believes this is the most efficient way to address this necessary step in ensuring consistent hazard information and eliminating conflicting requirements.

Many comments to the ANPR and the NPRM supported OSHA exempting certain standards such as electrical and explosive standards from harmonization at this time (Document ID # 0047, 0075, 0076, 0104, 0113, 0145, 0163, 0328, 0330, 0336, 0370, 0393, and 0408). For example, the standards in Subpart S contain requirements such as internal design criteria that, if changed, would impact their scope. OSHA's reasons for excluding these standards are explained below. In testimony at the hearing, the ACC (Document ID # 0494 Tr. 162) agreed, stating:

We agree with this approach and therefore would expect that there would be no impact on electrical area classification, facility [s]iting, mechanical integrity, electrical classification, storage quantities, unloading and storage location, ventilation requirements, spill protection, grounding and bonding, tank and vessel design, interlocks and safety devices and process hazard analysis.

As discussed in detail below, in the final rule PSM retains its current scope; HAZWOPER's definition of ''health hazard'' is modified; the definitions in the Flammable and Combustible Liquids standards are aligned with the GHS modifications to HCS; Welding, Cutting and Brazing labeling requirements were also modified to be consistent with HCS; and a few technical amendments have been made to other safety standards that currently use the term ''combustible'' in order to keep their scope the same. Also, no changes were made to standards that OSHA proposed to exclude from this rulemaking.

PSM

PSM standards for general industry and construction reference the HCS for their scopes, which are currently set forth in § 1910.119(a)(1)(ii) and § 1926.64(a)(1)(ii) as covering a process which involves a flammable liquid or gas (as defined in § 1910.1200(c) [§ 1926.59(c)] on site in one location, in a quantity of 10,000 pounds (4535.9 kg) or more, followed by the listed exceptions in the paragraph.

If OSHA did not modify this provision in this rulemaking, the scope of PSM would expand since the HCS's definition of flammable liquid changes from liquids with a flashpoint below 100 °F (37.8 °C) to the new GHS definition of liquids with a flashpoint at or below 199.4 °F (93 °C) (though, as discussed above, the scope of the HCS is unaffected). Keeping the reference to the HCS definition would mean that many more processes would have been covered by the PSM standards than when those standards were promulgated. OSHA does not intend to expand the scope of the PSM standards. Therefore, to maintain the scope of those standards, OSHA proposed to modify the language in the scope paragraphs § 1910.119(a)(1)(ii) and § 1926.64(a)(1)(ii) to read:

A process which involves a Category 1 flammable gas (as defined in § 1910.1200(c)) or flammable liquid with a flashpoint below 100 °F (37.8 °C) on site in one location, in a quantity of 10,000 pounds (4535.9 kg) or more * * *

In other words, for PSM, ''flammable gas'' includes Category 1 flammable gases and liquids only if they have flashpoints below 100 °F (37.8 °C) to be consistent with the criteria specified in the current HCS.

Commenters who considered the issue differed on what should be done (Document ID #0324, and 0402). For example, ACC, in responding the NPRM, supported OSHA's approach (Document ID # 0393). ACC noted that OSHA's proposed regulatory language for § 1910.119, the general industry PSM, appropriately reflected the new cut-off without changing the scope of the regulation (Document ID #0393). However, CGA requested that OSHA update paragraph (a)(1)(ii) of § 1910.119 to use GHS Category 1 flammable liquids as a cutoff for PSM coverage, stating, ''This would maintain consistency throughout the OSHA standards and harmonization with the GHS'' (Document ID #0324). The Society of Chemical Manufacturers and Affiliates (SOCMA) (Document ID #0402) was concerned that the change in the flashpoint trigger for flammable liquids from ''the current 100 °F to the new 140 °F * * * would significantly expand the number of products subject to OSHA 1910.106 (flammable liquids), and OSHA 1910.119 (Process Safety Standards).''

While OSHA agrees with CGA that using GHS Category 1 flammable liquids would maintain consistency throughout the OSHA standards, to do so would change the scope of the PSM standard by making it applicable only to flammable liquids with flashpoints below 73 °F (23 °C). This would significantly narrow the scope of PSM and lessen worker protection by eliminating from coverage flammable liquids with flashpoints from 73 °F to below 100 °F. However, to set the coverage of PSM to 140 °F (flammable liquid categories 1, 2 and 3 which require the hazard warning ''flammable'' to appear on labels), as SOCMA noted, would expand the coverage beyond the scope of the original standard.

OSHA has concluded that setting the flashpoint below 100 °F (37.8 °C), the previous HCS level, properly maintains the scope of the PSM standards as they were promulgated. As explained in the proposal, OSHA's approach to the other affected standards is to ''modify provisions of the standards that reference the HCS definitions to maintain coverage or consistency with the modified HCS'' (74 FR 50404, Sept. 30, 2009). It is beyond the scope of this rulemaking to consider whether, as a substantive matter, the scope of the PSM standards should be changed. Thus, OSHA is neither increasing nor decreasing the scope of the PSM standard; consequently, the same products in the same quantities will be covered. The final rule adopts the proposed changes to the PSM standards noted above.

HAZWOPER

In the NPRM, OSHA updated the definition of health hazard in its HAZWOPER standards, § 1910.120(a)(3) for general industry and § 1926.65(a)(3) for construction, so that the terminology is aligned with the GHS health hazards in § 1910.1200, Appendix A. The final rule retains the proposed definition.

In proposing this change, OSHA was concerned that some of the terminology in HAZWOPER, such as neurotoxin and nephrotoxin, which were partly defined by reference to the HCS, would no longer be consistent with the GHS-modified HCS. For consistency, the proposal removed such terms from HAZWOPER and are now subsumed within the HCS specific target organ toxicity category, thus maintaining the same hazard communication requirements in both HAZWOPER and HCS. By updating the definition of ''health hazard'' in the HAZWOPER standards to clearly reference HCS, employers will have the proper reference to HCS and, in there, the proper guidance on how to classify the health hazards. OSHA received no contrary comment, and the final rule adopts the definition of health hazard as proposed.

The ACC requested that OSHA clarify how the HAZWOPER standards would be affected by OSHA's adoption of the GHS flammable and combustible liquid classifications in § 1910.106, § 1926.152, and § 1926.155 (Document ID # 0393 and 0530). ACC seems to be asking why OSHA did not reference the new definitions (GHS categories) of flammable liquids in HAZWOPER. OSHA believes the HAZWOPER standards would not be directly affected by the GHS-harmonized categories of flammable liquids, and therefore ACC's concern is misplaced. The HAZWOPER standards are program standards, and they do not contain any specific references to flammable or combustible liquids. It is true that the HAZWOPER standards state that all requirements of Parts 1910 and 1926 of CFR title 29 apply to hazardous waste and emergency response (§ 1910.120(a)(2) and § 1926.65(a)(2)). Thus, where HAZWOPER-covered employees are responding to an emergency situation where flammable liquids have been stored or need to be temporarily stored during clean-up, the flammable liquid standards might apply. OSHA believes that even in those situations, GHS harmonization of flammable liquids will

have little or no effect on the HAZWOPER standards, because the substantive requirements of these standards have not significantly changed.

Welding, Cutting and Brazing—General Requirements

OSHA is harmonizing the requirements in the Welding, Cutting and Brazing standard, § 1910.252, by adding a Hazard Communication paragraph and bringing in line with the GHS and OSHA's substance-specific health standards the terminology in the labeling requirements for filler metals and fusible granular materials, filler metals containing cadmium, and fluxes containing fluorine compounds.

The final rule retains the proposed text of the Hazard Communication paragraph at § 1910.252(c)(1)(iv). Similar to the substance-specific standards, the welding standard's hazard communication paragraph requires employers to include welding contaminants in a program established to comply with the HCS (§ 1910.1200). Also, similar to the substance-specific standards, OSHA has added a date paragraph requiring employers to be using new labels by June 1, 2015, the date by which manufacturers and importers must comply with the labeling and SDS requirements of the revised HCS.

In addition to adding the general Hazard Communication paragraph, OSHA reorganized some of the paragraphs in § 1910.252 so as to place the general reference to HCS in the correct position in the standard, § 1910.252(c)(1)(iv). To accomplish this, OSHA moved the ''Additional considerations for hazard communication in welding, cutting, and brazing,'' including filler and fusible granular materials, materials containing cadmium, and materials containing fluorine compounds, from paragraphs (c)(1)(iv)(A) through (C) to new paragraphs (c)(1)(v)(A) through (D).

The proposal inserted a cross reference to § 1910.1200 in the welding standards hazard determination section. In addition, as with the substance-specific standards, the proposal deleted specific label language requirements for welding materials containing cadmium and fluorine and instead listed specific health endpoints to be considered in the classification.

OSHA received one comment on the proposed changes from the Gases and Welding Distributors Association, Inc. (GAWDA). While GAWDA generally supported OSHA's rulemaking effort, GAWDA requested that OSHA change ''suppliers'' of welding materials to ''manufacturers'' in § 1910.252(c)(1)(v)(A) of the proposal (Document ID # 0388). GAWDA stated the term ''supplier'' is undefined and might include different entities in the supply chain; furthermore, elsewhere OSHA places the responsibility of hazard determination on manufacturers, importers, and distributors. However, OSHA would like to point out that the term ''supplier'' is used in the current standard, which requires suppliers to determine the hazards in § 1910.252(1)(c)(iv): ''The suppliers of welding materials shall determine the hazard, if any, associated with the use of their materials in welding, cutting, etc.'' OSHA assumes that ''suppliers'' will continue to use the same method that they are currently using to determine the hazards of their materials. To change this term could result in a substantive change in the scope of this standard and would be beyond the scope of this rulemaking. Therefore OSHA will retain the word ''suppliers'' as proposed.

In addition, as discussed in the preamble to the proposal, *See* 74 FR 50417 (Sept. 30, 2009), current § 1910.252(c)(iv) does not merely require suppliers to determine the hazards of their products, but also to ensure that labels properly convey those hazards. A requirement that a supplier only determine the hazard of its products is of little value if they do not also convey information about those hazards on to the persons who use it. The final rule provides additional clarity that suppliers of welding products covered by the standard label as well as determine the hazard.

The changes to this standard were predicated on achieving consistency with the GHS modifications to HCS and other OSHA substance-specific standards, and OSHA has concluded that the modifications as proposed and as explained in the previous paragraphs will effectuate harmonizing the standard's terminology with HCS. In addition, this action also contributes to internal consistency by making the Welding, Cutting, and Brazing standard similar to the substance-specific health standards.

Flammable and Combustible Liquids

OSHA proposed to align the definitions of flammable and combustible liquids in both the general industry and construction standards to conform to the GHS modifications to the HCS. In particular, the proposal changed the definitions of flammable liquid categories and deleted the term and definition of combustible liquids (*See* Table XIII–6 for comparison of the GHS-modified HCS definitions and the current flammable and combustible definitions that were contained in 29 CFR 1910.106 and 29 CFR 1926.155). OSHA has concluded that the proposed changes to the § 1910.106 and § 1926.155 definitions are reasonably necessary and appropriate and carried them forward into the final rule. In addition, to essentially maintain the scope of the standards, OSHA proposed, and is maintaining in the final rule, the addition of the flashpoint cut-off value where the GHS flammable liquid categories overlapped with the current HCS classes. The Alliance of Hazardous Materials Professionals and David Levine of Product Safety Solutions agreed, stating: ''The elimination of the term 'combustible' and substitution of actual flash point data provide a more meaningful definition in the affected standards'' (Document ID # 0313 and 0327).

OSHA proposed to drop the current rules' classifications of flammable and combustible liquids in favor of the GHS flammable liquid classifications. This meant that all liquids under the proposal would fall into GHS flammable liquid Categories 1 through 4, and that the term ''Combustible Liquids'' in §§ 1910.106, 1910.107, 1910.123, 1910.125, 1926.152, and 1926.155 was proposed to be deleted since the GHS does not have a hazard class titled ''Combustible liquids.'' However, the GHS does require the hazard statement ''combustible liquid'' on the label for Category 4 Flammable liquids (flashpoint greater than 60 °C (140 °F) but not greater than 93 °C (199.4°F)).

In addition, the current general industry Spray Finishing standard, § 1910.107, relies on the current § 1910.106 definition of Class IIIB liquids (liquids with a flashpoint over 93 °C). Therefore the proposal amends § 1910.107 to replace its use of the term ''combustible liquids,'' which has no corresponding GHS category, with the phrase ''Liquids with a Flashpoint Greater than 93 °C (199.4 °F).'' With the new terminology, the protection provided by the original standards remains the same.

OSHA believed that most of the proposed changes in the definitions were not significant. The move to GHS categories entails nominal changes to the flashpoint values for flammable and combustible liquids from 22.8 °C (73 °F) (current Class IA/B cut-off) to 23 °C (73.4 °F) (GHS Category 1/2 cut-off) and from 93.3 °C (200 °F) (current Class IIIB cut-off) to 93 °C (199.4 °F) (GHS Category 4). OSHA believes these changes in flash point represent simple rounding to the closest significant value

and that they would have no significant effect on the scope of its standards or on employee safety. ACC agreed with OSHA, stating that ''the elimination of the term 'combustible liquid' in § 1910.107 does not significantly change the requirements of the standards and should not adversely affect industry's ability to comply with the standard'' (Document ID #0393). OSHA has concluded these new whole numbers are minute changes and that the rounded numbers coincide with GHS, are easier to understand and remember, and therefore will improve communication of hazards.

However, OSHA requested comment in the proposal on one change that was potentially significant. Under the proposal, the boiling points used to define the threshold for the current Flammable Class IA in § 1910.106 shifted from the cut-off value of 37.8 °C (100 °F) to a cut-off value of 35 °C (95 °F) for GHS Category 1. Likewise, the boiling points in the proposed definition of Flammable Class IB (§ 1910.106) shift from equal to or greater than (≥) 37.8 °C (100 °F) to greater than (≥) 35 °C (95 °F) in GHS Category 2 (*See* Table XIII–6). The Agency believed the changes would be necessary to make OSHA standards internally consistent and consistent with the GHS modifications to HCS. However, as discussed in the NPRM, OSHA was concerned that changing the boiling point cut-off for the highly flammable liquids classified as Flammable IA could, under the GHS modifications to HCS, lead to a subset of these chemicals being classified as GHS Category 2 Flammable Liquids. Since some of the storage and handling requirements are based on the hazard category, the proposal would allow a facility to use larger tanks to store liquids with boiling points between 37.8 °C (100 °F) and 35 °C (95 °F). OSHA was concerned that this practice could decrease safety. OSHA reviewed the properties related to the flammability of approximately 900 chemical substances (754 liquids) listed in the *CRC Handbook of Chemistry and Physics* [85th edition]. Approximately 1 percent of this list of flammable liquids would result in a reclassification from the current Flammable and Combustible Liquids Standard Class IA to GHS Category 2. While this is a small percentage of the total flammable liquids, it represents approximately 15 percent of the Flammable and Combustible Liquids Standard Class IA liquids on this list. OSHA was concerned that this was an instance where the benefits of harmonization could have been in conflict with the measure of safety currently provided and therefore requested comments on this issue.

Most agreed with OSHA that resulting reclassifications of liquids with borderline flashpoints from the old Class IA to the GHS Category 2 was not significant (Document ID #0313, 0324, 0327, 0328, 0338, 0352, 0365, 0366, 0370, 0376, 0382, 0383, 0393, 0405, 0408, 0410, and 0494 Tr. 56). National Association of Chemical Distributers (NACD) stated that ''Several NACD members handle flammable liquids under Category 1 and 2. However, the proposed changes would result in few operational changes'' (Document ID # 0341). Several commenters pointed out that aligning the definitions for flammable liquids is consistent with the single worldwide definition for these hazards (Document ID #0313 and 0327). ORC (Document ID #0370) stated:

> ORC agrees that the methods OSHA proposes to classify flammable liquids Category 1and 2 and flammable aerosols are similar enough to the current definitions that substances that are currently regulated by OSHA would continue to be regulated and that few, if any, changes would result in a shift in regulatory coverage.

The National Fire Protection Association (NFPA) (Document ID #0366 and 0497 Tr. 56) stated:

> NFPA agrees with OSHA's assessment regarding the slight adjustment resulting from the change in criteria for flash point and boiling point for flammable liquid categories when applying the GHS criteria. NFPA believes the overall impact of the changed flash point and boiling point will be negligible.

The American Petroleum Institute (API) urged OSHA to be consistent across all standards (Document ID #0376). Further, the ACC commented that in reference to the boiling point cut-off for Category 1 and 2 flammable liquids, they believe the language (in the NPRM) is sufficient to reflect the cut-off without changing the scope of the regulation (Document ID #0393).

However, some commenters expressed concern that the shift in flammability criteria would require facilities to modify their storage facilities to maintain compliance with § 1910.106, and consequently storage receptacles would have to be smaller, leading to less storage and greater costs (ISSA, Document ID # 0399). That concern is misplaced because the change from OSHA's old flammable and combustible classes to GHS categories involves a *lowering* of the boiling point cut-offs by 2.8 °C (5.04 °F), so that employers will still be able to use current handling and storage practices affected by the change. Likewise, current storage and handling practices for chemicals whose boiling points fall between 37.8 °C and 35 °C would still be allowed under the proposal. SOCMA commented that changing the definition would expand the number of products subject to § 1910.106 (Document ID #0402). That is also not correct. Due to the rounding of GHS flashpoints, cut-offs are slightly less stringent (*See* Table XIII–6) and no new chemicals would be regulated.

TABLE XIII–6—FLAMMABLE LIQUID DEFINITIONS

GHS			Flammable and combustible liquids standard (29 CFR 1910.106)		
Category	Flashpoint °C (°F)	Boiling point °C (°F)	Class	Flashpoint °C (°F)	Boiling point °C (°F)
Flammable 1	<23 (73.4)	≤35 (95)	Flammable Class IA	<22.8 (73)	<37.8 (100)
Flammable 2	<23 (73.4)	>35 (95)	Flammable Class IB	<22.8 (73)	≥37.8 (100)
Flammable 3	≥23 (73.4) and ≤60 (140)		Flammable Class IC Combustible Class II.	≥22.8 (73) and <37.8 (100). ≥37.8 (100) and <60 (140).	.
Flammable 4	>60 (140) and ≤93 (199.4).		Combustible Class IIIA	≥60 (140) and <93.3 (200).	
None			Combustible Class IIIB	≥93.3 (200)	

The American Society of Safety Engineers (ASSE) agreed with OSHA's assessment of the storage issue. ASSE noted that the differences in boiling points from the original § 1910.106 to the GHS Categories could increase the number of gallons allowed to be stored in rooms and cabinets as well as the size of containers for certain liquids. However, in its opinion, the ''slightly'' increased boiling point would be of ''little significance'' (Document ID #0336). Therefore, based on the analysis discussed above and the comments received, OSHA has concluded that the shift in boiling point and the minor changes in temperatures and the re-categorizing of flammable liquids are insignificant and will have a negligible impact on the protection provided by the standards that use these terms.

Most commenters supported OSHA's proposal to incorporate the GHS definitions for flammable liquids into its safety standards (Document ID #0313, 0327, 0328, 0338, 0365, 0376, 0405, 0408, and 0410). Some stressed the ''consistency'' benefits from harmonization (Document ID #0338, 0405, and 0408). ASSE (Document ID #0336) said:

> In response to OSHA's proposal to eliminate the term ''combustible liquid'' in 29 CFR 1910.106, 1910.107, 1910.123, 1910.124, 1910.125, and 1926.155 for liquids with a flashpoint above 100 degrees F., ASSE believes this list of standards is appropriate. * * * However, ASSE urges OSHA to remove the term ''combustible liquid'' for all liquids and use the GHS criteria for all flammable liquids.

The National Paint and Coatings Association (NPCA), in supporting the removal of the term ''combustible liquid,'' noted that it was consistent with DOT (Document ID #0328).

Although there was considerable support for the changes OSHA made in the proposal to the flammable and combustible liquid categories, OSHA also received comments suggesting that the deletion of the ''combustible'' designation and the combining of NFPA Class 1C flammable and Class II combustible liquids into new Category Flammable 3, would lead to confusion among engineers, employers, and employees, which could result in potential accidents (Document ID #0344, 0366, 0381, 0399, 0402, 0498, 0500, 0514, and 0643). In addition, some commenters questioned whether the OSHA standards that address flammable liquids that are not covered by GHS (Combustible Class IIIB) are best handled by replacing the term ''combustible'' with a quantitative definition so as to maintain their coverage (Document ID #0336, 0366, and 0497 Tr. 56–58 and 68).

Some organizations, though they supported the proposed changes in general, had some specific concerns, particularly with how the OSHA GHS harmonization works with other national standards, including consensus standards. Clariant Corporation opined that eliminating the term ''combustible liquid'' will likely cause some confusion since it is still used by NFPA and DOT but urged OSHA to adopt the GHS criteria to maintain global consistency (Document ID #0383). However, OSHA points out that, as mentioned above by NPCA, the GHS criteria are consistent with DOT. The American Federation of State, County and Municipal Employees (AFSCME) favored OSHA's GHS harmonization, but sought clarification or additional guidance on how secondary labeling systems such as NFPA's 704 Diamond or the Hazardous Materials Information System (HMIS) would be used once GHS was in effect (Document ID #0414).

NFPA testified that the GHS categories would conflict with NFPA's established hazard ratings in NFPA 704, which has been in effect since the 1950s. NFPA recommended that the term ''combustible liquid'' not be deleted (Document ID #0497 Tr. 59–64). In addition, NFPA expressed concern that there may be additional confusion since the rating system in NFPA 704 expresses the most hazardous as a ''4'' while the GHS classification criteria expresses the most hazardous as Category ''1''. The International Fire Marshals Association (IFMA), echoing the sentiments of the NFPA, agreed that users have been relying on the NFPA 704 Hazard Rating and the Hazardous Material Information System (HMIS) systems for a long time and would be confused by the change (Document ID #0497 Tr. 80–84).

These commenters were concerned that the proposed realignment of the flammable liquid categories would result in confusion among employees, emergency responders, authorities having jurisdiction, and others who have been used to the distinction between flammable and combustible liquids (Document ID #0344, 0366, 0381, 0399, 0402, 0498, 0500, 0514, 0643, and 0497 Tr. 56–58). NFPA (Document ID #0366) stated:

> NFPA is also concerned with the elimination of the ''combustible liquids'' classification that will occur with the adoption of GHS as we believe there will be considerable confusion among the workers who have been instructed to take specific precautions for various liquids based on whether they were identified as ''flammable or combustible.'' Further, we believe that the elimination of the ''combustible liquid'' classification may cause confusion among emergency responders and authorities having jurisdiction, who have until now understood that ''flammable liquids'' can be expected to be ignitable at ambient temperatures, while ''combustible liquids'' typically require some degree of heating to reach their flash point temperatures. This lack of definition may also be an issue, albeit to a lesser extent, among designers who have been trained to apply certain fire protection measures to ''flammable liquids'', but not to ''combustible liquids.'' The immediate recognition that has existed in the workplace for decades may be removed by the proposed rule; NFPA cautions OSHA that confusion among workers has the potential to be more significant than OSHA has acknowledged.

See also Document ID #0497 Tr. 56–58.

As an initial matter, OSHA notes liquids with a flashpoint greater than or equal to 60 °C (140 °F) and less than 93.3 °C (200 °F), which are currently classified as ''combustible,'' will be labeled as ''combustible liquids'' under the final rule. Thus this minimizes the potential for the confusion that NFPA suggests for these chemicals.

In any event, OSHA believes that there is currently confusion and inconsistency in this area. For example, OSHA standards have several cutoff values for flammable and combustible liquids. In OSHA's general industry standard at § 1910.106, 100 °F is the cut-off between flammable liquids and combustible liquids, but in construction, § 1926.155, 140 °F is the cut-off between flammable and combustible. Even the NFPA's standards are confusing. In NFPA 30, the hazard levels are structured from Ia/b/c to III b, with Ia being the highest, while in NFPA 704 the hazard levels range from 1 to 4, where the highest hazard category is 4 and the lowest is 1. NFPA classification and rating systems have been in existence since the 1950s and while the NFPA rating system is widely used, it is still not universally used or understood. Testimony from Mr. Frederick of the United Steelworkers indicated that NFPA is a good quick reference although (he believed) it does not cover all hazards, but it is used to alert workers that they must look elsewhere for additional information (Document ID #0499 Tr. 155–169).

In addition, OSHA reviewed randomly chosen SDSs for liquids classified under the current standard to determine how NFPA ratings correlated to hazard warnings. As shown in Table XIII–7, the hazard warnings were inconsistent, while the MSDSs were all technically correct for physical properties. For example, the hazard warning for flammable liquids with a

NFPA rating of 3 ranges from ''Flammable Liquid'' to ''Extremely Flammable'' to ''Severe.'' Notably, cyclohexanone, currently classified as a combustible liquid under § 1910.106, bears the hazard statement ''Flammable.''

TABLE XIII–7—MSDS COMMUNICATIONS OF FLAMMABLE LIQUID HAZARD WARNINGS

Docket #	Chemical name	Flashpoint	NFPA rating listed	Hazard warning
0565	Toluene	40.7 °F	3	Flammable Liquid
0566	Turpentine	95 °F	3	Flammable Liquid
0570	Aliphatic Hydrocarbons	120 °F	None listed	Flammable Liquid
0571	Reagent N Hexane	−22 °F	3	Extremely Flammable
0567	Paint Thinner	104 °F	2	Combustible
0557	Reagent Alcohol	55 °F	3	Severe (flammable)
0599	Cyclohexane	0 °F	3	Extremely Flammable
0560	Cyclohexanone	111 °F	2	Flammable

OSHA believes that this rulemaking will promote greater harmonization of hazard warnings in the future. Now, when a chemical falls in a particular flammable liquid hazard category, the HCS requirements will dictate the appropriate hazard warning. At least one comment alleges this has already happened in the United States. Dr. Michele Sullivan pointed out that the U.S. Department of Transportation (DOT) is already aligned with the GHS physical hazard criteria (the GHS criteria for physical hazard was based on the DOT physical hazard criteria); thus is already aligned with GHS flammable liquid criteria. Therefore, OSHA is aligning with DOT with this rulemaking (49 CFR 173.120 and Document ID #0382).

Neither the proposal nor final rule prohibits the use of NFPA or HMIS rating systems. They do not prohibit the use of NFPA definitions for employers taking preventive measures in designing facilities or implementing fire protection systems such as automatic sprinklers to ensure a safer situation. OSHA's requirements, even with the substitution of the term ''flammable'' for ''combustible,'' do not prohibit safer workplace designs or installations. Furthermore, OSHA expects that engineers and other professionals will use the actual flashpoints and other properties of the liquids themselves in design and installation of controls rather than a designation of a liquid as ''flammable'' or ''combustible.'' IFMA agreed with this premise (Document ID #0497 Tr. 84–85). In any event, even if the engineer, facility designer, or employer is somehow misled by § 1910.106's use of the term ''flammable,'' which has traditionally connoted a higher level of hazard, the result should be an error on the side of safety, rather than of less protection.

During the public hearings, ORC Worldwide commented on OSHA's review of the standards affected by this rulemaking, stating support for the ''concurrent harmonization of hazard definitions in most OSHA standards.'' However, ORC also ''agrees with member concern that changes to definitions in § 1910.106, Flammable and Combustible Liquids, while not increasing the scope of the standard, may cause confusion to workers who are familiar with NFPA nomenclature for these materials'' (Document ID #0494 Tr. 91–92). OSHA asked ORC to elaborate on this concern and provide support for their testimony. In response, ORC (Document ID #0643) provided two hypothetical situations it believes show that confusion over the realignment of flammable and combustible liquid categories could be significant:

> Consider an engineer who is designing a new warehouse. (New) Category 3 liquids are to be stored therein, and these are liquids which were previously called ''combustible.'' Engineer does not design an electrical classification for the area. He does not realize that the new category may also include some liquids which are flammable. Because of this design outage, an electrical issue causes a fire and the warehouse burns down.
>
> Consider a dry cleaning business that is using a (new) Category 3 solvent and does not include automatic sprinklers because the team is familiar with this solvent as being ''combustible'' under the previous NFPA definitions. A different, more effective solvent is proposed, also (new) Category 3, and is accepted as being ''similar''—the manufacturer reassures them that the new solvent is in the same flammability category as the previous one. But this one is indeed flammable and would require automatic sprinkler protection under NFPA rules. A fire starts with the new solvent, and because no automatic sprinklers exist onsite, the dry cleaner burns down.

OSHA thanks ORC Worldwide for their testimony and for providing examples of where revisions to standards affected by this rulemaking might cause confusion. With regard to the situations presented by ORC, OSHA understands that the engineer designing the sprinkler system would be required to follow local and state building codes, along with NFPA codes or other building codes, such as NFPA 1 (Fire Code), NFPA 13 (Standard for the Installation of Sprinkler Systems), NFPA 30 (Flammable and Combustible Liquids Code), NFPA 32 (Standard for Dry Cleaning Plants), NFPA 5000 (Building Construction and Safety Code), and the International Building Code (published by the International Code Council) as well as any OSHA standards that would apply.

The design of a system is not predicated on one physical property, and a prudent engineer or sprinkler designer should be aware that there are special requirements for the storage of combustible and flammable liquids. The codes and standards mentioned above all refer to NFPA 30 for requirements related to the storage and use of flammable and combustible liquids. There are restrictions on maximum container size, maximum storage height, and maximum total quantity stored based on flashpoint.

With regard to the change in solvent used at a dry cleaning facility, the argument remains the same as for the design engineer mentioned above. The flashpoint determines the classification of the chemical. The automatic sprinkler system design would be based on the flashpoint and not the class of chemical being used. OSHA concludes that commenters' concerns about confusion are not well founded and has decided to retain the GHS definition for flammable liquids as proposed in the final rule.

Two commenters, Procter & Gamble and ISSA, believed OSHA was adopting the 140 °F flashpoint cut-off as the definition of a flammable liquid and that this would conflict with the current flashpoint cut-off of 100 °F in § 1910.106 (Document ID #0381 and 0399). Procter & Gamble, arguing that the GHS was designed for hazard communications and not intended to regulate design criteria and that aligning

the GHS criteria for flammable liquids in OSHA's safety standards would have unintended consequences (Document ID #0381), offered OSHA two options:

Option 1: Leave the current OSHA definition of flammable liquids unchanged. This is easy, clear, and no-cost to U.S. industry. Option 2: In principle, GHS is a labeling and hazard communication system, and was not intended to regulate the design and operation of facilities. OSHA 1910.106, by comparison, is a risk management regulation used in such design and operation. If OSHA adopts the GHS Building Block of 140 °F, leave the parallel definition of 100 °F intact in 1910.106. This dual system will create some confusion, but will minimize the negative effects listed above.

As an initial matter, Procter & Gamble misunderstood how OSHA incorporated the GHS flammable liquid definitions into the safety standards. This change was made only to align terminology. In fact, OSHA agrees that the GHS was not intended to regulate design criteria. Therefore, OSHA proposed to leave the standard's design criteria intact by using the actual measurable flashpoint as the defining criterion. The proposal, adopted by the final rule, is similar to Procter & Gamble's Option 2 and accomplishes both harmonization with GHS and retention of OSHA's long-established and effective risk management practice.

Finally, there were concerns that realigning the flammability criteria could affect contracts. Phylmar Regulatory Roundtable (PRR), which did not oppose OSHA's alignment of definitions of flammable and combustible liquids with the GHS categories, was concerned the reclassification of chemicals may cause conflicts in contracts with customers. PRR stated that the contracts require specifications in products manufactured, engineering controls, personal protective equipment, and specified instructions. PRR claimed that in such a situation the manufacturer by contract is permitted no deviation from the contract or process standards (Document ID #0514). However, as stated above, OSHA has not changed the scope or the requirements of its standards. Therefore, OSHA has concluded there is unlikely to be any interference with contracts. Moreover, where distinctions must be made in the OSHA requirements between the former Class 1C flammable liquids and Class II combustible liquids, the OSHA requirements have specified such distinctions with specific flashpoints. The contents and scopes of the regulatory paragraphs are not affected by GHS reclassifications or terminology changes, nor are OSHA's ventilation, respiratory protection, and personal protective equipment standards. In addition, OSHA did not change standards, like its electrical standards, that address internal design criteria.

OSHA has decided to remain consistent with GHS and not create additional flammable liquid categories. However, § 1910.106(18)(ii)(b) defines Combustible Class IIIB liquids as liquids with flashpoints at or above 200 °F (93.3 °C). While Class IIIB liquids are not included in the scope of § 1910.106, there is no such exemption in the Spray Finishing standard, § 1910.107 (OSHA letter of interpretation, Aug. 15, 2006). In order to preserve coverage in standards such as Spray Finishing, these liquids are now called ''Liquids with a Flashpoint of >93 °C (199.4 °F).'' Similar to § 1910.106, the use of the flashpoint cut-off is the best way to stay as close to the GHS and maintain scope and consistency within the standards. The Soap and Detergent Association (SDA) and the Consumer Specialty Products Association (CSPA) in a joint comment stated that OSHA should ''correct'' § 1910.107(e) and (e)(4) and § 1910.124(c)(2) to read ''Liquids with a Flashpoint at or below 199.4 °F'' to be consistent with the GHS criteria (Document ID #0344). However, if OSHA were to adhere strictly to GHS in this instance and drop the higher flashpoint category, protection from this hazard would be lost and safety compromised.

Several commenters addressed this issue. ASSE stated that their ''members do not see the need for the fifth category of 'Flammable Liquids Over a Flash Point of 93.3 °C.' Specific flash point criteria should be used'' (Document ID #0336). NFPA expressed general concern about the elimination of the Class IIIB liquids by the adoption of the GHS categorization system, though they acknowledged that OSHA had proposed to extend liquids as ''flammable liquid with flash point greater than 93 °C'' (Document ID #0366 and 0497 Tr. 56–58). The point was further clarified upon questioning at the hearing where NFPA agreed that by extending the liquids to flashpoints greater than 199.4 °F, OSHA was providing the coverage for § 1910.107 that had always been there. In addition, NFPA recommended it be further clarified that these liquids with the higher flashpoints belong to § 1910.107 and are not part of GHS Category 4 (Document ID #0497 Tr. 68).

In addition, Intercontinental Chemical Corporation recommended that OSHA create six new categories matching the six classes in the original § 1910.106 (Document ID #0500). The Agency believes that this approach would be inconsistent with GHS, since the GHS classifications and categories, including flammable liquid Categories 1–4, were established by international committees and are in place. OSHA's intent in this rulemaking is to harmonize the HCS with the existing GHS classifications and categories, not to make new categories.

In summary, OSHA views this rulemaking as a step towards eliminating current inconsistencies. OSHA believes the potential confusion with other agency policies, standards, consensus standards, and traditional practices suggested by the commenters are not likely to occur for several reasons. First, the changes in the final rule will bring internal consistency to the OSHA standards covered. OSHA standards currently have several cut-off values for flammable and combustible liquids. In OSHA's general industry standard (§ 1910.106), 100 °F is the cut-off between the flammable and combustible liquids, but in construction, § 1926.155, 140 °F is the cut-off between flammable and combustible. Harmonizing these standards, which have been out of sync for many years, will bring needed consistency to the safety standards. In addition, as noted above, substantive requirements have not changed, and therefore designs are not affected.

Second, the changes to the standards do not require changes in work practices. Rather, what have changed are a few regulatory terms used in the standards. Commenters who thought that such changes in definitions and terminology would result in significant and costly modifications to facility design and operation are incorrect, as the old requirements in the standards remain and no facility design and operation changes are required (Document ID #0344, 0381, and 0399). The requirements for what were known formerly as combustible liquids remain the same even though they are now categorized as flammable liquids.

Third, there is growing awareness of the GHS ''flammable liquids'' definition. Other agencies, such as DOT, are already aligned with the GHS definition for flammable liquids (49 CFR 173.120), and OSHA believes that its ANPR and NPRM have raised awareness of the definition.

Change occurs in every area of employment, and employers and workers get trained and adjust to the change; OSHA believes these minor changes will be accepted and adopted. OSHA's flammable and combustible liquid storage requirements have always been based on the flashpoint and boiling point of the liquid; OSHA does not

believe that facility designs rely on whether the liquid is labeled as flammable or combustible. (*See* Document ID #0497 Tr. 84–85) Thus, OSHA has concluded that the allegations of impacts on facility design and operations are perceptual rather than actual. This is especially true in light of the fact that certain OSHA standards were exempted from the terminology changes if these changes were to affect internal design criteria of any area of the workplace. OSHA has therefore concluded that the proposed changes to the § 1910.106 definitions are reasonably necessary and appropriate and has carried them forward into the final rule.

OSHA will be doing outreach to affected parties and working with professional and trade associations to help users become familiar with and competent in applying these modifications. ORC testified that the changes may cause confusion to workers familiar with NFPA nomenclature, and agreed with OSHA that, with training, any confusion resulting from the change from NFPA definitions and terminology to GHS definitions and terminology would be overcome. ORC (Document ID #0494 Tr. 100–101) further stated that potential confusion would not be a reason to delay moving forward with finalizing the standard:

> There's a significant problem with lack of harmonization of chemical control approaches in the United States, and we would like to see, as we said in our testimony, some sort of formalization because we think it's the only thing that's going to work here, formalization of regular contacts between the NFPA and OSHA.

Mike Wright, representing the United Steelworkers (Document ID #0494 Tr. 76–77), put it succinctly, stating:

> The whole point of harmonization is to reconcile different standards, which may be conflicting. That means something has to change. * * * Ultimately, in the short term will there be some confusion? Yes. Can we minimize that through good training, through good information? Yes, and we ought to, but ultimately I think we have a globally harmonized system that's been adopted on a worldwide level and then we have various national organizations—very important ones like the NFPA—which may deviate in the way they communicate hazards from that globally harmonized system.
>
> With respect to my friends at the NFPA, who I think do wonderful work, I think their job is to harmonize their system to the Globally Harmonized System. We hope that happens as soon as possible, and I'm confident that it will.
>
> You know, ultimately we need to go to one * * * system worldwide. We have that system now. It will take some time and a little bit of confusion to conform every other kind of national voluntary system to that, but that work has to be done.

OSHA agrees and believes users of the new GHS flammable liquid categories will implement its new terminology in their work.

Minor Safety Standard Changes

The note in the PSM construction standard, § 1926.64(d)(1)(vii), has been changed. In the current standard, paragraph (d)(1)(vii), the note states, ''Material Safety Data Sheets meeting the requirements of 29 CFR 1926.59(g) may be used to comply with this requirement to the extent they contain the information required by this subparagraph.'' The note has been changed to ''Safety Data Sheets (SDSs) meeting the requirements of 29 CFR 1910.1200(g) . * * *''

To correct a technical error and to complete alignment across standards, § 1910.106(j), Scope, has been made consistent with § 1910.106(a)(19) and § 1910.1200, Appendix B. Proposed § 1910.106(j) stated that it ''applie[d] to the handling, storage, and use of flammable liquids with a flashpoint *below* 199.4 °F (93 °C) unless otherwise noted.'' (Emphasis added). Final § 1910.106(j) is now consistent with § 1910.106(a)(19) and § 1910.1200 in that it applies to ''* * * flammable liquids with a flashpoint *at or below* 199.4 °F (93 °C) * * *'' (Emphasis added).

In § 1926.155, OSHA proposed to harmonize the definitions of flammable and combustible liquids to be consistent with the GHS categories of flammable liquids (*i.e.,* the updating of the definition of flammable liquids and the removal of the definition for combustible liquids), and this change is carried through to the final rule. The final rule also removes ''or combustible'' in the other standards in Subpart F, to maintain consistency with the ''Definitions'' in § 1926.155. In § 1926.150(c)(vi), which currently states, ''A fire extinguisher, rated not less than 10B, shall be provided within 50 feet of wherever more than 5 gallons of flammable or combustible liquids or 5 pounds of flammable gas are being used on the jobsite,'' the term ''or combustible'' has been removed. Likewise, the Agency is correcting § 1926.151(b)(3) by removing ''or combustible.'' In § 1926.151(a)(4), Portable battery powered lighting, which states that ''the storage, handling, or use of flammable gases or liquids, shall be * * * approved for the hazardous locations,'' the term ''flammable liquids'' has been changed to ''Category 1, 2, or 3 flammable liquids.'' This change maintains the scope set by the flashpoint ranges for the Subpart (as defined by the original § 1926.155 paragraphs (c) and (h)).

The Soap and Detergent Association and Consumer Specialty Products Association, in a joint comment (Document ID #0344), suggested that OSHA change the term ''pilot light'' to ''indicating light.'' As discussed previously, this type of change is outside of the scope of this rulemaking since it does not pertain to hazard communication or GHS harmonization. Therefore, OSHA is not adopting that suggestion at this time.

Methods To Determine Flashpoints

OSHA proposed to update the methods that may be used to determine flashpoints in the NPRM. These methods include updated ASTM methods, ISO methods, and British, French, and German national standards for the testing. The methods are listed in Appendix B.6 of § 1910.1200 and are also referenced in Revision 3 of the GHS (2009), Chapter 2.6.

In the definitions of § 1910.106, the current standard allowed only ASTM D–56–70 and ASTM D–93–71 as testing methods to determine flashpoints. In § 1926.155, which applies to Subpart F of the construction standards (Fire Protection and Prevention), OSHA currently allows only ASTM D–56–69 and ASTM D–93–69 for such determinations. The current HCS allows only ASTM D 56–79, ASTM D 93–79, and ASTM D 3278–78. The methods allowed in § 1910.155 were adopted in the late 1960s, and the methods for § 1910.106 and § 1926.1200 were adopted in the 1970s.

The NPRM updated the methods in § 1910.1200 to conform to the GHS. However, flashpoint methods in § 1910.1200 had always differed from methods in § 1910.106 and § 1926.155. Instead of revamping the older test methods in OSHA's other standards, the proposal allowed a broader test selection. OSHA kept the tests currently permitted in § 1910.106 and § 1926.155 because they were in the original OSHA standards, but allowed methods in the GHS-modified HCS be used as well. The final rule adopts these changes.

Thus, the final rule amends § 1910.106 and § 1926.155 to allow ASTM D–56–70 and ASTM D–93–71 for § 1910.106; ASTM D–56–69 and ASTM D–93–69 for § 1910.155; and the equivalent testing methods permitted in the HCS, § 1910.1200, Appendix B.6, Physical Hazard Criteria. For example, as amended by the final rule, § 1910.106(a)(14)(i) states that for a liquid which has a viscosity of less than 45 SUS at 100 °F (37.8 °C), does not

contain suspended solids, and does not have a tendency to form a surface film while under test, the procedure specified in the Standard Method of Test for Flashpoint by Tag Closed Tester (ASTM D–56–70), which is incorporated by reference as specified in § 1910.6, or an equivalent test method as defined in Appendix B to § 1910.1200—Physical Hazard Criteria, must be used.

By equivalent test method, OSHA means employers can select any of the test methods in Appendix B.6 or in Chapter 2.6 of Revision 3 of the GHS (2009).

The only comments on this issue recommended additional methods for determining flashpoints (Document ID #0344 and 0381). The Soap and Detergent Association/Consumer Specialty Products Association (Document ID #0344) and the Procter & Gamble Company (Document ID #0381) recommended OSHA include ASTM D6450 on the list of approved methods for determining the flashpoints of liquids in the ''incorporation by reference'' list in § 1910.106. OSHA is not prepared to adopt this method at this time. The determination of flashpoint test methods for GHS falls under a Sub-committee of the United Nations Economic and Social Council's Committee of Experts on the Transport of Dangerous Goods (UNCEDTG). Commenters who wish the GHS to incorporate ASTM D6450 should direct their requests to that body, and if the method is incorporated into the GHS, OSHA will consider the matter at that time.

Flammable Aerosols

OSHA currently defines the term ''flammable aerosol'' in § 1910.106 and in § 1910.1200 by reference to a definition developed by the Consumer Product Safety Commission under the Federal Hazardous Substances Act. *See* 16 CFR 1500.45; *See also* 15 U.S.C. 1261(l). The current HCS defines flammable aerosol as an aerosol that, when tested by the method described in 16 CFR 1500.45, yields a flame projection exceeding 18 inches at full valve opening, or a flashback (a flame extending back to the valve) at any degree of valve opening.

The current § 1910.106 definitions for ''aerosol'' and ''flammable aerosol'' are provided in (§ 1910.106(a)(1)) and (§ 1910.106(a)(13)) and are different from those in the revised Hazard Communication Standard. In the current § 1910.106, an aerosol is defined as a material which is dispensed from its container as a mist, spray, or foam by a propellant under pressure. However, in the current § 1910.106, a flammable aerosol is defined as an aerosol which is required to be labeled ''Flammable'' under the Federal Hazardous Substances Labeling Act (15 U.S.C. 1261). For the purposes of § 1910.106(d), such aerosols are considered Class IA liquids.

OSHA proposed to remove the definitions of ''aerosol'' and ''flammable aerosol'' from § 1910.106 and instead insert its GHS-consistent definitions along with references to Appendix B.3 of the GHS-modified HCS. In response to OSHA's proposed action, National Paint and Coatings Association and Alliance of Hazardous Materials Professionals both said that, while they were not prepared to offer specific impact information on operations, ''to align OSHA definitions for * * * Flammable Aerosols is fully consistent with the concept of a 'single world-wide' definition for these hazards.'' (Document ID #0313 and 0327).

OSHA agrees with these comments and has included the revised definition of ''flammable aerosols'' in the final rule. The revised definition in the Flammable liquids standard, § 1910.106, duplicates the flammable aerosols definition contained in Appendix B to § 1910.1200—Physical Hazard Criteria. For the purposes of § 1910.106(d), such aerosols are considered Category 1 flammable liquids.

The GHS-modified definition and classification criteria for flammable aerosols can be found in Appendix B.3 of HCS.

OSHA's decision to change the definition of aerosols to be consistent with the GHS-modified HCS is based not only upon harmonizing its own standards with those followed by other countries who have or are considering adopting GHS, but also to harmonize with DOT's definition for flammable aerosols, which is also consistent with the GHS. *See* 49 CFR 173.115(k).

Dr. Michelle Sullivan (Document ID #0382), alluding to flammable aerosols, pointed out that flammable categories will differ among regulatory authorities. She stated:

> [T]he GHS flammable aerosol criteria are linked to the criteria for flammable liquid, flammable solid and flammable gas, the flammable aerosol criteria depend on the hazard categories/building blocks of these other hazards * * * some regulatory authorities will adopt categories 1–4 while others will adopt categories 1–3 * * * [and thus] * * * the flammable aerosol criteria will differ for these regulatory authorities.

Regarding Dr. Sullivan's comment, OSHA acknowledges that other regulatory bodies, when adopting GHS, may choose different building blocks. However, the basis for classification will still be based on the same criteria and will lead to harmonization of similarly covered materials. This does not affect OSHA's decision to strive for both domestic and international harmonization.

Finally, OSHA believes that the GHS classification criteria are similar enough to the current § 1910.106 and § 1910.1200 criteria that all aerosols currently regulated by OSHA would continue to be so, and that few, if any, new aerosols would be subject to OSHA regulation. Indeed, OSHA raised this issue in the NPRM and received no comments to the contrary.

Standards Not Included in This Rulemaking

OSHA did not propose to change standards that incorporate by reference other consensus standards, such as NFPA codes, or are based on consensus standards when those consensus standards are used for internal design criteria only and do not reference the HCS for applicable scope or incorporation into the SDS. These standards include Subpart S—Electrical, in Part 1910 (General Industry), and Subpart K—Electrical, in Part 1926 (Construction). Many commenters on the ANPR were particularly concerned that a change in OSHA's definitions would create an incompatibility with local building codes (Document ID #0047, 0075, 0076, 0104, 0113, 0145 and 0163). They alleged that, in many cases, this would require extensive rewiring to meet the Subpart S requirements on hazardous locations and would lead to conflicts with local electrical codes.

Many commenters on the NPRM supported OSHA's exemption of these standards (Document ID #0328, 0330, 0336, 0370, 0393, and 0408). Ameren expressed concern that if OSHA harmonized the electrical and blasting agents standards (Part 1910 Subpart S, § 1910.109, and Part 1926 Subpart K, § 1926.914) with the GHS, such changes would require training of affected employees on the changes (Document ID #0330). ASSE agreed with OSHA's decision not to propose updates to the electrical standards (general industry 1910 Subpart S and construction 1926 Subpart K) or explosives and blasting agents (general industry § 1910.109 and construction § 1926.914), since these subparts are ''self-contained'' in that they do not rely on other OSHA standards for regulatory scope or definitions but reference external organizations such as the National Fire Protection Association (NFPA) (Document ID #0336). The American Iron and Steel Institute agreed (Document ID #0408). ORC strongly

supported OSHA's approach of not updating these standards but waiting until the referenced external organizations adopted the GHS elements (Document ID #0370).

Wacker Chemical Company, PRR, and ACC urged OSHA to update electrical and explosive and blasting agents standards if the consensus organizations could come to agreement, and they expressed their concerns regarding potential conflicts with local codes and regulations (Document ID #0335, 0339, and 0393). Wacker Chemical Corporation encouraged OSHA to work closely with organizations (NFPA and others) that develop fire and electrical codes to ensure there is consistent application of these codes to area classification, building construction, equipment electrical ratings, etc. (Document ID #0335). Wacker Chemical suggested that OSHA could make progress with the consensus organizations (Document ID #0335). PRR recommended harmonization updates of electrical and explosive standards if the updates would enhance safety and the ease of doing business in the global market (Document ID #0339). The ACC agreed with OSHA's decision not to change standards that incorporate consensus standards by reference (*i.e.,* design criteria) (Document ID #0393). ACC requested OSHA clarify in its final rule that harmonization would not affect the International Building Code and the International Fire Code such that users will not be unduly required to upgrade buildings to conform to requirements for hazardous occupancies. By its decision regarding standards not included in this rulemaking, OSHA is making it clear that upgrading buildings is not within the scope of this rulemaking.

OSHA agrees with those comments that expressed the desire to harmonize but also expressed concern over the potential effects of internal codes. OSHA concluded that exempting those standards where conflicts with internal codes could occur at this time was appropriate. OSHA agrees with ACC that impacting electrical area classification, facility siting, and wiring configuration is not appropriate. Therefore, because of these potential conflicts with internal design criteria, OSHA is not harmonizing the electrical and other standards that depend on internal design criteria and local building codes.

Explosives and Blasting Agents

OSHA did not propose to harmonize the Explosive and Blasting Agents standards, § 1910.109 (general industry) and § 1926, Subpart U (construction). At the time of the proposal, a separate rulemaking to revise them was in progress. That rulemaking has since been terminated (75 FR 5545, Feb. 3, 2010). However, the HCS has always covered hazardous chemicals regulated by OSHA's Explosive and Blasting Agents standards. Although the rulemaking on explosives and blasting agents has ceased, the general requirements in the GHS-modified HCS and specific requirements in its appendices still apply to explosives and blasting agents that can be considered hazardous chemicals. Manufacturers and importers must evaluate chemicals to classify their health and physical hazards in accordance with paragraph (d) of the HCS, must affix labels in accordance with paragraph (f) in HCS, and must provide SDSs in accordance with paragraph (g) of the HCS. Appendix B.1 of the GHS-modified HCS contains specific classification criteria for explosives. Furthermore, labels are required by the Department of Transportation (DOT) for the transportation of packages or containment devices that contain hazardous materials meeting one or more of DOT's hazard class definitions. *See* 49 CFR Part 172 Subpart E. In addition, OSHA's general industry standard § 1910.1201, ''Retention of DOT markings, placards, and labels,'' requires that DOT labels, placards, or markings be retained under certain conditions. Thus, explosives and blasting agents are already covered by the GHS-modified HCS and § 1910.1201.

The few commenters who addressed the issue supported OSHA's decision not to include the Explosive and Blasting Agents standards (§ 1910.109 and § 1926.914) in the proposal (Document ID #0328, 0330, 0336, 0362, and 0370).

As to the continuing coverage of HCS, a representative from Institute Makers of Explosives stated that the commercial explosives industry understands the importance of GHS, has been prepared for several years to implement GHS, and would not experience any impacts to explosives operations that were not already anticipated (Document ID #0362).

Galaxy Fireworks noted that § 1910.109(k)(1) excludes the sale and ''use (public display)'' of pyrotechnics (fireworks) from the explosives standard (Document ID #0355). Galaxy Fireworks' concern was the potential for the proposal to create a regulation that overlaps with the existing requirements of the Department of Transportation and the Consumer Product Safety Commission. Galaxy urged OSHA to work with these other agencies in amending the HCS to develop regulations that would apply uniformly to the fireworks industry and with other organizations to further harmonization (Document ID #0335). OSHA agrees and believes its global harmonization efforts embodied in this rulemaking go a long way toward the overall goal of consistency.

Maritime

OSHA received one comment, from Northrop Grumman Shipbuilding, which stated that OSHA had omitted modification of the shipyard Part 1915 safety standards for GHS harmonization (Document ID # 0395). More specifically, Northrop Grumman believed that the maritime standards that contain requirements for flammable and combustible liquids required review and updating to be GHS harmonized, just as the flammable and combustible liquids the General Industry Part 1910 and Construction Part 1926 standards were proposed to be reviewed and updated.

OSHA did not propose to update the maritime standards, other than the substance-specific standards mentioned above, in this rulemaking. Unlike the standards in general industry and construction, the maritime standards (Shipyard Employment, Part 1915; Marine Terminals, Part 1917; and Longshoring, Part 1918) have always addressed flammables and combustibles in their own unique way, reflecting the special conditions of maritime work. These parts do not use flashpoint criteria to distinguish between flammable and combustible liquids. The terminology in the maritime standards that addresses flammable and combustible materials, including liquids, differs from the general industry and construction standards. For example, § 1915.12(b)(1) (Flammable atmospheres) and § 1915.54 (Welding, cutting and heating of hollow metal containers not covered by § 1915.12) require competent-person testing and contain detailed instructions on the specific maritime work covered.

There are a few paragraphs in the maritime standards where flammable and combustible liquids requirements reference flashpoint criteria but in these cases, flashpoints are not used for the purpose of distinguishing flammable from combustible liquids. Examples include Subpart P, Fire Protection, § 1915.501 through § 1915.509, where flammable liquid is defined as liquids with flashpoints below 100 °F (37.8 °C). Combustible liquids are neither defined nor mentioned in this Subpart, although combustible materials are mentioned and not defined. Other maritime standards such as § 1915.14 (Hot work)

and § 1915.35 (Painting) specify flashpoints for certain requirements, but these are not distinctions of flashpoints defining flammable or combustible liquids. The final rule does not modify these criteria.

OSHA has issued a maritime compliance tool, ''Tool Bag Directive for the Part 1915 Shipyard Employment Standards,'' that includes specific interpretations of the maritime standards. The Tool Bag Directive references specific general industry standards in order to provide further guidance related to some of the more general maritime requirements. A specific case is how general industry standard § 1910.106 is used. The Tool Bag Directive informs users that if specific Part 1915 shipyard requirements give flashpoint criteria, those requirements take precedence. However, where definitions of flammable and combustible liquids are not specified in the Part 1915 shipyard standards, the definitions of § 1910.106 are to apply. The final rule's changes do not significantly modify the substantive requirements of § 1910.106, and the Tool Bag Directive's interpretive policy will continue after the final rule becomes effective, using the new definitions in § 1910.106.

In a similar manner, OSHA has a compliance tool for Parts 1917 ''Marine Terminals'' and 1918 ''Longshoring'' called the Tool Shed Directive. This Directive notes that the requirements of § 1910.1200 apply to operations covered by Parts 1917 and 1918. *See also* 1917.1(a)(2)(vi); 1918.1(b)(4). Therefore, all the requirements in the GHS-modified HCS (§ 1910.1200), and its appendices will apply to the maritime industry. In addition, part 1910 applies to marine terminal operations that fall within the exception found at § 1917.1(a)(1)(i): ''facilities used solely for the bulk storage, handling, and transfer of flammable, non-flammable, and combustible liquids and gases.'' The final rule's changes to § 1910.106 will therefore apply to facilities handling flammable and combustible liquids that fall within this exclusion, but again, as explained above, the substantive requirements of § 1910.106 have not changed significantly.

Construction

The Building and Construction Trades Department (BCTD) requested that OSHA clarify inconsistencies in the construction standards, particularly by updating the Part 1926 standards to conform to the proposed requirements for and definitions of ''flammable'' and the related deletion of the term ''combustible'' liquids (Document ID # 0359). BCTD gave examples of §§ 1926.152, 1926.155, 1926.66 and Subpart K of Part 1926 and requested that OSHA conduct a thorough review of the Part 1926 construction standards. Though it had done so once in preparing the NPRM, OSHA again conducted a thorough review of Part 1926. OSHA had already proposed to modify § 1926.152 (Flammable and combustible liquids) and § 1926.155 (Definitions) as well as § 1926.64 (Process Safety Management), § 1926.65 (HAZWOPER), and the substance-specific health standards in construction in the NPRM. As explained above, OSHA has made further revisions in the construction regulations regarding process safety management (§ 1926.64(d)(1)(vii)) and fire protection and prevention (§ 1926.150(c)(vi), § 1926.151(a)(4)), and § 1926.151(b)(3)) in this final rule.

Like Subpart S in general industry, § 1926.66 (Criteria for design and construction of spray booths) belongs to the category of construction standards that incorporate other consensus standards by reference, such as NFPA codes, or are based on consensus standards when those consensus standards are used for internal design criteria only and do not reference HCS for applicable scope or incorporation into the SDS. Clearly, there is no reason to change the terminology in § 1926.66. As noted above, Part 1926, Subpart K (Electrical), belongs in this category. Other similar standards are § 1926.351 (Arc Welding and Cutting), and Part 1926, Subpart V (Power Transmission and Distribution). OSHA is not modifying these standards for the same reasons listed above for general industry.

Similar to the discussion regarding the Maritime standards, OSHA did not propose modifications of standards that do not contain definitions that are applicable to standards in the Subpart or explicitly reference standards that contain the definitions. The standards may contain phrases with the terms ''flammable liquid'' or ''combustible liquid,'' but the definitions of the terms are absent. Standards belonging to this category of undefined terms include § 1926.66(c)(9)(i) (Criteria for design and construction of spray booths), § 1926.252(e) (Disposal of waste materials), § 1926.307(p)(2)(ii) (Mechanical power-transmission apparatus), § 1926.352(c) and (h) (Fire prevention), § 1926.803(l)(13) (Compressed air), and § 1926.1101, Appendix B (Sampling and Analysis for Asbestos). In addition, some of these standards' requirements use the term ''flammable liquid'' without the term ''combustible liquid,'' and some of the requirements use the term ''combustible liquid'' without the term ''flammable liquid.'' As with the maritime standards, since OSHA has not changed the actual requirements of § 1910.106 or § 1926.155, OSHA does not anticipate that the final rule will affect the requirements of other OSHA standards that use some of the same terminology.

In addition, OSHA did not modify standards that refer to flammable and combustible materials, storage piles, etc. that are not liquids. Examples are § 1926.550(a)(15)(vii)(C) (Cranes and derricks), which refers to combustible and flammable materials; § 1926.956(b)(3) (Underground lines), which refers to combustible gases; and § 1926.352(c) (Fire prevention), which refers to flammable compounds. In addition, § 1926.154(e)(1) (Temporary heating devices) mentions ''flammable liquids,'' but the term was not the focus of the standard. The requirement mentions flammable liquid-fired heaters, but the focus is on safety controls for the particular piece of equipment. Safety training and education, § 1926.21(b)(5), is another example that contains some of the terminology, but its focus is on safety training. Flammable liquids are treated in a general sense, *i.e.,* grouped with gases or toxic materials.

Miscellaneous

A commenter from the International Chemical Workers Union Council recommended OSHA include a conversion formula for Centigrade and Fahrenheit or, at a minimum, provide the equivalent degrees when addressing flammable and combustible liquids, since in general employers and employees in the U.S. are more familiar with degrees Fahrenheit (Document ID # 456). OSHA proposed to provide temperature equivalents, and in the final standard equivalents are included where there are requirements for flammable and combustible liquids. The formulas for conversion are:

(9/5) °C + 32 = °F or (5/9)(°F–32) = °C

Since the formulas for conversion are standard formulas found in textbooks, and since equivalents have been provided wherever possible for flammable and combustible liquids, OSHA has determined that it is not necessary to state the formulas for conversion in the actual regulations.

XIV. Authority and Signature

This document was prepared under the direction of David Michaels, Assistant Secretary of Labor for Occupational Safety and Health, U.S.

Department of Labor, 200 Constitution Avenue NW., Washington, DC 20210. It is issued under the authority of sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); 5 U.S.C. 553; Section 304, Clean Air Act Amendments of 1990 (Pub. L. 101–549, reprinted at 29 U.S.C.A. 655 Note); Section 41, Longshore and Harbor Workers' Compensation Act (33 U.S.C. 941); Section 107, Contract Work Hours and Safety Standards Act (40 U.S.C. 3704); Section 1031, Housing and Community Development Act of 1992 (42 U.S.C. 4853); Section 126, Superfund Amendments and Reauthorization Act of 1986, as amended (reprinted at 29 U.S.C.A. 655 Note); Secretary of Labor's Order No. 1–2012 (77 FR 3912); and 29 CFR Part 1911.

List of Subjects

29 CFR Part 1910

Asbestos, Blood, Chemicals, Diving, Fire prevention, Gases, Hazard communication, Hazardous substances, Health records, Incorporation by reference, Labeling, Labels, Laboratories, Occupational safety and health, Reporting and recordkeeping requirements, Safety data sheets, Signs and symbols, and Training.

29 CFR Part 1915

Hazard communication, Hazardous substances, Labels, Longshore and harbor workers, Occupational safety and health, Reporting and recordkeeping requirements, Safety data sheets, Signs and symbols, Training, and Vessels.

29 CFR Part 1926

Chemicals, Construction industry, Diving, Fire prevention, Gases, Hazard communication, Hazardous substances, Health records, Labels, Lead, Occupational safety and health, Reporting and recordkeeping requirements, Safety data sheets, Signs and symbols, and Training.

Signed at Washington, DC, on February 23, 2012.

David Michaels,

Assistant Secretary of Labor for Occupational Safety and Health.

Final Amendments

For the reasons discussed in the preamble, the Occupational Safety and Health Administration amends 29 CFR parts 1910, 1915 and 1926 as set forth below:

PART 1910—OCCUPATIONAL SAFETY AND HEALTH STANDARDS

Subpart A—[Amended]

■ 1. Revise the authority citation for subpart A of part 1910 to read as follows:

Authority: Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355) or 1–2012 (77 FR 3912), as applicable.

Section 1910.6 also issued under 5 U.S.C. 553. Sections 1910.6, 1910.7, and 1910.8 also issued under 29 CFR Part 1911. Section 1910.7(f) also issued under 31 U.S.C. 9701, 29 U.S.C. 9a, 5 U.S.C. 553; Pub. L. 106–113 (113 Stat. 1501A–222); Pub. L. 111–8 and 111–317 and OMB Circular A–25 (dated July 8, 1993) (58 FR 38142, July 15, 1993).

■ 2. Amend § 1910.6 by revising paragraphs (a)(4) and (h), the introductory text of paragraph (q), and by adding new paragraphs (q)(37), (y), and (z) to read as follows:

§ 1910.6 Incorporation by reference

(a) * * *

(4) Copies of standards listed in this section and issued by private standards organizations are available for purchase from the issuing organizations at the addresses or through the other contact information listed below for these private standards organizations. In addition, these standards are available for inspection at any Regional Office of the Occupational Safety and Health Administration (OSHA), or at the OSHA Docket Office, U.S. Department of Labor, 200 Constitution Avenue NW., Room N–2625, Washington, DC 20210; telephone: 202–693–2350 (TTY number: 877–889–5627). They are also available for inspection at the National Archives and Records Administration (NARA). For information on the availability of these standards at NARA, telephone: 202–741–6030, or go to *http://www.archives.gov/federal_register/code_of_federal_regulations/ibr_locations.html.*

* * * * *

(h) Copies of the standards listed below in this paragraph (h) are available for purchase from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428–2959; Telephone: 610–832–9585; Fax: 610–832–9555; Email: *seviceastm.org;* Web site: *http://www.astm.org.* Copies of historical standards or standards that ASTM does not have may be purchased from Information Handling Services, Global Engineering Documents, 15 Inverness Way East, Englewood, CO 80112; Telephone: 1–800–854–7179; Email: *global@ihs.com;* Web sites: *http://global.ihs.com* or *http://www.store.ihs.com.*

(1) ASTM A 47–68, Malleable Iron Castings, IBR approved for § 1910.111.

(2) ASTM A 53–69, Welded and Seamless Steel Pipe, IBR approved for §§ 1910.110 and 1910.111.

(3) ASTM A 126–66, Gray Iron Casting for Valves, Flanges and Pipe Fitting, IBR approved for § 1910.111.

(4) ASTM A 391–65 (ANSI G61.1–1968), Alloy Steel Chain, IBR approved for § 1910.184.

(5) ASTM A 395–68, Ductile Iron for Use at Elevated Temperatures, IBR approved for § 1910.111.

(6) ASTM B 88–66A, Seamless Copper Water Tube, IBR approved for § 1910.252.

(7) ASTM B 88–69, Seamless Copper Water Tube, IBR approved for § 1910.110.

(8) ASTM B 117–64, Salt Spray (Fog) Test, IBR approved for § 1910.268.

(9) ASTM B 210–68, Aluminum-Alloy Drawn Seamless Tubes, IBR approved for § 1910.110.

(10) ASTM B 241–69, Standard Specifications for Aluminum-Alloy Seamless Pipe and Seamless Extruded Tube, IBR approved for § 1910.110.

(11) ASTM D 5–65, Test for Penetration by Bituminous Materials, IBR approved for § 1910.106.

(12) ASTM D 56–70, Test for Flash Point by Tag Closed Tester, IBR approved for § 1910.106.

(13) ASTM D 56–05, Standard Test Method for Flash Point by Tag Closed Cup Tester, Approved May 1, 2005, IBR approved for Appendix B to § 1910.1200.

(14) ASTM D 86–62, Test for Distillation of Petroleum Products, IBR approved for §§ 1910.106 and 1910.119.

(15) ASTM D 86–07a, Standard Test Method for Distillation of Petroleum Products at Atmospheric Pressure, Approved April 1, 2007, IBR approved for Appendix B to § 1910.1200.

(16) ASTM D 88–56, Test for Saybolt Viscosity, IBR approved for § 1910.106.

(17) ASTM D 93–71, Test for Flash Point by Pensky Martens, IBR approved for § 1910.106.

(18) ASTM D 93–08, Standard Test Methods for Flash Point by Pensky-Martens Closed Cup Tester, Approved Oct. 15, 2008, IBR approved for Appendix B to § 1910.1200.

(19) ASTM D 240–02 (Reapproved 2007), Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter, Approved May 1, 2007, IBR approved for Appendix B to § 1910.1200.

(20) ASTM D 323–68, Standard Test Method of Test for Vapor Pressure of Petroleum Products (Reid Method), IBR approved for § 1910.106.

(21) ASTM D 445–65, Test for Viscosity of Transparent and Opaque Liquids, IBR approved for § 1910.106.

(22) ASTM D 1078–05, Standard Test Method for Distillation Range of Volatile Organic Liquids, Approved May 15, 2005, IBR approved for Appendix B to § 1910.1200.

(23) ASTM D 1692–68, Test for Flammability of Plastic Sheeting and Cellular Plastics, IBR approved for § 1910.103.

(24) ASTM D 2161–66, Conversion Tables for SUS, IBR approved for § 1910.106.

(25) ASTM D 3278–96 (Reapproved 2004) E1, Standard Test Methods for Flash Point of Liquids by Small Scale Closed-Cup Apparatus, Approved November 1, 2004, IBR approved for Appendix B to § 1910.1200.

(26) ASTM D 3828–07a, Standard Test Methods for Flash Point by Small Scale Closed Cup Tester, Approved July 15, 2007, IBR approved for Appendix B to § 1910.1200.

(27) ASTM F–2412–2005, Standard Test Methods for Foot Protection, IBR approved for § 1910.136.

(28) ASTM F–2413–2005, Standard Specification for Performance Requirements for Protective Footwear, IBR approved for § 1910.136.

Subpart H—[Amended]

■ 3. The authority citation for subpart H is revised to read as follows:

Authority: Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), or 5–2007 (72 FR 31159), 4–2010 (75 FR 55355) or 1–2012 (77 FR 3912), as applicable; and 29 CFR part 1911.

Sections 1910.103, 1910.106 through 1910.111, and 1910.119, 1910.120, and 1910.122 through 1910.126 also issued under 29 CFR part 1911.

Section 1910.119 also issued under Section 304, Clean Air Act Amendments of 1990 (Pub. L. 101–549), reprinted at 29 U.S.C.A. 655 Note.

Section 1910.120 also issued under Section 126, Superfund Amendments and Reauthorization Act of 1986 as amended (29 U.S.C.A. 655 Note), and 5 U.S.C. 553.

■ 4. Amend § 1910.106 as follows:

■ A. Revise the section heading;

■ B. Revise paragraphs (a)(13), (a)(14)(i) through (a)(14)(iii), and (a)(19);

■ C. Remove the last sentence of paragraph (a)(17);

■ D. Remove and reserve paragraph (a)(18);

■ E. Remove the words ''or combustible'' wherever they appear in § 1910.106.

■ F. Remove the words ''and combustible'' in paragraphs (d)(5)(vi) introductory text, (e)(2) introductory text, (j)(1) and (j)(3);

■ G. Revise paragraphs (b)(2)(iv)(*f*) and (*g*), (b)(2)(vi)(*b*), (b)(2)(viii)(*e*), (b)(3)(i), (b)(3)(iv)(*a*), (b)(3)(iv)(*c*), (b)(3)(v)(*d*), and (b)(4)(iv)(*e*);

■ H. Revise paragraphs (d)(1)(ii)(*b*), (d)(2)(iii) introductory text and (d)(2)(iii)(*a*)(*2*), Table H–12, paragraphs (d)(3)(i), (d)(4)(iii), (d)(4)(iv), Tables H–14 through H–17, and paragraph (d)(7)(i)(*b*);

■ I. Revise paragraphs (e)(2)(ii)(*b*)(*1*), (e)(2)(ii)(*b*)(*2*), (e)(2)(ii)(*b*)(*3*), (e)(2)(iv)(*a*), (e)(2)(iv)(*c*), (e)(3)(v)(*a*), (e)(3)(v)(*b*), (e)(4)(i), (e)(6)(ii), and (e)(7)(i)(*c*);

■ J. Revise paragraphs (f)(1)(i), (f)(1)(ii), (f)(2)(ii), (f)(2)(iii)(*a*), (f)(2)(iii)(*b*), (f)(2)(iii)(*c*), (f)(3)(i), (f)(3)(ii), (f)(3)(iv)(*a*)(*1*), (f)(3)(iv)(*a*)(*2*), (f)(3)(iv)(*d*)(*2*), (f)(3)(v), (f)(3)(vi), (f)(4)(viii)(*e*), (f)(5)(i), (f)(6), and (f)(8);

■ K. Revise paragraphs (g)(1)(i)(*c*), (g)(1)(i)(*e*) introductory text, (g)(1)(i)(*f*), (g)(1)(iii)(*a*), (g)(1)(iii)(*b*), (g)(1)(iii)(*c*), (g)(1)(v), (g)(3)(iv)(*a*), (g)(3)(iv)(*b*),

(g)(3)(iv)(*c*), (g)(3)(v)(*a*), (g)(3)(vi)(*a*), Table H–19, and paragraphs (g)(4)(iii)(*d*), (g)(5)(i), (g)(6)(iv), and (g)(7); and

■ L. Revise paragraphs (h)(3)(i)(*a*), (h)(3)(iii)(*b*), (h)(3)(iv), (h)(5), (h)(7)(i)(*b*), (h)(7)(iii)(*c*), and (j).

The revisions read as follows:

§ 1910.106 Flammable liquids.

* * * * *

(a) * * *

(13) Flammable aerosol shall mean a flammable aerosol as defined by Appendix B to § 1910.1200—Physical Hazard Criteria. For the purposes of paragraph (d) of this section, such aerosols are considered Category 1 flammable liquids.

(14) * * *

(i) For a liquid which has a viscosity of less than 45 SUS at 100 °F (37.8 °C), does not contain suspended solids, and does not have a tendency to form a surface film while under test, the procedure specified in the Standard Method of Test for Flashpoint by Tag Closed Tester (ASTM D–56–70), which is incorporated by reference as specified in § 1910.6, or an equivalent test method as defined in Appendix B to § 1910.1200—Physical Hazard Criteria, shall be used.

(ii) For a liquid which has a viscosity of 45 SUS or more at 100 °F (37.8 °C), or contains suspended solids, or has a tendency to form a surface film while under test, the Standard Method of Test for Flashpoint by Pensky-Martens Closed Tester (ASTM D–93–71) or an equivalent method as defined by Appendix B to § 1910.1200—Physical Hazard Criteria, shall be used except that the methods specified in Note 1 to section 1.1 of ASTM D–93–71 may be used for the respective materials specified in the Note. The preceding ASTM standard is incorporated by reference as specified in § 1910.6.

(iii) For a liquid that is a mixture of compounds that have different volatilities and flashpoints, its flashpoint shall be determined by using the procedure specified in paragraph (a)(14)(i) or (ii) of this section on the liquid in the form it is shipped.

* * * * *

(18) [Reserved]

(19) *Flammable liquid* means any liquid having a flashpoint at or below 199.4 °F (93 °C). Flammable liquids are divided into four categories as follows:

(i) Category 1 shall include liquids having flashpoints below 73.4 °F (23 °C) and having a boiling point at or below 95 °F (35 °C).

(ii) Category 2 shall include liquids having flashpoints below 73.4 °F (23 °C) and having a boiling point above 95 °F (35 °C).

(iii) Category 3 shall include liquids having flashpoints at or above 73.4 °F (23 °C) and at or below 140 °F (60 °C). When a Category 3 liquid with a flashpoint at or above 100 °F (37.8 °C) is heated for use to within 30 °F (16.7 °C) of its flashpoint, it shall be handled in accordance with the requirements for a Category 3 liquid with a flashpoint below 100 °F (37.8 °C).

(iv) Category 4 shall include liquids having flashpoints above 140 °F (60 °C) and at or below 199.4 °F (93 °C). When a Category 4 flammable liquid is heated for use to within 30 °F (16.7 °C) of its flashpoint, it shall be handled in accordance with the requirements for a Category 3 liquid with a flashpoint at or above 100 °F (37.8 °C).

(v) When liquid with a flashpoint greater than 199.4 °F (93 °C) is heated for use to within 30 °F (16.7 °C) of its flashpoint, it shall be handled in accordance with the requirements for a Category 4 flammable liquid.

* * * * *

(b) * * *

(2) * * *

(iv) * * *

(*f*)*(1)* Tanks and pressure vessels storing Category 1 flammable liquids shall be equipped with venting devices which shall be normally closed except when venting to pressure or vacuum conditions. Tanks and pressure vessels storing Category 2 flammable liquids and Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C) shall be equipped with venting devices which shall be normally closed except when venting under pressure or vacuum conditions, or with approved flame arresters.

(2) Exemption: Tanks of 3,000 bbls (barrels). capacity or less containing crude petroleum in crude-producing areas and outside aboveground atmospheric tanks under 1,000 gallons capacity containing other than Category 1 flammable liquids may have open vents. (*See* paragraph (b)(2)(vi)(*b*) of this section.)

(*g*) Flame arresters or venting devices required in paragraph (b)(2)(iv)(*f*) of this section may be omitted for Category 2 flammable liquids and Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C) where conditions are such that their use may, in case of obstruction, result in tank damage.

* * * * *

(vi) * * *

(b) Where vent pipe outlets for tanks storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are adjacent to buildings or public ways, they shall be located so that the vapors are released at a safe point outside of buildings and not less than 12 feet above the adjacent ground level. In order to aid their dispersion, vapors shall be discharged upward or horizontally away from closely adjacent walls. Vent outlets shall be located so that flammable vapors will not be trapped by eaves or other obstructions and shall be at least five feet from building openings.

* * * * *

(viii) * * *

(e) For Category 2 flammable liquids and Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasolines, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity. A fill pipe entering the top of a tank shall terminate within 6 inches of the bottom of the tank and shall be installed to avoid excessive vibration.

* * * * *

(3) * * *

(i) *Location.* Excavation for underground storage tanks shall be made with due care to avoid undermining of foundations of existing structures. Underground tanks or tanks under buildings shall be so located with respect to existing building foundations and supports that the loads carried by the latter cannot be transmitted to the tank. The distance from any part of a tank storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), to the nearest wall of any basement or pit shall be not less than 1 foot, and to any property line that may be built upon, not less than 3 feet. The distance from any part of a tank storing Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids to the nearest wall of any basement, pit or property line shall be not less than 1 foot.

* * * * *

(iv) * * *

(a) Location and arrangement of vents for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C). Vent pipes from tanks storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be so located that the discharge point is outside of buildings, higher than the fill pipe opening, and not less than 12 feet above the adjacent ground level. Vent pipes shall discharge only upward in order to disperse vapors. Vent pipes 2 inches or less in nominal inside

diameter shall not be obstructed by devices that will cause excessive back pressure. Vent pipe outlets shall be so located that flammable vapors will not enter building openings, or be trapped under eaves or other obstructions. If the vent pipe is less than 10 feet in length, or greater than 2 inches in nominal inside diameter, the outlet shall be provided with a vacuum and pressure relief device or there shall be an approved flame arrester located in the vent line at the outlet or within the approved distance from the outlet.

* * * * *

(*c*) Location and arrangement of vents for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids. Vent pipes from tanks storing Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids shall terminate outside of the building and higher than the fill pipe opening. Vent outlets shall be above normal snow level. They may be fitted with return bends, coarse screens or other devices to minimize ingress of foreign material.

* * * * *

(v) * * *

(*d*) For Category 2 flammable liquids and Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasolines, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity by terminating within 6 inches of the bottom of the tank.

* * * * *

(4) * * *

(iv) * * *

(*e*) For Category 2 flammable liquids and Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasoline, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity by terminating within 6 inches of the bottom of the tank.

* * * * *

(d) * * *

(1) * * *

(ii) * * *

(*b*) Category 1, 2, or 3 flammable liquids in the fuel tanks of a motor vehicle, aircraft, boat, or portable or stationary engine;

* * * * *

(2) * * *

(iii) *Size.* Flammable liquid containers shall be in accordance with Table H–12, except that glass or plastic containers of no more than 1-gallon capacity may be used for a Category 1 or 2 flammable liquid if:

(*a*) * * *

(*2*) The user's process either would require more than 1 pint of a Category 1 flammable liquid or more than 1 quart of a Category 2 flammable liquid of a single assay lot to be used at one time, or would require the maintenance of an analytical standard liquid of a quality which is not met by the specified standards of liquids available, and the quantity of the analytical standard liquid required to be used in any one control process exceeds one-sixteenth the capacity of the container allowed under Table H–12 for the category of liquid; or

* * * * *

TABLE H–12—MAXIMUM ALLOWABLE SIZE OF CONTAINERS AND PORTABLE TANKS FOR FLAMMABLE LIQUIDS

Container type	Category 1	Category 2	Category 3	Category 4
Glass or approved plastic	1 pt	1 qt	1 gal	1 gal.
Metal (other than DOT drums)	1 gal	5 gal	5 gal	5 gal.
Safety cans	2 gal	5 gal	5 gal	5 gal.
Metal drums (DOT specifications)	60 gal	60 gal	60 gal	60 gal.
Approved portable tanks	660 gal	660 gal	660 gal	660 gal.

Note: Container exemptions: (a) Medicines, beverages, foodstuffs, cosmetics, and other common consumer items, when packaged according to commonly accepted practices, shall be exempt from the requirements of 1910.106(d)(2)(i) and (ii).

(3) * * *

(i) *Maximum capacity.* Not more than 60 gallons of Category 1, 2, or 3 flammable liquids, nor more than 120 gallons of Category 4 flammable liquids may be stored in a storage cabinet.

* * * * *

(4) * * *

(iii) *Wiring.* Electrical wiring and equipment located in inside storage rooms used for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be approved under subpart S of this part for Class I, Division 2 Hazardous Locations; for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids, shall be approved for general use.

(iv) *Ventilation.* Every inside storage room shall be provided with either a gravity or a mechanical exhaust ventilation system. Such system shall be designed to provide for a complete change of air within the room at least six times per hour. If a mechanical exhaust system is used, it shall be controlled by a switch located outside of the door. The ventilating equipment and any lighting fixtures shall be operated by the same switch. A pilot light shall be installed adjacent to the switch if Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are dispensed within the room. Where gravity ventilation is provided, the fresh air intake, as well as the exhaust outlet from the room, shall be on the exterior of the building in which the room is located.

* * * * *

BILLING CODE 4510–26–P

TABLE H-14 - INDOOR CONTAINER STORAGE

Category liquid	Storage level	Gallons	
		Protected storage maximum per pile	Unprotected storage maximum per pile
1	Ground and upper floors.....	2,750	660
		(50)	(12)
	Basement.....	Not permitted	Not permitted
2	Ground and upper floors.....	5,500	1,375
		(100)	(25)
	Basement.....	Not permitted	Not permitted
3 ..... FP<100F	Ground and upper floors.....	16,500	4,125
		(300)	(75)
	Basement.....	Not permitted	Not permitted
3 .... FP≥100F	Ground and upper floors.....	16,500	4,125
		(300)	(75)
	Basement.....	5,500	Not permitted
		(100)	
4 ...	Ground and upper floors.....	55,000	13,750
		(1,000)	(250)
	Basement.....	8,250	Not permitted
		(450)	

NOTE 1: When 2 or more categories of materials are stored in a single pile, the maximum gallonage permitted in that pile shall be the smallest of the 2 or more separate maximum gallonages.

NOTE 2: Aisles shall be provided so that no container is more than 12 ft. from an aisle. Main aisles shall be at least 3 ft. wide and side aisles at least 4 ft. wide.

NOTE 3: Each pile shall be separated from each other by at least 4 ft.

NOTE 4: FP means Flashpoint.

(Number in parenthesis indicate corresponding number of 55-gal. drums.)

TABLE H-15 - INDOOR PORTABLE TANK STORAGE

Category	Storage level	Gallons	
		Protected storage maximum per pile	Unprotected storage maximum per pile
1	Ground and upper floors	Not permitted	Not permitted
	Basement	Not permitted	Not permitted
2	Ground and upper floors	20,000	2,000
	Basement	Not permitted	Not permitted
3 FP<100F	Ground and upper floors	40,000	5,500
	Basement	Not permitted	Not permitted
3 FP≥100F	Ground and upper floors	40,000	5,500
	Basement	20,000	Not permitted
4	Ground and upper floors	60,000	22,000
	Basement	20,000	Not permitted

NOTE 1: When 1 or more categories of materials are stored in a single pile, the maximum gallonage permitted in that pile shall be the smallest of the 2 or more separate maximum gallonages.

NOTE 2: Aisles shall be provided so that no portable tank is more than 12 ft. from an aisle. Main aisles shall be at least 8 ft. wide and side aisles at least 4 ft. wide.

NOTE 3: Each pile shall be separated from each other by at least 4 ft.

NOTE 4: FP means Flashpoint.

TABLE H-16 - OUTDOOR CONTAINER STORAGE

1-Category	2-Maximum per pile	3-Distance between piles	4-Distance to property line that can be built upon	5-Distance to street, alley, public way
	gallons	feet	feet	feet
1	1,100	5	20	10
2	2,200	5	20	10
3 FP<100F.	4,400	5	20	10
3 FP≥100F.	8,800	5	10	5
4	22,000	5	10	5

NOTE 1: When 2 or more categories of materials are stored in a single pile, the maximum gallonage in that pile shall be the smallest of the 2 or more separate gallonages.

NOTE 2: Within 200 ft. of each container, there shall be a 12 ft. wide access way to permit approach of fire control apparatus.

NOTE 3: The distances listed apply to properties that have protection for exposures as defined. If there are exposures, and such protection for exposures does not exist, the distances in column 4 shall be doubled.

NOTE 4: When total quantity stored does not exceed 50 percent of maximum per pile, the distances in columns 4 and 5 may be reduced 50 percent, but not less than 3 ft.

NOTE 5: FP means flashpoint.

TABLE H-17 - OUTDOOR PORTABLE TANK STORAGE

1-Category	2-Maximum per pile	3-Distance between piles	4-Distance to property line that can be built upon	5-Distance to street, alley, public way
	gallons	feet	feet	feet
1	2,200	5	20	10
2	4,400	5	20	10
3 FP<100F.	8,800	5	20	10
3 FP≥100F.	17,600	5	10	5
4	44,000	5	10	5

NOTE 1: When 2 or more categories of materials are stored in a single pile, the maximum gallonage in that pile shall be the smallest of the 2 or more separate gallonages.

NOTE 2: Within 200 ft. of each portable tank, there shall be a 12 ft. wide access way to permit approach of fire control apparatus.

NOTE 3: The distances listed apply to properties that have protection for exposures as defined. If there are exposures, and such protection for exposures does not exist, the distances in column 4 shall be doubled.

NOTE 4: When total quantity stored does not exceed 50 percent of maximum per pile, the distances in columns 4 and 5 may be reduced 50 percent, but not less than 3 ft.

NOTE 5: FP means flashpoint.

BILLING CODE 4510–26–C

(7) * * *

(i) * * *

(*b*) At least one portable fire extinguisher having a rating of not less than 12–B units must be located not less than 10 feet, nor more than 25 feet, from any Category 1, 2, or 3 flammable liquid storage area located outside of a storage room but inside a building.

* * * * *

(e) * * *

(2) * * *

(ii) * * *

(*b*) * * *

(*1*) 25 gallons of Category 1 flammable liquids in containers

(*2*) 120 gallons of Category 2, 3, or 4 flammable liquids in containers

(*3*) 660 gallons of Category 2, 3, or 4 flammable liquids in a single portable tank.

* * * * *

(iv) * * *

(*a*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be kept in covered containers when not actually in use.

* * * * *

(*c*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), may be used only where there are no open flames or other sources of ignition within the possible path of vapor travel.

* * * * *

(3) * * *

(v) * * *

(*a*) Areas as defined in paragraph (e)(3)(i) of this section using Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be ventilated at a rate of not less than 1 cubic foot per minute per square foot of solid floor area. This shall be accomplished by natural or mechanical ventilation with discharge or exhaust to a safe location outside of the building. Provision shall be made for introduction of makeup air in such a manner as not to short circuit the ventilation. Ventilation shall be arranged to include all floor areas or pits where flammable vapors may collect.

(*b*) Equipment used in a building and the ventilation of the building shall be designed so as to limit flammable vapor-air mixtures under normal operating conditions to the interior of equipment, and to not more than 5 feet from equipment which exposes Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), to the air. Examples of such equipment are dispensing stations, open centrifuges, plate and frame filters, open vacuum filters, and surfaces of open equipment.

* * * * *

(4) * * *

(i) Tank vehicle and tank car loading or unloading facilities shall be separated from aboveground tanks, warehouses, other plant buildings or nearest line of adjoining property which may be built upon by a distance of 25 feet for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), and 15 feet for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids, measured from the nearest

position of any fill stem. Buildings for pumps or shelters for personnel may be a part of the facility. Operations of the facility shall comply with the appropriate portions of paragraph (f)(3) of this section.

* * * * *

(6) * * *

(ii) *Grounding.* Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be dispensed into containers unless the nozzle and container are electrically interconnected. Where the metallic floorplate on which the container stands while filling is electrically connected to the fill stem or where the fill stem is bonded to the container during filling operations by means of a bond wire, the provisions of this section shall be deemed to have been complied with.

(7) * * *

(i) * * *

(*c*) Locations where flammable vapor-air mixtures may exist under abnormal conditions and for a distance beyond Division 1 locations shall be classified Division 2 according to the requirements of subpart S of this part. These locations include an area within 20 feet horizontally, 3 feet vertically beyond a Division 1 area, and up to 3 feet above floor or grade level within 25 feet, if indoors, or 10 feet if outdoors, from any pump, bleeder, withdrawal fitting, meter, or similar device handling Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C). Pits provided with adequate mechanical ventilation within a Division 1 or 2 area shall be classified Division 2. If only Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids are handled, then ordinary electrical equipment is satisfactory though care shall be used in locating electrical apparatus to prevent hot metal from falling into open equipment.

* * * * *

(f) * * *

(1) * * *

(i) *Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C).* Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be stored in closed containers, or in storage tanks above ground outside of buildings, or underground in accordance with paragraph (b) of this section.

(ii) *Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids.* Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids shall be stored in containers, or in tanks within buildings or above ground outside of buildings, or underground in accordance with paragraph (b) of this section.

* * * * *

(2) * * *

(ii) *Heating.* Rooms in which Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are stored or handled shall be heated only by means not constituting a source of ignition, such as steam or hot water. Rooms containing heating appliances involving sources of ignition shall be located and arranged to prevent entry of flammable vapors.

(iii) * * *

(*a*) Ventilation shall be provided for all rooms, buildings, or enclosures in which Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are pumped or dispensed. Design of ventilation systems shall take into account the relatively high specific gravity of the vapors. Ventilation may be provided by adequate openings in outside walls at floor level unobstructed except by louvers or coarse screens. Where natural ventilation is inadequate, mechanical ventilation shall be provided.

(*b*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be stored or handled within a building having a basement or pit into which flammable vapors may travel, unless such area is provided with ventilation designed to prevent the accumulation of flammable vapors therein.

(*c*) Containers of Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be drawn from or filled within buildings unless provision is made to prevent the accumulation of flammable vapors in hazardous concentrations. Where mechanical ventilation is required, it shall be kept in operation while flammable liquids with a flashpoint below 100 °F (37.8 °C) are being handled.

(3) * * *

(i) *Separation.* Tank vehicle and tank car loading or unloading facilities shall be separated from aboveground tanks, warehouses, other plant buildings or nearest line of adjoining property that may be built upon by a distance of 25 feet for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), and 15 feet for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids measured from the nearest position of any fill spout. Buildings for pumps or shelters for personnel may be a part of the facility.

(ii) *Category restriction.* Equipment such as piping, pumps, and meters used for the transfer of Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), between storage tanks and the fill stem of the loading rack shall not be used for the transfer of Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids.

* * * * *

(iv) * * *

(*a*) * * *

(*1*) Where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are loaded, or

(*2*) Where Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids are loaded into vehicles which may contain vapors from previous cargoes of Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C).

* * * * *

(*d*) * * *

(*2*) Where no Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are handled at the loading facility and the tank vehicles loaded are used exclusively for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids; and

* * * * *

(v) *Stray currents.* Tank car loading facilities where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are loaded through open domes shall be protected against stray currents by bonding the pipe to at least one rail and to the rack structure if of metal. Multiple lines entering the rack area shall be electrically bonded together. In addition, in areas where excessive stray currents are known to exist, all pipe entering the rack area shall be provided with insulating sections to electrically isolate the rack piping from the pipelines. No bonding between the tank car and the rack or piping is required during either loading or unloading of Category 3 flammable liquids with a

flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids.

(vi) *Container filling facilities.* Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be dispensed into containers unless the nozzle and container are electrically interconnected. Where the metallic floorplate on which the container stands while filling is electrically connected to the fill stem or where the fill stem is bonded to the container during filling operations by means of a bond wire, the provisions of this section shall be deemed to have been complied with.

(4) * * *

(viii) * * *

(*e*) In addition to the requirements of paragraph (f)(4)(viii)(*d*) of this section, each line conveying Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), leading to a wharf shall be provided with a readily accessible block valve located on shore near the approach to the wharf and outside of any diked area. Where more than one line is involved, the valves shall be grouped in one location.

* * * * *

(5) * * *

(i) *Application.* This paragraph (f)(5)(i) shall apply to areas where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are stored or handled. For areas where only Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids are stored or handled, the electrical equipment may be installed in accordance with the provisions of Subpart S of this part, for ordinary locations.

* * * * *

(6) *Sources of ignition.* Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be handled, drawn, or dispensed where flammable vapors may reach a source of ignition. Smoking shall be prohibited except in designated localities. ''No Smoking'' signs shall be conspicuously posted where hazard from flammable liquid vapors is normally present.

* * * * *

(8) *Fire control.* Suitable fire-control devices, such as small hose or portable fire extinguishers, shall be available to locations where fires are likely to occur. Additional fire-control equipment may be required where a tank of more than 50,000 gallons individual capacity contains Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), and where an unusual exposure hazard exists from surrounding property. Such additional fire-control equipment shall be sufficient to extinguish a fire in the largest tank. The design and amount of such equipment shall be in accordance with approved engineering standards.

* * * * *

(g) * * *

(1) * * *

(i) * * *

(*c*) Apparatus dispensing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), into the fuel tanks of motor vehicles of the public shall not be located at a bulk plant unless separated by a fence or similar barrier from the area in which bulk operations are conducted.

* * * * *

(*e*) The provisions of paragraph (g)(1)(i)(*a*) of this section shall not prohibit the dispensing of flammable liquids with a flashpoint below 100 °F (37.8 °C) in the open from a tank vehicle to a motor vehicle. Such dispensing shall be permitted provided:

* * * * *

(*f*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be stored or handled within a building having a basement or pit into which flammable vapors may travel, unless such area is provided with ventilation designed to prevent the accumulation of flammable vapors therein.

* * * * *

(iii) * * *

(*a*) Except where stored in tanks as provided in paragraph (g)(1)(ii) of this section, no Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be stored within any service station building except in closed containers of aggregate capacity not exceeding 60 gallons. One container not exceeding 60 gallons capacity equipped with an approved pump is permitted.

(*b*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), may be transferred from one container to another in lubrication or service rooms of a service station building provided the electrical installation complies with Table H–19 and provided that any heating equipment complies with paragraph (g)(6) of this section.

(*c*) Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids may be stored and dispensed inside service station buildings from tanks of not more than 120 gallons capacity each.

* * * * *

(v) *Dispensing into portable containers.* No delivery of any Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be made into portable containers unless the container is constructed of metal, has a tight closure with screwed or spring cover, and is fitted with a spout or so designed so the contents can be poured without spilling.

* * * * *

(3) * * *

(iv) * * *

(*a*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be transferred from tanks by means of fixed pumps so designed and equipped as to allow control of the flow and to prevent leakage or accidental discharge.

(*b*)(*1*) Only listed devices may be used for dispensing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C). No such device may be used if it shows evidence of having been dismantled.

(*2*) Every dispensing device for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), installed after December 31, 1978, shall contain evidence of listing so placed that any attempt to dismantle the device will result in damage to such evidence, visible without disassembly or dismounting of the nozzle.

(*c*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be dispensed by pressure from drums, barrels, and similar containers. Approved pumps taking suction through the top of the container or approved self-closing faucets shall be used.

* * * * *

(v) * * *

(*a*) This paragraph (g)(3)(v) shall apply to systems for dispensing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), where such liquids are transferred from storage to individual or multiple dispensing units by pumps located elsewhere than at the dispensing units.

* * * * *

(vi) * * *

(*a*) A listed manual or automatic-closing type hose nozzle valve shall be provided on dispensers used for the dispensing of Category 1 or 2 flammable

liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C).

* * * * *

(4) * * *

(iii) * * *

BILLING CODE 4510–26–P

TABLE H-19 - ELECTRICAL EQUIPMENT HAZARDOUS AREAS - SERVICE STATIONS

Location	Class I Group D division	Extent of classified area
Underground tank:		
Fill opening.....	1	Any pit, box or space below grade level, any part of which is within the Division 1 or 2 classified area.
	2	Up to 18 inches above grade level within a horizontal radius of 10 feet from a loose fill connection and within a horizontal radius of 5 feet from a tight fill connection.
Vent-Discharging Upward.	1	Within 3 feet of open end of vent, extending in all directions.
	2	Area between 3 feet and 5 feet of open end of vent, extending in all directions.
Dispenser:		
Pits	1	Any pit, box or space below grade level, any part of which is within the Division 1 or 2 classified area.
Dispenser enclosure ..	1	The area 4 feet vertically above base within the enclosure and 18 inches horizontally in all directions.
Outdoor	2	Up to 18 inches above grade level within 20 feet horizontally of any edge of enclosure.
Indoor:		
With mechanical ventilation	2	Up to 18 inches above grade or floor level within 20 feet horizontally of any edge of enclosure.
With gravity ventilation	2	Up to 18 inches above grade or floor level within 25 feet horizontally of any edge of enclosure.

Remote pump - Outdoor.	1	Any pit, box or space below grade level if any part is within a horizontal distance of 10 feet from any edge of the pump.
	2	Within 3 feet of any edge of the pump, extending in all directions. Also up to 18 inches above grade level within 10 feet horizontally from any edge of the pump.
Remote pump - Indoor..	1	Entire area within any pit.
	2	Within 5 feet of any edge of pump, extending in all directions. Also up to 3 feet above floor or grade level within 25 feet horizontally from any edge of pump.
Lubrication or service room	1	Entire area within any pit.
	2	Area up to 18 inches above floor or grade level within entire lubrication room.
Dispenser for Liquids with a flashpoint below 100 ^{0}F (37.8 ^{o}C)(1).....	2	Within 3 feet of any fill or dispensing point, extending in all directions.
Special enclosure inside building per 1910.106(f)(1)(ii).	1	Entire enclosure.
Sales, storage and rest rooms.....	(2)	If there is any opening to these rooms within the extent of a Division 1 area, the entire room shall be classified as Division 1.

Footnote (1) Category 1 or 2 flammable liquids, or for Category 3 flammable liquids with a flashpoint below 100 ^{0}F (37.8 ^{0}C).
Footnote(2) Ordinary

BILLING CODE 4510–26–C

(*d*) Piping handling Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be grounded to control stray currents.

(5) * * *

(i) *Application.* This paragraph (g)(5) shall apply to areas where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are stored or handled. For areas where Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids are stored or handled the electrical equipment may be installed in accordance with the provisions of subpart S of this part, for ordinary locations.

* * * * *

(6) * * *

(iv) *Work areas.* Heating equipment using gas or oil fuel may be installed in the lubrication, sales, or service room where there is no dispensing or transferring of Category 1 or 2 flammable liquids or 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), provided the bottom of the combustion chamber is at least 18 inches above the floor and the heating equipment is protected from physical damage by vehicles. Heating equipment using gas or oil fuel listed for use in garages may be installed in the lubrication or service room where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are dispensed provided the equipment is installed at least 8 feet above the floor.

* * * * *

(7) *Drainage and waste disposal.* Provision shall be made in the area where Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are dispensed to prevent spilled liquids from flowing into the interior of service station buildings. Such provision may be by grading driveways, raising door sills, or other equally effective means. Crankcase drainings and flammable liquids shall not be dumped into sewers but shall be stored in tanks or drums

outside of any building until removed from the premises.

* * * * *

(h) * * *

(3) * * *

(i) * * *

(*a*) Processing buildings shall be of fire-resistance or noncombustible construction, except heavy timber construction with load-bearing walls may be permitted for plants utilizing only stable Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids. Except as provided in paragraph (h)(2)(ii) of this section or in the case of explosion resistant walls used in conjunction with explosion relieving facilities, see paragraph (h)(3)(iv) of this section, load-bearing walls are prohibited. Buildings shall be without basements or covered pits.

* * * * *

(iii) * * *

(*b*) Equipment used in a building and the ventilation of the building shall be designed so as to limit flammable vapor-air mixtures under normal operating conditions to the interior of equipment, and to not more than 5 feet from equipment which exposes Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), to the air. Examples of such equipment are dispensing stations, open centrifuges, plate and frame filters, open vacuum filters, and surfaces of open equipment.

(iv) *Explosion relief.* Areas where Category 1 or unstable liquids are processed shall have explosion venting through one or more of the following methods:

* * * * *

(5) *Tank vehicle and tank car loading and unloading.* Tank vehicle and tank car loading or unloading facilities shall be separated from aboveground tanks, warehouses, other plant buildings, or nearest line of adjoining property which may be built upon by a distance of 25 feet for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), and 15 feet for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) and Category 4 flammable liquids measured from the nearest position of any fill stem. Buildings for pumps or shelters for personnel may be a part of the facility. Operations of the facility shall comply with the appropriate portions of paragraph (f)(3) of this section.

* * * * *

(7) * * *

(i) * * *

(*b*) Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall not be dispensed into containers unless the nozzle and container are electrically interconnected. Where the metallic floorplate on which the container stands while filling is electrically connected to the fill stem or where the fill stem is bonded to the container during filling operations by means of a bond wire, the provisions of this section shall be deemed to have been complied with.

* * * * *

(iii) * * *

(*c*) Locations where flammable vapor-air mixtures may exist under abnormal conditions and for a distance beyond Division 1 locations shall be classified Division 2 according to the requirements of subpart S of this part. These locations include an area within 20 feet horizontally, 3 feet vertically beyond a Division 1 area, and up to 3 feet above floor or grade level within 25 feet, if indoors, or 10 feet if outdoors, from any pump, bleeder, withdrawal fitting, meter, or similar device handling Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C). Pits provided with adequate mechanical ventilation within a Division 1 or 2 area shall be classified Division 2. If Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids only are handled, then ordinary electrical equipment is satisfactory though care shall be used in locating electrical apparatus to prevent hot metal from falling into open equipment.

* * * * *

(j) *Scope.* This section applies to the handling, storage, and use of flammable liquids with a flashpoint at or below 199.4 °F (93 °C) unless otherwise noted. This section does not apply to:

* * * * *

■ 5. Amend § 1910.107 as follows:

■ A. Amend paragraphs (c)(9)(i), (e)(1), (e)(2), (e)(3), (e)(6)(iv), (e)(8), and (e)(9) by removing the terms ''flammable or combustible liquids'' wherever it appears and adding in its place the phrase ''flammable liquids or liquids with a flashpoint greater than 199.4 °F (93 °C)''; and

■ B. Revise the heading of paragraph (e), and (e)(4) to read as follows:

§ 1910.107 Spray finishing using flammable and combustible materials.

* * * * *

(e) *Flammable liquids and liquids with a flashpoint greater than 199.4 °F (93 °C)*

* * * * *

(4) *Transferring liquids.* Except as provided in paragraph (e)(5) of this section the withdrawal of flammable liquids and liquids with a flashpoint greater than 199.4 °F (93 °C) from containers having a capacity of greater than 60 gallons shall be by approved pumps. The withdrawal of flammable liquids or liquids with a flashpoint greater than 199.4 °F (93 °C) from containers and the filling of containers, including portable mixing tanks, shall be done only in a suitable mixing room or in a spraying area when the ventilating system is in operation. Adequate precautions shall be taken to protect against liquid spillage and sources of ignition.

* * * * *

■ 6. Amend § 1910.119 to revise paragraphs (a)(1)(ii) introductory text, (a)(1)(ii)(B) and the definition of ''Trade secret'' in paragraph (b) to read as follows:

§ 1910.119 Process safety management of highly hazardous chemicals.

* * * * *

(a) * * *

(1) * * *

(ii) A process which involves a Category 1 flammable gas (as defined in 1910.1200(c)) or a flammable liquid with a flashpoint below 100 °F (37.8 °C) on site in one location, in a quantity of 10,000 pounds (4535.9 kg) or more except for:

* * * * *

(B) Flammable liquids with a flashpoint below 100 °F (37.8 °C) stored in atmospheric tanks or transferred which are kept below their normal boiling point without benefit of chilling or refrigeration.

* * * * *

(b) * * *

Trade secret means any confidential formula, pattern, process, device, information or compilation of information that is used in an employer's business, and that gives the employer an opportunity to obtain an advantage over competitors who do not know or use it. *See* Appendix E to § 1910.1200—Definition of a Trade Secret (which sets out the criteria to be used in evaluating trade secrets).

* * * * *

■ 7. In § 1910.120, revise the definition of the term *Health hazard* in paragraph (a)(3) to read as follows:

§ 1910.120 Hazardous waste operations and emergency response.

(a) * * *

(3) * * *

Health hazard means a chemical or a pathogen where acute or chronic health

effects may occur in exposed employees. It also includes stress due to temperature extremes. The term *health hazard* includes chemicals that are classified in accordance with the Hazard Communication Standard, 29 CFR 1910.1200, as posing one of the following hazardous effects: Acute toxicity (any route of exposure); skin corrosion or irritation; serious eye damage or eye irritation; respiratory or skin sensitization; germ cell mutagenicity; carcinogenicity; reproductive toxicity; specific target organ toxicity (single or repeated exposure); aspiration toxicity or simple asphyxiant. (*See* Appendix A to § 1910.1200—Health Hazard Criteria (Mandatory) for the criteria for determining whether a chemical is classified as a health hazard.)

* * * * *

■ 8. Amend paragraph (d) of § 1910.123 by removing the definition of ''Combustible liquid'' and revising the definitions of the terms ''Flammable liquid'' and ''Flashpoint'' to read as follows:

§ 1910.123 Dipping and coating operations: Coverage and definitions.

* * * * *

(d) * * *

Flammable liquid means any liquid having a flashpoint at or below 199.4 °F (93 °C).

Flashpoint means the minimum temperature at which a liquid gives off a vapor in sufficient concentration to ignite if tested in accordance with the test methods in Appendix B to § 1910.1200—Physical Hazard Criteria.

* * * * *

■ 9. In § 1910.124, revise paragraph (c)(2) introductory text to read as follows:

§ 1910.124 General requirements for dipping and coating operations.

* * * * *

(c) * * *

(2) You must ensure that any exhaust air re-circulated from a dipping or coating operation using flammable liquids or liquids with flashpoints greater than 199.4 °F (93 °C) is:

* * * * *

■ 10. Amend § 1910.125 by revising the section heading and the introductory text (including the table) to read as follows:

§ 1910.125 Additional requirements for dipping and coating operations that use flammable liquids or liquids with flashpoints greater than 199.4 °F (93 °C).

If you use flammable liquids, you must comply with the requirements of this section as well as the requirements of §§ 1910.123, 1910.124, and 1910.126, as applicable.

You must also comply with this section if:	And:
• The flashpoint of the liquid is 199.4 °F (93 °C) or above	• The liquid is heated as part of the operation; or • A heated object is placed in the liquid.

■ 11. Amend the introductory text of paragraph (c) of § 1910.126 by removing the words ''or combustible''.

Subpart Q—[Amended]

■ 12. The authority citation for subpart Q continues to read as follows:

Authority: Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, and 657); Secretary of Labor's Orders Nos. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355), or 1–2012 (77 FR 3912), as applicable; and 29 CFR part 1911.

■ 13. Amend § 1910.252 as follows;
■ A. Revise paragraph (c)(1)(iv);
■ B. Add new paragraphs (c)(1)(v) and (c)(1)(vi).

§ 1910.252 General requirements.

* * * * *

(c) * * *

(1) * * *

(iv) *Hazard communication.* The employer shall include the potentially hazardous materials employed in fluxes, coatings, coverings, and filler metals, all of which are potentially used in welding and cutting, or are released to the atmosphere during welding and cutting, in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of such materials and safety data sheets, and is trained in accordance with the provisions of § 1910.1200. Potentially hazardous materials shall include but not be limited to the materials itemized in paragraphs (c)(5) through (c)(12) of this section.

(v) *Additional considerations for hazard communication in welding, cutting, and brazing.* (A) The suppliers shall determine and shall label in accordance with § 1910.1200 any hazards associated with the use of their materials in welding, cutting, and brazing.

(B) In addition to any requirements imposed by § 1910.1200, all filler metals and fusible granular materials shall carry the following notice, as a minimum, on tags, boxes, or other containers:

Do not use in areas without adequate ventilation. *See* ANSI Z49.1–1967 Safety in Welding, Cutting, and Allied Processes published by the American Welding Society.

(C) Where brazing (welding) filler metals contain cadmium in significant amounts, the labels shall indicate the hazards associated with cadmium including cancer, lung and kidney effects, and acute toxicity effects.

(D) Where brazing and gas welding fluxes contain fluorine compounds, the labels shall indicate the hazards associated with fluorine compounds including eye and respiratory tract effects.

(vi) Prior to June 1, 2015, employers may include the following information on labels in lieu of the labeling requirements in paragraph (c)(1)(v) of this section:

(A) All filler metals and fusible granular materials shall carry the following notice, as a minimum, on tags, boxes, or other containers:

CAUTION

Welding may produce fumes and gases hazardous to health. Avoid breathing these fumes and gases. Use adequate ventilation. *See* ANSI Z49.1–1967 Safety in Welding and Cutting published by the American Welding Society.

(B) Brazing (welding) filler metals containing cadmium in significant amounts shall carry the following notice on tags, boxes, or other containers:

WARNING
CONTAINS CADMIUM—POISONOUS FUMES MAY BE FORMED ON HEATING

Do not breathe fumes. Use only with adequate ventilation such as fume collectors, exhaust ventilators, or air-supplied respirators. *See* ANSI Z49.1–1967. If chest pain, cough, or fever develops after use call physician immediately.

(C) Brazing and gas welding fluxes containing fluorine compounds shall have a cautionary wording to indicate that they contain fluorine compounds. One such cautionary wording recommended by the American Welding

Society for brazing and gas welding fluxes reads as follows:

CAUTION
CONTAINS FLUORIDES

This flux when heated gives off fumes that may irritate eyes, nose and throat.

1. Avoid fumes—use only in well-ventilated spaces.

2. Avoid contact of flux with eyes or skin.

3. Do not take internally.

* * * * *

Subpart Z—[Amended]

■ 14. Revise the authority citation for subpart Z to read as follows:

Authority: Sections 4, 6, 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355), or 1–2012 (77 FR 3912), as applicable; and 29 CFR part 1911.

All of subpart Z issued under section 6(b) of the Occupational Safety and Health Act of 1970, except those substances that have exposure limits listed in Tables Z–1, Z–2, and Z–3 of 29 CFR 1910.1000. The latter were issued under section 6(a) (29 U.S.C. 655(a)).

Section 1910.1000, Tables Z–1, Z–2 and Z–3 also issued under 5 U.S.C. 553, but not under 29 CFR part 1911 except for the arsenic (organic compounds), benzene, cotton dust, and chromium (VI) listings.

Section 1910.1001 also issued under section 107 of the Contract Work Hours and Safety Standards Act (40 U.S.C. 3704) and 5 U.S.C. 553.

Section 1910.1002 also issued under 5 U.S.C. 553, but not under 29 U.S.C. 655 or 29 CFR part 1911.

Sections 1910.1018, 1910.1029, and 1910.1200 also issued under 29 U.S.C. 653.

Section 1910.1030 also issued under Pub. L. 106–430, 114 Stat. 1901.

Section 1910.1201 also issued under 49 U.S.C. 1801–1819 and 5 U.S.C. 533.

■ 15. Amend § 1910.1001 as follows:

■ A. Remove paragraph (j)(5);

■ B. Redesignate paragraphs (j)(1) through (j)(4) as paragraphs (j)(2) through (j)(5);

■ C. Revise paragraphs (h)(2)(iv), (h)(3)(vi), the newly redesignated paragraphs (j)(4), (j)(5), and the introductory text of paragraph (j)(6);

■ D. Add new paragraph (j)(1);

■ E. Amend Appendix F, to § 1910.1001, Paragraph [A] (6) by removing ''(j)(4)'' and adding in its place ''(j)(5)''.

The revisions and additions read as follows:

§ 1910.1001 Asbestos.

* * * * *

(h) * * *

(2) * * *

(iv) The employer shall ensure that containers of contaminated protective devices or work clothing, which are to be taken out of change rooms or the workplace for cleaning, maintenance or disposal, bear labels in accordance with paragraph (j) of this section.

(3) * * *

(vi) The employer shall ensure that contaminated clothing is transported in sealed impermeable bags, or other closed, impermeable containers, and labeled in accordance with paragraph (j) of this section.

* * * * *

(j) * * *

(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for asbestos.

(ii) In classifying the hazards of asbestos at least the following hazards are to be addressed: Cancer and lung effects.

(iii) Employers shall include asbestos in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of asbestos and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (j)(7) of this section.

* * * * *

(4) *Warning signs*—(i) *Posting.* Warning signs shall be provided and displayed at each regulated area. In addition, warning signs shall be posted at all approaches to regulated areas so that an employee may read the signs and take necessary protective steps before entering the area.

(ii) *Sign specifications:*

(A) The warning signs required by paragraph (j)(4)(i) of this section shall bear the following legend:

DANGER
ASBESTOS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
AUTHORIZED PERSONNEL ONLY

(B) In addition, where the use of respirators and protective clothing is required in the regulated area under this section, the warning signs shall include the following:

WEAR RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING IN THIS AREA

(C) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (j)(4)(ii)(A) of this section:

DANGER
ASBESTOS
CANCER AND LUNG DISEASE HAZARD
AUTHORIZED PERSONNEL ONLY

(D) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (j)(4)(ii)(B) of this section:

RESPIRATORS AND PROTECTIVE CLOTHING ARE REQUIRED IN THIS AREA

(iii) The employer shall ensure that employees working in and contiguous to regulated areas comprehend the warning signs required to be posted by paragraph (j)(4)(i) of this section. Means to ensure employee comprehension may include the use of foreign languages, pictographs and graphics.

(iv) At the entrance to mechanical rooms/areas in which employees reasonably can be expected to enter and which contain ACM and/or PACM, the building owner shall post signs which identify the material which is present, its location, and appropriate work practices which, if followed, will ensure that ACM and/or PACM will not be disturbed. The employer shall ensure, to the extent feasible, that employees who come in contact with these signs can comprehend them. Means to ensure employee comprehension may include the use of foreign languages, pictographs, graphics, and awareness training.

(5) *Warning labels*—(i) *Labeling.* Labels shall be affixed to all raw materials, mixtures, scrap, waste, debris, and other products containing asbestos fibers, or to their containers. When a building owner or employer identifies previously installed ACM and/or PACM, labels or signs shall be affixed or posted so that employees will be notified of what materials contain ACM and/or PACM. The employer shall attach such labels in areas where they will clearly be noticed by employees who are likely to be exposed, such as at the entrance to mechanical room/areas. Signs required by paragraph (j) of this section may be posted in lieu of labels so long as they contain the information required for labeling.

(ii) *Label specifications.* In addition to the requirements of paragraph (j)(1), the employer shall ensure that labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers include the following information:

DANGER
CONTAINS ASBESTOS FIBERS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
DO NOT BREATHE DUST
AVOID CREATING DUST

(iii) Prior to June 1, 2015, employers may include the following information on raw materials, mixtures or labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers in lieu of the labeling requirements in paragraphs (j)(1)(i) and (j)(5)(ii) of this section:

DANGER
CONTAINS ASBESTOS FIBERS
AVOID CREATING DUST
CANCER AND LUNG DISEASE HAZARD

(6) The provisions for labels and for safety data sheets required by paragraph (j) of this section do not apply where:

* * * * *

■ 16. Amend § 1910.1003 as follows:
■ A. In the last sentence in paragraph (c)(4)(v) remove the words ''paragraphs (e)(2), (3), and (4)'' and add the words ''paragraph (e)'' in their place;
■ B. Revise the heading of paragraph (e);
■ C. Revise paragraphs (e)(1) and (e)(2).
■ D. Remove paragraph (e)(3); and
■ E. Redesignate paragraphs (e)(4) and (e)(5) as (e)(3) and (e)(4).

The revisions read as follows:

§ 1910.1003 13 Carcinogens (4-nitrobiphenyl, etc.).

* * * * *

(e) *Communication of hazards*—(1) *Hazard communication.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for each carcinogen listed in paragraph (e)(1)(iv) of this section.

(ii) In classifying the hazards of carcinogens listed in paragraph (e)(1)(iv) of this section, at least the hazards listed in paragraph (e)(1)(iv) are to be addressed.

(iii) Employers shall include the carcinogens listed in paragraph (e)(1)(iv) of this section in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of the carcinogens listed in paragraph (e)(1)(iv) and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (e)(4) of this section.

(iv) List of Carcinogens:

(A) 4-Nitrobiphenyl: Cancer.

(B) alpha-Naphthylamine: Cancer; skin irritation; and acute toxicity effects.

(C) Methyl chloromethyl ether: Cancer; skin, eye and respiratory effects; acute toxicity effects; and flammability.

(D) 3,3′-Dichlorobenzidine (and its salts): Cancer and skin sensitization.

(E) bis-Chloromethyl ether: Cancer; skin, eye, and respiratory tract effects; acute toxicity effects; and flammability.

(F) beta-Naphthylamine: Cancer and acute toxicity effects.

(G) Benzidine: Cancer and acute toxicity effects.

(H) 4-Aminodiphenyl: Cancer.

(I) Ethyleneimine: Cancer; mutagenicity; skin and eye effects; liver effects; kidney effects; acute toxicity effects; and flammability.

(J) beta-Propiolactone: Cancer; skin irritation; eye effects; and acute toxicity effects.

(K) 2-Acetylaminofluorene: Cancer.

(L) 4-Dimethylaminoazo-benzene: Cancer; skin effects; and respiratory tract irritation.

(M) N-Nitrosodimethylamine: Cancer; liver effects; and acute toxicity effects.

(2) *Signs.* (i) The employer shall post entrances to regulated areas with signs bearing the legend:

DANGER
(CHEMICAL IDENTIFICATION)
MAY CAUSE CANCER
AUTHORIZED PERSONNEL ONLY

(ii) The employer shall post signs at entrances to regulated areas containing operations covered in paragraph (c)(5) of this section. The signs shall bear the legend:

DANGER
(CHEMICAL IDENTIFICATION)
MAY CAUSE CANCER
WEAR AIR-SUPPLIED HOODS,
IMPERVIOUS SUITS, AND PROTECTIVE EQUIPMENT IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(iii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (e)(2)(i) of this section:

CANCER-SUSPECT AGENT
AUTHORIZED PERSONNEL ONLY

(iv) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (e)(2)(ii) of this section:

CANCER-SUSPECT AGENT EXPOSED IN THIS AREA
IMPERVIOUS SUIT INCLUDING GLOVES, BOOTS, AND AIR-SUPPLIED HOOD REQUIRED AT ALL TIMES
AUTHORIZED PERSONNEL ONLY

(v) Appropriate signs and instructions shall be posted at the entrance to, and exit from, regulated areas, informing employees of the procedures that must be followed in entering and leaving a regulated area.

* * * * *

■ 17. Revise § 1910.1017 paragraph (l) to read as follows:

§ 1910.1017 Vinyl chloride.

* * * * *

(l) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for vinyl chloride and polyvinyl chloride.

(ii) In classifying the hazards of vinyl chloride at least the following hazards are to be addressed: Cancer; central nervous system effects; liver effects; blood effects; and flammability.

(iii) Employers shall include vinyl chloride in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of vinyl chloride and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (j) of this section.

(2) *Signs.* (i) The employer shall post entrances to regulated areas with legible signs bearing the legend:

DANGER
VINYL CHLORIDE
MAY CAUSE CANCER
AUTHORIZED PERSONNEL ONLY

(ii) The employer shall post signs at areas containing hazardous operations or where emergencies currently exist. The signs shall be legible and bear the legend:

DANGER
VINYL CHLORIDE
MAY CAUSE CANCER
WEAR RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(iii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (l)(2)(i) of this section:

CANCER-SUSPECT AGENT AREA
AUTHORIZED PERSONNEL ONLY

(iv) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (l)(2)(ii) of this section:

CANCER-SUSPECT AGENT IN THIS AREA
PROTECTIVE EQUIPMENT REQUIRED
AUTHORIZED PERSONNEL ONLY

(3) *Labels.* (i) In addition to the other requirements in this paragraph (l), the employer shall ensure that labels for containers of polyvinyl chloride resin waste from reactors or other waste contaminated with vinyl chloride are legible and include the following information:

CONTAMINATED WITH VINYL CHLORIDE
MAY CAUSE CANCER

(ii) Prior to June 1, 2015, employers may include the following information on labels of containers of polyvinyl chloride resin waste from reactors or other waste contaminated with vinyl

chloride in lieu of the labeling requirements in paragraphs (l)(3)(i) of this section:

CONTAMINATED WITH VINYL CHLORIDE
CANCER-SUSPECT AGENT

(4) Prior to June 1, 2015, employers may include the following information for containers of polyvinyl chloride in lieu of the labeling requirements in paragraphs (l)(1)(i) of this section:

POLYVINYL CHLORIDE (OR TRADE NAME)
Contains
VINYL CHLORIDE
VINYL CHLORIDE IS A CANCER-SUSPECT AGENT

(5)(i) Prior to June 1, 2015, employers may include either the following information in either paragraph (l)(5)(i) or (l)(5)(ii) of this section on containers of vinyl chloride in lieu of the labeling requirements in paragraph (l)(1)(i) of this section:

VINYL CHLORIDE
EXTREMELY FLAMMABLE GAS UNDER PRESSURE
CANCER-SUSPECT AGENT

(ii) In accordance with 49 CFR Parts 170–189, with the additional legend applied near the label or placard:

CANCER-SUSPECT AGENT

(6) No statement shall appear on or near any required sign, label, or instruction which contradicts or detracts from the effect of any required warning, information, or instruction.

* * * * *

■ 18. Revise § 1910.1018 paragraphs (j)(2)(vii) and (p) to read as follows:

§ 1910.1018 Inorganic arsenic.

* * * * *

(j) * * *

(2) * * *

(vii) Labels on contaminated protective clothing and equipment.

(A) The employer shall ensure that the containers of contaminated protective clothing and equipment in the workplace or which are to be removed from the workplace are labeled and that the labels include the following information:

DANGER: CONTAMINATED WITH INORGANIC ARSENIC. MAY CAUSE CANCER. DO NOT REMOVE DUST BY BLOWING OR SHAKING. DISPOSE OF INORGANIC ARSENIC CONTAMINATED WASH WATER IN ACCORDANCE WITH APPLICABLE LOCAL, STATE OR FEDERAL REGULATIONS.

(B) Prior to June 1, 2015, employers may include the following information on containers of protective clothing and equipment in lieu of the labeling requirements in paragraphs (j)(2)(vii) of this section:

CAUTION: Clothing contaminated with inorganic arsenic; do not remove dust by blowing or shaking. Dispose of inorganic arsenic contaminated wash water in accordance with applicable local, State or Federal regulations.

* * * * *

(p) *Communication of hazards*—(1) *Hazard communication—General.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for inorganic arsenic.

(ii) In classifying the hazards of inorganic arsenic at least the following hazards are to be addressed: Cancer; liver effects; skin effects; respiratory irritation; nervous system effects; and acute toxicity effects.

(iii) Employers shall include inorganic arsenic in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of inorganic arsenic and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (o) of this section.

(iv) The employer shall ensure that no statement appears on or near any sign or label required by this paragraph (p) which contradicts or detracts from the meaning of the required sign or label.

(2) *Signs.* (i) The employer shall post signs demarcating regulated areas bearing the legend:

DANGER
INORGANIC ARSENIC
MAY CAUSE CANCER
DO NOT EAT, DRINK OR SMOKE
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(ii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (p)(2)(i) of this section:

DANGER
INORGANIC ARSENIC
CANCER HAZARD
AUTHORIZED PERSONNEL ONLY
NO SMOKING OR EATING
RESPIRATOR REQUIRED

(iii) The employer shall ensure that signs required by this paragraph (p) are illuminated and cleaned as necessary so that the legend is readily visible.

(3)(i) Prior to June 1, 2015, in lieu of the labeling requirements in paragraphs (p)(1)(i) of this section, employers may apply precautionary labels to all shipping and storage containers of inorganic arsenic, and to all products containing inorganic arsenic, bearing the following legend:

DANGER
CONTAINS INORGANIC ARSENIC
CANCER HAZARD
HARMFUL IF INHALED OR SWALLOWED
USE ONLY WITH ADEQUATE VENTILATION OR RESPIRATORY PROTECTION

(ii) Labels are not required when the inorganic arsenic in the product is bound in such a manner so as to make unlikely the possibility of airborne exposure to inorganic arsenic. (Possible examples of products not requiring labels are semiconductors, light emitting diodes and glass.)

* * * * *

■ 19. Amend § 1910.1025 as follows:

■ A. Revise paragraph (g)(2)(vii) and paragraph (m);

■ B. Revise Appendix B to § 1910.1025, paragraph xi.

The revisions read as follows:

§ 1910.1025 Lead.

* * * * *

(g) * * *

(2) * * *

(vii) Labeling of contaminated protective clothing and equipment.

(A) The employer shall ensure that labels of bags or containers of contaminated protective clothing and equipment include the following information:

DANGER: CLOTHING AND EQUIPMENT CONTAMINATED WITH LEAD. MAY DAMAGE FERTILITY OR THE UNBORN CHILD. CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM. DO NOT EAT, DRINK OR SMOKE WHEN HANDLING. DO NOT REMOVE DUST BY BLOWING OR SHAKING. DISPOSE OF LEAD CONTAMINATED WASH WATER IN ACCORDANCE WITH APPLICABLE LOCAL, STATE, OR FEDERAL REGULATIONS.

(B) Prior to June 1, 2015, employers may include the following information on bags or containers of contaminated protective clothing and equipment in lieu of the labeling requirements in paragraphs (g)(2)(vii)(A) of this section:

CAUTION: CLOTHING CONTAMINATED WITH LEAD. DO NOT REMOVE DUST BY BLOWING OR SHAKING. DISPOSE OF LEAD CONTAMINATED WASH WATER IN ACCORDANCE WITH APPLICABLE LOCAL, STATE, OR FEDERAL REGULATIONS.

* * * * *

(m) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for lead.

(ii) In classifying the hazards of lead at least the following hazards are to be addressed: Reproductive/developmental

toxicity; central nervous system effects; kidney effects; blood effects; and acute toxicity effects.

(iii) Employers shall include lead in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of lead and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (l) of this section.

(2) *Signs.* (i) The employer shall post the following warning signs in each work area where the PEL is exceeded:

DANGER
LEAD
MAY DAMAGE FERTILITY OR THE UNBORN CHILD
CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM
DO NOT EAT, DRINK OR SMOKE IN THIS AREA

(ii) The employer shall ensure that no statement appears on or near any sign required by this paragraph (m)(2) which contradicts or detracts from the meaning of the required sign.

(iii) The employer shall ensure that signs required by this paragraph (m)(2) are illuminated and cleaned as necessary so that the legend is readily visible.

(iv) The employer may use signs required by other statutes, regulations, or ordinances in addition to, or in combination with, signs required by this paragraph (m)(2).

(v) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (m)(2)(ii) of this section:

WARNING
LEAD WORK AREA
POISON
NO SMOKING OR EATING

* * * * *

Appendix B to § 1910.1025—Employee Standard Summary

* * * * *

xi. SIGNS—PARAGRAPH (m)

The standard requires that the following warning sign be posted in the work areas when the exposure to lead exceeds the PEL:

DANGER
LEAD
MAY DAMAGE FERTILITY OR THE UNBORN CHILD
CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM
DO NOT EAT, DRINK OR SMOKE IN THIS AREA

However, prior to June 1, 2016, employers may use the following legend in lieu of that specified above:

WARNING
LEAD WORK AREA
POISON
NO SMOKING OR EATING

* * * * *

■ 20. Revise § 1910.1026, paragraphs (h)(2)(iv) and (l)(1) to read as follows:

§ 1910.1026 Chromium (VI).

* * * * *

(h) * * *

(2) * * *

(iv) The employer shall ensure that bags or containers of contaminated protective clothing or equipment that are removed from change rooms for laundering, cleaning, maintenance, or disposal are labeled in accordance with the requirements of the Hazard Communication Standard, § 1910.1200.

* * * * *

(l) * * *

(1) *Hazard communication—general* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for chromium (VI).

(ii) In classifying the hazards of chromium (VI) at least the following hazards are to be addressed: Cancer, eye irritation, and skin sensitization.

(iii) Employers shall include chromium (VI) in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of chromium (VI) and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (l)(2) of this section.

* * * * *

■ 21. Revise § 1910.1027 paragraphs (k)(7), (m)(1), (m)(2), and (m)(3) to read as follows:

§ 1910.1027 Cadmium.

* * * * *

(k) * * *

(7) Waste, scrap, debris, bags, containers, personal protective equipment, and clothing contaminated with cadmium and consigned for disposal shall be collected and disposed of in sealed impermeable bags or other closed, impermeable containers. These bags and containers shall be labeled in accordance with paragraph (m) of this section.

* * * * *

(m) * * *

(1) *Hazard communication.—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for cadmium.

(ii) In classifying the hazards of cadmium at least the following hazards are to be addressed: Cancer; lung effects; kidney effects; and acute toxicity effects.

(iii) Employers shall include cadmium in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of cadmium and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (m)(4) of this section.

(2) *Warning signs.* (i) Warning signs shall be provided and displayed in regulated areas. In addition, warning signs shall be posted at all approaches to regulated areas so that an employee may read the signs and take necessary protective steps before entering the area.

(ii) Warning signs required by paragraph (m)(2)(i) of this section shall bear the following legend:

DANGER
CADMIUM
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS AND KIDNEYS
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(iii) The employer shall ensure that signs required by this paragraph (m)(2) are illuminated, cleaned, and maintained as necessary so that the legend is readily visible.

(iv) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (m)(2)(ii) of this section:

DANGER
CADMIUM
CANCER HAZARD
CAN CAUSE LUNG AND KIDNEY DISEASE
AUTHORIZED PERSONNEL ONLY
RESPIRATORS REQUIRED IN THIS AREA

(3) *Warning labels.* (i) Shipping and storage containers containing cadmium or cadmium compounds shall bear appropriate warning labels, as specified in paragraph (m)(1) of this section.

(ii) The warning labels for containers of contaminated protective clothing, equipment, waste, scrap, or debris shall include at least the following information:

DANGER
CONTAINS CADMIUM
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS AND KIDNEYS
AVOID CREATING DUST

(iii) Prior to June 1, 2015, employers may include the following information on shipping and storage containers containing cadmium, cadmium compounds, or cadmium contaminated clothing, equipment, waste, scrap, or debris in lieu of the labeling

requirements specified in paragraphs (m)(1)(i) and (m)(3)(ii) of this section:

DANGER
CONTAINS CADMIUM
CANCER HAZARD
AVOID CREATING DUST
CAN CAUSE LUNG AND KIDNEY DISEASE

(iv) Where feasible, installed cadmium products shall have a visible label or other indication that cadmium is present.

* * * * *

■ 22. Revise § 1910.1028, paragraph (j) heading, and paragraphs (j)(1) and (j)(2) to read as follows:

§ 1910.1028 Benzene.

* * * * *

(j) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for benzene.

(ii) In classifying the hazards of benzene at least the following hazards are to be addressed: Cancer; central nervous system effects; blood effects; aspiration; skin, eye, and respiratory tract irritation; and flammability.

(iii) Employers shall include benzene in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of benzene and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (j)(3) of this section.

(2) *Warning signs and labels.* (i)The employer shall post signs at entrances to regulated areas. The signs shall bear the following legend:

DANGER
BENZENE
MAY CAUSE CANCER
HIGHLY FLAMMABLE LIQUID AND VAPOR
DO NOT SMOKE
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(ii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (j)(2)(i) of this section:

DANGER
BENZENE
CANCER HAZARD
FLAMMABLE—NO SMOKING
AUTHORIZED PERSONNEL ONLY
RESPIRATOR REQUIRED

(iii) The employer shall ensure that labels or other appropriate forms of warning are provided for containers of benzene within the workplace. There is no requirement to label pipes. The labels shall comply with the requirements of paragraph (j)(1) of this section and § 1910.1200(f).

(iv) Prior to June 1, 2015, employers shall include the following legend or similar language on the labels or other appropriate forms of warning:

DANGER
CONTAINS BENZENE
CANCER HAZARD

* * * * *

■ 23. Revise § 1910.1029 paragraph (l) heading, and paragraphs (l)(1) through (l)(3) to read as follows:

§ 1910.1029 Coke oven emissions.

* * * * *

(l) *Communication of hazards*—(1) *Hazard communication—general.* The employer shall include coke oven emissions in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of chemicals and substances associated with coke oven processes and to safety data sheets, and is trained in accordance with the provisions of HCS and paragraph (k) of this section. The employer shall ensure that at least the following hazard is addressed: Cancer.

(2) *Signs.* (i) The employer shall post signs in the regulated area bearing the legend:

DANGER
COKE OVEN EMISSIONS
MAY CAUSE CANCER
DO NOT EAT, DRINK OR SMOKE
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(ii) In addition, the employer shall post signs in the areas where the permissible exposure limit is exceeded bearing the legend:

WEAR RESPIRATORY PROTECTION IN THIS AREA

(iii) The employer shall ensure that no statement appears on or near any sign required by this paragraph (l) which contradicts or detracts from the effects of the required sign.

(iv) The employer shall ensure that signs required by this paragraph (l)(2) are illuminated and cleaned as necessary so that the legend is readily visible.

(v) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (l)(2)(i) of this section:

DANGER
CANCER HAZARD
AUTHORIZED PERSONNEL ONLY
NO SMOKING OR EATING

(vi) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (l)(2)(ii) of this section:

DANGER
RESPIRATOR REQUIRED

(3) *Labels.* (i) The employer shall ensure that labels of containers of contaminated protective clothing and equipment include the following information:

CONTAMINATED WITH COKE EMISSIONS
MAY CAUSE CANCER
DO NOT REMOVE DUST BY BLOWING OR SHAKING

(ii) Prior to June 1, 2015, employers may include the following information on contaminated protective clothing and equipment in lieu of the labeling requirements in paragraph (l)(3)(i) of this section:

CAUTION
CLOTHING CONTAMINATED WITH COKE EMISSIONS
DO NOT REMOVE DUST BY BLOWING OR SHAKING

* * * * *

■ 24. Revise § 1910.1043 paragraph (j) to read as follows:

§ 1910.1043 Cotton dust.

* * * * *

(j) *Signs.* (1) The employer shall post the following warning sign in each work area where the permissible exposure limit for cotton dust is exceeded:

DANGER
COTTON DUST
CAUSES DAMAGE TO LUNGS
(BYSSINOSIS)
WEAR RESPIRATORY PROTECTION IN THIS AREA

(2) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (j)(1) of this section:

WARNING
COTTON DUST WORK AREA
MAY CAUSE ACUTE OR DELAYED
LUNG INJURY
(BYSSINOSIS)
RESPIRATORS
REQUIRED IN THIS AREA

* * * * *

■ 25. Revise § 1910.1044 paragraphs (j)(2)(v), (k)(1)(iii)(*b*), and paragraph (o) to read as follows:

§ 1910.1044 1,2-dibromo-3-chloropropane.

* * * * *

(j) * * *

(2) * * *

(v) Containers of DBCP-contaminated protective devices or work clothing which are to be taken out of change rooms or the workplace for cleaning, maintenance or disposal shall bear

labels with the following information: CONTAMINATED WITH 1,2–Dibromo-3-chloropropane (DBCP), MAY CAUSE CANCER.

* * * * *

(k) * * *

(1) * * *

(iii) * * *

(*b*) Portable vacuum units used to collect DBCP may not be used for other cleaning purposes and shall be labeled as prescribed by paragraph (j)(2)(v) of this section.

* * * * *

(o) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for DBCP.

(ii) In classifying the hazards of DBCP at least the following hazards are to be addressed: Cancer; reproductive effects; liver effects; kidney effects; central nervous system effects; skin, eye and respiratory tract irritation; and acute toxicity effects.

(iii) Employers shall include DBCP in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of DBCP and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (n) of this section.

(iv) The employer shall ensure that no statement appears on or near any sign or label required by this paragraph (o) which contradicts or detracts from the meaning of the required sign or label.

(2) *Signs.* (i) The employer shall post signs to clearly indicate all regulated areas. These signs shall bear the legend:

DANGER
1,2-Dibromo-3-chloropropane
MAY CAUSE CANCER
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(ii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (o)(2) of this section:

DANGER
1,2-Dibromo-3-chloropropane
(Insert appropriate trade or common names)
CANCER HAZARD
AUTHORIZED PERSONNEL ONLY
RESPIRATOR REQUIRED

(3) *Labels.* (i) Where DBCP or products containing DBCP are sold, distributed or otherwise leave the employer's workplace bearing appropriate labels required by EPA under the regulations in 40 CFR Part 162, the labels required by this paragraph (o)(3) need not be affixed.

(ii) The employer shall ensure that the precautionary labels required by this paragraph (o)(3) are readily visible and legible.

(iii) Prior to June 1, 2015, employers may include the following information on containers of DBCP or products containing DBCP, DBCP-contaminated protective devices or work clothing or DBCP-contaminated portable vacuums in lieu of the labeling requirements in paragraphs (j)(2)(v), (k)(l)(iii)(b) and (o)(1)(i) of this section:

DANGER
1,2-Dibromo-3-chloropropane
CANCER HAZARD

* * * * *

■ 26. Revise § 1910.1045 paragraph (p) to read as follows:

§ 1910.1045 Acrylonitrile.

* * * * *

(p) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for AN and AN-based materials not exempted under paragraph (a)(2) of this section.

(ii) In classifying the hazards of AN and AN-based materials at least the following hazards are to be addressed: Cancer; central nervous system effects; liver effects; skin sensitization; skin, respiratory, and eye irritation; acute toxicity effects; and flammability.

(iii) Employers shall include AN and AN-based materials in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of AN and AN-based materials and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (o) of this section.

(iv) The employer shall ensure that no statement appears on or near any sign or label required by this paragraph (p) that contradicts or detracts from the required sign or label.

(2) *Signs.* (i) The employer shall post signs to clearly indicate all workplaces where AN concentrations exceed the permissible exposure limits. The signs shall bear the following legend:

DANGER
ACRYLONITRILE (AN)
MAY CAUSE CANCER
RESPIRATORY PROTECTION MAY BE REQURED IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(ii) The employer shall ensure that signs required by this paragraph (p)(2) are illuminated and cleaned as necessary so that the legend is readily visible.

(iii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (p)(2)(i) of this section:

DANGER
ACRYLONITRILE (AN)
CANCER HAZARD
AUTHORIZED PERSONNEL ONLY
RESPIRATORS MAY BE REQUIRED

(3) *Labels.* (i) The employer shall ensure that precautionary labels are in compliance with paragraph (p)(1)(i) of this section and are affixed to all containers of liquid AN and AN-based materials not exempted under paragraph (a)(2) of this section. The employer shall ensure that the labels remain affixed when the materials are sold, distributed, or otherwise leave the employer's workplace.

(ii) Prior to June 1, 2015, employers may include the following information on precautionary labels required by this paragraph (p)(3) in lieu of the labeling requirements in paragraph (p)(1) of this section:

DANGER
CONTAINS ACRYLONITRILE (AN)
CANCER HAZARD

(iii) The employer shall ensure that the precautionary labels required by this paragraph (p)(3) are readily visible and legible.

* * * * *

■ 27. Revise § 1910.1047 paragraph (j) heading, and paragraphs (j)(1) and (j)(2) to read as follows:

§ 1910.1047 Ethylene oxide.

* * * * *

(j) *Communication of hazards*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for EtO.

(ii) In classifying the hazards of EtO at least the following hazards are to be addressed: Cancer; reproductive effects; mutagenicity; central nervous system; skin sensitization; skin, eye and respiratory tract irritation; acute toxicity effects; and flammability.

(iii) Employers shall include EtO in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of EtO and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (j)(3) of this section.

(2) *Signs and labels*—(i) *Signs.* (A) The employer shall post and maintain legible signs demarcating regulated areas and entrances or access ways to regulated areas that bear the following legend:

DANGER
ETHYLENE OXIDE
MAY CAUSE CANCER
MAY DAMAGE FERTILITY OR THE UNBORN CHILD
RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING MAY BE REQUIRED IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(B) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (j)(2)(i)(A) of this section:

DANGER
ETHYLENE OXIDE
CANCER HAZARD AND REPRODUCTIVE HAZARD
AUTHORIZED PERSONNEL ONLY
RESPIRATORS AND PROTECTIVE CLOTHING MAY BE REQUIRED TO BE WORN IN THIS AREA

(ii) *Labels.* (A) The employer shall ensure that labels are affixed to all containers of EtO whose contents are capable of causing employee exposure at or above the action level or whose contents may reasonably be foreseen to cause employee exposure above the excursion limit, and that the labels remain affixed when the containers of EtO leave the workplace. For the purposes of this paragraph (j)(2)(ii), reaction vessels, storage tanks, and pipes or piping systems are not considered to be containers.

(B) Prior to June 1, 2015, employers may include the following information on containers of EtO in lieu of the labeling requirements in paragraph (j)(1)(i) of this section:

(*1*) DANGER
CONTAINS ETHYLENE OXIDE
CANCER HAZARD AND REPRODUCTIVE HAZARD;
(*2*) A warning statement against breathing airborne concentrations of EtO.

(C) The labeling requirements under this section do not apply where EtO is used as a pesticide, as such term is defined in the Federal Insecticide, Fungicide, and Rodenticide Act (7 U.S.C. 136 et seq.), when it is labeled pursuant to that Act and regulations issued under that Act by the Environmental Protection Agency.

* * * * *

■ 28. Revise § 1910.1048 paragraphs (e)(1), (h)(2)(ii), (j)(4) and (m) to read as follows:

§ 1910.1048 Formaldehyde.

* * * * *

(e) * * *

(1) *Signs.* (i) The employer shall establish regulated areas where the concentration of airborne formaldehyde exceeds either the TWA or the STEL and post all entrances and access ways with signs bearing the following legend:

DANGER
FORMALDEHYDE
MAY CAUSE CANCER
CAUSES SKIN, EYE, AND RESPIRATORY IRRITATION
AUTHORIZED PERSONNEL ONLY

(ii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (e)(1)(i) of this section:

DANGER
FORMALDEHYDE
IRRITANT AND POTENTIAL CANCER HAZARD
AUTHORIZED PERSONNEL ONLY

* * * * *

(h) * * *

(2) * * *

(ii) When formaldehyde-contaminated clothing and equipment is ventilated, the employer shall establish storage areas so that employee exposure is minimized.

(A) *Signs.* Storage areas for contaminated clothing and equipment shall have signs bearing the following legend:

DANGER
FORMALDEHYDE-CONTAMINATED [CLOTHING] EQUIPMENT
MAY CAUSE CANCER
CAUSES SKIN, EYE AND RESPIRATORY IRRITATION
DO NOT BREATHE VAPOR
DO NOT GET ON SKIN

(B) *Labels.* The employer shall ensure containers for contaminated clothing and equipment are labeled consistent with the Hazard Communication Standard, § 1910.1200, and shall, as a minimum, include the following:

DANGER
FORMALDEHYDE-CONTAMINATED [CLOTHING] EQUIPMENT
MAY CAUSE CANCER
CAUSES SKIN, EYE, AND RESPIRATORY IRRITATION
DO NOT BREATHE VAPOR
DO NOT GET ON SKIN

(C) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (h)(2)(ii)(A) of this section:

DANGER
FORMALDEHYDE-CONTAMINATED [CLOTHING] EQUIPMENT
AVOID INHALATION AND SKIN CONTACT

(D) Prior to June 1, 2015, employers may include the following information on containers of protective clothing and equipment in lieu of the labeling requirements in paragraphs (h)(2)(ii)(B) of this section:

DANGER
FORMALDEHYDE-CONTAMINATED [CLOTHING] EQUIPMENT
AVOID INHALATION AND SKIN CONTACT

* * * * *

(j) * * *

(4) Formaldehyde-contaminated waste and debris resulting from leaks or spills shall be placed for disposal in sealed containers bearing a label warning of formaldehyde's presence and of the hazards associated with formaldehyde. The employer shall ensure that the labels are in accordance with paragraph (m) of this section.

* * * * *

(m) *Communication of hazards.* (1) *Hazard communication—General.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for formaldehyde.

(ii) In classifying the hazards of formaldehyde at least the following hazards are to be addressed: Cancer; skin and respiratory sensitization; eye, skin and respiratory tract irritation; acute toxicity effects; and flammability.

(iii) Employers shall include formaldehyde in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of formaldehyde and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (n) of this section.

(iv) Paragraphs (m)(1)(i), (m)(1)(ii), and (m)(1)(iii) of this section apply to chemicals associated with formaldehyde gas, all mixtures or solutions composed of greater than 0.1 percent formaldehyde, and materials capable of releasing formaldehyde into the air at concentrations reaching or exceeding 0.1 ppm.

(v) In making the determinations of anticipated levels of formaldehyde release, the employer may rely on objective data indicating the extent of potential formaldehyde release under reasonably foreseeable conditions of use.

(2)(i) In addition to the requirements in paragraphs (m)(1) through (m)(1)(iv) of this section, for materials listed in paragraph (m)(1)(iv) capable of releasing formaldehyde at levels above 0.5 ppm, labels shall appropriately address all hazards as defined in paragraph (d) of § 1910.1200 and Appendices A and B to § 1910.1200, including cancer and respiratory sensitization, and shall

contain the hazard statement ''May Cause Cancer.''

(ii) As a minimum, for all materials listed in paragraph (m)(1)(i) and (iv) of this section capable of releasing formaldehyde at levels of 0.1 ppm to 0.5 ppm, labels shall identify that the product contains formaldehyde; list the name and address of the responsible party; and state that physical and health hazard information is readily available from the employer and from safety data sheets.

(iii) Prior to June 1, 2015, employers may include the phrase ''Potential Cancer Hazard'' in lieu of ''May Cause Cancer'' as specified in paragraph (m)(2)(i) of this section.

* * * * *

■ 29. Amend § 1910.1050 as follows:
■ A. Revise the heading of paragraph (k);
■ B. Revise paragraphs (k)(1) and (k)(2);
■ C. Redesignate paragraphs (k)(3) and (k)(4) as (k)(4) and (k)(5);
■ D. Add new paragraph (k)(3).

The revisions and additions read as follows:

§ 1910.1050 Methylenedianiline.

* * * * *

(k) *Communication of hazards*—(1) *Hazard communication—general.*

(i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for MDA.

(ii) In classifying the hazards of MDA at least the following hazards are to be addressed: Cancer; liver effects; and skin sensitization.

(iii) Employers shall include MDA in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of MDA and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (k)(4) of this section.

(2) *Signs and labels*—(i) *Signs.* (A) The employer shall post and maintain legible signs demarcating regulated areas and entrances or access ways to regulated areas that bear the following legend:

DANGER
MDA
MAY CAUSE CANCER
CAUSES DAMAGE TO THE LIVER
RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING MAY BE REQUIRED IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(B) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (k)(2)(i)(A) of this section:

DANGER
MDA
MAY CAUSE CANCER
LIVER TOXIN
AUTHORIZED PERSONNEL ONLY
RESPIRATORS AND PROTECTIVE CLOTHING MAY BE REQUIRED TO BE WORN IN THIS AREA

(ii) *Labels.* Prior to June 1, 2015, employers may include the following information workplace labels in lieu of the labeling requirements in paragraph (k)(1) of this section:

(A) For pure MDA:

DANGER
CONTAINS MDA
MAY CAUSE CANCER
LIVER TOXIN

(B) For mixtures containing MDA:

DANGER
CONTAINS MDA
CONTAINS MATERIALS WHICH MAY CAUSE CANCER
LIVER TOXIN

(3) *Safety data sheets (SDS).* In meeting the obligation to provide safety data sheets, employers shall make appropriate use of the information found in Appendices A and B to § 1910.1050.

* * * * *

■ 30. Revise § 1910.1051 paragraph (l)(1) to read as follows:

§ 1910.1051 1,3-Butadiene.

* * * * *

(l) * * *

(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for BD.

(ii) In classifying the hazards of BD at least the following hazards are to be addressed: Cancer; eye and respiratory tract irritation; center nervous system effects; and flammability.

(iii) Employers shall include BD in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of BD and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (l)(2) of this section.

* * * * *

■ 31. Amend § 1910.1052 as follows:
■ A. Revise paragraph (k);
■ B. Remove the phrase ''material safety data sheets (MSDS)'' and add in its place the phrase ''safety data sheets (SDS)'' where it appears in Appendix A, Paragraph X.E.

The revisions read as follows:

§ 1910.1052 Methylene chloride.

* * * * *

(k) *Hazard communication.*—(1) *Hazard communication—general.* (i) Chemical manufacturers, importers, distributors and employers shall comply with all requirements of the Hazard Communication Standard (HCS) (§ 1910.1200) for MC.

(ii) In classifying the hazards of MC at least the following hazards are to be addressed: Cancer, cardiac effects (including elevation of carboxyhemoglobin), central nervous system effects, liver effects, and skin and eye irritation.

(iii) Employers shall include MC in the hazard communication program established to comply with the HCS (§ 1910.1200). Employers shall ensure that each employee has access to labels on containers of MC and to safety data sheets, and is trained in accordance with the requirements of HCS and paragraph (l) of this section.

(2) [Reserved]

* * * * *

■ 32. Amend § 1910.1200 as follows:
■ A. Remove the word ''material'' before the word ''safety'' in the phrase ''material safety data sheet'' or ''material safety data sheets'' wherever they appear in paragraphs (b)(3)(ii), (b)(4)(ii), (e)(1) introductory text, (e)(2)(i), (g)(4), (g)(6)(i) through (iv), (g)(7)(i) through (vii), (g)(9), (g)(11), (h)(1), (h)(2)(iii), and (i)(1)(ii);
■ B. Remove the word ''Material'' before the word ''safety'' in the phrase ''Material safety data sheets'' wherever they appear in paragraphs (g)(10) and (g)(11). In paragraphs (g)(10) and (g)(11) in the first sentence, capitalize the first letter of the word ''safety''.
■ C. Remove the following definitions in paragraph (c) *Combustible liquid, Compressed gas, Explosive, Flammable, Flashpoint, Hazard warning, Identity, Material safety data sheet (MSDS), Organic peroxide, Oxidizer, Pyrophoric, Unstable (reactive),* and *Water-reactive;*
■ D. Revise the following definitions in paragraph (c) *Chemical, Chemical name, Health hazard, Label, Mixture, Physical hazard,* and *Trade secret;*
■ E. Redesignate the definition of the term *Hazardous chemical* in alphabetical order in paragraph (c) and revise the definition;
■ F. Add the following definitions in alphabetical order in paragraph (c) *Classification, Hazard category, Hazard class, Hazard not otherwise classified, Hazard statement, Label elements, Pictogram, Precautionary statement, Product identifier, Pyrophoric gas, Safety Data Sheet (SDS), Signal word, Simple asphyxiant,* and *Substance;*
■ G. Remove the following phrases: ''in'' before the phrase ''in their work area(s)''

in paragraph (g)(10); ''specific chemical identity'' in paragraph (i)(10)(ii); and ''or percentage of mixture'' in paragraph (i)(13);

■ H. Revise paragraphs (a), (b)(1), (b)(3)(iv), (b)(5)(iv), (b)(6)(ii), paragraph (d) (heading), paragraphs (d)(1) through (d)(3), (e)(1)(i), (f), paragraph (g) (heading), paragraphs (g)(1), (g)(2), (g)(3), (g)(5), (g)(8), (g)(11), (h)(1), (h)(3)(ii), (h)(3)(iv), (i)(1) introductory text, (i)(1)(iii) and (iv), (i)(2), (i)(3) introductory text, (i)(3)(iii), (i)(7) introductory text, (i)(7)(iii), (i)(7)(v), (i)(9)(i), (i)(10), (i)(11), and (j).

■ I. Remove Appendices A, B, and E to § 1910.1200.

■ J. Redesignate Appendix D to § 1910.1200 as Appendix E to § 1910.1200.

■ K. Add new Appendices A, B, C, D and F to § 1910.1200.

The revisions and additions read as follows:

§ 1910.1200 Hazard communication.

(a) *Purpose.* (1) The purpose of this section is to ensure that the hazards of all chemicals produced or imported are classified, and that information concerning the classified hazards is transmitted to employers and employees. The requirements of this section are intended to be consistent with the provisions of the United Nations Globally Harmonized System of Classification and Labelling of Chemicals (GHS), Revision 3. The transmittal of information is to be accomplished by means of comprehensive hazard communication programs, which are to include container labeling and other forms of warning, safety data sheets and employee training.

(2) This occupational safety and health standard is intended to address comprehensively the issue of classifying the potential hazards of chemicals, and communicating information concerning hazards and appropriate protective measures to employees, and to preempt any legislative or regulatory enactments of a state, or political subdivision of a state, pertaining to this subject. Classifying the potential hazards of chemicals and communicating information concerning hazards and appropriate protective measures to employees, may include, for example, but is not limited to, provisions for: developing and maintaining a written hazard communication program for the workplace, including lists of hazardous chemicals present; labeling of containers of chemicals in the workplace, as well as of containers of chemicals being shipped to other workplaces; preparation and distribution of safety data sheets to employees and downstream employers; and development and implementation of employee training programs regarding hazards of chemicals and protective measures. Under section 18 of the Act, no state or political subdivision of a state may adopt or enforce any requirement relating to the issue addressed by this Federal standard, except pursuant to a Federally-approved state plan.

(b) * * *

(1) This section requires chemical manufacturers or importers to classify the hazards of chemicals which they produce or import, and all employers to provide information to their employees about the hazardous chemicals to which they are exposed, by means of a hazard communication program, labels and other forms of warning, safety data sheets, and information and training. In addition, this section requires distributors to transmit the required information to employers. (Employers who do not produce or import chemicals need only focus on those parts of this rule that deal with establishing a workplace program and communicating information to their workers.)

* * * * *

(3) * * *

(iv) Laboratory employers that ship hazardous chemicals are considered to be either a chemical manufacturer or a distributor under this rule, and thus must ensure that any containers of hazardous chemicals leaving the laboratory are labeled in accordance with paragraph (f) of this section, and that a safety data sheet is provided to distributors and other employers in accordance with paragraphs (g)(6) and (g)(7) of this section.

* * * * *

(5) * * *

(iv) Any distilled spirits (beverage alcohols), wine, or malt beverage intended for nonindustrial use, as such terms are defined in the Federal Alcohol Administration Act (27 U.S.C. 201 et seq.) and regulations issued under that Act, when subject to the labeling requirements of that Act and labeling regulations issued under that Act by the Bureau of Alcohol, Tobacco, Firearms and Explosives;

* * * * *

(6) * * *

(ii) Any hazardous substance as such term is defined by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (42 U.S.C. 9601 et seq.) when the hazardous substance is the focus of remedial or removal action being conducted under CERCLA in accordance with Environmental Protection Agency regulations.

* * * * *

(c) * * *

Chemical means any substance, or mixture of substances.

* * * * *

Chemical name means the scientific designation of a chemical in accordance with the nomenclature system developed by the International Union of Pure and Applied Chemistry (IUPAC) or the Chemical Abstracts Service (CAS) rules of nomenclature, or a name that will clearly identify the chemical for the purpose of conducting a hazard classification.

Classification means to identify the relevant data regarding the hazards of a chemical; review those data to ascertain the hazards associated with the chemical; and decide whether the chemical will be classified as hazardous according to the definition of hazardous chemical in this section. In addition, classification for health and physical hazards includes the determination of the degree of hazard, where appropriate, by comparing the data with the criteria for health and physical hazards.

* * * * *

Hazard category means the division of criteria within each hazard class, e.g., oral acute toxicity and flammable liquids include four hazard categories. These categories compare hazard severity within a hazard class and should not be taken as a comparison of hazard categories more generally.

Hazard class means the nature of the physical or health hazards, e.g., flammable solid, carcinogen, oral acute toxicity.

Hazard not otherwise classified (HNOC) means an adverse physical or health effect identified through evaluation of scientific evidence during the classification process that does not meet the specified criteria for the physical and health hazard classes addressed in this section. This does not extend coverage to adverse physical and health effects for which there is a hazard class addressed in this section, but the effect either falls below the cut-off value/concentration limit of the hazard class or is under a GHS hazard category that has not been adopted by OSHA (e.g., acute toxicity Category 5).

Hazard statement means a statement assigned to a hazard class and category that describes the nature of the hazard(s) of a chemical, including, where appropriate, the degree of hazard.

Hazardous chemical means any chemical which is classified as a physical hazard or a health hazard, a

simple asphyxiant, combustible dust, pyrophoric gas, or hazard not otherwise classified.

Health hazard means a chemical which is classified as posing one of the following hazardous effects: acute toxicity (any route of exposure); skin corrosion or irritation; serious eye damage or eye irritation; respiratory or skin sensitization; germ cell mutagenicity; carcinogenicity; reproductive toxicity; specific target organ toxicity (single or repeated exposure); or aspiration hazard. The criteria for determining whether a chemical is classified as a health hazard are detailed in Appendix A to § 1910.1200—Health Hazard Criteria.

* * * * *

Label means an appropriate group of written, printed or graphic information elements concerning a hazardous chemical that is affixed to, printed on, or attached to the immediate container of a hazardous chemical, or to the outside packaging.

Label elements means the specified pictogram, hazard statement, signal word and precautionary statement for each hazard class and category.

Mixture means a combination or a solution composed of two or more substances in which they do not react.

Physical hazard means a chemical that is classified as posing one of the following hazardous effects: explosive; flammable (gases, aerosols, liquids, or solids); oxidizer (liquid, solid or gas); self-reactive; pyrophoric (liquid or solid); self-heating; organic peroxide; corrosive to metal; gas under pressure; or in contact with water emits flammable gas. *See* Appendix B to § 1910.1200—Physical Hazard Criteria.

Pictogram means a composition that may include a symbol plus other graphic elements, such as a border, background pattern, or color, that is intended to convey specific information about the hazards of a chemical. Eight pictograms are designated under this standard for application to a hazard category.

Precautionary statement means a phrase that describes recommended measures that should be taken to minimize or prevent adverse effects resulting from exposure to a hazardous chemical, or improper storage or handling.

Product identifier means the name or number used for a hazardous chemical on a label or in the SDS. It provides a unique means by which the user can identify the chemical. The product identifier used shall permit cross-references to be made among the list of hazardous chemicals required in the written hazard communication program, the label and the SDS.

* * * * *

Pyrophoric gas means a chemical in a gaseous state that will ignite spontaneously in air at a temperature of 130 degrees F (54.4 degrees C) or below.

* * * * *

Safety data sheet (SDS) means written or printed material concerning a hazardous chemical that is prepared in accordance with paragraph (g) of this section.

Signal word means a word used to indicate the relative level of severity of hazard and alert the reader to a potential hazard on the label. The signal words used in this section are ''danger'' and ''warning.'' ''Danger'' is used for the more severe hazards, while ''warning'' is used for the less severe.

Simple asphyxiant means a substance or mixture that displaces oxygen in the ambient atmosphere, and can thus cause oxygen deprivation in those who are exposed, leading to unconsciousness and death.

* * * * *

Substance means chemical elements and their compounds in the natural state or obtained by any production process, including any additive necessary to preserve the stability of the product and any impurities deriving from the process used, but excluding any solvent which may be separated without affecting the stability of the substance or changing its composition.

Trade secret means any confidential formula, pattern, process, device, information or compilation of information that is used in an employer's business, and that gives the employer an opportunity to obtain an advantage over competitors who do not know or use it. Appendix E to § 1910.1200—Definition of Trade Secret, sets out the criteria to be used in evaluating trade secrets.

* * * * *

(d) *Hazard classification.* (1) Chemical manufacturers and importers shall evaluate chemicals produced in their workplaces or imported by them to classify the chemicals in accordance with this section. For each chemical, the chemical manufacturer or importer shall determine the hazard classes, and, where appropriate, the category of each class that apply to the chemical being classified. Employers are not required to classify chemicals unless they choose not to rely on the classification performed by the chemical manufacturer or importer for the chemical to satisfy this requirement.

(2) Chemical manufacturers, importers or employers classifying chemicals shall identify and consider the full range of available scientific literature and other evidence concerning the potential hazards. There is no requirement to test the chemical to determine how to classify its hazards. Appendix A to § 1910.1200 shall be consulted for classification of health hazards, and Appendix B to § 1910.1200 shall be consulted for the classification of physical hazards.

(3) *Mixtures.* (i) Chemical manufacturers, importers, or employers evaluating chemicals shall follow the procedures described in Appendices A and B to § 1910.1200 to classify the hazards of the chemicals, including determinations regarding when mixtures of the classified chemicals are covered by this section.

(ii) When classifying mixtures they produce or import, chemical manufacturers and importers of mixtures may rely on the information provided on the current safety data sheets of the individual ingredients, except where the chemical manufacturer or importer knows, or in the exercise of reasonable diligence should know, that the safety data sheet misstates or omits information required by this section.

* * * * *

(e) * * *

(1) * * *

(i) A list of the hazardous chemicals known to be present using a product identifier that is referenced on the appropriate safety data sheet (the list may be compiled for the workplace as a whole or for individual work areas); and,

* * * * *

(f) *Labels and other forms of warning*—(1) *Labels on shipped containers.* The chemical manufacturer, importer, or distributor shall ensure that each container of hazardous chemicals leaving the workplace is labeled, tagged, or marked. Hazards not otherwise classified do not have to be addressed on the container. Where the chemical manufacturer or importer is required to label, tag or mark the following information shall be provided:

(i) Product identifier;

(ii) Signal word;

(iii) Hazard statement(s);

(iv) Pictogram(s);

(v) Precautionary statement(s); and,

(vi) Name, address, and telephone number of the chemical manufacturer, importer, or other responsible party.

(2) The chemical manufacturer, importer, or distributor shall ensure that the information provided under paragraphs (f)(1)(i) through (v) of this section is in accordance with Appendix

C to § 1910.1200, for each hazard class and associated hazard category for the hazardous chemical, prominently displayed, and in English (other languages may also be included if appropriate).

(3) The chemical manufacturer, importer, or distributor shall ensure that the information provided under paragraphs (f)(1)(ii) through (iv) of this section is located together on the label, tag, or mark.

(4*) Solid materials.* (i) For solid metal (such as a steel beam or a metal casting), solid wood, or plastic items that are not exempted as articles due to their downstream use, or shipments of whole grain, the required label may be transmitted to the customer at the time of the initial shipment, and need not be included with subsequent shipments to the same employer unless the information on the label changes;

(ii) The label may be transmitted with the initial shipment itself, or with the safety data sheet that is to be provided prior to or at the time of the first shipment; and,

(iii) This exception to requiring labels on every container of hazardous chemicals is only for the solid material itself, and does not apply to hazardous chemicals used in conjunction with, or known to be present with, the material and to which employees handling the items in transit may be exposed (for example, cutting fluids or pesticides in grains).

(5) Chemical manufacturers, importers, or distributors shall ensure that each container of hazardous chemicals leaving the workplace is labeled, tagged, or marked in accordance with this section in a manner which does not conflict with the requirements of the Hazardous Materials Transportation Act (49 U.S.C. 1801 *et seq.*) and regulations issued under that Act by the Department of Transportation.

(6) Workplace labeling. Except as provided in paragraphs (f)(7) and (f)(8) of this section, the employer shall ensure that each container of hazardous chemicals in the workplace is labeled, tagged or marked with either:

(i) The information specified under paragraphs (f)(1)(i) through (v) of this section for labels on shipped containers; or,

(ii) Product identifier and words, pictures, symbols, or combination thereof, which provide at least general information regarding the hazards of the chemicals, and which, in conjunction with the other information immediately available to employees under the hazard communication program, will provide employees with the specific information regarding the physical and health hazards of the hazardous chemical.

(7) The employer may use signs, placards, process sheets, batch tickets, operating procedures, or other such written materials in lieu of affixing labels to individual stationary process containers, as long as the alternative method identifies the containers to which it is applicable and conveys the information required by paragraph (f)(6) of this section to be on a label. The employer shall ensure the written materials are readily accessible to the employees in their work area throughout each work shift.

(8) The employer is not required to label portable containers into which hazardous chemicals are transferred from labeled containers, and which are intended only for the immediate use of the employee who performs the transfer. For purposes of this section, drugs which are dispensed by a pharmacy to a health care provider for direct administration to a patient are exempted from labeling.

(9) The employer shall not remove or deface existing labels on incoming containers of hazardous chemicals, unless the container is immediately marked with the required information.

(10) The employer shall ensure that workplace labels or other forms of warning are legible, in English, and prominently displayed on the container, or readily available in the work area throughout each work shift. Employers having employees who speak other languages may add the information in their language to the material presented, as long as the information is presented in English as well.

(11) Chemical manufacturers, importers, distributors, or employers who become newly aware of any significant information regarding the hazards of a chemical shall revise the labels for the chemical within six months of becoming aware of the new information, and shall ensure that labels on containers of hazardous chemicals shipped after that time contain the new information. If the chemical is not currently produced or imported, the chemical manufacturer, importer, distributor, or employer shall add the information to the label before the chemical is shipped or introduced into the workplace again.

(g) *Safety data sheets.* (1) Chemical manufacturers and importers shall obtain or develop a safety data sheet for each hazardous chemical they produce or import. Employers shall have a safety data sheet in the workplace for each hazardous chemical which they use.

(2) The chemical manufacturer or importer preparing the safety data sheet shall ensure that it is in English (although the employer may maintain copies in other languages as well), and includes at least the following section numbers and headings, and associated information under each heading, in the order listed (*See* Appendix D to § 1910.1200—Safety Data Sheets, for the specific content of each section of the safety data sheet):

(i) Section 1, Identification;

(ii) Section 2, Hazard(s) identification;

(iii) Section 3, Composition/information on ingredients;

(iv) Section 4, First-aid measures;

(v) Section 5, Fire-fighting measures;

(vi) Section 6, Accidental release measures;

(vii) Section 7, Handling and storage;

(viii) Section 8, Exposure controls/personal protection;

(ix) Section 9, Physical and chemical properties;

(x) Section 10, Stability and reactivity;

(xi) Section 11, Toxicological information;

(xii) Section 12, Ecological information;

(xiii) Section 13, Disposal considerations;

(xiv) Section 14, Transport information;

(xv) Section 15, Regulatory information; and

(xvi) Section 16, Other information, including date of preparation or last revision.

Note 1 to paragraph (g)(2): To be consistent with the GHS, an SDS must also include the headings in paragraphs (g)(2)(xii) through (g)(2)(xv) in order.

Note 2 to paragraph (g)(2): OSHA will not be enforcing information requirements in sections 12 through 15, as these areas are not under its jurisdiction.

(3) If no relevant information is found for any sub-heading within a section on the safety data sheet, the chemical manufacturer, importer or employer preparing the safety data sheet shall mark it to indicate that no applicable information was found.

* * * * *

(5) The chemical manufacturer, importer or employer preparing the safety data sheet shall ensure that the information provided accurately reflects the scientific evidence used in making the hazard classification. If the chemical manufacturer, importer or employer preparing the safety data sheet becomes newly aware of any significant information regarding the hazards of a chemical, or ways to protect against the hazards, this new information shall be added to the safety data sheet within three months. If the chemical is not

currently being produced or imported, the chemical manufacturer or importer shall add the information to the safety data sheet before the chemical is introduced into the workplace again.

* * * * *

(8) The employer shall maintain in the workplace copies of the required safety data sheets for each hazardous chemical, and shall ensure that they are readily accessible during each work shift to employees when they are in their work area(s). (Electronic access and other alternatives to maintaining paper copies of the safety data sheets are permitted as long as no barriers to immediate employee access in each workplace are created by such options.)

* * * * *

(11) Safety data sheets shall also be made readily available, upon request, to designated representatives, the Assistant Secretary, and the Director, in accordance with the requirements of § 1910.1020(e).

(h) * * *

(1) Employers shall provide employees with effective information and training on hazardous chemicals in their work area at the time of their initial assignment, and whenever a new chemical hazard the employees have not previously been trained about is introduced into their work area. Information and training may be designed to cover categories of hazards (e.g., flammability, carcinogenicity) or specific chemicals. Chemical-specific information must always be available through labels and safety data sheets.

* * * * *

(3) * * *

(ii) The physical, health, simple asphyxiation, combustible dust, and pyrophoric gas hazards, as well as hazards not otherwise classified, of the chemicals in the work area;

* * * * *

(iv) The details of the hazard communication program developed by the employer, including an explanation of the labels received on shipped containers and the workplace labeling system used by their employer; the safety data sheet, including the order of information and how employees can obtain and use the appropriate hazard information.

(i) * * *

(1) The chemical manufacturer, importer, or employer may withhold the specific chemical identity, including the chemical name, other specific identification of a hazardous chemical, or the exact percentage (concentration) of the substance in a mixture, from the safety data sheet, provided that:

* * * * *

(iii) The safety data sheet indicates that the specific chemical identity and/or percentage of composition is being withheld as a trade secret; and,

(iv) The specific chemical identity and percentage is made available to health professionals, employees, and designated representatives in accordance with the applicable provisions of this paragraph (i).

(2) Where a treating physician or nurse determines that a medical emergency exists and the specific chemical identity and/or specific percentage of composition of a hazardous chemical is necessary for emergency or first-aid treatment, the chemical manufacturer, importer, or employer shall immediately disclose the specific chemical identity or percentage composition of a trade secret chemical to that treating physician or nurse, regardless of the existence of a written statement of need or a confidentiality agreement. The chemical manufacturer, importer, or employer may require a written statement of need and confidentiality agreement, in accordance with the provisions of paragraphs (i)(3) and (4) of this section, as soon as circumstances permit.

(3) In non-emergency situations, a chemical manufacturer, importer, or employer shall, upon request, disclose a specific chemical identity or percentage composition, otherwise permitted to be withheld under paragraph (i)(1) of this section, to a health professional (i.e. physician, industrial hygienist, toxicologist, epidemiologist, or occupational health nurse) providing medical or other occupational health services to exposed employee(s), and to employees or designated representatives, if:

* * * * *

(iii) The request explains in detail why the disclosure of the specific chemical identity or percentage composition is essential and that, in lieu thereof, the disclosure of the following information to the health professional, employee, or designated representative, would not satisfy the purposes described in paragraph (i)(3)(ii) of this section:

* * * * *

(7) If the chemical manufacturer, importer, or employer denies a written request for disclosure of a specific chemical identity or percentage composition, the denial must:

* * * * *

(iii) Include evidence to support the claim that the specific chemical identity or percent of composition is a trade secret;

* * * * *

(v) Explain in detail how alternative information may satisfy the specific medical or occupational health need without revealing the trade secret.

* * * * *

(9) * * *

(i) The chemical manufacturer, importer, or employer has supported the claim that the specific chemical identity or percentage composition is a trade secret;

* * * * *

(10) * * *

(i) If OSHA determines that the specific chemical identity or percentage composition requested under paragraph (i)(3) of this section is not a ''bona fide'' trade secret, or that it is a trade secret, but the requesting health professional, employee, or designated representative has a legitimate medical or occupational health need for the information, has executed a written confidentiality agreement, and has shown adequate means to protect the confidentiality of the information, the chemical manufacturer, importer, or employer will be subject to citation by OSHA.

(ii) If a chemical manufacturer, importer, or employer demonstrates to OSHA that the execution of a confidentiality agreement would not provide sufficient protection against the potential harm from the unauthorized disclosure of a trade secret, the Assistant Secretary may issue such orders or impose such additional limitations or conditions upon the disclosure of the requested chemical information as may be appropriate to assure that the occupational health services are provided without an undue risk of harm to the chemical manufacturer, importer, or employer.

(11) If a citation for a failure to release trade secret information is contested by the chemical manufacturer, importer, or employer, the matter will be adjudicated before the Occupational Safety and Health Review Commission in accordance with the Act's enforcement scheme and the applicable Commission rules of procedure. In accordance with the Commission rules, when a chemical manufacturer, importer, or employer continues to withhold the information during the contest, the Administrative Law Judge may review the citation and supporting documentation ''in camera'' or issue appropriate orders to protect the confidentiality of such matters.

* * * * *

(j) *Effective dates.* (1) Employers shall train employees regarding the new label elements and safety data sheets format by December 1, 2013.

(2) Chemical manufacturers, importers, distributors, and employers

shall be in compliance with all modified provisions of this section no later than June 1, 2015, except:

(i) After December 1, 2015, the distributor shall not ship containers labeled by the chemical manufacturer or importer unless the label has been modified to comply with paragraph (f)(1) of this section.

(ii) All employers shall, as necessary, update any alternative workplace labeling used under paragraph (f)(6) of this section, update the hazard communication program required by paragraph (h)(1), and provide any additional employee training in accordance with paragraph (h)(3) for newly identified physical or health hazards no later than June 1, 2016.

(3) Chemical manufacturers, importers, distributors, and employers may comply with either § 1910.1200 revised as of October 1, 2011, or the current version of this standard, or both during the transition period.

Appendix A to § 1910.1200—Health Hazard Criteria (Mandatory)

A.0 GENERAL CLASSIFICATION CONSIDERATIONS

A.0.1 Classification

A.0.1.1 The term ''hazard classification'' is used to indicate that only the intrinsic hazardous properties of chemicals are considered. Hazard classification incorporates three steps:

(a) Identification of relevant data regarding the hazards of a chemical;

(b) Subsequent review of those data to ascertain the hazards associated with the chemical;

(c) Determination of whether the chemical will be classified as hazardous and the degree of hazard.

A.0.1.2 For many hazard classes, the criteria are semi-quantitative or qualitative and expert judgment is required to interpret the data for classification purposes.

A.0.2 Available Data, Test Methods and Test Data Quality

A.0.2.1 There is no requirement for testing chemicals.

A.0.2.2 The criteria for determining health hazards are test method neutral, i.e., they do not specify particular test methods, as long as the methods are scientifically validated.

A.0.2.3 The term ''scientifically validated'' refers to the process by which the reliability and the relevance of a procedure are established for a particular purpose. Any test that determines hazardous properties, which is conducted according to recognized scientific principles, can be used for purposes of a hazard determination for health hazards. Test conditions need to be standardized so that the results are reproducible with a given substance, and the standardized test yields ''valid'' data for defining the hazard class of concern.

A.0.2.4 Existing test data are acceptable for classifying chemicals, although expert judgment also may be needed for classification purposes.

A.0.2.5 The effect of a chemical on biological systems is influenced, by the physico-chemical properties of the substance and/or ingredients of the mixture and the way in which ingredient substances are biologically available. A chemical need not be classified when it can be shown by conclusive experimental data from scientifically validated test methods that the chemical is not biologically available.

A.0.2.6 For classification purposes, epidemiological data and experience on the effects of chemicals on humans (e.g., occupational data, data from accident databases) shall be taken into account in the evaluation of human health hazards of a chemical.

A.0.3 Classification Based on Weight of Evidence

A.0.3.1 For some hazard classes, classification results directly when the data satisfy the criteria. For others, classification of a chemical shall be determined on the basis of the total weight of evidence using expert judgment. This means that all available information bearing on the classification of hazard shall be considered together, including the results of valid *in vitro* tests, relevant animal data, and human experience such as epidemiological and clinical studies and well-documented case reports and observations.

A.0.3.2 The quality and consistency of the data shall be considered. Information on chemicals related to the material being classified shall be considered as appropriate, as well as site of action and mechanism or mode of action study results. Both positive and negative results shall be considered together in a single weight-of-evidence determination.

A.0.3.3 Positive effects which are consistent with the criteria for classification, whether seen in humans or animals, shall normally justify classification. Where evidence is available from both humans and animals and there is a conflict between the findings, the quality and reliability of the evidence from both sources shall be evaluated in order to resolve the question of classification. Reliable, good quality human data shall generally have precedence over other data. However, even well-designed and conducted epidemiological studies may lack a sufficient number of subjects to detect relatively rare but still significant effects, or to assess potentially confounding factors. Therefore, positive results from well-conducted animal studies are not necessarily negated by the lack of positive human experience but require an assessment of the robustness, quality and statistical power of both the human and animal data.

A.0.3.4 Route of exposure, mechanistic information, and metabolism studies are pertinent to determining the relevance of an effect in humans. When such information raises doubt about relevance in humans, a lower classification may be warranted. When there is scientific evidence demonstrating that the mechanism or mode of action is not relevant to humans, the chemical should not be classified.

A.0.3.5 Both positive and negative results are considered together in the weight of evidence determination. However, a single positive study performed according to good scientific principles and with statistically and biologically significant positive results may justify classification.

A.0.4 Considerations for the Classification of Mixtures

A.0.4.1 For most hazard classes, the recommended process of classification of mixtures is based on the following sequence:

(a) Where test data are available for the complete mixture, the classification of the mixture will always be based on those data;

(b) Where test data are not available for the mixture itself, the bridging principles designated in each health hazard chapter of this appendix shall be considered for classification of the mixture;

(c) If test data are not available for the mixture itself, and the available information is not sufficient to allow application of the above-mentioned bridging principles, then the method(s) described in each chapter for estimating the hazards based on the information known will be applied to classify the mixture (e.g., application of cut-off values/concentration limits).

A.0.4.2 An exception to the above order or precedence is made for Carcinogenicity, Germ Cell Mutagenicity, and Reproductive Toxicity. For these three hazard classes, mixtures shall be classified based upon information on the ingredient substances, unless on a case-by-case basis, justification can be provided for classifying based upon the mixture as a whole. See chapters A.5, A.6, and A.7 for further information on case-by-case bases.

A.0.4.3 Use of cut-off values/concentration limits.

A.0.4.3.1 When classifying an untested mixture based on the hazards of its ingredients, cut-off values/concentration limits for the classified ingredients of the mixture are used for several hazard classes. While the adopted cut-off values/concentration limits adequately identify the hazard for most mixtures, there may be some that contain hazardous ingredients at lower concentrations than the specified cut-off values/concentration limits that still pose an identifiable hazard. There may also be cases where the cut-off value/concentration limit is considerably lower than the established non-hazardous level for an ingredient.

A.0.4.3.2 If the classifier has information that the hazard of an ingredient will be evident (i.e., it presents a health risk) below the specified cut-off value/concentration limit, the mixture containing that ingredient shall be classified accordingly.

A.0.4.3.3 In exceptional cases, conclusive data may demonstrate that the hazard of an ingredient will not be evident (i.e., it does not present a health risk) when present at a level above the specified cut-off value/concentration limit(s). In these cases the mixture may be classified according to those data. The data must exclude the possibility that the ingredient will behave in the mixture in a manner that would increase the hazard over that of the pure substance. Furthermore, the mixture must not contain ingredients that would affect that determination.

A.0.4.4 Synergistic or antagonistic effects.

When performing an assessment in accordance with these requirements, the evaluator must take into account all available information about the potential occurrence of synergistic effects among the ingredients of the mixture. Lowering classification of a mixture to a less hazardous category on the basis of antagonistic effects may be done only if the determination is supported by sufficient data.

A.0.5 Bridging Principles for the Classification of Mixtures Where Test Data Are Not Available for the Complete Mixture

A.0.5.1 Where the mixture itself has not been tested to determine its toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data shall be used in accordance with the following bridging principles, subject to any specific provisions for mixtures for each hazard class. These principles ensure that the classification process uses the available data to the greatest extent possible in characterizing the hazards of the mixture.

A.0.5.1.1 Dilution.

For mixtures classified in accordance with A.1 through A.10 of this Appendix, if a tested mixture is diluted with a diluent that has an equivalent or lower toxicity classification than the least toxic original ingredient, and which is not expected to affect the toxicity of other ingredients, then:

(a) The new diluted mixture shall be classified as equivalent to the original tested mixture; or

(b) For classification of acute toxicity in accordance with A.1 of this Appendix, paragraph A.1.3.6 (the additivity formula) shall be applied.

A.0.5.1.2 Batching.

For mixtures classified in accordance with A.1 through A.10 of this Appendix, the toxicity of a tested production batch of a mixture can be assumed to be substantially equivalent to that of another untested production batch of the same mixture, when produced by or under the control of the same *chemical manufacturer,* unless there is reason to believe there is significant variation such that the toxicity of the untested batch has changed. If the latter occurs, a new classification is necessary.

A.0.5.1.3 Concentration of mixtures.

For mixtures classified in accordance with A.1, A.2, A.3, A.8, A.9, or A.10 of this Appendix, if a tested mixture is classified in Category 1, and the concentration of the ingredients of the tested mixture that are in Category 1 is increased, the resulting untested mixture shall be classified in Category 1.

A.0.5.1.4 Interpolation within one toxicity category.

For mixtures classified in accordance with A.1, A.2, A.3, A.8, A.9, or A.10 of this Appendix, for three mixtures (A, B and C) with identical ingredients, where mixtures A and B have been tested and are in the same toxicity category, and where untested mixture C has the same toxicologically active ingredients as mixtures A and B but has concentrations of toxicologically active ingredients intermediate to the concentrations in mixtures A and B, then mixture C is assumed to be in the same toxicity category as A and B.

A.0.5.1.5 Substantially similar mixtures.

For mixtures classified in accordance with A.1 through A.10 of this Appendix, given the following set of conditions:

(a) Where there are two mixtures:

(i) A + B;

(ii) C + B;

(b) The concentration of ingredient B is essentially the same in both mixtures;

(c) The concentration of ingredient A in mixture (i) equals that of ingredient C in mixture (ii);

(d) And data on toxicity for A and C are available and substantially equivalent; i.e., they are in the same hazard category and are not expected to affect the toxicity of B; then

If mixture (i) or (ii) is already classified based on test data, the other mixture can be assigned the same hazard category.

A.0.5.1.6 Aerosols.

For mixtures classified in accordance with A.1, A.2, A.3, A.4, A.8, or A.9 of this Appendix, an aerosol form of a mixture shall be classified in the same hazard category as the tested, non-aerosolized form of the mixture, provided the added propellant does not affect the toxicity of the mixture when spraying.

A.1 ACUTE TOXICITY

A.1.1 Definition

Acute toxicity refers to those adverse effects occurring following oral or dermal administration of a single dose of a substance, or multiple doses given within 24 hours, or an inhalation exposure of 4 hours.

A.1.2 Classification Criteria for Substances

A.1.2.1 Substances can be allocated to one of four toxicity categories based on acute toxicity by the oral, dermal or inhalation route according to the numeric cut-off criteria as shown in Table A.1.1. Acute toxicity values are expressed as (approximate) LD50 (oral, dermal) or LC50 (inhalation) values or as acute toxicity estimates (ATE). See the footnotes following Table A.1.1 for further explanation on the application of these values.

TABLE A.1.1—ACUTE TOXICITY HAZARD CATEGORIES AND ACUTE TOXICITY ESTIMATE (ATE) VALUES DEFINING THE RESPECTIVE CATEGORIES

Exposure route	Category 1	Category 2	Category 3	Category 4
Oral (mg/kg bodyweight) *see: Note (a), Note (b)*	≤5	>5 and ≤50	>50 and ≤300	>300 and ≤2000.
Dermal (mg/kg bodyweight) *see: Note (a), Note (b)*	≤5	>50 and ≤200	>200 and ≤1000	>1000 and ≤2000.
Inhalation—Gases (ppmV) *see: Note (a), Note (b), Note (c)*	≤100	>100 and ≤500	>500 and ≤2500	>2500 and ≤20000.
Inhalation—Vapors (mg/l) *see: Note (a), Note (b), Note (c), Note (d).*	≤0.5	>0.5 and ≤2.0	>2.0 and ≤10.0	>10.0 and ≤20.0.
Inhalation—Dusts and Mists (mg/l) *see: Note (a), Note (b), Note (c)*	≤0.05	>0.05 and ≤0.5	>0.5 and ≤1.0	>1.0 and ≤5.0.

Note: *Gas concentrations are expressed in parts per million per volume (ppmV).*

Notes to Table A.1.1:

(a) *The acute toxicity estimate (ATE) for the classification of a substance is derived using the LD_{50}/LC_{50} Stewardwhere available;*

(b) The acute toxicity estimate (ATE) for the classification of a substance or ingredient in a mixture is derived using:

(i) the LD_{50}/LC_{50} where available. Otherwise,

(ii) the appropriate conversion value from Table 1.2 that relates to the results of a range test, or

(iii) the appropriate conversion value from Table 1.2 that relates to a classification category;

(c) Inhalation cut-off values in the table are based on 4 hour testing exposures. Conversion of existing inhalation toxicity data which has been generated according to 1 hour exposure is achieved by dividing by a factor of 2 for gases and vapors and 4 for dusts and mists;

(d) For some substances the test atmosphere will be a vapor which consists of a combination of liquid and gaseous phases. For other substances the test atmosphere may consist of a vapor which is nearly all the gaseous phase. In these latter cases, classification is based on ppmV as follows: Category 1 (100 ppmV), Category 2 (500 ppmV), Category 3 (2500 ppmV), Category 4 (20000 ppmV).

The terms ''dust'', ''mist'' and ''vapor'' are defined as follows:

(i) Dust: solid particles of a substance or mixture suspended in a gas (usually air);

(ii) Mist: liquid droplets of a substance or mixture suspended in a gas (usually air);

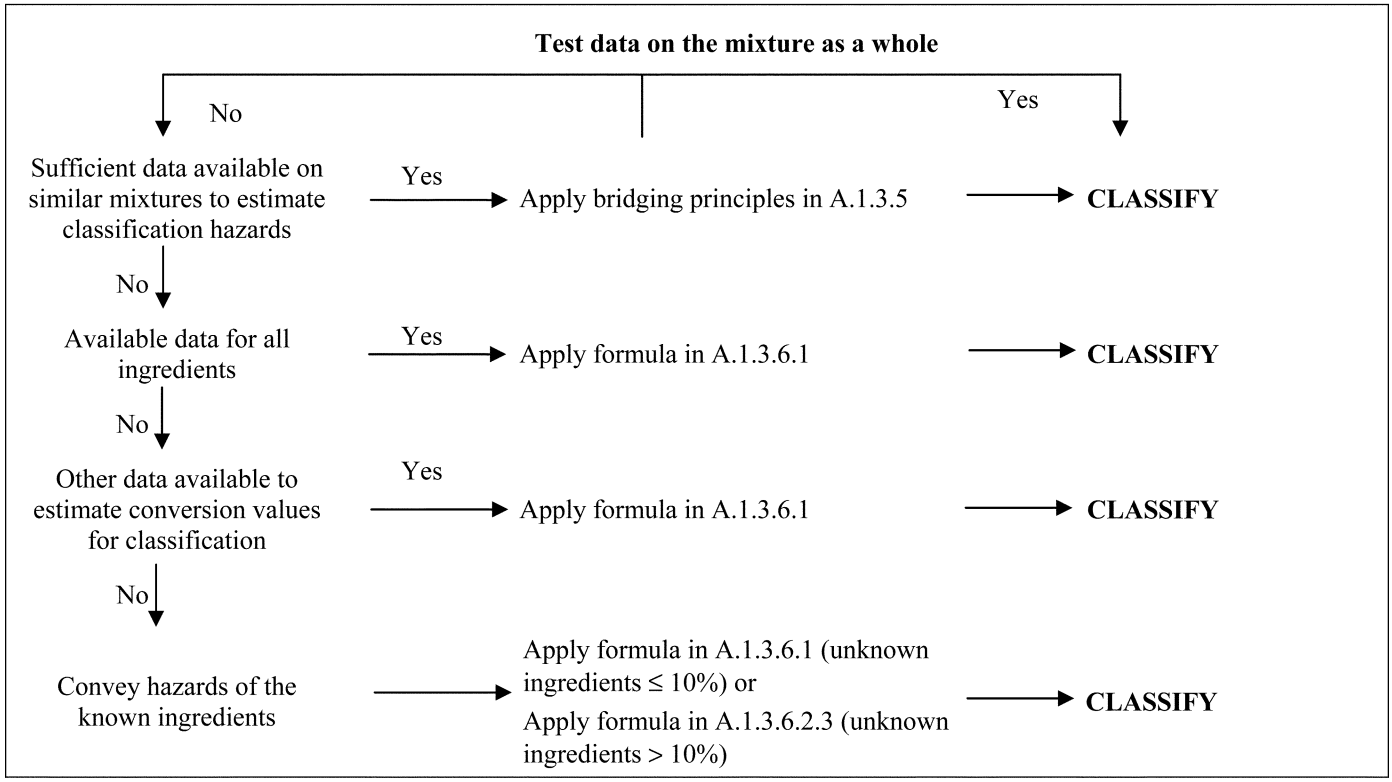
(iii) Vapor: the gaseous form of a substance or mixture released from its liquid or solid state.

A.1.2.3 The preferred test species for evaluation of acute toxicity by the oral and inhalation routes is the rat, while the rat or rabbit are preferred for evaluation of acute dermal toxicity. Test data already generated for the classification of chemicals under existing systems should be accepted when reclassifying these chemicals under the harmonized system. When experimental data for acute toxicity are available in several animal species, scientific judgment should be used in selecting the most appropriate LD_{50} value from among scientifically validated tests.

A.1.3 Classification Criteria for Mixtures

A.1.3.1 The approach to classification of mixtures for acute toxicity is tiered, and is dependent upon the amount of information available for the mixture itself and for its ingredients. The flow chart of Figure A.1.1 indicates the process that must be followed:

Figure A.1.1: Tiered approach to classification of mixtures for acute toxicity



A.1.3.2 Classification of mixtures for acute toxicity may be carried out for each route of exposure, but is only required for one route of exposure as long as this route is followed (estimated or tested) for all ingredients and there is no relevant evidence to suggest acute toxicity by multiple routes. When there is relevant evidence of acute toxicity by multiple routes of exposure, classification is to be conducted for all appropriate routes of exposure. All available information shall be considered. The pictogram and signal word used shall reflect the most severe hazard category; and all relevant hazard statements shall be used.

A.1.3.3 For purposes of classifying the hazards of mixtures in the tiered approach:

(a) The ''relevant ingredients'' of a mixture are those which are present in concentrations ≥1% (weight/weight for solids, liquids, dusts, mists and vapors and volume/volume for gases). If there is reason to suspect that an ingredient present at a concentration <1% will affect classification of the mixture for acute toxicity, that ingredient shall also be considered relevant. Consideration of ingredients present at a concentration <1% is particularly important when classifying untested mixtures which contain ingredients that are classified in Category 1 and Category 2;

(b) Where a classified mixture is used as an ingredient of another mixture, the actual or derived acute toxicity estimate (ATE) for that mixture is used when calculating the classification of the new mixture using the formulas in A.1.3.6.1 and A.1.3.6.2.4.

(c) If the converted acute toxicity point estimates for all ingredients of a mixture are within the same category, then the mixture should be classified in that category.

(d) When only range data (or acute toxicity hazard category information) are available for ingredients in a mixture, they may be converted to point estimates in accordance with Table A.1.2 when calculating the classification of the new mixture using the formulas in A.1.3.6.1 and A.1.3.6.2.4.

A.1.3.4 Classification of Mixtures Where Acute Toxicity Test Data Are Available for the Complete Mixture

Where the mixture itself has been tested to determine its acute toxicity, it is classified according to the same criteria as those used for substances, presented in Table A.1.1. If test data for the mixture are not available, the procedures presented below must be followed.

A.1.3.5 Classification of Mixtures Where Acute Toxicity Test Data Are Not Available for the Complete Mixture: Bridging Principles

A.1.3.5.1 Where the mixture itself has not been tested to determine its acute toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution, Batching, Concentration of mixtures, Interpolation within one toxicity category, Substantially similar mixtures, and Aerosols.

A.1.3.6 Classification of Mixtures Based on Ingredients of the Mixture (Additivity Formula)

A.1.3.6.1 Data available for all ingredients.

The acute toxicity estimate (ATE) of ingredients is considered as follows:

(a) Include ingredients with a known acute toxicity, which fall into any of the acute toxicity categories, or have an oral or dermal LD_{50} greater than 2000 but less than or equal to 5000 mg/kg body weight (or the equivalent dose for inhalation);

(b) Ignore ingredients that are presumed not acutely toxic (e.g., water, sugar);

(c) Ignore ingredients if the data available are from a limit dose test (at the upper threshold for Category 4 for the appropriate route of exposure as provided in Table A.1.1) and do not show acute toxicity.

Ingredients that fall within the scope of this paragraph are considered to be ingredients with a known acute toxicity estimate (ATE). See note (b) to Table A.1.1 and paragraph A.1.3.3 for appropriate application of available data to the equation below, and paragraph A.1.3.6.2.4.

The ATE of the mixture is determined by calculation from the ATE values for all relevant ingredients according to the following formula below for oral, dermal or inhalation toxicity:

$$\frac{100}{\mathrm{ATEmix}} = \sum_{n} \frac{\mathrm{Ci}}{\mathrm{ATE}_{i}}$$

Where:

Ci = concentration of ingredient i

n ingredients and i is running from 1 to n

ATEi = acute toxicity estimate of ingredient i.

A.1.3.6.2 Data are not available for one or more ingredients of the mixture.

A.1.3.6.2.1 Where an ATE is not available for an individual ingredient of the mixture, but available information provides a derived conversion value, the formula in A.1.3.6.1 may be applied. This information may include evaluation of:

(a) Extrapolation between oral, dermal and inhalation acute toxicity estimates. Such an evaluation requires appropriate pharmacodynamic and pharmacokinetic data;

(b) Evidence from human exposure that indicates toxic effects but does not provide lethal dose data;

(c) Evidence from any other toxicity tests/assays available on the substance that indicates toxic acute effects but does not necessarily provide lethal dose data; or

(d) Data from closely analogous substances using structure/activity relationships.

A.1.3.6.2.2 This approach requires substantial supplemental technical information, and a highly trained and experienced expert, to reliably estimate acute toxicity. If sufficient information is not available to reliably estimate acute toxicity, proceed to the provisions of A.1.3.6.2.3.

A.1.3.6.2.3 In the event that an ingredient with unknown acute toxicity is used in a mixture at a concentration ≥1%, and the mixture has not been classified based on testing of the mixture as a whole, the mixture cannot be attributed a definitive acute toxicity estimate. In this situation the mixture is classified based on the known ingredients only. (Note: A statement that × percent of the mixture consists of ingredient(s) of unknown toxicity is required on the label and safety data sheet in such cases; see Appendix C to this section, Allocation of Label Elements and Appendix D to this section, Safety Data Sheets.)

Where an ingredient with unknown acute toxicity is used in a mixture at a concentration ≥1%, and the mixture is not classified based on testing of the mixture as a whole, a statement that X% of the mixture consists of ingredient(s) of unknown acute toxicity is required on the label and safety data sheet in such cases; see Appendix C to this section, Allocation of Label Elements and Appendix D to this section, Safety Data Sheets.)

A.1.3.6.2.4 If the total concentration of the relevant ingredient(s) with unknown acute toxicity is ≤10% then the formula presented in A.1.3.6.1 must be used. If the total concentration of the relevant ingredient(s) with unknown acute toxicity is >10%, the formula presented in A.1.3.6.1 is corrected to adjust for the percentage of the unknown ingredient(s) as follows:

$$\frac{100 - \left(\sum C_{unknown} \text{ if} > 10\%\right)}{ATE_{mix}} = \sum_{n} \frac{Ci}{ATE_{i}}$$

TABLE A.1.2—CONVERSION FROM EXPERIMENTALLY OBTAINED ACUTE TOXICITY RANGE VALUES (OR ACUTE TOXICITY HAZARD CATEGORIES) TO ACUTE TOXICITY POINT ESTIMATES FOR USE IN THE FORMULAS FOR THE CLASSIFICATION OF MIXTURES

Exposure routes	Classification category or experimentally obtained acute toxicity range estimate	Converted acute toxicity point estimate
Oral (mg/kg bodyweight)	0 <Category 1 ≤5	0.5
	5 <Category 2 ≤50	5
	50 <Category 3 ≤300	100
	300 <Category 4 ≤2000	500
Dermal (mg/kg bodyweight)	0 <Category 1 ≤50	5
	50 <Category 2 ≤200	50
	200 <Category 3 ≤1000	300
	1000 <Category 4 ≤2000	1100
Gases (ppmV)	0 <Category 1 ≤100	10
	100 <Category 2 ≤500	100
	500 <Category 3 ≤2500	700
	2500 <Category 4 ≤20000	4500
Vapors (mg/l)	0 <Category 1 ≤0.5	0.05
	0.5 <Category 2 ≤2.0	0.5
	2.0 <Category 3 ≤10.0	3
	10.0 <Category 4 ≤20.0	11
Dust/mist (mg/l)	0 <Category 1 ≤0.05	0.005
	0.05 <Category 2 ≤0.5	0.05
	0.5 <Category 3 ≤1.0	0.5
	1.0 <Category 4 ≤5.0	1.5

Note: Gas concentrations are expressed in parts per million per volume (ppmV).

A.2 SKIN CORROSION/IRRITATION

A.2.1 Definitions and General Considerations

A.2.1.1 *Skin corrosion* is the production of irreversible damage to the skin; namely, visible necrosis through the epidermis and into the dermis, following the application of a test substance for up to 4 hours. Corrosive reactions are typified by ulcers, bleeding, bloody scabs, and, by the end of observation at 14 days, by discoloration due to blanching of the skin, complete areas of alopecia, and scars. Histopathology should be considered to evaluate questionable lesions.

Skin irritation is the production of reversible damage to the skin following the application of a test substance for up to 4 hours.

A.2.1.2 Skin corrosion/irritation shall be classified using a tiered approach as detailed in figure A.2.1. Emphasis shall be placed upon existing human data (See A.0.2.6), followed by other sources of information. Classification results directly when the data satisfy the criteria in this section. In case the criteria cannot be directly applied, classification of a substance or a mixture is made on the basis of the total weight of evidence (See A.0.3.1). This means that all available information bearing on the determination of skin corrosion/irritation is considered together, including the results of appropriate scientifically validated in-vitro tests, relevant animal data, and human data such as epidemiological and clinical studies and well-documented case reports and observations.

A.2.2 Classification Criteria for Substances Using Animal Test Data

A.2.2.1 Corrosion

A.2.2.1.1 A corrosive substance is a chemical that produces destruction of skin tissue, namely, visible necrosis through the epidermis and into the dermis, in at least 1 of 3 tested animals after exposure up to a 4-hour duration. Corrosive reactions are typified by ulcers, bleeding, bloody scabs and, by the end of observation at 14 days, by discoloration due to blanching of the skin, complete areas of alopecia and scars. Histopathology should be considered to discern questionable lesions.

A.2.2.1.2 Three sub-categories of Category 1 are provided in Table A.2.1, all of which shall be regulated as Category 1.

TABLE A.2.1—SKIN CORROSION CATEGORY AND SUB-CATEGORIES

Category 1: corrosive	Corrosive sub-categories	Corrosive in ≥1 of 3 animals	
		Exposure	Observation
	1A	≤3 min	≤1 h.
	1B	>3 min ≤1 h	≤14 days.
	1C	>1 h ≤4 h	≤14 days.

A.2.2.2 Irritation

A.2.2.2.1 A single irritant category (Category 2) is presented in the Table A.2.2. The major criterion for the irritant category is that at least 2 tested animals have a mean score of ≥2.3 ≤4.0.

TABLE A.2.2—SKIN IRRITATION CATEGORY

	Criteria
Irritant (Category 2)	(1) Mean value of ≥2.3 ≤4.0 for erythema/eschar or for edema in at least 2 of 3 tested animals from gradings at 24, 48 and 72 hours after patch removal or, if reactions are delayed, from grades on 3 consecutive days after the onset of skin reactions; or (2) Inflammation that persists to the end of the observation period normally 14 days in at least 2 animals, particularly taking into account alopecia (limited area), hyperkeratosis, hyperplasia, and scaling; or (3) In some cases where there is pronounced variability of response among animals, with very definite positive effects related to chemical exposure in a single animal but less than the criteria above.

A.2.2.2.2 Animal irritant responses within a test can be quite variable, as they are with corrosion. A separate irritant criterion accommodates cases when there is a significant irritant response but less than the mean score criterion for a positive test. For example, a substance might be designated as an irritant if at least 1 of 3 tested animals shows a very elevated mean score throughout the study, including lesions persisting at the end of an observation period of normally 14 days. Other responses could also fulfil this criterion. However, it should be ascertained that the responses are the result of chemical exposure. Addition of this criterion increases the sensitivity of the classification system.

A.2.2.2.3 Reversibility of skin lesions is another consideration in evaluating irritant responses. When inflammation persists to the end of the observation period in 2 or more test animals, taking into consideration alopecia (limited area), hyperkeratosis, hyperplasia and scaling, then a chemical should be considered to be an irritant.

A.2.3 Classification Criteria for Substances Using Other Data Elements

A.2.3.1 Existing human and animal data including information from single or repeated exposure should be the first line of analysis, as they give information directly relevant to effects on the skin. If a substance is highly toxic by the dermal route, a skin corrosion/irritation study may not be practicable since the amount of test substance to be applied would considerably exceed the toxic dose and, consequently, would result in the death of the animals. When observations are made of skin corrosion/irritation in acute toxicity studies and are observed up through the limit dose, these data may be used for classification provided that the dilutions used and species tested are equivalent. *In vitro* alternatives that have been scientifically validated shall be used to make classification decisions. Solid substances (powders) may become corrosive or irritant when moistened or in contact with moist skin or mucous membranes. Likewise, pH extremes like ≤2 and ≥11.5 may indicate skin effects, especially when associated with significant buffering capacity. Generally, such substances are expected to produce significant effects on the skin. In the absence of any other information, a substance is considered corrosive (Skin Category 1) if it has a pH ≤2 or a pH ≥11.5. However, if consideration of alkali/acid reserve suggests the substance or mixture may not be corrosive despite the low or high pH value, then further evaluation may be necessary. In some cases enough information may be available from structurally related compounds to make classification decisions.

A.2.3.2 A *tiered approach* to the evaluation of initial information shall be used (Figure A.2.1) recognizing that all elements may not be relevant in certain cases.

A.2.3.3 The tiered approach explains how to organize information on a substance and to make a weight-of-evidence decision about hazard assessment and hazard classification.

A.2.3.4 All the above information that is available on a substance shall be evaluated. Although information might be gained from the evaluation of single parameters within a

tier, there is merit in considering the totality of existing information and making an overall weight of evidence determination. This is especially true when there is information available on some but not all parameters. Emphasis shall be placed upon existing human experience and data, followed by animal experience and testing data, followed by other sources of information, but case-by-case determinations are necessary.

BILLING CODE 4510–26–P

Figure A.2.1: Tiered evaluation of skin corrosion and irritation potential

Step	Parameter	Finding	Conclusion
1a	Existing human or animal data[1]	Skin corrosive	Category 1[2]
	↓ Not corrosive or no data		
1b	Existing human or animal data[1]	Skin irritant	Category 2[2]
	↓ Not an irritant or no data		
1c	Existing human or animal data[1]	Not a skin corrosive or skin irritant	Not classified
	↓ No/Insufficient data		
2:	Other, existing skin data in animals[3]	Skin corrosive Skin irritant	Category 1[2] Category 2[2]
	↓ No/Insufficient data		
3:	Existing skin corrosive *ex vivo / in vitro* data[4]	Positive: Skin corrosive	Category 1[2]
	↓ Not corrosive or no data		
	Existing skin irritation *ex vivo / in vitro* data[4]	Positive: Skin irritant	Category 2[2]
	↓	Negative: Not a skin irritant[5]	Not classified
	↓ No/Insufficient data		
4:	pH-Based assessment (with consideration of buffering capacity of the chemical, or no buffering capacity data)[5]	pH ≤ 2 or ≥ 11.5	Category 1[2]
	↓ Not a pH extreme, No pH data or extreme pH with low/no buffering capacity		
5:	Validated Structure/Activity Relationship (SAR) models	Skin corrosive	Category 1[2]
	↓ No/Insufficient data	Skin irritant	Category 2[2]
6:	Consideration of the total Weight of Evidence[6]	Skin corrosive	Category 1[2]
	↓ No concern based on consideration of the sum of available data	Skin irritant	Category 2[2]
7:	**Not Classified**		Not classified

Notes to Figure A.2.1:

[1] *Evidence of existing human or animal data may be derived from single or repeated exposure(s) in occupational, consumer, transportation, or emergency response scenarios; from ethically-conducted human clinical studies; or from purposely-generated data from animal studies conducted according to scientifically validated test methods (at present, there is no internationally accepted test method for human skin irritation testing).*

[2] *Classify in the appropriate harmonized category, as shown in Tables A.2.1 and A.2.2.*

[3] *Pre-existing animal data (e.g. from an acute dermal toxicity test or a sensitisation test) should be carefully reviewed to determine if sufficient skin corrosion/irritation evidence is available through other, similar information. For example, classification/categorization may be done on the basis of whether a chemical has or has not produced any skin irritation in an acute dermal toxicity test in animals at the limit dose, or produces very toxic effects in an acute dermal toxicity test in animals. In the latter case, the chemical would be classified as being very hazardous by the dermal route for acute toxicity, and it would be moot whether the chemical is also irritating or corrosive on the skin. It should be kept in mind in evaluating acute dermal toxicity information that the reporting of dermal lesions may be incomplete, testing and observations may be made on a species other than the rabbit, and species may differ in sensitivity in their responses.*

[4] *Evidence from studies using scientifically validated protocols with isolated human/animal tissues or other, non-tissue-based, though scientifically validated, protocols should be assessed. Examples of scientifically validated test methods for skin corrosion include OECD TG 430 (Transcutaneous Electrical Resistance Test (TER)), 431 (Human Skin Model Test), and 435 (Membrane Barrier Test Method). OECD TG 439 (Reconstructed Human Epidermis Test Method) is a scientifically validated in vitro test method for skin irritation.*

[5] *Measurement of pH alone may be adequate, but assessment of acid or alkali reserve (buffering capacity) would be preferable. Presently, there is no scientifically validated and internationally accepted method for assessing this parameter.*

[6] *All information that is available on a chemical should be considered and an overall determination made on the total weight of evidence. This is especially true when there is conflict in information available on some parameters. Professional judgment should be exercised in making such a determination.*

BILLING CODE 4510–26–C

A.2.4 Classification Criteria for Mixtures

A.2.4.1 Classification of Mixtures When Data Are Available for the Complete Mixture

A.2.4.1.1 The mixture shall be classified using the criteria for substances (See A.2.3).

A.2.4.2 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.2.4.2.1 Where the mixture itself has not been tested to determine its skin corrosion/irritation, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following bridging principles, as found in paragraph A.0.5 of this Appendix: Dilution, Batching, Concentration of mixtures, Interpolation within one toxicity category, Substantially similar mixtures, and Aerosols.

A.2.4.3 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.2.4.3.1 For purposes of classifying the skin corrosion/irritation hazards of mixtures in the tiered approach:

The ''relevant ingredients'' of a mixture are those which are present in concentrations >1% (weight/weight for solids, liquids, dusts, mists and vapors and volume/volume for gases.) If the classifier has reason to suspect that an ingredient present at a concentration <1% will affect classification of the mixture for skin corrosion/irritation, that ingredient shall also be considered relevant.

A.2.4.3.2 In general, the approach to classification of mixtures as irritant or corrosive to skin when data are available on the ingredients, but not on the mixture as a whole, is based on the theory of additivity, such that each corrosive or irritant ingredient contributes to the overall irritant or corrosive properties of the mixture in proportion to its potency and concentration. A weighting factor of 10 is used for corrosive ingredients when they are present at a concentration below the concentration limit for classification with Category 1, but are at a concentration that will contribute to the classification of the mixture as an irritant. The mixture is classified as corrosive or irritant when the sum of the concentrations of such ingredients exceeds a cut-off value/concentration limit.

A.2.4.3.3 Table A.2.3 below provides the cut-off value/concentration limits to be used to determine if the mixture is considered to be an irritant or a corrosive to the skin.

A.2.4.3.4 Particular care shall be taken when classifying certain types of chemicals such as acids and bases, inorganic salts, aldehydes, phenols, and surfactants. The approach explained in A.2.4.3.1 and A.2.4.3.2 might not work given that many of such substances are corrosive or irritant at concentrations <1%. For mixtures containing strong acids or bases the pH should be used as classification criteria since pH will be a better indicator of corrosion than the concentration limits of Table A.2.3. A mixture containing corrosive or irritant ingredients that cannot be classified based on the additivity approach shown in Table A.2.3, due to chemical characteristics that make this approach unworkable, should be classified as Skin Category 1 if it contains ≥1% of a corrosive ingredient and as Skin Category 2 when it contains ≥3% of an irritant ingredient. Classification of mixtures with ingredients for which the approach in Table A.2.3 does not apply is summarized in Table A.2.4 below.

A.2.4.3.5 On occasion, reliable data may show that the skin corrosion/irritation of an ingredient will not be evident when present at a level above the generic concentration cut-off values mentioned in Tables A.2.3 and A.2.4. In these cases the mixture could be classified according to those data (See *Use of cut-off values/concentration limits,* paragraph A.0.4.3 of this Appendix).

A.2.4.3.6 If there are data showing that (an) ingredient(s) may be corrosive or irritant at a concentration of <1% (corrosive) or <3% (irritant), the mixture shall be classified accordingly (See *Use of cut-off values/concentration limits,* paragraph A.0.4.3 of this Appendix).

TABLE A.2.3—CONCENTRATION OF INGREDIENTS OF A MIXTURE CLASSIFIED AS SKIN CATEGORY 1 OR 2 THAT WOULD TRIGGER

[Category 1 or 2]

Sum of ingredients classified as:	Concentration triggering classification of a mixture as:	
	Skin corrosive	Skin irritant
	Category 1	Category 2
Skin Category 1	≥5%	≥1% but <5%.
Skin Category 2		≥10%.
(10 × Skin Category 1) + Skin Category 2		≥10%.

TABLE A.2.4—CONCENTRATION OF INGREDIENTS OF A MIXTURE FOR WHICH THE ADDITIVITY APPROACH DOES NOT APPLY, THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE AS HAZARDOUS TO SKIN

Ingredient:	Concentration:	Mixture classified as: Skin
Acid with pH ≤2	≥1%	Category 1.
Base with pH ≥11.5	≥1%	Category 1.
Other corrosive (Category 1) ingredients for which additivity does not apply	≥1%	Category 1.
Other irritant (Category 2) ingredients for which additivity does not apply, including acids and bases	≥3%	Category 2.

A.3 SERIOUS EYE DAMAGE/EYE IRRITATION

A.3.1 Definitions and General Considerations

A.3.1.1 *Serious eye damage* is the production of tissue damage in the eye, or serious physical decay of vision, following application of a test substance to the anterior surface of the eye, which is not fully reversible within 21 days of application.

Eye irritation is the production of changes in the eye following the application of test substance to the anterior surface of the eye, which are fully reversible within 21 days of application.

A.3.1.2 Serious eye damage/eye irritation shall be classified using a tiered approach as detailed in Figure A.3.1. Emphasis shall be placed upon existing human data (See A.0.2.6), followed by animal data, followed by other sources of information. Classification results directly when the data satisfy the criteria in this section. In case the criteria cannot be directly applied, classification of a substance or a mixture is made on the basis of the total weight of evidence (See A.0.3.1). This means that all available information bearing on the determination of serious eye damage/eye irritation is considered together, including the results of appropriate scientifically validated *in vitro* tests, relevant animal data, and human data such as epidemiological and clinical studies and well-documented case reports and observations.

A.3.2 Classification Criteria for Substances Using Animal Test Data

A.3.2.1 Irreversible effects on the eye/serious damage to eyes (Category 1).

A single hazard category is provided in Table A.3.1, for substances that have the potential to seriously damage the eyes. Category 1, irreversible effects on the eye, includes the criteria listed below. These observations include animals with grade 4 cornea lesions and other severe reactions (e.g. destruction of cornea) observed at any time during the test, as well as persistent corneal opacity, discoloration of the cornea by a dye substance, adhesion, pannus, and interference with the function of the iris or other effects that impair sight. In this context, persistent lesions are considered those which are not fully reversible within an observation period of normally 21 days. Category 1 also contains substances fulfilling the criteria of corneal opacity ≥3 and/or iritis >1.5 detected in a Draize eye test with rabbits, because severe lesions like these usually do not reverse within a 21-day observation period.

TABLE A.3.1—IRREVERSIBLE EYE EFFECTS

A substance is classified as Serious Eye Damage Category 1 (irreversible effects on the eye) when it produces:
(a) at least in one tested animal, effects on the cornea, iris or conjunctiva that are not expected to reverse or have not fully reversed within an observation period of normally 21 days; and/or
(b) at least in 2 of 3 tested animals, a positive response of:
(i) corneal opacity ≥3; and/or
(ii) iritis >1.5;
calculated as the mean scores following grading at 24, 48 and 72 hours after instillation of the substance.

A.3.2.2 Reversible effects on the eye (Category 2).

A single category is provided in Table A.3.2 for substances that have the potential to induce reversible eye irritation.

TABLE A.3.2—REVERSIBLE EYE EFFECTS

A substance is classified as Eye irritant Category 2A (irritating to eyes) when it produces in at least in 2 of 3 tested animals a positive response of:
(i) corneal opacity ≥1; and/or
(ii) iritis ≥1; and/or
(iii) conjunctival redness ≥2; and/or
(iv) conjunctival edema (chemosis) ≥2

TABLE A.3.2—REVERSIBLE EYE EFFECTS—Continued

calculated as the mean scores following grading at 24, 48 and 72 hours after instillation of the substance, and which fully reverses within an observation period of normally 21 days.
An eye irritant is considered mildly irritating to eyes (Category 2B) when the effects listed above are fully reversible within 7 days of observation.

A.3.2.3 For those chemicals where there is pronounced variability among animal responses, this information may be taken into account in determining the classification.

A.3.3 Classification Criteria for Substances Using Other Data Elements

A.3.3.1 Existing human and animal data should be the first line of analysis, as they give information directly relevant to effects on the eye. Possible skin corrosion shall be evaluated prior to consideration of serious eye damage/eye irritation in order to avoid testing for local effects on eyes with skin corrosive substances. *In vitro* alternatives that have been scientifically validated and accepted shall be used to make classification decisions. Likewise, pH extremes like ≤2 and ≥11.5, may indicate serious eye damage, especially when associated with significant buffering capacity. Generally, such substances are expected to produce significant effects on the eyes. In the absence of any other information, a mixture/substance is considered to cause serious eye damage (Eye Category 1) if it has a pH ≤2 or ≥11.5. However, if consideration of acid/alkaline reserve suggests the substance may not have the potential to cause serious eye damage despite the low or high pH value, then further evaluation may be necessary. In some cases enough information may be available from structurally related compounds to make classification decisions.

A.3.3.2 A tiered approach to the evaluation of initial information shall be used where applicable, recognizing that all elements may not be relevant in certain cases (Figure A.3.1).

A.3.3.3 The tiered approach explains how to organize existing information on a substance and to make a weight-of-evidence decision, where appropriate, about hazard assessment and hazard classification.

A.3.3.4 All the above information that is available on a substance shall be evaluated. Although information might be gained from the evaluation of single parameters within a tier, consideration should be given to the totality of existing information and making an overall weight-of-evidence determination. This is especially true when there is conflict in information available on some parameters.

BILLING CODE 4510–26–P

Figure A.3.1 Evaluation strategy for serious eye damage and eye irritation (See also Figure A.2.1)

Step	Parameter	Finding	Conclusion
1a:	Existing human or animal data, eye[1]	Serious Eye Damage	Category 1[2]
		Eye Irritant	Category 2[2]
	No/insufficient data or unknown		
1b:	Existing human or animal data, skin corrosion	Skin corrosive	Category 1[2]
	No/insufficient data or unknown		
1c:	Existing human or animal data, eye[1]	Existing data that show that substance does not cause serious eye damage or eye irritation	Not Classified
	No/insufficient data		
2:	Other, existing skin/eye data in animals[3]	Yes; existing data that show that substance may cause serious eye damage or eye irritation	Category1 or Category 2[2]
	No/insufficient data		
3:	Existing *ex vivo / in vitro* data[4]	Positive: serious eye damage	Category 1[2]
		Positive: eye irritant	Category 2[2]
	No/insufficient data / negative response		
4:	pH-Based assessment (with consideration of buffering capacity of the chemical, or no buffering capacity data)[5]	pH ≤ 2 or ≥11.5	Category 1[2]
	Not a pH extreme, no pH data, or extreme pH with low/no buffering capacity		
5:	Validated structure/activity relationship (SAR) models	Severe damage to eyes	Category 1[2]
		Eye irritant	Category 2[2]
		Skin Corrosive	Category 1[2]
	No/insufficient data		
6:	Consideration of the total weight of evidence[6]	Serious eye damage	Category 1[2]
		Eye irritant	Category 2[2]
	No concern based on consideration of the sum of available data		
7:	**Not Classified**		

Notes to Figure A.3.1:

[1] *Evidence of existing human or animal data may be derived from single or repeated exposure(s) in occupational, consumer, transportation, or emergency response scenarios; from ethically-conducted human clinical studies; or from purposely-generated data from animal studies conducted according to scientifically validated test methods. At present, there are no internationally accepted test methods for human skin or eye irritation testing.*

[2] *Classify in the appropriate harmonized category, as shown in Tables A.3.1 and A.3.2.*

[3] *Pre-existing animal data should be carefully reviewed to determine if sufficient skin or eye corrosion/irritation evidence is available through other, similar information.*

[4] *Evidence from studies using scientifically validated protocols with isolated human/animal tissues or other, non-tissue-based, though scientifically validated, protocols should be assessed. Examples of, scientifically validated test methods for identifying eye corrosives and severe irritants (i.e., Serious Eye Damage) include OECD TG 437 (Bovine Corneal Opacity and Permeability (BCOP)) and TG 438 (Isolated Chicken Eye). Positive test results from a scientifically validated in vitro test for skin corrosion would likely also lead to a conclusion to classify as causing Serious Eye Damage.*

[5] *Measurement of pH alone may be adequate, but assessment of acid or alkali reserve (buffering capacity) would be preferable.*

[6] *All information that is available on a chemical should be considered and an overall determination made on the total weight of evidence. This is especially true when there is conflict in information available on some parameters. The weight of evidence including information on skin irritation could lead to classification of eye irritation. It is recognized that not all skin irritants are eye irritants as well. Professional judgment should be exercised in making such a determination.*

BILLING CODE 4510–26–C

A.3.4 Classification Criteria for Mixtures

A.3.4.1 Classification of Mixtures When Data Are Available for the Complete Mixture

A.3.4.1.1 The mixture will be classified using the criteria for substances.

A.3.4.1.2 Unlike other hazard classes, there are alternative tests available for skin corrosivity of certain types of chemicals that can give an accurate result for classification purposes, as well as being simple and relatively inexpensive to perform. When considering testing of the mixture, chemical manufacturers are encouraged to use a tiered weight of evidence strategy as included in the criteria for classification of substances for skin corrosion and serious eye damage and eye irritation to help ensure an accurate classification, as well as avoid unnecessary animal testing. In the absence of any other information, a mixture is considered to cause serious eye damage (Eye Category 1) if it has a pH ≤2 or ≥11.5. However, if consideration of acid/alkaline reserve suggests the substance or mixture may not have the potential to cause serious eye damage despite the low or high pH value, then further evaluation may be necessary.

A.3.4.2 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.3.4.2.1 Where the mixture itself has not been tested to determine its skin corrosivity or potential to cause serious eye damage or eye irritation, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following bridging principles, as found in paragraph A.0.5 of this Appendix: Dilution, Batching, Concentration of mixtures, Interpolation within one toxicity category, Substantially similar mixtures, and Aerosols.

A.3.4.3 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.3.4.3.1 For purposes of classifying the eye corrosion/irritation hazards of mixtures in the tiered approach:

The ''relevant ingredients'' of a mixture are those which are present in concentrations >1% (weight/weight for solids, liquids, dusts, mists and vapors and volume/volume for gases). If the classifier has reason to suspect that an ingredient present at a concentration <1% will affect classification of the mixture for eye corrosion/irritation, that ingredient shall also be considered relevant.

A.3.4.3.2 In general, the approach to classification of mixtures as seriously damaging to the eye or eye irritant when data are available on the ingredients, but not on the mixture as a whole, is based on the theory of additivity, such that each corrosive or irritant ingredient contributes to the overall irritant or corrosive properties of the mixture in proportion to its potency and concentration. A weighting factor of 10 is used for corrosive ingredients when they are present at a concentration below the concentration limit for classification with Category 1, but are at a concentration that will contribute to the classification of the mixture as an irritant. The mixture is classified as seriously damaging to the eye or eye irritant when the sum of the concentrations of such ingredients exceeds a threshold cut-off value/concentration limit.

A.3.4.3.3 Table A.3.3 provides the cut-off value/concentration limits to be used to determine if the mixture should be classified as seriously damaging to the eye or an eye irritant.

A.3.4.3.4 Particular care must be taken when classifying certain types of chemicals such as acids and bases, inorganic salts, aldehydes, phenols, and surfactants. The approach explained in A.3.4.3.1 and A.3.4.3.2 might not work given that many of such substances are corrosive or irritant at concentrations <1%. For mixtures containing strong acids or bases, the pH should be used as classification criteria (See A.3.4.1) since pH will be a better indicator of serious eye damage than the concentration limits of Table A.3.3. A mixture containing corrosive or irritant ingredients that cannot be classified based on the additivity approach applied in Table A.3.3 due to chemical characteristics that make this approach unworkable, should be classified as Eye Category 1 if it contains ≥1% of a corrosive ingredient and as Eye Category 2 when it contains ≥3% of an irritant ingredient. Classification of mixtures with ingredients for which the approach in Table A.3.3 does not apply is summarized in Table A.3.4.

A.3.4.3.5 On occasion, reliable data may show that the reversible/irreversible eye effects of an ingredient will not be evident when present at a level above the generic cut-off values/concentration limits mentioned in Tables A.3.3 and A.3.4. In these cases the mixture could be classified according to those data (See also A.0.4.3 *Use of cut-off values/concentration limits*''). On occasion, when it is expected that the skin corrosion/irritation or the reversible/irreversible eye effects of an ingredient will not be evident when present at a level above the generic concentration/cut-off levels mentioned in Tables A.3.3 and A.3.4, testing of the mixture may be considered. In those cases, the tiered weight of evidence strategy should be applied as referred to in section A.3.3, Figure A.3.1 and explained in detail in this chapter.

A.3.4.3.6 If there are data showing that (an) ingredient(s) may be corrosive or irritant at a concentration of <1% (corrosive) or <3% (irritant), the mixture should be classified accordingly (See also paragraph A.0.4.3, *Use of cut-off values/concentration limits*).

TABLE A.3.3—CONCENTRATION OF INGREDIENTS OF A MIXTURE CLASSIFIED AS SKIN CATEGORY 1 AND/OR EYE CATEGORY 1 OR 2 THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURES AS HAZARDOUS TO THE EYE

Sum of ingredients classified as:	Concentration triggering classification of a mixture as:	
	Irreversible eye effects	Reversible eye effects
	Category 1	Category 2
Eye or Skin Category 1	≥3%	≥1% but <3%.

TABLE A.3.3—CONCENTRATION OF INGREDIENTS OF A MIXTURE CLASSIFIED AS SKIN CATEGORY 1 AND/OR EYE CATEGORY 1 OR 2 THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURES AS HAZARDOUS TO THE EYE—Continued

Sum of ingredients classified as:	Concentration triggering classification of a mixture as:	
	Irreversible eye effects	Reversible eye effects
	Category 1	Category 2
Eye Category 2		≥10%.
(10 × Eye Category 1) + Eye Category 2		≥10%.
Skin Category 1 + Eye Category 1	≥3%	≥1% but <3%.
10 × (Skin Category 1 + Eye Category 1) + Eye Category 2		≥10%.

Note: *A mixture may be classified as Eye Category 2B in cases when all relevant ingredients are classified as Eye Category 2B.*

TABLE A.3.4—CONCENTRATION OF INGREDIENTS OF A MIXTURE FOR WHICH THE ADDITIVITY APPROACH DOES NOT APPLY, THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE AS HAZARDOUS TO THE EYE

Ingredient	Concentration	Mixture classified as: Eye
Acid with pH ≤2	≥1%	Category 1.
Base with pH ≥11.5	≥1%	Category 1.
Other corrosive (Category 1) ingredients for which additivity does not apply	≥1%	Category 1.
Other irritant (Category 2) ingredients for which additivity does not apply, including acids and bases	≥3%	Category 2.

A.4 RESPIRATORY OR SKIN SENSITIZATION

A.4.1 Definitions and General Considerations

A.4.1.1 *Respiratory sensitizer* means a chemical that will lead to hypersensitivity of the airways following inhalation of the chemical.

Skin sensitizer means a chemical that will lead to an allergic response following skin contact.

A.4.1.2 For the purpose of this chapter, sensitization includes two phases: the first phase is induction of specialized immunological memory in an individual by exposure to an allergen. The second phase is elicitation, i.e., production of a cell-mediated or antibody-mediated allergic response by exposure of a sensitized individual to an allergen.

A.4.1.3 For respiratory sensitization, the pattern of induction followed by elicitation phases is shared in common with skin sensitization. For skin sensitization, an induction phase is required in which the immune system learns to react; clinical symptoms can then arise when subsequent exposure is sufficient to elicit a visible skin reaction (elicitation phase). As a consequence, predictive tests usually follow this pattern in which there is an induction phase, the response to which is measured by a standardized elicitation phase, typically involving a patch test. The local lymph node assay is the exception, directly measuring the induction response. Evidence of skin sensitization in humans normally is assessed by a diagnostic patch test.

A.4.1.4 Usually, for both skin and respiratory sensitization, lower levels are necessary for elicitation than are required for induction.

A.4.1.5 The hazard class ''respiratory or skin sensitization'' is differentiated into:

(a) Respiratory sensitization; and

(b) Skin sensitization.

A.4.2 Classification Criteria for Substances

A.4.2.1 Respiratory Sensitizers

A.4.2.1.1 Hazard Categories.

A.4.2.1.1.1 Effects seen in either humans or animals will normally justify classification in a weight of evidence approach for respiratory sensitizers. Substances may be allocated to one of the two sub-categories 1A or 1B using a weight of evidence approach in accordance with the criteria given in Table A.4.1 and on the basis of reliable and good quality evidence from human cases or epidemiological studies and/or observations from appropriate studies in experimental animals.

A.4.2.1.1.2 Where data are not sufficient for sub-categorization, respiratory sensitizers shall be classified in Category 1.

TABLE A.4.1—HAZARD CATEGORY AND SUB-CATEGORIES FOR RESPIRATORY SENSITIZERS

Category 1	Respiratory sensitizer
	A substance is classified as a respiratory sensitizer. (a) if there is evidence in humans that the substance can lead to specific respiratory hypersensitivity and/or (b) if there are positive results from an appropriate animal test.[1]
Sub-category 1A	Substances showing a high frequency of occurrence in humans; or a probability of occurrence of a high sensitization rate in humans based on animal or other tests.[1] Severity of reaction may also be considered.
Sub-category 1B	Substances showing a low to moderate frequency of occurrence in humans; or a probability of occurrence of a low to moderate sensitization rate in humans based on animal or other tests.[1] Severity of reaction may also be considered.

A.4.2.1.2 Human evidence.

A.4.2.1.2.1 Evidence that a substance can lead to specific respiratory hypersensitivity will normally be based on human experience. In this context, hypersensitivity is normally seen as asthma, but other hypersensitivity reactions such as rhinitis/conjunctivitis and alveolitis are also considered. The condition will have the clinical character of an allergic reaction. However, immunological mechanisms do not have to be demonstrated.

A.4.2.1.2.2 When considering the human evidence, it is necessary that in addition to

[1] *At this writing, recognized and validated animal models for the testing of respiratory hypersensitivity are not available. Under certain circumstances, data from animal studies may provide valuable information in a weight of evidence assessment.*

the evidence from the cases, the following be taken into account:

(a) The size of the population exposed;

(b) The extent of exposure.

A.4.2.1.2.3 The evidence referred to above could be:

(a) Clinical history and data from appropriate lung function tests related to exposure to the substance, confirmed by other supportive evidence which may include:

(i) *In vivo* immunological test (e.g., skin prick test);

(ii) *In vitro* immunological test (e.g., serological analysis);

(iii) Studies that may indicate other specific hypersensitivity reactions where immunological mechanisms of action have not been proven, e.g., repeated low-level irritation, pharmacologically mediated effects;

(iv) A chemical structure related to substances known to cause respiratory hypersensitivity;

(b) Data from positive bronchial challenge tests with the substance conducted according to accepted guidelines for the determination of a specific hypersensitivity reaction.

A.4.2.1.2.4 Clinical history should include both medical and occupational history to determine a relationship between exposure to a specific substance and development of respiratory hypersensitivity. Relevant information includes aggravating factors both in the home and workplace, the onset and progress of the disease, family history and medical history of the patient in question. The medical history should also include a note of other allergic or airway disorders from childhood and smoking history.

A.4.2.1.2.5 The results of positive bronchial challenge tests are considered to provide sufficient evidence for classification on their own. It is, however, recognized that in practice many of the examinations listed above will already have been carried out.

A.4.2.1.3 Animal studies.

A.4.2.1.3.1 Data from appropriate animal studies [2] which may be indicative of the potential of a substance to cause sensitization by inhalation in humans [3] may include:

(a) Measurements of Immunoglobulin E (IgE) and other specific immunological parameters, for example in mice

(b) Specific pulmonary responses in guinea pigs.

A.4.2.2 Skin Sensitizers

A.4.2.2.1 Hazard categories.

A.4.2.2.1.1 Effects seen in either humans or animals will normally justify classification in a weight of evidence approach for skin sensitizers. Substances may be allocated to one of the two sub-categories 1A or 1B using a weight of evidence approach in accordance with the criteria given in Table A.4.2 and on the basis of reliable and good quality evidence from human cases or epidemiological studies and/or observations from appropriate studies in experimental animals according to the guidance values provided in A.4.2.2.2.1 and A.4.2.2.3.2 for sub-category 1A and in A.4.2.2.2.2 and A.4.2.2.3.3 for sub-category 1B.

A.4.2.2.1.2 Where data are not sufficient for sub-categorization, skin sensitizers shall be classified in Category 1.

TABLE A.4.2—HAZARD CATEGORY AND SUB-CATEGORIES FOR SKIN SENSITIZERS

Category 1	Skin sensitizer
	A substance is classified as a skin sensitizer. (a) if there is evidence in humans that the substance can lead to sensitization by skin contact in a substantial number of persons, or (b) if there are positive results from an appropriate animal test.
Sub-category 1A	Substances showing a high frequency of occurrence in humans and/or a high potency in animals can be presumed to have the potential to produce significant sensitization in humans. Severity of reaction may also be considered.
Sub-category 1B	Substances showing a low to moderate frequency of occurrence in humans and/or a low to moderate potency in animals can be presumed to have the potential to produce sensitization in humans. Severity of reaction may also be considered.

A.4.2.2.2 Human evidence.

A.4.2.2.2.1 Human evidence for sub-category 1A may include:

(a) Positive responses at ≤500 μg/cm^2 (Human Repeat Insult Patch Test (HRIPT), Human Maximization Test (HMT)—induction threshold);

(b) Diagnostic patch test data where there is a relatively high and substantial incidence of reactions in a defined population in relation to relatively low exposure;

(c) Other epidemiological evidence where there is a relatively high and substantial incidence of allergic contact dermatitis in relation to relatively low exposure.

A.4.2.2.2.2 Human evidence for sub-category 1B may include:

(a) Positive responses at >500 μg/cm^2 (HRIPT, HMT—induction threshold);

(b) Diagnostic patch test data where there is a relatively low but substantial incidence of reactions in a defined population in relation to relatively high exposure;

(c) Other epidemiological evidence where there is a relatively low but substantial incidence of allergic contact dermatitis in relation to relatively high exposure.

A.4.2.2.3 Animal studies

A.4.2.2.3.1 For Category 1, when an adjuvant type test method for skin sensitization is used, a response of at least 30% of the animals is considered as positive. For a non-adjuvant Guinea pig test method a response of at least 15% of the animals is considered positive. For Category 1, a stimulation index of three or more is considered a positive response in the local lymph node assay.[4]

A.4.2.2.3.2 Animal test results for sub-category 1A can include data with values indicated in Table A.4.3 below:

TABLE A.4.3—ANIMAL TEST RESULTS FOR SUB-CATEGORY 1A

Assay	Criteria
Local lymph node assay	EC3 value ≤2%.
Guinea pig maximization test	≥30% responding at ≤0.1% intradermal induction dose *or* ≥60% responding at >0.1% to ≤1% intradermal induction dose.
Buehler assay	≥15% responding at ≤0.2% topical induction dose *or*

[2] *At this writing, recognized and validated animal models for the testing of respiratory hypersensitivity are not available. Under certain circumstances, data from animal studies may provide valuable information in a weight of evidence assessment.*

[3] *The mechanisms by which substances induce symptoms of asthma are not yet fully known. For preventive measures, these substances are considered respiratory sensitizers. However, if on the basis of the evidence, it can be demonstrated that these substances induce symptoms of asthma by irritation only in people with bronchial hyperactivity, they should not be considered as respiratory sensitizers.*

[4] *Test methods for skin sensitization are described in OECD Guideline 406 (the Guinea Pig Maximization test and the Buehler guinea pig test) and Guideline 429 (Local Lymph Node Assay). Other methods may be used provided that they are scientifically validated. The Mouse Ear Swelling Test (MEST), appears to be a reliable screening test to detect moderate to strong sensitizers, and can be used, in accordance with professional judgment, as a first stage in the assessment of skin sensitization potential.*

TABLE A.4.3—ANIMAL TEST RESULTS FOR SUB-CATEGORY 1A—Continued

Assay	Criteria
	≥60% responding at >0.2% to ≤20% topical induction dose.

Note: *EC3 refers to the estimated concentration of test chemical required to induce a stimulation index of 3 in the local lymph node assay.*

A.4.2.2.3.3 Animal test results for sub-category 1B can include data with values indicated in Table A.4.4 below:

TABLE A.4.4—ANIMAL TEST RESULTS FOR SUB-CATEGORY 1B

Assay	Criteria
Local lymph node assay	EC3 value >2%.
Guinea pig maximization test	≥30% to <60% responding at >0.1% to ≤1% intradermal induction dose or ≥30% responding at >1% intradermal induction dose.
Buehler assay	≥15% to <60% responding at >0.2% to ≤20% topical induction dose or ≥15% responding at >20% topical induction dose.

Note: *EC3 refers to the estimated concentration of test chemical required to induce a stimulation index of 3 in the local lymph node assay.*

A.4.2.2.4 Specific considerations.

A.4.2.2.4.1 For classification of a substance, evidence shall include one or more of the following using a weight of evidence approach:

(a) Positive data from patch testing, normally obtained in more than one dermatology clinic;

(b) Epidemiological studies showing allergic contact dermatitis caused by the substance. Situations in which a high proportion of those exposed exhibit characteristic symptoms are to be looked at with special concern, even if the number of cases is small;

(c) Positive data from appropriate animal studies;

(d) Positive data from experimental studies in man (See paragraph A.0.2.6 of this Appendix);

(e) Well documented episodes of allergic contact dermatitis, normally obtained in more than one dermatology clinic;

(f) Severity of reaction.

A.4.2.2.4.2 Evidence from animal studies is usually much more reliable than evidence from human exposure. However, in cases where evidence is available from both sources, and there is conflict between the results, the quality and reliability of the evidence from both sources must be assessed in order to resolve the question of classification on a case-by-case basis. Normally, human data are not generated in controlled experiments with volunteers for the purpose of hazard classification but rather as part of risk assessment to confirm lack of effects seen in animal tests. Consequently, positive human data on skin sensitization are usually derived from case-control or other, less defined studies. Evaluation of human data must, therefore, be carried out with caution as the frequency of cases reflect, in addition to the inherent properties of the substances, factors such as the exposure situation, bioavailability, individual predisposition and preventive measures taken. Negative human data should not normally be used to negate positive results from animal studies. For both animal and human data, consideration should be given to the impact of vehicle.

A.4.2.2.4.3 If none of the above-mentioned conditions are met, the substance need not be classified as a skin sensitizer. However, a combination of two or more indicators of skin sensitization, as listed below, may alter the decision. This shall be considered on a case-by-case basis.

(a) Isolated episodes of allergic contact dermatitis;

(b) Epidemiological studies of limited power, e.g., where chance, bias or confounders have not been ruled out fully with reasonable confidence;

(c) Data from animal tests, performed according to existing guidelines, which do not meet the criteria for a positive result described in A.4.2.2.3, but which are sufficiently close to the limit to be considered significant;

(d) Positive data from non-standard methods;

(e) Positive results from close structural analogues.

A.4.2.2.4.4 Immunological contact urticaria.

A.4.2.2.4.4.1 Substances meeting the criteria for classification as respiratory sensitizers may, in addition, cause immunological contact urticaria. Consideration shall be given to classifying these substances as skin sensitizers.

A.4.2.2.4.4.2 Substances which cause immunological contact urticaria without meeting the criteria for respiratory sensitizers shall be considered for classification as skin sensitizers.

A.4.2.2.4.4.3 There is no recognized animal model available to identify substances which cause immunological contact urticaria. Therefore, classification will normally be based on human evidence, similar to that for skin sensitization.

A.4.3 Classification Criteria for Mixtures

A.4.3.1 Classification of Mixtures When Data Are Available for the Complete Mixture

When reliable and good quality evidence, as described in the criteria for substances, from human experience or appropriate studies in experimental animals, is available for the mixture, then the mixture shall be classified by weight of evidence evaluation of these data. Care must be exercised in evaluating data on mixtures that the dose used does not render the results inconclusive.

A.4.3.2 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.4.3.2.1 Where the mixture itself has not been tested to determine its sensitizing properties, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following agreed bridging principles as found in paragraph A.0.5 of this Appendix: Dilution, Batching, Concentration of mixtures, Interpolation, Substantially similar mixtures, and Aerosols.

A.4.3.3 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

The mixture shall be classified as a respiratory or skin sensitizer when at least one ingredient has been classified as a respiratory or skin sensitizer and is present at or above the appropriate cut-off value/concentration limit for the specific endpoint as shown in Table A.4.5.

TABLE A.4.5—CUT-OFF VALUES/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS EITHER RESPIRATORY SENSITIZERS OR SKIN SENSITIZERS THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE

Ingredient classified as:	Cut-off values/concentration limits triggering classification of a mixture as:		
	Respiratory Sensitizer Category 1		Skin Sensitizer Category 1
	Solid/liquid	Gas	All physical states
Respiratory Sensitizer, Category 1	≥0.1%	≥0.1%	
Respiratory Sensitizer, Sub-category 1A	≥0.1%	≥0.1%	
Respiratory Sensitizer, Sub-category 1B	≥1.0%	≥0.2%	
Skin Sensitizer, Category 1			≥0.1%
Skin Sensitizer, Sub-category 1A			≥0.1%
Skin Sensitizer, Sub-category 1B			≥1.0%

A.5 GERM CELL MUTAGENICITY

A.5.1 Definitions and General Considerations

A.5.1.1 A *mutation* is defined as a permanent change in the amount or structure of the genetic material in a cell. The term *mutation* applies both to heritable genetic changes that may be manifested at the phenotypic level and to the underlying DNA modifications when known (including, for example, specific base pair changes and chromosomal translocations). The term *mutagenic* and *mutagen* will be used for agents giving rise to an increased occurrence of mutations in populations of cells and/or organisms.

A.5.1.2 The more general terms *genotoxic* and *genotoxicity* apply to agents or processes which alter the structure, information content, or segregation of DNA, including those which cause DNA damage by interfering with normal replication processes, or which in a non-physiological manner (temporarily) alter its replication. Genotoxicity test results are usually taken as indicators for mutagenic effects.

A.5.1.3 This hazard class is primarily concerned with chemicals that may cause mutations in the germ cells of humans that can be transmitted to the progeny. However, mutagenicity/genotoxicity tests *in vitro* and in mammalian somatic cells *in vivo* are also considered in classifying substances and mixtures within this hazard class.

A.5.2 Classification Criteria for Substances

A.5.2.1 The classification system provides for two different categories of germ cell mutagens to accommodate the weight of evidence available. The two-category system is described in the Figure A.5.1.

FIGURE A.5.1—HAZARD CATEGORIES FOR GERM CELL MUTAGENS

CATEGORY 1: Substances known to induce heritable mutations or to be regarded as if they induce heritable mutations in the germ cells of humans.

Category 1A: Substances known to induce heritable mutations in germ cells of humans.

Positive evidence from human epidemiological studies.

Category 1B: Substances which should be regarded as if they induce heritable mutations in the germ cells of humans.

(a) Positive result(s) from *in vivo* heritable germ cell mutagenicity tests in mammals; or

(b) Positive result(s) from *in vivo* somatic cell mutagenicity tests in mammals, in combination with some evidence that the substance has potential to cause mutations to germ cells. This supporting evidence may, for example, be derived from mutagenicity/genotoxicity tests in germ cells *in vivo,* or by demonstrating the ability of the substance or its metabolite(s) to interact with the genetic material of germ cells; or

(c) Positive results from tests showing mutagenic effects in the germ cells of humans, without demonstration of transmission to progeny; for example, an increase in the frequency of aneuploidy in sperm cells of exposed people.

CATEGORY 2: Substances which cause concern for humans owing to the possibility that they may induce heritable mutations in the germ cells of humans.

Positive evidence obtained from experiments in mammals and/or in some cases from *in vitro* experiments, obtained from:

(a) Somatic cell mutagenicity tests *in vivo,* in mammals; or

(b) Other *in vivo* somatic cell genotoxicity tests which are supported by positive results from *in vitro* mutagenicity assays.

Note: *Substances which are positive in in vitro mammalian mutagenicity assays, and which also show chemical structure activity relationship to known germ cell mutagens, should be considered for classification as Category 2 mutagens.*

A.5.2.2 Specific considerations for classification of substances as germ cell mutagens:

A.5.2.2.1 To arrive at a classification, test results are considered from experiments determining mutagenic and/or genotoxic effects in germ and/or somatic cells of exposed animals. Mutagenic and/or genotoxic effects determined in *in vitro* tests shall also be considered.

A.5.2.2.2 The system is hazard based, classifying chemicals on the basis of their intrinsic ability to induce mutations in germ cells. The scheme is, therefore, not meant for the (quantitative) risk assessment of chemical substances.

A.5.2.2.3 Classification for heritable effects in human germ cells is made on the basis of scientifically validated tests. Evaluation of the test results shall be done using expert judgment and all the available evidence shall be weighed for classification.

A.5.2.2.4 The classification of substances shall be based on the total weight of evidence available, using expert judgment. In those instances where a single well-conducted test is used for classification, it shall provide clear and unambiguously positive results. The relevance of the route of exposure used in the study of the substance compared to the route of human exposure should also be taken into account.

A.5.3 Classification Criteria for Mixtures [5]

A.5.3.1 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.5.3.1.1 Classification of mixtures shall be based on the available test data for the

[5] *It should be noted that the classification criteria for health hazards usually include a tiered scheme in which test data available on the complete mixture are considered as the first tier in the evaluation, followed by the applicable bridging principles, and lastly, cut-off values/concentration limits or additivity. However, this approach is not used for Germ Cell Mutagenicity. These criteria for Germ Cell Mutagenicity consider the cut-off values/concentration limits as the primary tier and allow*

Continued

individual ingredients of the mixture using cut-off values/concentration limits for the ingredients classified as germ cell mutagens.

A.5.3.1.2 The mixture will be classified as a mutagen when at least one ingredient has been classified as a Category 1A, Category 1B or Category 2 mutagen and is present at or above the appropriate cut-off value/concentration limit as shown in Table A.5.1 below for Category 1 and 2 respectively.

TABLE A.5.1—CUT-OFF VALUES/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS GERM CELL MUTAGENS THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE

Ingredient classified as:	Cut-off/concentration limits triggering classification of a mixture as:	
	Category 1 mutagen	Category 2 mutagen
Category 1A/B mutagen	≥0.1%	
Category 2 mutagen		≥1.0%

Note: *The cut-off values/concentration limits in the table above apply to solids and liquids (w/w units) as well as gases (v/v units).*

A.5.3.2 Classification of Mixtures When Data Are Available for the Mixture Itself

The classification may be modified on a case-by-case basis based on the available test data for the mixture as a whole. In such cases, the test results for the mixture as a whole must be shown to be conclusive taking into account dose and other factors such as duration, observations and analysis (e.g. statistical analysis, test sensitivity) of germ cell mutagenicity test systems.

A.5.3.3 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.5.3.3.1 Where the mixture itself has not been tested to determine its germ cell mutagenicity hazard, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution, Batching, and Substantially similar mixtures.

A.5.4 Examples of Scientifically Validated Test Methods

A.5.4.1 Examples of *in vivo* heritable germ cell mutagenicity tests are:
(a) Rodent dominant lethal mutation test (OECD 478)
(b) Mouse heritable translocation assay (OECD 485)
(c) Mouse specific locus test

A.5.4.2 Examples of *in vivo* somatic cell mutagenicity tests are:
(a) Mammalian bone marrow chromosome aberration test (OECD 475)
(b) Mouse spot test (OECD 484)
(c) Mammalian erythrocyte micronucleus test (OECD 474)

A.5.4.3 Examples of mutagenicity/genotoxicity tests in germ cells are:
(a) Mutagenicity tests:
(i) Mammalian spermatogonial chromosome aberration test (OECD 483)
(ii) Spermatid micronucleus assay
(b) Genotoxicity tests:
(i) Sister chromatid exchange analysis in spermatogonia
(ii) Unscheduled DNA synthesis test (UDS) in testicular cells

A.5.4.4 Examples of genotoxicity tests in somatic cells are:
(a) Liver Unscheduled DNA Synthesis (UDS) *in vivo* (OECD 486)
(b) Mammalian bone marrow Sister Chromatid Exchanges (SCE)

A.5.4.5 Examples of *in vitro* mutagenicity tests are:
(a) *In vitro* mammalian chromosome aberration test (OECD 473)
(b) *In vitro* mammalian cell gene mutation test (OECD 476)
(c) Bacterial reverse mutation tests (OECD 471)

A.5.4.6 As new, scientifically validated tests arise, these may also be used in the total weight of evidence to be considered.

A.6 CARCINOGENICITY

A.6.1 Definitions

Carcinogen means a substance or a mixture of substances which induce cancer or increase its incidence. Substances and mixtures which have induced benign and malignant tumors in well-performed experimental studies on animals are considered also to be presumed or suspected human carcinogens unless there is strong evidence that the mechanism of tumor formation is not relevant for humans.

Classification of a substance or mixture as posing a carcinogenic hazard is based on its inherent properties and does not provide information on the level of the human cancer risk which the use of the substance or mixture may represent.

A.6.2 Classification Criteria for Substances [6]

A.6.2.1 For the purpose of classification for carcinogenicity, substances are allocated to one of two categories based on strength of evidence and additional weight of evidence considerations. In certain instances, route-specific classification may be warranted.

FIGURE A.6.1—HAZARD CATEGORIES FOR CARCINOGENS

CATEGORY 1: Known or presumed human carcinogens.

The classification of a substance as a Category 1 carcinogen is done on the basis of epidemiological and/or animal data. This classification is further distinguished on the basis of whether the evidence for classification is largely from human data (Category 1A) or from animal data (Category 1B):

Category 1A: Known to have carcinogenic potential for humans. Classification in this category is largely based on human evidence.

Category 1B: Presumed to have carcinogenic potential for humans. Classification in this category is largely based on animal evidence.

The classification of a substance in Category 1A and 1B is based on strength of evidence together with weight of evidence considerations (See paragraph A.6.2.5). Such evidence may be derived from:

—human studies that establish a causal relationship between human exposure to a substance and the development of cancer (known human carcinogen); or

—animal experiments for which there is sufficient evidence to demonstrate animal carcinogenicity (presumed human carcinogen).

In addition, on a case by case basis, scientific judgment may warrant a decision of presumed human carcinogenicity derived from studies showing limited evidence of carcinogenicity in humans together with limited evidence of carcinogenicity in experimental animals.

CATEGORY 2: Suspected human carcinogens.

the classification to be modified only on a case-by-case evaluation based on available test data for the mixture as a whole.

[6] *See Non-mandatory Appendix F Part A for further guidance regarding hazard classification for carcinogenicity. This appendix is consistent with the GHS adn is provided as guidance excerpted from the International Agency for Research on Cancer (IARC) ''Monographs on the Evaluation of Carcinogenic Risks to Humans'' (2006).*

FIGURE A.6.1—HAZARD CATEGORIES FOR CARCINOGENS—Continued

The classification of a substance in Category 2 is done on the basis of evidence obtained from human and/or animal studies, but which is not sufficiently convincing to place the substance in Category 1A or B. This classification is based on strength of evidence together with weight of evidence considerations (See paragraph A.6.2.5). Such evidence may be from either limited evidence of carcinogenicity in human studies or from limited evidence of carcinogenicity in animal studies.
Other considerations: Where the weight of evidence for the carcinogenicity of a substance does not meet the above criteria, any positive study conducted in accordance with established scientific principles, and which reports statistically significant findings regarding the carcinogenic potential of the substance, must be noted on the safety data sheet.

A.6.2.2 Classification as a carcinogen is made on the basis of evidence from reliable and acceptable methods, and is intended to be used for substances which have an intrinsic property to produce such toxic effects. The evaluations are to be based on all existing data, peer-reviewed published studies and additional data accepted by regulatory agencies.

A.6.2.3 *Carcinogen classification* is a one-step, criterion-based process that involves two interrelated determinations: evaluations of strength of evidence and consideration of all other relevant information to place substances with human cancer potential into hazard categories.

A.6.2.4 *Strength of evidence* involves the enumeration of tumors in human and animal studies and determination of their level of statistical significance. Sufficient human evidence demonstrates causality between human exposure and the development of cancer, whereas sufficient evidence in animals shows a causal relationship between the agent and an increased incidence of tumors. Limited evidence in humans is demonstrated by a positive association between exposure and cancer, but a causal relationship cannot be stated. Limited evidence in animals is provided when data suggest a carcinogenic effect, but are less than sufficient. (Guidance on consideration of important factors in the classification of carcinogenicity and a more detailed description of the terms ''limited'' and ''sufficient'' have been developed by the International Agency for Research on Cancer (IARC) and are provided in non-mandatory Appendix F).

A.6.2.5 *Weight of evidence:* Beyond the determination of the strength of evidence for carcinogenicity, a number of other factors should be considered that influence the overall likelihood that an agent may pose a carcinogenic hazard in humans. The full list of factors that influence this determination is very lengthy, but some of the important ones are considered here.

A.6.2.5.1 These factors can be viewed as either increasing or decreasing the level of concern for human carcinogenicity. The relative emphasis accorded to each factor depends upon the amount and coherence of evidence bearing on each. Generally there is a requirement for more complete information to decrease than to increase the level of concern. Additional considerations should be used in evaluating the tumor findings and the other factors in a case-by-case manner.

A.6.2.5.2 Some important factors which may be taken into consideration, when assessing the overall level of concern are:

(a) Tumor type and background incidence;

(b) Multisite responses;

(c) Progression of lesions to malignancy;

(d) Reduced tumor latency;

Additional factors which may increase or decrease the level of concern include:

(e) Whether responses are in single or both sexes;

(f) Whether responses are in a single species or several species;

(g) Structural similarity or not to a substance(s) for which there is good evidence of carcinogenicity;

(h) Routes of exposure;

(i) Comparison of absorption, distribution, metabolism and excretion between test animals and humans;

(j) The possibility of a confounding effect of excessive toxicity at test doses; and,

(k) Mode of action and its relevance for humans, such as mutagenicity, cytotoxicity with growth stimulation, mitogenesis, immunosuppression.

Mutagenicity: It is recognized that genetic events are central in the overall process of cancer development. Therefore evidence of mutagenic activity *in vivo* may indicate that a substance has a potential for carcinogenic effects.

A.6.2.5.3 A substance that has not been tested for carcinogenicity may in certain instances be classified in Category 1A, Category 1B, or Category 2 based on tumor data from a structural analogue together with substantial support from consideration of other important factors such as formation of common significant metabolites, e.g., for benzidine congener dyes.

A.6.2.5.4 The classification should also take into consideration whether or not the substance is absorbed by a given route(s); or whether there are only local tumors at the site of administration for the tested route(s), and adequate testing by other major route(s) show lack of carcinogenicity.

A.6.2.5.5 It is important that whatever is known of the physico-chemical, toxicokinetic and toxicodynamic properties of the substances, as well as any available relevant information on chemical analogues, i.e., structure activity relationship, is taken into consideration when undertaking classification.

A.6.3 Classification Criteria for Mixtures [7]

A.6.3.1 The mixture shall be classified as a carcinogen when at least one ingredient has been classified as a Category 1 or Category 2 carcinogen and is present at or above the appropriate cut-off value/concentration limit as shown in Table A.6.1.

TABLE A.6.1—CUT-OFF VALUES/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS CARCINOGEN THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE

Ingredient classified as:	Category 1 carcinogen	Category 2 carcinogen
Category 1 carcinogen	≥0.1%	
Category 2 carcinogen		≥0.1% (note 1).

Note: *If a Category 2 carcinogen ingredient is present in the mixture at a concentration between 0.1% and 1%, information is required on the SDS for a product. However, a label warning is optional. If a Category 2 carcinogen ingredient is present in the mixture at a concentration of ≥1%, both an SDS and a label is required and the information must be included on each.*

[7] *It should be noted that the classification criteria for health hazards usually include a tiered scheme in which test data available on the complete mixture are considered as the first tier in the evaluation, followed by the applicable bridging principles, and lastly, cut-off values/concentration limit or additivity. However, this approach is not used for Carcinogenicity. These criteria for Carcinogenicity consider the cut-off values/concentration limits as the primary tier and allow the classification to be modified only on a case-by-case evaluation based on available test data for the mixture as a whole.*

A.6.3.2 Classification of Mixtures When Data Are Available for the Complete Mixture

A mixture may be classified based on the available test data for the mixture as a whole. In such cases, the test results for the mixture as a whole must be shown to be conclusive taking into account dose and other factors such as duration, observations and analysis (e.g., statistical analysis, test sensitivity) of carcinogenicity test systems.

A.6.3.3 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

Where the mixture itself has not been tested to determine its carcinogenic hazard, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data will be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution; Batching; and Substantially similar mixtures.

A.6.4 Classification of Carcinogenicity [8]

A.6.4.1 Chemical manufacturers, importers and employers evaluating chemicals may treat the following sources as establishing that a substance is a carcinogen or potential carcinogen for hazard communication purposes in lieu of applying the criteria described herein:

A.6.4.1.1 National Toxicology Program (NTP), ''Report on Carcinogens'' (latest edition);

A.6.4.1.2 International Agency for Research on Cancer (IARC) ''Monographs on the Evaluation of Carcinogenic Risks to Humans'' (latest editions)

A.6.4.2 Where OSHA has included cancer as a health hazard to be considered by classifiers for a chemical covered by 29 CFR part 1910, Subpart Z, Toxic and Hazardous Substances, chemical manufacturers, importers, and employers shall classify the chemical as a carcinogen.

A.7 REPRODUCTIVE TOXICITY

A.7.1 Definitions and General Considerations

A.7.1.1 *Reproductive toxicity* includes *adverse effects on sexual function and fertility* in adult males and females, as well as *adverse effects on development of the offspring.* Some reproductive toxic effects cannot be clearly assigned to either impairment of sexual function and fertility or to developmental toxicity. Nonetheless, chemicals with these effects shall be classified as reproductive toxicants.

For classification purposes, the known induction of genetically based inheritable effects in the offspring is addressed in *Germ cell mutagenicity* (See A.5).

A.7.1.2 *Adverse effects on sexual function and fertility* means any effect of chemicals that interferes with reproductive ability or sexual capacity. This includes, but is not limited to, alterations to the female and male reproductive system, adverse effects on onset of puberty, gamete production and transport, reproductive cycle normality, sexual behaviour, fertility, parturition, pregnancy outcomes, premature reproductive senescence, or modifications in other functions that are dependent on the integrity of the reproductive systems.

A.7.1.3 *Adverse effects on development of the offspring* means any effect of chemicals which interferes with normal development of the conceptus either before or after birth, which is induced during pregnancy or results from parental exposure. These effects can be manifested at any point in the life span of the organism. The major manifestations of developmental toxicity include death of the developing organism, structural abnormality, altered growth and functional deficiency.

A.7.1.4 Adverse effects on or via lactation are also included in reproductive toxicity, but for classification purposes, such effects are treated separately (See A.7.2.1).

A.7.2 Classification Criteria for Substances

A.7.2.1 For the purpose of classification for reproductive toxicity, substances shall be classified in one of two categories in accordance with Figure A.7.1(a). Effects on sexual function and fertility, and on development, shall be considered. In addition, effects on or via lactation shall be classified in a separate hazard category in accordance with Figure A.7.1(b).

FIGURE A.7.1(a)—HAZARD CATEGORIES FOR REPRODUCTIVE TOXICANTS

CATEGORY 1: Known or presumed human reproductive toxicant.

Substance shall be classified in Category 1 for reproductive toxicity when they are known to have produced an adverse effect on sexual function and fertility or on development in humans or when there is evidence from animal studies, possibly supplemented with other information, to provide a strong presumption that the substance has the capacity to interfere with reproduction in humans. The classification of a substance is further distinguished on the basis of whether the evidence for classification is primarily from human data (Category 1A) or from animal data (Category 1B).

Category 1A: Known human reproductive toxicant.

The classification of a substance in this category is largely based on evidence from humans.

Category 1B: Presumed human reproductive toxicant.

The classification of a substance in this category is largely based on evidence from experimental animals. Data from animal studies shall provide sufficient evidence of an adverse effect on sexual function and fertility or on development in the absence of other toxic effects, or if occurring together with other toxic effects the adverse effect on reproduction is considered not to be a secondary non-specific consequence of other toxic effects. However, when there is mechanistic information that raises doubt about the relevance of the effect for humans, classification in Category 2 may be more appropriate.

CATEGORY 2: Suspected human reproductive toxicant.

Substances shall be classified in Category 2 for reproductive toxicity when there is some evidence from humans or experimental animals, possibly supplemented with other information, of an adverse effect on sexual function and fertility, or on development, in the absence of other toxic effects, or if occurring together with other toxic effects the adverse effect on reproduction is considered not to be a secondary non-specific consequence of the other toxic effects, and where the evidence is not sufficiently convincing to place the substance in Category 1. For instance, deficiencies in the study may make the quality of evidence less convincing, and in view of this, Category 2 would be the more appropriate classification.

FIGURE A.7.1(b)—HAZARD CATEGORY FOR EFFECTS ON OR VIA LACTATION

EFFECTS ON OR VIA LACTATION

Effects on or via lactation shall be classified in a separate single category. Chemicals that are absorbed by women and have been shown to interfere with lactation or that may be present (including metabolites) in breast milk in amounts sufficient to cause concern for the health of a breastfed child, shall be classified to indicate this property hazardous to breastfed babies. This classification shall be assigned on the basis of:

(a) absorption, metabolism, distribution and excretion studies that indicate the likelihood the substance would be present in potentially toxic levels in breast milk; and/or

[8] *See Non-mandatory Appendix F for further guidance regarding hazard classification for carcinogenicity and how to relate carcinogenicity classification information from IARC and NTP to GHS.*

FIGURE A.7.1(b)—HAZARD CATEGORY FOR EFFECTS ON OR VIA LACTATION—Continued

(b) results of one or two generation studies in animals which provide clear evidence of adverse effect in the offspring due to transfer in the milk or adverse effect on the quality of the milk; and/or
(c) human evidence indicating a hazard to babies during the lactation period.

A.7.2.2 Basis of Classification

A.7.2.2.1 Classification is made on the basis of the criteria, outlined above, an assessment of the total weight of evidence, and the use of expert judgment. Classification as a reproductive toxicant is intended to be used for substances which have an intrinsic, specific property to produce an adverse effect on reproduction and substances should not be so classified if such an effect is produced solely as a non-specific secondary consequence of other toxic effects.

A.7.2.2.2 In the evaluation of toxic effects on the developing offspring, it is important to consider the possible influence of maternal toxicity.

A.7.2.2.3 For human evidence to provide the primary basis for a Category 1A classification there must be reliable evidence of an adverse effect on reproduction in humans. Evidence used for classification shall be from well conducted epidemiological studies, if available, which include the use of appropriate controls, balanced assessment, and due consideration of bias or confounding factors. Less rigorous data from studies in humans may be sufficient for a Category 1A classification if supplemented with adequate data from studies in experimental animals, but classification in Category 1B may also be considered.

A.7.2.3 Weight of Evidence

A.7.2.3.1 Classification as a reproductive toxicant is made on the basis of an assessment of the total weight of evidence using expert judgment. This means that all available information that bears on the determination of reproductive toxicity is considered together. Included is information such as epidemiological studies and case reports in humans and specific reproduction studies along with sub-chronic, chronic and special study results in animals that provide relevant information regarding toxicity to reproductive and related endocrine organs. Evaluation of substances chemically related to the material under study may also be included, particularly when information on the material is scarce. The weight given to the available evidence will be influenced by factors such as the quality of the studies, consistency of results, nature and severity of effects, level of statistical significance for intergroup differences, number of endpoints affected, relevance of route of administration to humans and freedom from bias. Both positive and negative results are considered together in a weight of evidence determination. However, a single, positive study performed according to good scientific principles and with statistically or biologically significant positive results may justify classification (See also A.7.2.2.3).

A.7.2.3.2 Toxicokinetic studies in animals and humans, site of action and mechanism or mode of action study results may provide relevant information, which could reduce or increase concerns about the hazard to human health. If it is conclusively demonstrated that the clearly identified mechanism or mode of action has no relevance for humans or when the toxicokinetic differences are so marked that it is certain that the hazardous property will not be expressed in humans then a chemical which produces an adverse effect on reproduction in experimental animals should not be classified.

A.7.2.3.3 In some reproductive toxicity studies in experimental animals the only effects recorded may be considered of low or minimal toxicological significance and classification may not necessarily be the outcome. These effects include, for example, small changes in semen parameters or in the incidence of spontaneous defects in the fetus, small changes in the proportions of common fetal variants such as are observed in skeletal examinations, or in fetal weights, or small differences in postnatal developmental assessments.

A.7.2.3.4 Data from animal studies shall provide sufficient evidence of specific reproductive toxicity in the absence of other systemic toxic effects. However, if developmental toxicity occurs together with other toxic effects in the dam (mother), the potential influence of the generalized adverse effects should be assessed to the extent possible. The preferred approach is to consider adverse effects in the embryo/fetus first, and then evaluate maternal toxicity, along with any other factors which are likely to have influenced these effects, as part of the weight of evidence. In general, developmental effects that are observed at maternally toxic doses should not be automatically discounted. Discounting developmental effects that are observed at maternally toxic doses can only be done on a case-by-case basis when a causal relationship is established or refuted.

A.7.2.3.5 If appropriate information is available it is important to try to determine whether developmental toxicity is due to a specific maternally mediated mechanism or to a non-specific secondary mechanism, like maternal stress and the disruption of homeostasis. Generally, the presence of maternal toxicity should not be used to negate findings of embryo/fetal effects, unless it can be clearly demonstrated that the effects are secondary non-specific effects. This is especially the case when the effects in the offspring are significant, e.g., irreversible effects such as structural malformations. In some situations it is reasonable to assume that reproductive toxicity is due to a secondary consequence of maternal toxicity and discount the effects, for example if the chemical is so toxic that dams fail to thrive and there is severe inanition; they are incapable of nursing pups; or they are prostrate or dying.

A.7.2.4 Maternal Toxicity

A.7.2.4.1 Development of the offspring throughout gestation and during the early postnatal stages can be influenced by toxic effects in the mother either through non-specific mechanisms related to stress and the disruption of maternal homeostasis, or by specific maternally-mediated mechanisms. So, in the interpretation of the developmental outcome to decide classification for developmental effects it is important to consider the possible influence of maternal toxicity. This is a complex issue because of uncertainties surrounding the relationship between maternal toxicity and developmental outcome. Expert judgment and a weight of evidence approach, using all available studies, shall be used to determine the degree of influence to be attributed to maternal toxicity when interpreting the criteria for classification for developmental effects. The adverse effects in the embryo/fetus shall be first considered, and then maternal toxicity, along with any other factors which are likely to have influenced these effects, as weight of evidence, to help reach a conclusion about classification.

A.7.2.4.2 Based on pragmatic observation, it is believed that maternal toxicity may, depending on severity, influence development via non-specific secondary mechanisms, producing effects such as depressed fetal weight, retarded ossification, and possibly resorptions and certain malformations in some strains of certain species. However, the limited numbers of studies which have investigated the relationship between developmental effects and general maternal toxicity have failed to demonstrate a consistent, reproducible relationship across species. Developmental effects which occur even in the presence of maternal toxicity are considered to be evidence of developmental toxicity, unless it can be unequivocally demonstrated on a case by case basis that the developmental effects are secondary to maternal toxicity. Moreover, classification shall be considered where there is a significant toxic effect in the offspring, e.g., irreversible effects such as structural malformations, embryo/fetal lethality, or significant post-natal functional deficiencies.

A.7.2.4.3 Classification shall not automatically be discounted for chemicals that produce developmental toxicity only in association with maternal toxicity, even if a specific maternally-mediated mechanism has been demonstrated. In such a case, classification in Category 2 may be considered more appropriate than Category 1. However, when a chemical is so toxic that maternal death or severe inanition results, or the dams (mothers) are prostrate and incapable of nursing the pups, it is reasonable to assume that developmental toxicity is produced solely as a secondary consequence of maternal toxicity and discount the developmental effects.

Classification is not necessarily the outcome in the case of minor developmental changes, e.g., a small reduction in fetal/pup body weight or retardation of ossification when seen in association with maternal toxicity.

A.7.2.4.4 Some of the endpoints used to assess maternal toxicity are provided below. Data on these endpoints, if available, shall be evaluated in light of their statistical or biological significance and dose-response relationship.

(a) Maternal mortality: An increased incidence of mortality among the treated dams over the controls shall be considered evidence of maternal toxicity if the increase occurs in a dose-related manner and can be attributed to the systemic toxicity of the test material. Maternal mortality greater than 10% is considered excessive and the data for that dose level shall not normally be considered to need further evaluation.

(b) Mating index (Number of animals with seminal plugs or sperm/Number of mated × 100)

(c) Fertility index (Number of animals with implants/Number of matings × 100)

(d) Gestation length (If allowed to deliver)

(e) Body weight and body weight change: Consideration of the maternal body weight change and/or adjusted (corrected) maternal body weight shall be included in the evaluation of maternal toxicity whenever such data are available. The calculation of an adjusted (corrected) mean maternal body weight change, which is the difference between the initial and terminal body weight minus the gravid uterine weight (or alternatively, the sum of the weights of the fetuses), may indicate whether the effect is maternal or intrauterine. In rabbits, the body weight gain may not be a useful indicator of maternal toxicity because of normal fluctuations in body weight during pregnancy.

(f) Food and water consumption (if relevant): The observation of a significant decrease in the average food or water consumption in treated dams (mothers) compared to the control group may be useful in evaluating maternal toxicity, particularly when the test material is administered in the diet or drinking water. Changes in food or water consumption must be evaluated in conjunction with maternal body weights when determining if the effects noted are reflective of maternal toxicity or more simply, unpalatability of the test material in feed or water.

(g) Clinical evaluations (including clinical signs, markers, and hematology and clinical chemistry studies): The observation of increased incidence of significant clinical signs of toxicity in treated dams (mothers) relative to the control group is useful in evaluating maternal toxicity. If this is to be used as the basis for the assessment of maternal toxicity, the types, incidence, degree and duration of clinical signs shall be reported in the study. Clinical signs of maternal intoxication include, but are not limited to: coma, prostration, hyperactivity, loss of righting reflex, ataxia, or labored breathing.

(h) Post-mortem data: Increased incidence and/or severity of post-mortem findings may be indicative of maternal toxicity. This can include gross or microscopic pathological findings or organ weight data, including absolute organ weight, organ-to-body weight ratio, or organ-to-brain weight ratio. When supported by findings of adverse histopathological effects in the affected organ(s), the observation of a significant change in the average weight of suspected target organ(s) of treated dams (mothers), compared to those in the control group, may be considered evidence of maternal toxicity.

A.7.2.5 Animal and Experimental Data

A.7.2.5.1 A number of scientifically validated test methods are available, including methods for developmental toxicity testing (e.g., OECD Test Guideline 414, ICH Guideline S5A, 1993), methods for peri- and post-natal toxicity testing (e.g., ICH S5B, 1995), and methods for one or two-generation toxicity testing (e.g., OECD Test Guidelines 415, 416)

A.7.2.5.2 Results obtained from screening tests (e.g., OECD Guidelines 421—Reproduction/Developmental Toxicity Screening Test, and 422—Combined Repeated Dose Toxicity Study with Reproduction/Development Toxicity Screening Test) can also be used to justify classification, although the quality of this evidence is less reliable than that obtained through full studies.

A.7.2.5.3 Adverse effects or changes, seen in short- or long-term repeated dose toxicity studies, which are judged likely to impair reproductive function and which occur in the absence of significant generalized toxicity, may be used as a basis for classification, e.g., histopathological changes in the gonads.

A.7.2.5.4 Evidence from *in vitro* assays, or non-mammalian tests, and from analogous substances using structure-activity relationship (SAR), can contribute to the procedure for classification. In all cases of this nature, expert judgment must be used to assess the adequacy of the data. Inadequate data shall not be used as a primary support for classification.

A.7.2.5.5 It is preferable that animal studies are conducted using appropriate routes of administration which relate to the potential route of human exposure. However, in practice, reproductive toxicity studies are commonly conducted using the oral route, and such studies will normally be suitable for evaluating the hazardous properties of the substance with respect to reproductive toxicity. However, if it can be conclusively demonstrated that the clearly identified mechanism or mode of action has no relevance for humans or when the toxicokinetic differences are so marked that it is certain that the hazardous property will not be expressed in humans then a substance which produces an adverse effect on reproduction in experimental animals should not be classified.

A.7.2.5.6 Studies involving routes of administration such as intravenous or intraperitoneal injection, which may result in exposure of the reproductive organs to unrealistically high levels of the test substance, or elicit local damage to the reproductive organs, e.g., by irritation, must be interpreted with extreme caution and on their own are not normally the basis for classification.

A.7.2.5.7 There is general agreement about the concept of a limit dose, above which the production of an adverse effect may be considered to be outside the criteria which lead to classification. Some test guidelines specify a limit dose, other test guidelines qualify the limit dose with a statement that higher doses may be necessary if anticipated human exposure is sufficiently high that an adequate margin of exposure would not be achieved. Also, due to species differences in toxicokinetics, establishing a specific limit dose may not be adequate for situations where humans are more sensitive than the animal model.

A.7.2.5.8 In principle, adverse effects on reproduction seen only at very high dose levels in animal studies (for example doses that induce prostration, severe inappetence, excessive mortality) do not normally lead to classification, unless other information is available, for example, toxicokinetics information indicating that humans may be more susceptible than animals, to suggest that classification is appropriate.

A.7.2.5.9 However, specification of the actual ''limit dose'' will depend upon the test method that has been employed to provide the test results.

A.7.3 Classification Criteria for Mixtures [9]

A.7.3.1 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.7.3.1.1 The mixture shall be classified as a reproductive toxicant when at least one ingredient has been classified as a Category 1 or Category 2 reproductive toxicant and is present at or above the appropriate cut-off value/concentration limit specified in Table A.7.1 for Category 1 and 2, respectively.

A.7.3.1.2 The mixture shall be classified for effects on or via lactation when at least one ingredient has been classified for effects on or via lactation and is present at or above the appropriate cut-off value/concentration limit specified in Table A.7.1 for the additional category for effects on or via lactation.

[9] *It should be noted that the classification criteria for health hazards usually include a tiered scheme in which test data available on the complete mixture are considered as the first tier in the evaluation, followed by the applicable bridging principles, and lastly, cut-off values/concentration limits or additivity. However, this approach is not used for Reproductive Toxicity. These criteria for Reproductive Toxicity consider the cut-off values/concentration limits as the primary tier and allow the classification to be modified only on a case-by-case evaluation based on available test data for the mixture as a whole.*

TABLE A.7.1—CUT-OFF VALUES/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS REPRODUCTIVE TOXICANTS OR FOR EFFECTS ON OR VIA LACTATION THAT TRIGGER CLASSIFICATION OF THE MIXTURE

Ingredients classified as:	Cut-off values/concentration limits triggering classification of a mixture as:		
	Category 1 reproductive toxicant	Category 2 reproductive toxicant	Additional category for effects on or via lactation
Category 1 reproductive toxicant	≥0.1%		
Category 2 reproductive toxicant		≥0.1%	
Additional category for effects on or via lactation			≥0.1%

A.7.3.2 Classification of Mixtures When Data Are Available for the Complete Mixture

Available test data for the mixture as a whole may be used for classification on a case-by-case basis. In such cases, the test results for the mixture as a whole must be shown to be conclusive taking into account dose and other factors such as duration, observations and analysis (e.g., statistical analysis, test sensitivity) of reproduction test systems.

A.7.3.3 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.7.3.3.1 Where the mixture itself has not been tested to determine its reproductive toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data shall be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution, Batching, and Substantially similar mixtures.

A.8 SPECIFIC TARGET ORGAN TOXICITY SINGLE EXPOSURE

A.8.1 Definitions and General Considerations

A.8.1.1 *Specific target organ toxicity—single exposure, (STOT–SE)* means specific, non-lethal target organ toxicity arising from a single exposure to a chemical. All significant health effects that can impair function, both reversible and irreversible, immediate and/or delayed and not specifically addressed in A.1 to A.7 and A.10 of this Appendix are included. Specific target organ toxicity following repeated exposure is classified in accordance with *SPECIFIC TARGET ORGAN TOXICITY—REPEATED EXPOSURE* (A.9 of this Appendix) and is therefore not included here.

A.8.1.2 Classification identifies the chemical as being a specific target organ toxicant and, as such, it presents a potential for adverse health effects in people who are exposed to it.

A.8.1.3 The adverse health effects produced by a single exposure include consistent and identifiable toxic effects in humans; or, in experimental animals, toxicologically significant changes which have affected the function or morphology of a tissue/organ, or have produced serious changes to the biochemistry or hematology of the organism, and these changes are relevant for human health. Human data is the primary source of evidence for this hazard class.

A.8.1.4 Assessment shall take into consideration not only significant changes in a single organ or biological system but also generalized changes of a less severe nature involving several organs.

A.8.1.5 Specific target organ toxicity can occur by any route that is relevant for humans, i.e., principally oral, dermal or inhalation.

A.8.1.6 The classification criteria for specific organ systemic toxicity single exposure are organized as criteria for substances Categories 1 and 2 (See A.8.2.1), criteria for substances Category 3 (See A.8.2.2) and criteria for mixtures (See A.8.3). See also Figure A.8.1.

A.8.2 Classification Criteria for Substances

A.8.2.1 Substances of Category 1 and Category 2

A.8.2.1.1 Substances shall be classified for immediate or delayed effects separately, by the use of expert judgment on the basis of the weight of all evidence available, including the use of recommended guidance values (See A.8.2.1.9). Substances shall then be classified in Category 1 or 2, depending upon the nature and severity of the effect(s) observed, in accordance with Figure A.8.1.

FIGURE A.8.1—HAZARD CATEGORIES FOR SPECIFIC TARGET ORGAN TOXICITY FOLLOWING SINGLE EXPOSURE

CATEGORY 1: Substances that have produced significant toxicity in humans, or that, on the basis of evidence from studies in experimental animals can be presumed to have the potential to produce significant toxicity in humans following single exposure

Substances are classified in Category 1 for STOT–SE on the basis of:

(a) reliable and good quality evidence from human cases or epidemiological studies; or

(b) observations from appropriate studies in experimental animals in which significant and/or severe toxic effects of relevance to human health were produced at generally low exposure concentrations. Guidance dose/concentration values are provided below (See A.8.2.1.9) to be used as part of weight-of-evidence evaluation.

CATEGORY 2: Substances that, on the basis of evidence from studies in experimental animals, can be presumed to have the potential to be harmful to human health following single exposure

Substances are classified in Category 2 for STOT–SE on the basis of observations from appropriate studies in experimental animals in which significant toxic effects, of relevance to human health, were produced at generally moderate exposure concentrations. Guidance dose/concentration values are provided below (See A.8.2.1.9) in order to help in classification.

In exceptional cases, human evidence can also be used to place a substance in Category 2 (See A.8.2.1.6).

CATEGORY 3: Transient target organ effects

There are target organ effects for which a substance does not meet the criteria to be classified in Categories 1 or 2 indicated above. These are effects which adversely alter human function for a short duration after exposure and from which humans may recover in a reasonable period without leaving significant alteration of structure or function. This category only includes narcotic effects and respiratory tract irritation. Substances are classified specifically for these effects as discussed in A.8.2.2.

Note: The primary target organ/system shall be identified where possible, and where this is not possible, the substance shall be identified as a general toxicant. The data shall be evaluated and, where possible, shall not include secondary effects (e.g., a hepatotoxicant can produce secondary effects in the nervous or gastro-intestinal systems).

A.8.2.1.2 The relevant route(s) of exposure by which the classified substance produces damage shall be identified.

A.8.2.1.3 Classification is determined by expert judgment, on the basis of the weight of all evidence available including the guidance presented below.

A.8.2.1.4 Weight of evidence of all available data, including human incidents, epidemiology, and studies conducted in experimental animals is used to substantiate specific target organ toxic effects that merit classification.

A.8.2.1.5 The information required to evaluate specific target organ toxicity comes either from single exposure in humans (e.g., exposure at home, in the workplace or environmentally), or from studies conducted in experimental animals. The standard animal studies in rats or mice that provide this information are acute toxicity studies which can include clinical observations and detailed macroscopic and microscopic examination to enable the toxic effects on target tissues/organs to be identified. Results of acute toxicity studies conducted in other species may also provide relevant information.

A.8.2.1.6 In exceptional cases, based on expert judgment, it may be appropriate to place certain substances with human evidence of target organ toxicity in Category 2: (a) when the weight of human evidence is not sufficiently convincing to warrant Category 1 classification, and/or (b) based on the nature and severity of effects. Dose/concentration levels in humans shall not be considered in the classification and any available evidence from animal studies shall be consistent with the Category 2 classification. In other words, if there are also animal data available on the substance that warrant Category 1 classification, the chemical shall be classified as Category 1.

A.8.2.1.7 Effects considered to support classification for Category 1 and 2

A.8.2.1.7.1 Classification is supported by evidence associating single exposure to the substance with a consistent and identifiable toxic effect.

A.8.2.1.7.2 Evidence from human experience/incidents is usually restricted to reports of adverse health consequences, often with uncertainty about exposure conditions, and may not provide the scientific detail that can be obtained from well-conducted studies in experimental animals.

A.8.2.1.7.3 Evidence from appropriate studies in experimental animals can furnish much more detail, in the form of clinical observations, and macroscopic and microscopic pathological examination and this can often reveal hazards that may not be life-threatening but could indicate functional impairment. Consequently all available evidence, and evidence relevance to human health, must be taken into consideration in the classification process. Relevant toxic effects in humans and/or animals include, but are not limited to:

(a) Morbidity resulting from single exposure;

(b) Significant functional changes, more than transient in nature, in the respiratory system, central or peripheral nervous systems, other organs or other organ systems, including signs of central nervous system depression and effects on special senses (e.g., sight, hearing and sense of smell);

(c) Any consistent and significant adverse change in clinical biochemistry, hematology, or urinalysis parameters;

(d) Significant organ damage that may be noted at necropsy and/or subsequently seen or confirmed at microscopic examination;

(e) Multi-focal or diffuse necrosis, fibrosis or granuloma formation in vital organs with regenerative capacity;

(f) Morphological changes that are potentially reversible but provide clear evidence of marked organ dysfunction; and,

(g) Evidence of appreciable cell death (including cell degeneration and reduced cell number) in vital organs incapable of regeneration.

A.8.2.1.8 Effects considered not to support classification for Category 1 and 2

Effects may be seen in humans and/or animals that do not justify classification. Such effects include, but are not limited to:

(a) Clinical observations or small changes in bodyweight gain, food consumption or water intake that may have some toxicological importance but that do not, by themselves, indicate ''significant'' toxicity;

(b) Small changes in clinical biochemistry, hematology or urinalysis parameters and/or transient effects, when such changes or effects are of doubtful or of minimal toxicological importance;

(c) Changes in organ weights with no evidence of organ dysfunction;

(d) Adaptive responses that are not considered toxicologically relevant; and,

(e) Substance-induced species-specific mechanisms of toxicity, i.e., demonstrated with reasonable certainty to be not relevant for human health, shall not justify classification.

A.8.2.1.9 Guidance values to assist with classification based on the results obtained from studies conducted in experimental animals for Category 1 and 2

A.8.2.1.9.1 In order to help reach a decision about whether a substance shall be classified or not, and to what degree it shall be classified (Category 1 vs. Category 2), dose/concentration ''guidance values'' are provided for consideration of the dose/concentration which has been shown to produce significant health effects. The principal argument for proposing such guidance values is that all chemicals are potentially toxic and there has to be a reasonable dose/concentration above which a degree of toxic effect is acknowledged.

A.8.2.1.9.2 Thus, in animal studies, when significant toxic effects are observed that indicate classification, consideration of the dose/concentration at which these effects were seen, in relation to the suggested guidance values, provides useful information to help assess the need to classify (since the toxic effects are a consequence of the hazardous property(ies) and also the dose/concentration).

A.8.2.1.9.3 The guidance value (C) ranges for single-dose exposure which has produced a significant non-lethal toxic effect are those applicable to acute toxicity testing, as indicated in Table A.8.1.

TABLE A.8.1—GUIDANCE VALUE RANGES FOR SINGLE-DOSE EXPOSURES

Route of exposure	Units	Guidance value ranges for:		
		Category 1	Category 2	Category 3
Oral (rat)	mg/kg body weight	C ≤300	2000 ≥C >300	Guidance values do not apply.
Dermal (rat or rabbit)	mg/kg body weight	C ≤1,000	2000 ≥C >1,000.	
Inhalation (rat) gas	ppmV/4h	C ≤2,500	20,000 ≥C >2,500.	
Inhalation (rat) vapor	mg/1/4h	C ≤10	20 ≥C >10.	
Inhalation (rat) dust/mist/fume.	mg/l/4h	C ≤1.0	5.0 ≥C >1.0.	

A.8.2.1.9.4 The guidance values and ranges mentioned in Table A.8.1 are intended only for guidance purposes, i.e., to be used as part of the weight of evidence approach, and to assist with decisions about classification. They are not intended as strict demarcation values. Guidance values are not provided for Category 3 since this classification is primarily based on human data; animal data may be included in the weight of evidence evaluation.

A.8.2.1.9.5 Thus, it is feasible that a specific profile of toxicity occurs at a dose/concentration below the guidance value, e.g., <2000 mg/kg body weight by the oral route, however the nature of the effect may result in the decision not to classify. Conversely, a specific profile of toxicity may be seen in animal studies occurring at above a guidance value, e.g., ≥2000 mg/kg body weight by the oral route, and in addition there is supplementary information from other sources, e.g., other single dose studies, or human case experience, which supports a conclusion that, in view of the weight of evidence, classification is the prudent action to take.

A.8.2.1.10 Other considerations

A.8.2.1.10.1 When a substance is characterized only by use of animal data the classification process includes reference to dose/concentration guidance values as one of

the elements that contribute to the weight of evidence approach.

A.8.2.1.10.2 When well-substantiated human data are available showing a specific target organ toxic effect that can be reliably attributed to single exposure to a substance, the substance shall be classified. Positive human data, regardless of probable dose, predominates over animal data. Thus, if a substance is unclassified because specific target organ toxicity observed was considered not relevant or significant to humans, if subsequent human incident data become available showing a specific target organ toxic effect, the substance shall be classified.

A.8.2.1.10.3 A substance that has not been tested for specific target organ toxicity shall, where appropriate, be classified on the basis of data from a scientifically validated structure activity relationship and expert judgment-based extrapolation from a structural analogue that has previously been classified together with substantial support from consideration of other important factors such as formation of common significant metabolites.

A.8.2.2 Substances of Category 3

A.8.2.2.1 Criteria for respiratory tract irritation

The criteria for classifying substances as Category 3 for respiratory tract irritation are:

(a) Respiratory irritant effects (characterized by localized redness, edema, pruritis and/or pain) that impair function with symptoms such as cough, pain, choking, and breathing difficulties are included. It is recognized that this evaluation is based primarily on human data;

(b) Subjective human observations supported by objective measurements of clear respiratory tract irritation (RTI) (e.g., electrophysiological responses, biomarkers of inflammation in nasal or bronchoalveolar lavage fluids);

(c) The symptoms observed in humans shall also be typical of those that would be produced in the exposed population rather than being an isolated idiosyncratic reaction or response triggered only in individuals with hypersensitive airways. Ambiguous reports simply of ''irritation'' should be excluded as this term is commonly used to describe a wide range of sensations including those such as smell, unpleasant taste, a tickling sensation, and dryness, which are outside the scope of classification for respiratory tract irritation;

(d) There are currently no scientifically validated animal tests that deal specifically with RTI; however, useful information may be obtained from the single and repeated inhalation toxicity tests. For example, animal studies may provide useful information in terms of clinical signs of toxicity (dyspnoea, rhinitis etc) and histopathology (e.g., hyperemia, edema, minimal inflammation, thickened mucous layer) which are reversible and may be reflective of the characteristic clinical symptoms described above. Such animal studies can be used as part of weight of evidence evaluation; and,

(e) This special classification will occur only when more severe organ effects including the respiratory system are not observed as those effects would require a higher classification.

A.8.2.2.2 Criteria for narcotic effects

The criteria for classifying substances in Category 3 for narcotic effects are:

(a) Central nervous system depression including narcotic effects in humans such as drowsiness, narcosis, reduced alertness, loss of reflexes, lack of coordination, and vertigo are included. These effects can also be manifested as severe headache or nausea, and can lead to reduced judgment, dizziness, irritability, fatigue, impaired memory function, deficits in perception and coordination, reaction time, or sleepiness; and,

(b) Narcotic effects observed in animal studies may include lethargy, lack of coordination righting reflex, narcosis, and ataxia. If these effects are not transient in nature, then they shall be considered for classification as Category 1 or 2.

A.8.3 Classification Criteria for Mixtures

A.8.3.1 Mixtures are classified using the same criteria as for substances, or alternatively as described below. As with substances, mixtures may be classified for specific target organ toxicity following single exposure, repeated exposure, or both.

A.8.3.2 Classification of Mixtures When Data Are Available for the Complete Mixture

When reliable and good quality evidence from human experience or appropriate studies in experimental animals, as described in the criteria for substances, is available for the mixture, then the mixture shall be classified by weight of evidence evaluation of this data. Care shall be exercised in evaluating data on mixtures, that the dose, duration, observation or analysis, do not render the results inconclusive.

A.8.3.3 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.8.3.3.1 Where the mixture itself has not been tested to determine its specific target organ toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data shall be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution, Batching, Concentration of mixtures, Interpolation within one toxicity category, Substantially similar mixtures, or Aerosols.

A.8.3.4 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.8.3.4.1 Where there is no reliable evidence or test data for the specific mixture itself, and the bridging principles cannot be used to enable classification, then classification of the mixture is based on the classification of the ingredient substances. In this case, the mixture shall be classified as a specific target organ toxicant (specific organ specified), following single exposure, repeated exposure, or both when at least one ingredient has been classified as a Category 1 or Category 2 specific target organ toxicant and is present at or above the appropriate cut-off value/concentration limit specified in Table A.8.2 for Categories 1 and 2, respectively.

TABLE A.8.2—CUT-OFF VALUES/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS A SPECIFIC TARGET ORGAN TOXICANT THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE AS CATEGORY 1 OR 2

Ingredient classified as:	Cut-off values/concentration limits triggering classification of a mixture as:	
	Category 1	Category 2
Category 1 Target organ toxicant	≥1.0%	
Category 2 Target organ toxicant		≥1.0%

A.8.3.4.2 These cut-off values and consequent classifications shall be applied equally and appropriately to both single- and repeated-dose target organ toxicants.

A.8.3.4.3 Mixtures shall be classified for either or both single and repeated dose toxicity independently.

A.8.3.4.4 Care shall be exercised when toxicants affecting more than one organ system are combined that the potentiation or synergistic interactions are considered, because certain substances can cause target organ toxicity at <1% concentration when other ingredients in the mixture are known to potentiate its toxic effect.

A.8.3.4.5 Care shall be exercised when extrapolating the toxicity of a mixture that contains Category 3 ingredient(s). A cut-off value/concentration limit of 20%, considered as an additive of all Category 3 ingredients for each hazard endpoint, is appropriate; however, this cut-off value/concentration limit may be higher or lower depending on the Category 3 ingredient(s) involved and the fact that some effects such as respiratory tract irritation may not occur below a certain concentration while other effects such as narcotic effects may occur below this 20% value. Expert judgment shall be exercised. Respiratory tract irritation and narcotic

effects are to be evaluated separately in accordance with the criteria given in A.8.2.2. When conducting classifications for these hazards, the contribution of each ingredient should be considered additive, unless there is evidence that the effects are not additive.

A.9 SPECIFIC TARGET ORGAN TOXICITY REPEATED OR PROLONGED EXPOSURE

A.9.1 Definitions and general considerations

A.9.1.1 *Specific target organ toxicity—repeated exposure (STOT–RE)* means specific target organ toxicity arising from repeated exposure to a substance or mixture. All significant health effects that can impair function, both reversible and irreversible, immediate and/or delayed and not specifically addressed in A.1 to A.7 and A.10 of this Appendix are included. Specific target organ toxicity following a single-event exposure is classified in accordance with *SPECIFIC TARGET ORGAN TOXICITY—SINGLE EXPOSURE* (A.8 of this Appendix) and is therefore not included here.

A.9.1.2 Classification identifies the substance or mixture as being a specific target organ toxicant and, as such, it may present a potential for adverse health effects in people who are exposed to it.

A.9.1.3 These adverse health effects produced by repeated exposure include consistent and identifiable toxic effects in humans, or, in experimental animals, toxicologically significant changes which have affected the function or morphology of a tissue/organ, or have produced serious changes to the biochemistry or hematology of the organism and these changes are relevant for human health. Human data will be the primary source of evidence for this hazard class.

A.9.1.4 Assessment shall take into consideration not only significant changes in a single organ or biological system but also generalized changes of a less severe nature involving several organs.

A.9.1.5 Specific target organ toxicity can occur by any route that is relevant for humans, e.g., principally oral, dermal or inhalation.

A.9.2 Classification Criteria for Substances

A.9.2.1 Substances shall be classified as STOT–RE by expert judgment on the basis of the weight of all evidence available, including the use of recommended guidance values which take into account the duration of exposure and the dose/concentration which produced the effect(s), (See A.9.2.9). Substances shall be placed in one of two categories, depending upon the nature and severity of the effect(s) observed, in accordance with Figure A.9.1.

FIGURE A.9.1—HAZARD CATEGORIES FOR SPECIFIC TARGET ORGAN TOXICITY FOLLOWING REPEATED EXPOSURE

CATEGORY 1: Substances that have produced significant toxicity in humans, or that, on the basis of evidence from studies in experimental animals can be presumed to have the potential to produce significant toxicity in humans following repeated or prolonged exposure

Substances are classified in Category 1 for specific target organ toxicity (repeated exposure) on the basis of:

(a) reliable and good quality evidence from human cases or epidemiological studies; or,

(b) observations from appropriate studies in experimental animals in which significant and/or severe toxic effects, of relevance to human health, were produced at generally low exposure concentrations. Guidance dose/concentration values are provided below (See A.9.2.9) to be used as part of weight-of-evidence evaluation.

CATEGORY 2: Substances that, on the basis of evidence from studies in experimental animals can be presumed to have the potential to be harmful to human health following repeated or prolonged exposure

Substances are classified in Category 2 for specific target organ toxicity (repeated exposure) on the basis of observations from appropriate studies in experimental animals in which significant toxic effects, of relevance to human health, were produced at generally moderate exposure concentrations. Guidance dose/concentration values are provided below (See A.9.2.9) in order to help in classification.

In exceptional cases human evidence can also be used to place a substance in Category 2 (See A.9.2.6).

Note: The primary target organ/system shall be identified where possible, or the substance shall be identified as a general toxicant. The data shall be carefully evaluated and, where possible, shall not include secondary effects (e.g., a hepatotoxicant can produce secondary effects in the nervous or gastro-intestinal systems).

A.9.2.2 The relevant route of exposure by which the classified substance produces damage shall be identified.

A.9.2.3 Classification is determined by expert judgment, on the basis of the weight of all evidence available including the guidance presented below.

A.9.2.4 Weight of evidence of all data, including human incidents, epidemiology, and studies conducted in experimental animals, is used to substantiate specific target organ toxic effects that merit classification.

A.9.2.5 The information required to evaluate specific target organ toxicity comes either from repeated exposure in humans, e.g., exposure at home, in the workplace or environmentally, or from studies conducted in experimental animals. The standard animal studies in rats or mice that provide this information are 28 day, 90 day or lifetime studies (up to 2 years) that include hematological, clinico-chemical and detailed macroscopic and microscopic examination to enable the toxic effects on target tissues/organs to be identified. Data from repeat dose studies performed in other species may also be used. Other long-term exposure studies, e.g., for carcinogenicity, neurotoxicity or reproductive toxicity, may also provide evidence of specific target organ toxicity that could be used in the assessment of classification.

A.9.2.6 In exceptional cases, based on expert judgment, it may be appropriate to place certain substances with human evidence of specific target organ toxicity in Category 2: (a) when the weight of human evidence is not sufficiently convincing to warrant Category 1 classification, and/or (b) based on the nature and severity of effects. Dose/concentration levels in humans shall not be considered in the classification and any available evidence from animal studies shall be consistent with the Category 2 classification. In other words, if there are also animal data available on the substance that warrant Category 1 classification, the substance shall be classified as Category 1.

A.9.2.7 Effects Considered To Support Classification

A.9.2.7.1 Classification is supported by reliable evidence associating repeated exposure to the substance with a consistent and identifiable toxic effect.

A.9.2.7.2 Evidence from human experience/incidents is usually restricted to reports of adverse health consequences, often with uncertainty about exposure conditions, and may not provide the scientific detail that can be obtained from well-conducted studies in experimental animals.

A.9.2.7.3 Evidence from appropriate studies in experimental animals can furnish much more detail, in the form of clinical observations, hematology, clinical chemistry, macroscopic and microscopic pathological examination and this can often reveal hazards that may not be life-threatening but could indicate functional impairment. Consequently all available evidence, and relevance to human health, must be taken into consideration in the classification process. Relevant toxic effects in humans and/or animals include, but are not limited to:

(a) Morbidity or death resulting from repeated or long-term exposure. Morbidity or death may result from repeated exposure, even to relatively low doses/concentrations, due to bioaccumulation of the substance or its metabolites, or due to the overwhelming of the de-toxification process by repeated exposure;

(b) Significant functional changes in the central or peripheral nervous systems or other organ systems, including signs of central nervous system depression and effects on special senses (e.g., sight, hearing and sense of smell);

(c) Any consistent and significant adverse change in clinical biochemistry, hematology, or urinalysis parameters;

(d) Significant organ damage that may be noted at necropsy and/or subsequently seen or confirmed at microscopic examination;

(e) Multi-focal or diffuse necrosis, fibrosis or granuloma formation in vital organs with regenerative capacity;

(f) Morphological changes that are potentially reversible but provide clear evidence of marked organ dysfunction (e.g., severe fatty change in the liver); and,

(g) Evidence of appreciable cell death (including cell degeneration and reduced cell number) in vital organs incapable of regeneration.

A.9.2.8 Effects Considered Not To Support Classification

Effects may be seen in humans and/or animals that do not justify classification. Such effects include, but are not limited to:

(a) Clinical observations or small changes in bodyweight gain, food consumption or water intake that may have some toxicological importance but that do not, by themselves, indicate ''significant'' toxicity;

(b) Small changes in clinical biochemistry, hematology or urinalysis parameters and/or transient effects, when such changes or effects are of doubtful or of minimal toxicological importance;

(c) Changes in organ weights with no evidence of organ dysfunction;

(d) Adaptive responses that are not considered toxicologically relevant;

(e) Substance-induced species-specific mechanisms of toxicity, i.e., demonstrated with reasonable certainty to be not relevant for human health, shall not justify classification.

A.9.2.9 Guidance Values To Assist With Classification Based on the Results Obtained From Studies Conducted in Experimental Animals

A.9.2.9.1 In studies conducted in experimental animals, reliance on observation of effects alone, without reference to the duration of experimental exposure and dose/concentration, omits a fundamental concept of toxicology, i.e., all substances are potentially toxic, and what determines the toxicity is a function of the dose/concentration and the duration of exposure. In most studies conducted in experimental animals the test guidelines use an upper limit dose value.

A.9.2.9.2 In order to help reach a decision about whether a substance shall be classified or not, and to what degree it shall be classified (Category 1 vs. Category 2), dose/concentration ''guidance values'' are provided in Table A.9.1 for consideration of the dose/concentration which has been shown to produce significant health effects. The principal argument for proposing such guidance values is that all chemicals are potentially toxic and there has to be a reasonable dose/concentration above which a degree of toxic effect is acknowledged. Also, repeated-dose studies conducted in experimental animals are designed to produce toxicity at the highest dose used in order to optimize the test objective and so most studies will reveal some toxic effect at least at this highest dose. What is therefore to be decided is not only what effects have been produced, but also at what dose/concentration they were produced and how relevant is that for humans.

A.9.2.9.3 Thus, in animal studies, when significant toxic effects are observed that indicate classification, consideration of the duration of experimental exposure and the dose/concentration at which these effects were seen, in relation to the suggested guidance values, provides useful information to help assess the need to classify (since the toxic effects are a consequence of the hazardous property(ies) and also the duration of exposure and the dose/concentration).

A.9.2.9.4 The decision to classify at all can be influenced by reference to the dose/concentration guidance values at or below which a significant toxic effect has been observed.

A.9.2.9.5 The guidance values refer to effects seen in a standard 90-day toxicity study conducted in rats. They can be used as a basis to extrapolate equivalent guidance values for toxicity studies of greater or lesser duration, using dose/exposure time extrapolation similar to Haber's rule for inhalation, which states essentially that the effective dose is directly proportional to the exposure concentration and the duration of exposure. The assessment should be done on a case-by-case basis; for example, for a 28-day study the guidance values below would be increased by a factor of three.

A.9.2.9.6 Thus for Category 1 classification, significant toxic effects observed in a 90-day repeated-dose study conducted in experimental animals and seen to occur at or below the (suggested) guidance values (C) as indicated in Table A.9.1 would justify classification:

TABLE A.9.1—GUIDANCE VALUES TO ASSIST IN CATEGORY 1 CLASSIFICATION

[Applicable to a 90-day study]

Route of exposure	Units	Guidance values (dose/concentration)
Oral (rat)	mg/kg body weight/day	C ≤10.
Dermal (rat or rabbit)	mg/kg body weight/day	C ≤20.
Inhalation (rat) gas	ppmV/6h/day	C ≤50.
Inhalation (rat) vapor	mg/liter/6h/day	C ≤0.2.
Inhalation (rat) dust/mist/fume	mg/liter/6h/day	C ≤0.02.

A.9.2.9.7 For Category 2 classification, significant toxic effects observed in a 90-day repeated-dose study conducted in experimental animals and seen to occur within the (suggested) guidance value ranges as indicated in Table A.9.2 would justify classification:

TABLE A.9.2—GUIDANCE VALUES TO ASSIST IN CATEGORY 2 CLASSIFICATION

[Applicable to a 90-day study]

Route of exposure	Units	Guidance values (dose/concentration)
Oral (rat)	mg/kg body weight/day	10 <C ≤100.
Dermal (rat or rabbit)	mg/kg body weight/day	20 <C ≤200.
Inhalation (rat) gas	ppmV/6h/day	50 <C ≤250.
Inhalation (rat) vapor	mg/liter/6h/day	0.2 <C ≤1.0.
Inhalation (rat) dust/mist/fume	mg/liter/6h/day	0.02 <C ≤0.2.

A.9.2.9.8 The guidance values and ranges mentioned in A.2.9.9.6 and A.2.9.9.7 are intended only for guidance purposes, i.e., to be used as part of the weight of evidence approach, and to assist with decisions about

classification. They are not intended as strict demarcation values.

A.9.2.9.9 Thus, it is possible that a specific profile of toxicity occurs in repeat-dose animal studies at a dose/concentration below the guidance value, e.g., <100 mg/kg body weight/day by the oral route, however the nature of the effect, e.g., nephrotoxicity seen only in male rats of a particular strain known to be susceptible to this effect, may result in the decision not to classify. Conversely, a specific profile of toxicity may be seen in animal studies occurring at above a guidance value, e.g., ≥100 mg/kg body weight/day by the oral route, and in addition there is supplementary information from other sources, e.g., other long-term administration studies, or human case experience, which supports a conclusion that, in view of the weight of evidence, classification is prudent.

A.9.2.10 Other Considerations

A.9.2.10.1 When a substance is characterized only by use of animal data the classification process includes reference to dose/concentration guidance values as one of the elements that contribute to the weight of evidence approach.

A.9.2.10.2 When well-substantiated human data are available showing a specific target organ toxic effect that can be reliably attributed to repeated or prolonged exposure to a substance, the substance shall be classified. Positive human data, regardless of probable dose, predominates over animal data. Thus, if a substance is unclassified because no specific target organ toxicity was seen at or below the dose/concentration guidance value for animal testing, if subsequent human incident data become available showing a specific target organ toxic effect, the substance shall be classified.

A.9.2.10.3 A substance that has not been tested for specific target organ toxicity may in certain instances, where appropriate, be classified on the basis of data from a scientifically validated structure activity relationship and expert judgment-based extrapolation from a structural analogue that has previously been classified together with substantial support from consideration of other important factors such as formation of common significant metabolites.

A.9.3 Classification Criteria for Mixtures

A.9.3.1 Mixtures are classified using the same criteria as for substances, or alternatively as described below. As with substances, mixtures may be classified for specific target organ toxicity following single exposure, repeated exposure, or both.

A.9.3.2 Classification of Mixtures When Data Are Available for the Complete Mixture

When reliable and good quality evidence from human experience or appropriate studies in experimental animals, as described in the criteria for substances, is available for the mixture, then the mixture shall be classified by weight of evidence evaluation of these data. Care shall be exercised in evaluating data on mixtures, that the dose, duration, observation or analysis, do not render the results inconclusive.

A.9.3.3 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.9.3.3.1 Where the mixture itself has not been tested to determine its specific target organ toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazards of the mixture, these data shall be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution; Batching; Concentration of mixtures; Interpolation within one toxicity category; Substantially similar mixtures; and Aerosols.

A.9.3.4 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.9.3.4.1 Where there is no reliable evidence or test data for the specific mixture itself, and the bridging principles cannot be used to enable classification, then classification of the mixture is based on the classification of the ingredient substances. In this case, the mixture shall be classified as a specific target organ toxicant (specific organ specified), following single exposure, repeated exposure, or both when at least one ingredient has been classified as a Category 1 or Category 2 specific target organ toxicant and is present at or above the appropriate cut-off value/concentration limit specified in Table A.9.3 for Category 1 and 2 respectively.

TABLE A.9.3—CUT-OFF VALUE/CONCENTRATION LIMITS OF INGREDIENTS OF A MIXTURE CLASSIFIED AS A SPECIFIC TARGET ORGAN TOXICANT THAT WOULD TRIGGER CLASSIFICATION OF THE MIXTURE AS CATEGORY 1 OR 2

Ingredient classified as:	Cut-off values/concentration limits triggering classification of a mixture as:	
	Category 1	Category 2
Category 1 Target organ toxicant	≥1.0%	.....
Category 2 Target organ toxicant	.....	≥1.0%

A.9.3.4.2 These cut-off values and consequent classifications shall be applied equally and appropriately to both single- and repeated-dose target organ toxicants.

A.9.3.4.3 Mixtures shall be classified for either or both single- and repeated-dose toxicity independently.

A.9.3.4.4 Care shall be exercised when toxicants affecting more than one organ system are combined that the potentiation or synergistic interactions are considered, because certain substances can cause specific target organ toxicity at <1% concentration when other ingredients in the mixture are known to potentiate its toxic effect.

A.10 ASPIRATION HAZARD

A.10.1 Definitions and General and Specific Considerations

A.10.1.1 *Aspiration* means the entry of a liquid or solid chemical directly through the oral or nasal cavity, or indirectly from vomiting, into the trachea and lower respiratory system.

A.10.1.2 Aspiration toxicity includes severe acute effects such as chemical pneumonia, varying degrees of pulmonary injury or death following aspiration.

A.10.1.3 Aspiration is initiated at the moment of inspiration, in the time required to take one breath, as the causative material lodges at the crossroad of the upper respiratory and digestive tracts in the laryngopharyngeal region.

A.10.1.4 Aspiration of a substance or mixture can occur as it is vomited following ingestion. This may have consequences for labeling, particularly where, due to acute toxicity, a recommendation may be considered to induce vomiting after ingestion. However, if the substance/mixture also presents an aspiration toxicity hazard, the recommendation to induce vomiting may need to be modified.

A.10.1.5 Specific Considerations

A.10.1.5.1 The classification criteria refer to kinematic viscosity. The following provides the conversion between dynamic and kinematic viscosity:

$$\frac{\text{Dynamic viscosity (mPa·s)}}{\text{Density (g/cm}^3\text{)}} = \text{Kinematic viscosity (mm}^2\text{/s)}$$

A.10.1.5.2 Although the definition of aspiration in A.10.1.1 includes the entry of solids into the respiratory system, classification according to (b) in table A.10.1 for Category 1 is intended to apply to liquid substances and mixtures only.

A.10.1.5.3 Classification of aerosol/mist products.

Aerosol and mist products are usually dispensed in containers such as self-pressurized containers, trigger and pump sprayers. Classification for these products shall be considered if their use may form a pool of product in the mouth, which then may be aspirated. If the mist or aerosol from a pressurized container is fine, a pool may not be formed. On the other hand, if a pressurized container dispenses product in a stream, a pool may be formed that may then be aspirated. Usually, the mist produced by trigger and pump sprayers is coarse and therefore, a pool may be formed that then may be aspirated. When the pump mechanism may be removed and contents are available to be swallowed then the classification of the products should be considered.

A.10.2 Classification Criteria for Substances

TABLE A.10.1—CRITERIA FOR ASPIRATION TOXICITY

Category	Criteria
Category 1: Chemicals known to cause human aspiration toxicity hazards or to be regarded as if they cause human aspiration toxicity hazard.	A substance shall be classified in Category 1: (a) If reliable and good quality human evidence indicates that it causes aspiration toxicity (See note); or (b) If it is a hydrocarbon and has a kinematic viscosity ≤20.5 mm²/s, measured at 40 °C.

Note: Examples of substances included in Category 1 are certain hydrocarbons, turpentine and pine oil.

A.10.3 Classification Criteria for Mixtures

A.10.3.1 Classification When Data Are Available for the Complete Mixture

A mixture shall be classified in Category 1 based on reliable and good quality human evidence.

A.10.3.2 Classification of Mixtures When Data Are Not Available for the Complete Mixture: Bridging Principles

A.10.3.2.1 Where the mixture itself has not been tested to determine its aspiration toxicity, but there are sufficient data on both the individual ingredients and similar tested mixtures to adequately characterize the hazard of the mixture, these data shall be used in accordance with the following bridging principles as found in paragraph A.0.5 of this Appendix: Dilution; Batching; Concentration of mixtures; Interpolation within one toxicity category; and Substantially similar mixtures. For application of the dilution bridging principle, the concentration of aspiration toxicants shall not be less than 10%.

A.10.3.3 Classification of Mixtures When Data Are Available for All Ingredients or Only for Some Ingredients of the Mixture

A.10.3.3.1 A mixture which contains ≥10% of an ingredient or ingredients classified in Category 1, and has a kinematic viscosity ≤20.5 mm²/s, measured at 40 °C, shall be classified in Category 1.

A.10.3.3.2 In the case of a mixture which separates into two or more distinct layers, one of which contains ≥10% of an ingredient or ingredients classified in Category 1 and has a kinematic viscosity ≤20.5 mm²/s, measured at 40 °C, then the entire mixture shall be classified in Category 1.

APPENDIX B TO § 1910.1200—PHYSICAL CRITERIA (MANDATORY)

B.1 EXPLOSIVES

B.1.1 Definitions and General Considerations

B.1.1.1 An *explosive chemical* is a solid or liquid chemical which is in itself capable by chemical reaction of producing gas at such a temperature and pressure and at such a speed as to cause damage to the surroundings. Pyrotechnic chemicals are included even when they do not evolve gases.

A *pyrotechnic chemical* is a chemical designed to produce an effect by heat, light, sound, gas or smoke or a combination of these as the result of non-detonative self-sustaining exothermic chemical reactions.

An *explosive item* is an item containing one or more explosive chemicals.

A *pyrotechnic item* is an item containing one or more pyrotechnic chemicals.

An *unstable explosive* is an explosive which is thermally unstable and/or too sensitive for normal handling, transport, or use.

An *intentional explosive* is a chemical or item which is manufactured with a view to produce a practical explosive or pyrotechnic effect.

B.1.1.2 The class of explosives comprises:

(a) Explosive chemicals;

(b) Explosive items, except devices containing explosive chemicals in such quantity or of such a character that their inadvertent or accidental ignition or initiation shall not cause any effect external to the device either by projection, fire, smoke, heat or loud noise; and

(c) Chemicals and items not included under (a) and (b) above which are manufactured with the view to producing a practical explosive or pyrotechnic effect.

B.1.2 Classification Criteria

Chemicals and items of this class shall be classified as unstable explosives or shall be assigned to one of the following six divisions depending on the type of hazard they present:

(a) Division 1.1—Chemicals and items which have a mass explosion hazard (a mass explosion is one which affects almost the entire quantity present virtually instantaneously);

(b) Division 1.2—Chemicals and items which have a projection hazard but not a mass explosion hazard;

(c) Division 1.3—Chemicals and items which have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard:

(i) Combustion of which gives rise to considerable radiant heat; or

(ii) Which burn one after another, producing minor blast or projection effects or both;

(d) Division 1.4—Chemicals and items which present no significant hazard: chemicals and items which present only a small hazard in the event of ignition or initiation. The effects are largely confined to the package and no projection of fragments of appreciable size or range is to be expected. An external fire shall not cause virtually instantaneous explosion of almost the entire contents of the package;

(e) Division 1.5—Very insensitive chemicals which have a mass explosion hazard: chemicals which have a mass explosion hazard but are so insensitive that there is very little probability of initiation or of transition from burning to detonation under normal conditions;

(f) Division 1.6—Extremely insensitive items which do not have a mass explosion hazard: items which contain only extremely insensitive detonating chemicals and which demonstrate a negligible probability of accidental initiation or propagation.

B.1.3 Additional Classification Considerations

B.1.3.1 Explosives shall be classified as unstable explosives or shall be assigned to one of the six divisions identified in B.1.2 in accordance with the three step procedure in Part I of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6). The first step is to ascertain whether the substance or mixture has explosive effects (Test Series 1). The second step is the acceptance procedure (Test Series 2 to 4) and the third step is the assignment to a hazard division (Test Series 5 to 7). The assessment whether a candidate for ''ammonium nitrate emulsion or suspension or gel, intermediate for blasting explosives (ANE)'' is insensitive enough for inclusion as an oxidizing liquid (See B.13) or an oxidizing solid (See B.14) is determined by Test Series 8 tests.

Note: Classification of solid chemicals shall be based on tests performed on the chemical as presented. If, for example, for the purposes of supply or transport, the same

chemical is to be presented in a physical form different from that which was tested and which is considered likely to materially alter its performance in a classification test, classification must be based on testing of the chemical in the new form.

B.1.3.2 Explosive properties are associated with the presence of certain chemical groups in a molecule which can react to produce very rapid increases in temperature or pressure. The screening procedure in B.1.3.1 is aimed at identifying the presence of such reactive groups and the potential for rapid energy release. If the screening procedure identifies the chemical as a potential explosive, the acceptance procedure (See section 10.3 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6)) is necessary for classification.

Note: Neither a Series 1 type (a) propagation of detonation test nor a Series 2 type (a) test of sensitivity to detonative shock is necessary if the exothermic decomposition energy of organic materials is less than 800 J/g.

B.1.3.3 If a mixture contains any known explosives, the acceptance procedure is necessary for classification.

B.1.3.4 A chemical is not classified as explosive if:

(a) There are no chemical groups associated with explosive properties present in the molecule. Examples of groups which may indicate explosive properties are given in Table A6.1 in Appendix 6 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6); or

(b) The substance contains chemical groups associated with explosive properties which include oxygen and the calculated oxygen balance is less than −200.

The oxygen balance is calculated for the chemical reaction:

$C_xH_yO_z + [x + (y/4) - (z/2)]\ O_2 \rightarrow x.\ CO_2 + (y/2)\ H_2O$

using the formula:

oxygen balance = $-1600\ [2x + (y/2) - z]$/molecular weight;

or

(c) The organic substance or a homogenous mixture of organic substances contains chemical groups associated with explosive properties but the exothermic decomposition energy is less than 500 J/g and the onset of exothermic decomposition is below 500 °C (932 °F). The exothermic decomposition energy may be determined using a suitable calorimetric technique; or

(d) For mixtures of inorganic oxidizing substances with organic material(s), the concentration of the inorganic oxidizing substance is:

(i) Less than 15%, by mass, if the oxidizing substance is assigned to Category 1 or 2;

(ii) Less than 30%, by mass, if the oxidizing substance is assigned to Category 3.

B.2 FLAMMABLE GASES

B.2.1 Definition

Flammable gas means a gas having a flammable range with air at 20 °C (68 °F) and a standard pressure of 101.3 kPa (14.7 psi).

B.2.2 Classification Criteria

A flammable gas shall be classified in one of the two categories for this class in accordance with Table B.2.1:

TABLE B.2.1—CRITERIA FOR FLAMMABLE GASES

Category	Criteria
1	Gases, which at 20 °C (68 °F) and a standard pressure of 101.3 kPa (14.7 psi): (a) are ignitable when in a mixture of 13% or less by volume in air; or (b) have a flammable range with air of at least 12 percentage points regardless of the lower flammable limit.
2	Gases, other than those of Category 1, which, at 20 °C (68 °F) and a standard pressure of 101.3 kPa (14.7 psi), have a flammable range while mixed in air.

Note: Aerosols should not be classified as flammable gases. See B.3.

B.2.3 Additional Classification Considerations

Flammability shall be determined by tests or by calculation in accordance with ISO 10156 (incorporated by reference; See § 1910.6). Where insufficient data are available to use this method, equivalent validated methods may be used.

B.3 FLAMMABLE AEROSOLS

B.3.1 Definition

Aerosol means any non-refillable receptacle containing a gas compressed, liquefied or dissolved under pressure, and fitted with a release device allowing the contents to be ejected as particles in suspension in a gas, or as a foam, paste, powder, liquid or gas.

B.3.2 Classification Criteria

B.3.2.1 Aerosols shall be considered for classification as flammable if they contain any component which is classified as flammable in accordance with this Appendix, i.e.:

Flammable liquids (See B.6);
Flammable gases (See B.2);
Flammable solids (See B.7).

Note 1: Flammable components do not include pyrophoric, self-heating or water-reactive chemicals.

Note 2: Flammable aerosols do not fall additionally within the scope of flammable gases, flammable liquids, or flammable solids.

B.3.2.2 A flammable aerosol shall be classified in one of the two categories for this class in accordance with Table B.3.1.

TABLE B.3.1—CRITERIA FOR FLAMMABLE AEROSOLS

Category	Criteria
1	Contains ≥85% flammable components and the chemical heat of combustion is ≥30 kJ/g; or (a) For spray aerosols, in the ignition distance test, ignition occurs at a distance ≥75 cm (29.5 in), or (b) For foam aerosols, in the aerosol foam flammability test. (i) The flame height is ≥20 cm (7.87 in) and the flame duration ≥2 s; or (ii) The flame height is ≥4 cm (1.57 in) and the flame duration ≥7 s.
2	Contains >1% flammable components, or the heat of combustion is ≥20 kJ/g; and (a) for spray aerosols, in the ignition distance test, ignition occurs at a distance ≥15 cm (5.9 in), or in the enclosed space ignition test, the (i) Time equivalent is ≤300 s/m^3; or (ii) Deflagration density is ≤300 g/m^3. (b) For foam aerosols, in the aerosol foam flammability test, the flame height is ≥4 cm and the flame duration is ≥2 s and it does not meet the criteria for Category 1.

Note: Aerosols not submitted to the flammability classification procedures in this Appendix shall be classified as extremely flammable (Category 1).

B.3.3 Additional Classification Considerations

B.3.3.1 To classify a flammable aerosol, data on its flammable components, on its chemical heat of combustion and, if applicable, the results of the aerosol foam flammability test (for foam aerosols) and of the ignition distance test and enclosed space test (for spray aerosols) are necessary.

B.3.3.2 The chemical heat of combustion (ΔHc), in kilojoules per gram (kJ/g), is the product of the theoretical heat of combustion (ΔHcomb), and a combustion efficiency, usually less than 1.0 (a typical combustion efficiency is 0.95 or 95%).

For a composite aerosol formulation, the chemical heat of combustion is the summation of the weighted heats of combustion for the individual components, as follows:

$$\Delta Hc\ (product) = \sum_{i}^{n} [\ wi\% \times \Delta Hc(i)]$$

Where:

ΔHc = chemical heat of combustion (kJ/g);
wi% = mass fraction of component i in the product;
ΔHc(i) = specific heat of combustion (kJ/g) of component i in the product;

The chemical heats of combustion shall be found in literature, calculated or determined by tests (See ASTM D240–02, ISO 13943, Sections 86.1 to 86.3, and NFPA 30B (incorporated by reference; See § 1910.6)).

B.3.3.3 The Ignition Distance Test, Enclosed Space Ignition Test and Aerosol Foam Flammability Test shall be performed in accordance with sub-sections 31.4, 31.5 and 31.6 of the of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6).

B.4 OXIDIZING GASES

B.4.1 Definition

Oxidizing gas means any gas which may, generally by providing oxygen, cause or contribute to the combustion of other material more than air does.

Note: ''Gases which cause or contribute to the combustion of other material more than air does'' means pure gases or gas mixtures with an oxidizing power greater than 23.5% (as determined by a method specified in ISO 10156 or 10156–2 (incorporated by reference, See § 1910.6) or an equivalent testing method.)

B.4.2 Classification Criteria

An oxidizing gas shall be classified in a single category for this class in accordance with Table B.4.1:

TABLE B.4.1—CRITERIA FOR OXIDIZING GASES

Category	Criteria
1	Any gas which may, generally by providing oxygen, cause or contribute to the combustion of other material more than air does.

B.4.3 Additional Classification Considerations

Classification shall be in accordance with tests or calculation methods as described in ISO 10156 (incorporated by reference; See § 1910.6) and ISO 10156–2 (incorporated by reference; See § 1910.6).

B.5 GASES UNDER PRESSURE

B.5.1 Definition

Gases under pressure are gases which are contained in a receptacle at a pressure of 200 kPa (29 psi) (gauge) or more, or which are liquefied or liquefied and refrigerated. They comprise compressed gases, liquefied gases, dissolved gases and refrigerated liquefied gases.

B.5.2 Classification Criteria

Gases under pressure shall be classified in one of four groups in accordance with Table B.5.1:

TABLE B.5.1—CRITERIA FOR GASES UNDER PRESSURE

Group	Criteria
Compressed gas	A gas which when under pressure is entirely gaseous at −50 °C (−8 °F), including all gases with a critical temperature[1] ≤ −50 °C (−58 °F).
Liquefied gas	A gas which when under pressure is partially liquid at temperatures above −50 °C (−58 °F). A distinction is made between: (a) High pressure liquefied gas: A gas with a critical temperature[1] between −50 °C (−58 °F) and +65 °C (149 °F); and (b) Low pressure liquefied gas: A gas with a critical temperature[1] above +65 °C (149 °F).
Refrigerated liquefied gas	A gas which is made partially liquid because of its low temperature.
Dissolved gas	A gas which when under pressure is dissolved in a liquid phase solvent.

[1] *The critical temperature is the temperature above which a pure gas cannot be liquefied, regardless of the degree of compression.*

B.6 FLAMMABLE LIQUIDS

B.6.1 Definition

Flammable liquid means a liquid having a flash point of not more than 93 °C (199.4 °F).

Flash point means the minimum temperature at which a liquid gives off vapor in sufficient concentration to form an ignitable mixture with air near the surface of the liquid, as determined by a method identified in Section B.6.3.

B.6.2 Classification Criteria

A flammable liquid shall be classified in one of four categories in accordance with Table B.6.1:

TABLE B.6.1—CRITERIA FOR FLAMMABLE LIQUIDS

Category	Criteria
1	Flash point <23 °C (73.4 °F) and initial boiling point ≤35 °C (95 °F).

TABLE B.6.1—CRITERIA FOR FLAMMABLE LIQUIDS—Continued

Category	Criteria
2	Flash point <23 °C (73.4 °F) and initial boiling point >35 °C (95 °F).
3	Flash point ≥23 °C (73.4 °F) and ≤60 °C (140 °F).
4	Flash point >60 °C (140 °F) and ≤93 °C (199.4 °F).

B.6.3 Additional Classification Considerations

The flash point shall be determined in accordance with ASTM D56–05, ASTM D3278, ASTM D3828, ASTM D93–08 (incorporated by reference; See § 1910.6), or any other method specified in GHS Revision 3, Chapter 2.6.

The initial boiling point shall be determined in accordance with ASTM D86–07a or ASTM D1078 (incorporated by reference; See § 1910.6).

B.7 FLAMMABLE SOLIDS

B.7.1 Definitions

Flammable solid means a solid which is a readily combustible solid, or which may cause or contribute to fire through friction.

Readily combustible solids are powdered, granular, or pasty chemicals which are dangerous if they can be easily ignited by brief contact with an ignition source, such as a burning match, and if the flame spreads rapidly.

B.7.2 Classification Criteria

B.7.2.1 Powdered, granular or pasty chemicals shall be classified as flammable solids when the time of burning of one or more of the test runs, performed in accordance with the test method described in the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), Part III, sub-section 33.2.1, is less than 45 s or the rate of burning is more than 2.2 mm/s (0.0866 in/s).

B.7.2.2 Powders of metals or metal alloys shall be classified as flammable solids when they can be ignited and the reaction spreads over the whole length of the sample in 10 min or less.

B.7.2.3 Solids which may cause fire through friction shall be classified in this class by analogy with existing entries (e.g., matches) until definitive criteria are established.

B.7.2.4 A flammable solid shall be classified in one of the two categories for this class using Method N.1 as described in Part III, sub-section 33.2.1 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.7.1:

TABLE B.7.1—CRITERIA FOR FLAMMABLE SOLIDS

Category	Criteria
1	Burning rate test: Chemicals other than metal powders: (a) Wetted zone does not stop fire; and (b) Burning time <45 s or burning rate >2.2 mm/s. Metal powders: Burning time ≤5 min.
2	Burning rate test: Chemicals other than metal powders: (a) Wetted zone stops the fire for at least 4 min; and (b) Burning time <45 s or burning rate >2.2 mm/s. Metal powders: Burning time >5 min and ≤10 min.

Note: Classification of solid chemicals shall be based on tests performed on the chemical as presented. If, for example, for the purposes of supply or transport, the same chemical is to be presented in a physical form different from that which was tested and which is considered likely to materially alter its performance in a classification test, classification must be based on testing of the chemical in the new form.

B.8 SELF-REACTIVE CHEMICALS

B.8.1 Definitions

Self-reactive chemicals are thermally unstable liquid or solid chemicals liable to undergo a strongly exothermic decomposition even without participation of oxygen (air). This definition excludes chemicals classified under this section as explosives, organic peroxides, oxidizing liquids or oxidizing solids.

A self-reactive chemical is regarded as possessing explosive properties when in laboratory testing the formulation is liable to detonate, to deflagrate rapidly or to show a violent effect when heated under confinement.

B.8.2 Classification Criteria

B.8.2.1 A self-reactive chemical shall be considered for classification in this class unless:

(a) It is classified as an explosive according to B.1 of this appendix;

(b) It is classified as an oxidizing liquid or an oxidizing solid according to B.13 or B.14 of this appendix, except that a mixture of oxidizing substances which contains 5% or more of combustible organic substances shall be classified as a self-reactive chemical according to the procedure defined in B.8.2.2;

(c) It is classified as an organic peroxide according to B.15 of this appendix;

(d) Its heat of decomposition is less than 300 J/g; or

(e) Its self-accelerating decomposition temperature (SADT) is greater than 75 °C (167 °F) for a 50 kg (110 lb) package.

B.8.2.2 Mixtures of oxidizing substances, meeting the criteria for classification as oxidizing liquids or oxidizing solids, which contain 5% or more of combustible organic substances and which do not meet the criteria mentioned in B.8.2.1 (a), (c), (d) or (e), shall be subjected to the self-reactive chemicals classification procedure in B.8.2.3. Such a mixture showing the properties of a self-reactive chemical type B to F shall be classified as a self-reactive chemical.

B.8.2.3 Self-reactive chemicals shall be classified in one of the seven categories of ''types A to G'' for this class, according to the following principles:

(a) Any self-reactive chemical which can detonate or deflagrate rapidly, as packaged, will be defined as self-reactive chemical TYPE A;

(b) Any self-reactive chemical possessing explosive properties and which, as packaged, neither detonates nor deflagrates rapidly, but is liable to undergo a thermal explosion in that package will be defined as self-reactive chemical TYPE B;

(c) Any self-reactive chemical possessing explosive properties when the chemical as packaged cannot detonate or deflagrate rapidly or undergo a thermal explosion will be defined as self-reactive chemical TYPE C;

(d) Any self-reactive chemical which in laboratory testing meets the criteria in (d)(i), (ii), or (iii) will be defined as self-reactive chemical TYPE D:

(i) Detonates partially, does not deflagrate rapidly and shows no violent effect when heated under confinement; or

(ii) Does not detonate at all, deflagrates slowly and shows no violent effect when heated under confinement; or

(iii) Does not detonate or deflagrate at all and shows a medium effect when heated under confinement;

(e) Any self-reactive chemical which, in laboratory testing, neither detonates nor deflagrates at all and shows low or no effect when heated under confinement will be defined as self-reactive chemical TYPE E;

(f) Any self-reactive chemical which, in laboratory testing, neither detonates in the cavitated state nor deflagrates at all and shows only a low or no effect when heated under confinement as well as low or no explosive power will be defined as self-reactive chemical TYPE F;

(g) Any self-reactive chemical which, in laboratory testing, neither detonates in the cavitated state nor deflagrates at all and shows no effect when heated under confinement nor any explosive power, provided that it is thermally stable (self-accelerating decomposition temperature is 60 °C (140 °F) to 75 °C (167 °F) for a 50 kg (110 lb) package), and, for liquid mixtures, a diluent having a boiling point greater than or equal to 150 °C (302 °F) is used for desensitization will be defined as self-reactive chemical TYPE G. If the mixture is not thermally stable or a diluent having a boiling point less than 150 °C (302 °F) is used for desensitization, the mixture shall be defined as self-reactive chemical TYPE F.

B.8.3 Additional Classification Considerations

B.8.3.1 For purposes of classification, the properties of self-reactive chemicals shall be determined in accordance with test series A to H as described in Part II of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6).

B.8.3.2 Self-accelerating decomposition temperature (SADT) shall be determined in accordance with the UN ST/SG/AC.10, Part II, section 28 (incorporated by reference; See § 1910.6).

B.8.3.3 The classification procedures for self-reactive substances and mixtures need not be applied if:

(a) There are no chemical groups present in the molecule associated with explosive or self-reactive properties; examples of such groups are given in Tables A6.1 and A6.2 in the Appendix 6 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6); or

(b) For a single organic substance or a homogeneous mixture of organic substances, the estimated SADT is greater than 75 °C (167 °F) or the exothermic decomposition energy is less than 300 J/g. The onset temperature and decomposition energy may be estimated using a suitable calorimetric technique (See 20.3.3.3 in Part II of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6)).

B.9 PYROPHORIC LIQUIDS

B.9.1 Definition

Pyrophoric liquid means a liquid which, even in small quantities, is liable to ignite within five minutes after coming into contact with air.

B.9.2 Classification Criteria

A pyrophoric liquid shall be classified in a single category for this class using test N.3 in Part III, sub-section 33.3.1.5 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.9.1:

TABLE B.9.1—CRITERIA FOR PYROPHORIC LIQUIDS

Category	Criteria
1	The liquid ignites within 5 min when added to an inert carrier and exposed to air, or it ignites or chars a filter paper on contact with air within 5 min.

B.9.3 Additional Classification Considerations

The classification procedure for pyrophoric liquids need not be applied when experience in production or handling shows that the chemical does not ignite spontaneously on coming into contact with air at normal temperatures (i.e., the substance is known to be stable at room temperature for prolonged periods of time (days)).

B.10 PYROPHORIC SOLIDS

B.10.1 Definition

Pyrophoric solid means a solid which, even in small quantities, is liable to ignite within five minutes after coming into contact with air.

B.10.2 Classification Criteria

A pyrophoric solid shall be classified in a single category for this class using test N.2 in Part III, sub-section 33.3.1.4 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.10.1:

TABLE B.10.1—CRITERIA FOR PYROPHORIC SOLIDS

Category	Criteria
1	The solid ignites within 5 min of coming into contact with air.

Note: Classification of solid chemicals shall be based on tests performed on the chemical as presented. If, for example, for the purposes of supply or transport, the same chemical is to be presented in a physical form different from that which was tested and which is considered likely to materially alter its performance in a classification test, classification must be based on testing of the chemical in the new form.

B.10.3 Additional Classification Considerations

The classification procedure for pyrophoric solids need not be applied when experience in production or handling shows that the chemical does not ignite spontaneously on coming into contact with air at normal temperatures (i.e., the chemical is known to be stable at room temperature for prolonged periods of time (days)).

B.11 SELF-HEATING CHEMICALS

B.11.1 Definition

A *self-heating chemical* is a solid or liquid chemical, other than a pyrophoric liquid or solid, which, by reaction with air and without energy supply, is liable to self-heat; this chemical differs from a pyrophoric liquid or solid in that it will ignite only when in large amounts (kilograms) and after long periods of time (hours or days).

Note: Self-heating of a substance or mixture is a process where the gradual reaction of that substance or mixture with oxygen (in air) generates heat. If the rate of heat production exceeds the rate of heat loss, then the temperature of the substance or mixture will rise which, after an induction time, may lead to self-ignition and combustion.

B.11.2 Classification Criteria

B.11.2.1 A self-heating chemical shall be classified in one of the two categories for this class if, in tests performed in accordance with test method N.4 in Part III, sub-section 33.3.1.6 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), the result meets the criteria shown in Table B.11.1.

TABLE B.11.1—CRITERIA FOR SELF-HEATING CHEMICALS

Category	Criteria
1	A positive result is obtained in a test using a 25 mm sample cube at 140 °C (284 °F).
2	A negative result is obtained in a test using a 25 mm cube sample at 140 °C (284 °F), a positive result is obtained in a test using a 100 mm sample cube at 140 °C (284 °F), and: (a) The unit volume of the chemical is more than 3 m^3; or (b) A positive result is obtained in a test using a 100 mm cube sample at 120 °C (248 °F) and the unit volume of the chemical is more than 450 liters; or (c) A positive result is obtained in a test using a 100 mm cube sample at 100 °C (212 °F).

B.11.2.2 Chemicals with a temperature of spontaneous combustion higher than 50 °C (122 °F) for a volume of 27 m^3 shall not be classified as self-heating chemicals.

B.11.2.3 Chemicals with a spontaneous ignition temperature higher than 50 °C (122 °F) for a volume of 450 liters shall not be classified in Category 1 of this class.

B.11.3 Additional Classification Considerations

B.11.3.1 The classification procedure for self-heating chemicals need not be applied if the results of a screening test can be adequately correlated with the classification test and an appropriate safety margin is applied.

B.11.3.2 Examples of screening tests are:

(a) The Grewer Oven test (VDI guideline 2263, part 1, 1990, Test methods for the Determination of the Safety Characteristics of Dusts) with an onset temperature 80°K above the reference temperature for a volume of 1 *l;*

(b) The Bulk Powder Screening Test (Gibson, N. Harper, D. J. Rogers, R. Evaluation of the fire and explosion risks in drying powders, Plant Operations Progress, 4 (3), 181–189, 1985) with an onset temperature 60°K above the reference temperature for a volume of 1 *l.*

B.12 CHEMICALS WHICH, IN CONTACT WITH WATER, EMIT FLAMMABLE GASES

B.12.1 Definition

Chemicals which, in contact with water, emit flammable gases are solid or liquid chemicals which, by interaction with water, are liable to become spontaneously flammable or to give off flammable gases in dangerous quantities.

B.12.2 Classification Criteria

B.12.2.1 A chemical which, in contact with water, emits flammable gases shall be classified in one of the three categories for this class, using test N.5 in Part III, sub-section 33.4.1.4 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.12.1:

TABLE B.12.1—CRITERIA FOR CHEMICALS WHICH, IN CONTACT WITH WATER, EMIT FLAMMABLE GASES

Category	Criteria
1	Any chemical which reacts vigorously with water at ambient temperatures and demonstrates generally a tendency for the gas produced to ignite spontaneously, or which reacts readily with water at ambient temperatures such that the rate of evolution of flammable gas is equal to or greater than 10 liters per kilogram of chemical over any one minute.
2	Any chemical which reacts readily with water at ambient temperatures such that the maximum rate of evolution of flammable gas is equal to or greater than 20 liters per kilogram of chemical per hour, and which does not meet the criteria for Category 1.
3	Any chemical which reacts slowly with water at ambient temperatures such that the maximum rate of evolution of flammable gas is equal to or greater than 1 liter per kilogram of chemical per hour, and which does not meet the criteria for Categories 1 and 2.

Note: Classification of solid chemicals shall be based on tests performed on the chemical as presented. If, for example, for the purposes of supply or transport, the same chemical is to be presented in a physical form different from that which was tested and which is considered likely to materially alter its performance in a classification test, classification must be based on testing of the chemical in the new form.

B.12.2.2 A chemical is classified as a chemical which, in contact with water emits flammable gases if spontaneous ignition takes place in any step of the test procedure.

B.12.3 Additional Classification Considerations

The classification procedure for this class need not be applied if:

(a) The chemical structure of the chemical does not contain metals or metalloids;

(b) Experience in production or handling shows that the chemical does not react with water, (e.g., the chemical is manufactured with water or washed with water); or

(c) The chemical is known to be soluble in water to form a stable mixture.

B.13 OXIDIZING LIQUIDS

B.13.1 Definition

Oxidizing liquid means a liquid which, while in itself not necessarily combustible, may, generally by yielding oxygen, cause, or contribute to, the combustion of other material.

B.13.2 Classification Criteria

An oxidizing liquid shall be classified in one of the three categories for this class using test O.2 in Part III, sub-section 34.4.2 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.13.1:

TABLE B.13.1—CRITERIA FOR OXIDIZING LIQUIDS

Category	Criteria
1	Any chemical which, in the 1:1 mixture, by mass, of chemical and cellulose tested, spontaneously ignites; or the mean pressure rise time of a 1:1 mixture, by mass, of chemical and cellulose is less than that of a 1:1 mixture, by mass, of 50% perchloric acid and cellulose;

TABLE B.13.1—CRITERIA FOR OXIDIZING LIQUIDS—Continued

Category	Criteria
2	Any chemical which, in the 1:1 mixture, by mass, of chemical and cellulose tested, exhibits a mean pressure rise time less than or equal to the mean pressure rise time of a 1:1 mixture, by mass, of 40% aqueous sodium chlorate solution and cellulose; and the criteria for Category 1 are not met;
3	Any chemical which, in the 1:1 mixture, by mass, of chemical and cellulose tested, exhibits a mean pressure rise time less than or equal to the mean pressure rise time of a 1:1 mixture, by mass, of 65% aqueous nitric acid and cellulose; and the criteria for Categories 1 and 2 are not met.

B.13.3 Additional Classification Considerations

B.13.3.1 For organic chemicals, the classification procedure for this class shall not be applied if:

(a) The chemical does not contain oxygen, fluorine or chlorine; or

(b) The chemical contains oxygen, fluorine or chlorine and these elements are chemically bonded only to carbon or hydrogen.

B.13.3.2 For inorganic chemicals, the classification procedure for this class shall not be applied if the chemical does not contain oxygen or halogen atoms.

B.13.3.3 In the event of divergence between test results and known experience in the handling and use of chemicals which shows them to be oxidizing, judgments based on known experience shall take precedence over test results.

B.13.3.4 In cases where chemicals generate a pressure rise (too high or too low), caused by chemical reactions not characterizing the oxidizing properties of the chemical, the test described in Part III, sub-section 34.4.2 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6) shall be repeated with an inert substance (e.g., diatomite (kieselguhr)) in place of the cellulose in order to clarify the nature of the reaction.

B.14 OXIDIZING SOLIDS

B.14.1 Definition

Oxidizing solid means a solid which, while in itself is not necessarily combustible, may, generally by yielding oxygen, cause, or contribute to, the combustion of other material.

B.14.2 Classification Criteria

An oxidizing solid shall be classified in one of the three categories for this class using test O.1 in Part III, sub-section 34.4.1 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.14.1:

TABLE B.14.1—CRITERIA FOR OXIDIZING SOLIDS

Category	Criteria
1	Any chemical which, in the 4:1 or 1:1 sample-to-cellulose ratio (by mass) tested, exhibits a mean burning time less than the mean burning time of a 3:2 mixture, by mass, of potassium bromate and cellulose.
2	Any chemical which, in the 4:1 or 1:1 sample-to-cellulose ratio (by mass) tested, exhibits a mean burning time equal to or less than the mean burning time of a 2:3 mixture (by mass) of potassium bromate and cellulose and the criteria for Category 1 are not met.
3	Any chemical which, in the 4:1 or 1:1 sample-to-cellulose ratio (by mass) tested, exhibits a mean burning time equal to or less than the mean burning time of a 3:7 mixture (by mass) of potassium bromate and cellulose and the criteria for Categories 1 and 2 are not met.

Note 1: Some oxidizing solids may present explosion hazards under certain conditions (e.g., when stored in large quantities). For example, some types of ammonium nitrate may give rise to an explosion hazard under extreme conditions and the ''Resistance to detonation test'' (IMO: Code of Safe Practice for Solid Bulk Cargoes, 2005, Annex 3, Test 5) may be used to assess this hazard. When information indicates that an oxidizing solid may present an explosion hazard, it shall be indicated on the Safety Data Sheet.

Note 2: Classification of solid chemicals shall be based on tests performed on the chemical as presented. If, for example, for the purposes of supply or transport, the same chemical is to be presented in a physical form different from that which was tested and which is considered likely to materially alter its performance in a classification test, classification must be based on testing of the chemical in the new form.

B.14.3 Additional Classification Considerations

B.14.3.1 For organic chemicals, the classification procedure for this class shall not be applied if:

(a) The chemical does not contain oxygen, fluorine or chlorine; or

(b) The chemical contains oxygen, fluorine or chlorine and these elements are chemically bonded only to carbon or hydrogen.

B.14.3.2 For inorganic chemicals, the classification procedure for this class shall not be applied if the chemical does not contain oxygen or halogen atoms.

B.14.3.3 In the event of divergence between test results and known experience in the handling and use of chemicals which shows them to be oxidizing, judgements based on known experience shall take precedence over test results.

B.15 ORGANIC PEROXIDES

B.15.1 Definition

B.15.1.1 *Organic peroxide* means a liquid or solid organic chemical which contains the bivalent –0–0– structure and as such is considered a derivative of hydrogen peroxide, where one or both of the hydrogen atoms have been replaced by organic radicals. The term organic peroxide includes organic peroxide mixtures containing at least one organic peroxide. Organic peroxides are thermally unstable chemicals, which may undergo exothermic self-accelerating decomposition. In addition, they may have one or more of the following properties:

(a) Be liable to explosive decomposition;

(b) Burn rapidly;

(c) Be sensitive to impact or friction;

(d) React dangerously with other substances.

B.15.1.2 An organic peroxide is regarded as possessing explosive properties when in laboratory testing the formulation is liable to detonate, to deflagrate rapidly or to show a violent effect when heated under confinement.

B.15.2 Classification Criteria

B.15.2.1 Any organic peroxide shall be considered for classification in this class, unless it contains:

(a) Not more than 1.0% available oxygen from the organic peroxides when containing not more than 1.0% hydrogen peroxide; or

(b) Not more than 0.5% available oxygen from the organic peroxides when containing more than 1.0% but not more than 7.0% hydrogen peroxide.

Note: The available oxygen content (%) of an organic peroxide mixture is given by the formula:

$$16 \times \sum_{i}^{n} \left(\frac{n_i \times c_i}{m_i} \right)$$

Where:

n_i = number of peroxygen groups per molecule of organic peroxide *i*;

c_i = concentration (mass %) of organic peroxide *i*;

m_i = molecular mass of organic peroxide *i*.

B.15.2.2 Organic peroxides shall be classified in one of the seven categories of ''Types A to G'' for this class, according to the following principles:

(a) Any organic peroxide which, as packaged, can detonate or deflagrate rapidly shall be defined as organic peroxide TYPE A;

(b) Any organic peroxide possessing explosive properties and which, as packaged, neither detonates nor deflagrates rapidly, but is liable to undergo a thermal explosion in that package shall be defined as organic peroxide TYPE B;

(c) Any organic peroxide possessing explosive properties when the chemical as packaged cannot detonate or deflagrate rapidly or undergo a thermal explosion shall be defined as organic peroxide TYPE C;

(d) Any organic peroxide which in laboratory testing meets the criteria in (d)(i), (ii), or (iii) shall be defined as organic peroxide TYPE D:

(i) Detonates partially, does not deflagrate rapidly and shows no violent effect when heated under confinement; or

(ii) Does not detonate at all, deflagrates slowly and shows no violent effect when heated under confinement; or

(iii) Does not detonate or deflagrate at all and shows a medium effect when heated under confinement;

(e) Any organic peroxide which, in laboratory testing, neither detonates nor deflagrates at all and shows low or no effect when heated under confinement shall be defined as organic peroxide TYPE E;

(f) Any organic peroxide which, in laboratory testing, neither detonates in the cavitated state nor deflagrates at all and shows only a low or no effect when heated under confinement as well as low or no explosive power shall be defined as organic peroxide TYPE F;

(g) Any organic peroxide which, in laboratory testing, neither detonates in the cavitated state nor deflagrates at all and shows no effect when heated under confinement nor any explosive power, provided that it is thermally stable (self-accelerating decomposition temperature is 60 °C (140 °F) or higher for a 50 kg (110 lb) package), and, for liquid mixtures, a diluent having a boiling point of not less than 150 °C (302 °F) is used for desensitization, shall be defined as organic peroxide TYPE G. If the organic peroxide is not thermally stable or a diluent having a boiling point less than 150 °C (302 °F) is used for desensitization, it shall be defined as organic peroxide TYPE F.

B.15.3 Additional Classification Considerations

B.15.3.1 For purposes of classification, the properties of organic peroxides shall be determined in accordance with test series A to H as described in Part II of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6).

B.15.3.2 Self-accelerating decomposition temperature (SADT) shall be determined in accordance with the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), Part II, section 28.

B.15.3.3 Mixtures of organic peroxides may be classified as the same type of organic peroxide as that of the most dangerous ingredient. However, as two stable ingredients can form a thermally less stable mixture, the SADT of the mixture shall be determined.

B.16 CORROSIVE TO METALS

B.16.1 Definition

A *chemical which is corrosive to metals* means a chemical which by chemical action will materially damage, or even destroy, metals.

B.16.2 Classification Criteria

A chemical which is corrosive to metals shall be classified in a single category for this class, using the test in Part III, sub-section 37.4 of the UN ST/SG/AC.10 (incorporated by reference; See § 1910.6), in accordance with Table B.16.1:

TABLE B.16.1—CRITERIA FOR CHEMICALS CORROSIVE TO METAL

Category	Criteria
1	Corrosion rate on either steel or aluminium surfaces exceeding 6.25 mm per year at a test temperature of 55 °C (131 °F) when tested on both materials.

Note: Where an initial test on either steel or aluminium indicates the chemical being tested is corrosive, the follow-up test on the other metal is not necessary.

B.16.3 Additional Classification Considerations

The specimen to be used for the test shall be made of the following materials:

(a) For the purposes of testing steel, steel types S235JR+CR (1.0037 resp.St 37–2), S275J2G3+CR (1.0144 resp.St 44–3), ISO 3574, Unified Numbering System (UNS) G 10200, or SAE 1020;

(b) For the purposes of testing aluminium: Non-clad types 7075–T6 or AZ5GU–T6.

APPENDIX C TO § 1910.1200—ALLOCATION OF LABEL ELEMENTS (MANDATORY)

C.1 The label for each hazardous chemical shall include the product identifier used on the safety data sheet.

C.1.1 The labels on shipped containers shall also include the name, address, and telephone number of the chemical manufacturer, importer, or responsible party.

C.2 The label for each hazardous chemical that is classified shall include the signal word, hazard statement(s), pictogram(s), and precautionary statement(s) specified in C.4 for each hazard class and associated hazard category, except as provided for in C.2.1 through C.2.4.

C.2.1 Precedence of Hazard Information

C.2.1.1 If the signal word ''Danger'' is included, the signal word ''Warning'' shall not appear;

C.2.1.2 If the skull and crossbones pictogram is included, the exclamation mark pictogram shall not appear where it is used for acute toxicity;

C.2.1.3 If the corrosive pictogram is included, the exclamation mark pictogram shall not appear where it is used for skin or eye irritation;

C.2.1.4 If the health hazard pictogram is included for respiratory sensitization, the exclamation mark pictogram shall not appear where it is used for skin sensitization or for skin or eye irritation.

C.2.2 Hazard Statement Text

C.2.2.1 The text of all applicable hazard statements shall appear on the label, except as otherwise specified. The information in italics shall be included as part of the hazard statement as provided. For example: ''causes damage to organs *(state all organs affected)* through prolonged or repeated exposure *(state route of exposure if no other routes of exposure cause the hazard)*''. Hazard statements may be combined where appropriate to reduce the information on the label and improve readability, as long as all of the hazards are conveyed as required.

C.2.2.2 If the chemical manufacturer, importer, or responsible party can demonstrate that all or part of the hazard statement is inappropriate to a specific substance or mixture, the corresponding statement may be omitted from the label.

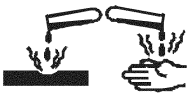
C.2.3 Pictograms

C.2.3.1 Pictograms shall be in the shape of a square set at a point and shall include a black hazard symbol on a white background with a red frame sufficiently wide to be clearly visible. A square red frame set at a point without a hazard symbol is not a pictogram and is not permitted on the label.

BILLING CODE 4510–26–P

C.2.3.2 One of eight standard hazard symbols shall be used in each pictogram. The eight hazard symbols are depicted in Figure C.1. A pictogram using the exclamation mark symbol is presented in Figure C.2, for the purpose of illustration.

Figure C.1 – Hazard Symbols and Classes

Flame	Flame Over Circle	Exclamation Mark	Exploding Bomb
Flammables Self Reactives Pyrophorics Self-heating Emits Flammable Gas Organic Peroxides	Oxidizers	Irritant Dermal Sensitizer Acute Toxicity (harmful) Narcotic Effects Respiratory Tract Irritation	Explosives Self Reactives Organic Peroxides
Corrosion	**Gas Cylinder**	**Health Hazard**	**Skull and Crossbones**
			


Corrosives	Gases Under Pressure	Carcinogen Respiratory Sensitizer Reproductive Toxicity Target Organ Toxicity Mutagenicity Aspiration Toxicity	Acute Toxicity (severe)

Figure C.2 – Exclamation Mark Pictogram

C.2.3.3 Where a pictogram required by the Department of Transportation under Title 49 of the Code of Federal Regulations appears on a shipped container, the pictogram specified in C.4 for the same hazard shall not appear.

BILLING CODE 4510–26–C

C.2.4 Precautionary Statement Text

C.2.4.1 There are four types of precautionary statements presented, ''prevention,'' ''response,'' ''storage,'' and ''disposal.'' The core part of the precautionary statement is presented in bold print. This is the text, except as otherwise specified, that shall appear on the label. Where additional information is required, it is indicated in plain text.

C.2.4.2 When a backslash or diagonal mark (/) appears in the precautionary statement text, it indicates that a choice has to be made between the separated phrases. In such cases, the chemical manufacturer, importer, or responsible party can choose the most appropriate phrase(s). For example, ''Wear protective gloves/protective clothing/eye protection/face protection'' could read ''wear eye protection''.

C.2.4.3 When three full stops (* * *) appear in the precautionary statement text, they indicate that all applicable conditions are not listed. For example, in ''Use explosion-proof electrical/ventilating/lighting/* * */equipment'', the use of ''* * *'' indicates that other equipment may need to be specified. In such cases, the chemical manufacturer, importer, or responsible party can choose the other conditions to be specified.

C.2.4.4 When text *in italics* is used in a precautionary statement, this indicates specific conditions applying to the use or allocation of the precautionary statement. For example, ''Use explosion-proof electrical/ventilating/lighting/* * */equipment'' is only required for flammable solids ''*if dust clouds can occur*''. Text in italics is intended to be an explanatory, conditional note and is not intended to appear on the label.

C.2.4.5 Where square brackets ([ ]) appear around text in a precautionary statement, this indicates that the text in square brackets is not appropriate in every case and should be used only in certain circumstances. In these cases, conditions for use explaining when the text should be used are provided. For example, one precautionary statement states: ''[In case of inadequate ventilation] wear respiratory protection.'' This statement is given with the condition for use ''– text in square brackets may be used if additional information is provided with the chemical at the point of use that explains what type of ventilation would be adequate for safe use''. This means that, if additional information is provided with the chemical explaining what type of ventilation would be adequate for safe use, the text in square brackets should be used and the statement would read: ''In case of inadequate ventilation wear respiratory protection.'' However, if the chemical is supplied without such ventilation information, the text in square brackets should not be used, and the precautionary statement should read: ''Wear respiratory protection.''

C.2.4.6 Precautionary statements may be combined or consolidated to save label space and improve readability. For example, ''Keep away from heat, sparks and open flame,'' ''Store in a well-ventilated place'' and ''Keep cool'' can be combined to read ''Keep away from heat, sparks and open flame and store in a cool, well-ventilated place.''

C.2.4.7 In most cases, the precautionary statements are independent (e.g., the phrases for explosive hazards do not modify those related to certain health hazards, and products that are classified for both hazard classes shall bear appropriate precautionary statements for both). Where a chemical is classified for a number of hazards, and the precautionary statements are similar, the most stringent shall be included on the label (this will be applicable mainly to preventive measures). An order of precedence may be imposed by the chemical manufacturer, importer or responsible party in situations where phrases concern ''Response.'' Rapid action may be crucial. For example, if a chemical is carcinogenic and acutely toxic, rapid action may be crucial, and first aid measures for acute toxicity will take precedence over those for long-term effects. In addition, medical attention to delayed health effects may be required in cases of incidental exposure, even if not associated with immediate symptoms of intoxication.

C.2.4.8 If the chemical manufacturer, importer, or responsible party can demonstrate that a precautionary statement is inappropriate to a specific substance or mixture, the precautionary statement may be omitted from the label.

C.3 Supplementary Hazard Information

C.3.1 To ensure that non-standardized information does not lead to unnecessarily wide variation or undermine the required information, supplementary information on the label is limited to when it provides further detail and does not contradict or cast doubt on the validity of the standardized hazard information.

C.3.2 Where the chemical manufacturer, importer, or distributor chooses to add supplementary information on the label, the placement of supplemental information shall not impede identification of information required by this section.

C.3.3 Where an ingredient with unknown acute toxicity is used in a mixture at a concentration ≥1%, and the mixture is not classified based on testing of the mixture as a whole, a statement that X% of the mixture consists of ingredient(s) of unknown acute toxicity is required on the label.

BILLING CODE 4510–26–P

C.4 REQUIREMENTS FOR SIGNAL WORDS, HAZARD STATEMENTS, PICTOGRAMS, AND PRECAUTIONARY STATEMENTS

C.4.1 ACUTE TOXICITY – ORAL
(Classified in Accordance with Appendix A.1)

Pictogram
Skull and crossbones

Hazard category	Signal word	Hazard statement
1	Danger	Fatal if swallowed
2	Danger	Fatal if swallowed

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Wash …thoroughly after handling. … Chemical manufacturer, importer, or distributor to specify parts of the body to be washed after handling. **Do not eat, drink or smoke when using this product.**	**If swallowed: Immediately call a poison center/doctor/…** … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice. **Specific treatment (see … on this label)** … Reference to supplemental first aid instruction. - *if immediate administration of antidote is required.* **Rinse mouth.**	**Store locked up.**	**Dispose of contents/container to…** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.1 ACUTE TOXICITY – ORAL (CONTINUED)
(Classified in Accordance with Appendix A.1)

Hazard category	Signal word	Hazard statement
3	Danger	Toxic if swallowed

C.4.6 SENSITIZATION - RESPIRATORY
(Classified in Accordance with Appendix A.4)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1 (including both sub-categories 1A and 1B)	Danger	May cause allergy or asthma symptoms or breathing difficulties if inhaled

Precautionary statements

Prevention	Response	Storage	Disposal
Avoid breathing dust/fume/gas/mist/ vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **[In case of inadequate ventilation] wear respiratory protection.** Chemical manufacturer, importer, or distributor to specify equipment - *Text in square brackets may be used if additional information is provided with the chemical at the point of use that explains what type of ventilation would be adequate for safe use*.	**If inhaled: If breathing is difficult, remove person to fresh air and keep comfortable for breathing.** **If experiencing respiratory symptoms: Call a poison center/doctor/…** … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice.		**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.7 SENSITIZATION - SKIN
(Classified in Accordance with Appendix A.4)

Pictogram
Exclamation mark

Hazard category	Signal word	Hazard statement
1 (including both sub-categories 1A and 1B)	Warning	May cause an allergic skin reaction

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Avoid breathing dust/fume/gas/mist/vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **Contaminated work clothing must not be allowed out of the workplace.** **Wear protective gloves.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**If on skin: Wash with plenty of water/**... … Chemical manufacturer, importer, or distributor may specify a cleansing agent if appropriate, or may recommend an alternative agent in exceptional cases if water is clearly inappropriate. **If skin irritation or rash occurs: Get medical advice/attention.** **Specific treatment (see ... on this label)** ... Reference to supplemental first aid instruction. - *Manufacturer, importer, or distributor may specify a cleansing agent if appropriate.* **Wash contaminated clothing before reuse.**		**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.8 GERM CELL MUTAGENICITY
(Classified in Accordance with Appendix A.5)

Pictogram
Health hazard

Hazard category	**Signal word**	Hazard statement
1A and 1B	Danger	May cause genetic defects <...>
2	Warning	Suspected of causing genetic defects <...>
		(state route of exposure if no other routes of exposure cause the hazard)

Precautionary statements

Prevention	**Response**	**Storage**	**Disposal**
Obtain special instructions before use. **Do not handle until all safety precautions have been read and understood.** **Wear protective gloves/protective clothing/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment, as required.	**If exposed or concerned: Get medical advice/attention.**	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.9 CARCINOGENICITY
(Classified in Accordance with Appendix A.6)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1A and 1B	Danger	May cause cancer <...>
2	Warning	Suspected of causing cancer <...>
		(state route of exposure if no other routes of exposure cause the hazard)

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Obtain special instructions before use. **Do not handle until all safety precautions have been read and understood.** **Wear protective gloves/protective clothing/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment, as required.	**If exposed or concerned: Get medical advice/attention.**	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

Note: If a Category 2 carcinogen ingredient is present in the mixture at a concentration between 0.1% and 1%, information is required on the SDS for a product; however, a label warning is optional. If a Category 2 carcinogen ingredient is present in the mixture at a concentration of ≥ 1%, both an SDS and a label is required and the information must be included on each.

C.4.10 TOXIC TO REPRODUCTION
(Classified in Accordance with Appendix A.7)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1A and 1B	Danger	May damage fertility or the unborn child <...> <<...>>
2	Warning	Suspected of damaging fertility or the unborn child <...> <<...>> *(state specific effect if known)* *(state route of exposure if no other routes of exposure cause the hazard)*

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Obtain special instructions before use. **Do not handle until all safety precautions have been read and understood.** **Wear protective gloves/protective clothing/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment, as required.	**If exposed or concerned: Get medical advice/attention.**	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.10 TOXIC TO REPRODUCTION (CONTINUED)
(Classified in Accordance with Appendix A.7)
(EFFECTS ON OR VIA LACTATION)

Pictogram
No Pictogram

Hazard category	Signal word	Hazard statement
No designated number	*No signal word*	May cause harm to breast-fed children

(See Table A.7.1 in Appendix A.7)

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Obtain special instructions before use. **Do not breathe dusts or mists.** - *if inhalable particles of dusts or mists may occur during use.* **Avoid contact during pregnancy/while nursing.** **Wash … thoroughly after handling.** **…**Chemical manufacturer, importer, or distributor to specify parts of the body to be washed after handling. **Do not eat, drink or smoke when using this product.**	**If exposed or concerned: Get medical advice/attention.**		

C.4.11 SPECIFIC TARGET ORGAN TOXICITY (Single Exposure)
(Classified in Accordance with Appendix A.8)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1	Danger	Causes damage to organs <...> <<...>> <...> *(or state all organs affected if known)* <<...>> *(state route of exposure if no other routes of exposure cause the hazard)*

Precautionary statements

Prevention	Response	Storage	Disposal
Do not breathe dust/fume/gas/mist/ vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **Wash …thoroughly after handling.** … Chemical manufacturer, importer, or distributor to specify parts of the body to be washed after handling. **Do not eat, drink or smoke when using this product.**	**If exposed: Call a poison center/doctor/…** … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice. **Specific treatment (see ... on this label)** ... Reference to supplemental first aid instruction. - *if immediate measures are required*.	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.11 SPECIFIC TARGET ORGAN TOXICITY (Single Exposure) (CONTINUED)
(Classified in Accordance with Appendix A.8)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
2	Warning	May cause damage to organs <...> <<...>> <...> *(or state all organs affected, if known)* <<...>> *(state route of exposure if no other routes of exposure cause the hazard)*

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Do not breathe dust/fume/gas/mist/vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **Wash … thoroughly after handling.** … Chemical manufacturer, importer, or distributor to specify parts of the body to be washed after handling. **Do not eat, drink or smoke when using this product.**	**If exposed or concerned: Call a poison center/doctor/…** … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice.	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.11 SPECIFIC TARGET ORGAN TOXICITY (Single Exposure) (CONTINUED)
(Classified in Accordance with Appendix A.8)

Pictogram
Exclamation mark

Hazard category	Signal word	Hazard statement
3	Warning	May cause respiratory irritation; or May cause drowsiness or dizziness

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Avoid breathing dust/fume/gas/mist/ vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **Use only outdoors or in a well-ventilated area.**	**If inhaled: Remove person to fresh air and keep comfortable for breathing.** **Call a poison center/doctor/…/if you feel unwell.** … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice.	**Store in a well-ventilated place. Keep container tightly closed.** - *if product is volatile so as to generate hazardous atmosphere.* **Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.12 SPECIFIC TARGET ORGAN TOXICITY (Repeated Exposure) (Classified in Accordance with Appendix A.9)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1	Danger	Causes damage to organs <...> through prolonged or repeated exposure <<...>> <...> *(state all organs affected, if known)* <<...>> *(state route of exposure if no other routes of exposure cause the hazard)*

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Do not breathe dust/fume/gas/mist/vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions. **Wash … thoroughly after handling.** …Chemical manufacturer, importer, or distributor to specify parts of the body to be washed after handling. **Do not eat, drink or smoke when using this product.**	**Get medical advice/attention if you feel unwell.**		**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.12 SPECIFIC TARGET ORGAN TOXICITY (Repeated Exposure) (CONTINUED)
(Classified in Accordance with Appendix A.9)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
2	Warning	May cause damage to organs <...> through prolonged or repeated exposure <<...>> <...> *(state all organs affected, if known)* <<...>> *(state route of exposure if no other routes of exposure cause the hazard)*

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Do not breathe dust/fume/gas/mist/vapors/spray. Chemical manufacturer, importer, or distributor to specify applicable conditions.	**Get medical advice/attention if you feel unwell.**		**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.13 ASPIRATION HAZARD
(Classified in Accordance with Appendix A.10)

Pictogram
Health hazard

Hazard category	Signal word	Hazard statement
1	Danger	May be fatal if swallowed and enters airways

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
	If swallowed: Immediately call a poison center/doctor/… … Chemical manufacturer, importer, or distributor to specify the appropriate source of emergency medical advice. **Do NOT induce vomiting.**	**Store locked up.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.14 EXPLOSIVES
(Classified in Accordance with Appendix B.1)

Hazard category	Signal word	Hazard statement
Unstable explosive	Danger	Unstable explosive

Pictogram

Exploding bomb

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Obtain special instructions before use. **Do not handle until all safety precautions have been read and understood.** **Wear personal protective equipment/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment, as required.	**Explosion risk in case of fire.** **Do NOT fight fire when fire reaches explosives.** **Evacuate area.**	**Store ...** …in accordance with local/regional/ national/international regulations (to be specified).	**Dispose of contents/container to ...** …in accordance with local/regional/ national/international regulations (to be specified).

C.4.14 EXPLOSIVES (CONTINUED)
(Classified in Accordance with Appendix B.1)

Pictogram
Exploding bomb

Hazard category	Signal word	Hazard statement
Division 1.1	Danger	Explosive; mass explosion hazard
Division 1.2	Danger	Explosive; severe projection hazard
Division 1.3	Danger	Explosive; fire, blast or projection hazard

Precautionary statements

Prevention	Response	Storage	Disposal
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep wetted with...** … Chemical manufacturer, importer, or distributor to specify appropriate material. - *if drying out increases explosion hazard, except as needed for manufacturing or operating processes (e.g., nitrocellulose).* **Ground/bond container and receiving equipment.** - *if the explosive is electrostatically sensitive.* **Do not subject to grinding/shock/…/friction.** …Chemical manufacturer, importer, or distributor to specify applicable rough handling. **Wear face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: evacuate area.** **Explosion risk in case of fire.** **Do NOT fight fire when fire reaches explosives.**	**Store ...** …in accordance with local/regional/national/ international regulations (to be specified).	**Dispose of contents/container to ...** … in accordance with local/ regional/national/ international regulations (to be specified).

Note: Unpackaged explosives or explosives repacked in packagings other than the original or similar packaging shall have the label elements assigned to Division 1.1 unless the hazard is shown to correspond to one of the hazard categories in Appendix B.1, in which case the corresponding symbol, signal word and/or the hazard statement shall be assigned.

C.4.14 EXPLOSIVES (CONTINUED)
(Classified in Accordance with Appendix B.1)

Pictogram
Exploding bomb[1]

Hazard category	Signal word	Hazard statement
Division 1.4	Warning	Fire or projection hazard

Precautionary statements[1]			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Ground/bond container and receiving equipment.** - *if the explosive is electrostatically sensitive.* **Do not subject to grinding/shock/…/friction.** Chemical manufacturer, importer, or distributor to specify applicable rough handling. **Wear face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Evacuate area.** **Explosion risk in case of fire.** - *except if explosives are 1.4S ammunition and components thereof.* **Do NOT fight fire when fire reaches explosives.** **Fight fire with normal precautions from a reasonable distance** - *if explosives are 1.4S ammunition and components thereof.*	**Store ...** …in accordance with local/regional/national/international regulations (to be specified).	**Dispose of contents/container to...** … in accordance with local/regional/national/international regulations (to be specified).

Note: Unpackaged explosives or explosives repacked in packagings other than the original or similar packaging shall have the label elements assigned to Division 1.1 unless the hazard is shown to correspond to one of the hazard categories in Appendix B.1, in which case the corresponding symbol, signal word and/or the hazard statement shall be assigned.[1]

---

[1] *Except no pictogram is required for explosives that are 1.4S small arms ammunition and components thereof. Labels for 1.4S small arms ammunition and components shall include appropriate precautionary statements.*

C.4.14 EXPLOSIVES (CONTINUED)
(Classified in Accordance with Appendix B.1)

Pictogram
No pictogram

Hazard category	Signal word	Hazard statement
Division 1.5	Danger	May mass explode in fire

Precautionary statements

Prevention	Response	Storage	Disposal
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep wetted with**... … Chemical manufacturer, importer, or distributor to specify appropriate material. **-** *if drying out increases explosion hazard, except as needed for manufacturing or operating processes (e.g., nitrocellulose).* **Ground/bond container and receiving equipment** - *if the explosive is electrostatically sensitive.* **Do not subject to grinding/shock/…/friction.** **…**Chemical manufacturer, importer, or distributor to specify applicable rough handling. **Wear face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Evacuate area.** **Explosion risk in case of fire.** **Do NOT fight fire when fire reaches explosives.**	**Store ...** …in accordance with local/regional/ national/international regulations (to be specified).	**Dispose of contents/container to ...** … in accordance with local/regional/ national/international regulations (to be specified).

Note: Unpackaged explosives or explosives repacked in packagings other than the original or similar packaging shall have the label elements assigned to Division 1.1 unless the hazard is shown to correspond to one of the hazard categories in Appendix B.1, in which case the corresponding symbol, signal word and/or the hazard statement shall be assigned.

C.4.14 EXPLOSIVES (CONTINUED)
(Classified in Accordance with Appendix B.1)

Pictogram
No pictogram

Hazard category	Signal word	Hazard statement
Division 1.6	*No signal word*	*No hazard statement*

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
None assigned.	None assigned	None assigned	None assigned

Note: Unpackaged explosives or explosives repacked in packagings other than the original or similar packaging shall have the label elements assigned to Division 1.1 unless the hazard is shown to correspond to one of the hazard categories in Appendix B.1, in which case the corresponding symbol, signal word and/or the hazard statement shall be assigned.

C.4.15 FLAMMABLE GASES
(Classified in Accordance with Appendix B.2)

Pictogram
Flame

Hazard category	Signal word	Hazard statement
1	Danger	Extremely flammable gas

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. -No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s).	**Leaking gas fire: Do not extinguish, unless leak can be stopped safely.** **Eliminate all ignition sources if safe to do so.**	**Store in well-ventilated place.**	

C.4.15 FLAMMABLE GASES (CONTINUED)
(Classified in Accordance with Appendix B.2)

Pictogram
No Pictogram

Hazard category	Signal word	Hazard statement
2	Warning	Flammable gas

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. -No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition sources(s).	**Leaking gas fire: Do not extinguish, unless leak can be stopped safely.** **Eliminate all ignition sources if safe to do so.**	**Store in well-ventilated place.**	

C.4.16 FLAMMABLE AEROSOLS
(Classified in Accordance with Appendix B.3)

Hazard category	Signal word	Hazard statement
1	Danger	Extremely flammable aerosol
2	Warning	Flammable aerosol

Pictogram
Flame

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. -No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition sources(s). **Do not spray on an open flame or other ignition source.** **Pressurized container: Do not pierce or burn, even after use.**		**Protect from sunlight. Do not expose to temperatures exceeding 50 °C/122 °F.**	

C.4.17 OXIDIZING GASES
(Classified in Accordance with Appendix B.4)

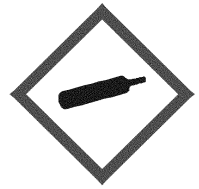
Hazard category	Signal word	Hazard statement
1	Danger	May cause or intensify fire; oxidizer

Pictogram
Flame over circle

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep/Store away from clothing/…/combustible materials. …Chemical manufacturer, importer, or distributor to specify other incompatible materials. **Keep reduction valves/valves and fittings free from oil and grease.**	**In case of fire: Stop leak if safe to do so.**	**Store in well-ventilated place.**	

C.4.18 GASES UNDER PRESSURE
(Classified in Accordance with Appendix B.5)

Pictogram
Gas cylinder



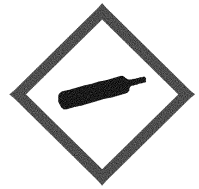
Hazard category	Signal word	Hazard statement
Compressed gas	Warning	Contains gas under pressure; may explode if heated
Liquefied gas	Warning	Contains gas under pressure; may explode if heated
Dissolved gas	Warning	Contains gas under pressure; may explode if heated

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
		Protect from sunlight. Store in a well-ventilated place.	

C.4.18 GASES UNDER PRESSURE (CONTINUED)
(Classified in Accordance with Appendix B.5)

Hazard category	Signal word	Hazard statement
Refrigerated liquefied gas	Warning	Contains refrigerated gas; may cause cryogenic burns or injury

Pictogram
Gas cylinder



Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Wear cold insulating gloves/face shield/eye protection.	**Thaw frosted parts with lukewarm water. Do not rub affected area.** **Get immediate medical advice/attention**	**Store in well-ventilated place.**	

C.4.19 FLAMMABLE LIQUIDS
(Classified in Accordance with Appendix B.6)

Pictogram
Flame

Hazard category	Signal word	Hazard statement
1	Danger	Extremely flammable liquid and vapor
2	Danger	Highly flammable liquid and vapor
3	Warning	Flammable liquid and vapor

Precautionary statements

Prevention	Response	Storage	Disposal
Keep away from heat/sparks/open flames/hot surfaces.– No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep container tightly closed.** **Ground/Bond container and receiving equipment** - *if electrostatically sensitive material is for reloading*. - *if product is volatile so as to generate hazardous atmosphere*. **Use explosion-proof electrical/ventilating/ lighting/.../equipment.** ... Chemical manufacturer, importer, or distributor to specify other equipment. **Use only non-sparking tools.** **Take precautionary measures against static discharge.** **Wear protective gloves/eye protection/face protection** Chemical manufacturer, importer, or distributor to specify type of equipment.	**If on skin (or hair): Take off immediately all contaminated clothing. Rinse skin with water/shower.** **In case of fire: Use ... to extinguish.** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk.*	**Store in a well-ventilated place. Keep cool.**	**Dispose of contents/container to...** … in accordance with local/regional/national/ international regulations (to be specified).

C.4.19 FLAMMABLE LIQUIDS (CONTINUED)
(Classified in Accordance with Appendix B.6)

Pictogram
No Pictogram

Hazard category	Signal word	Hazard statement
4	Warning	Combustible liquid

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from flames and hot surfaces. – No smoking. **Wear protective gloves/eye protection/face protection** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish.** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk.*	**Store in a well-ventilated place. Keep cool.**	**Dispose of contents/container to...** in accordance with local/regional/national/international regulations (to be specified).

C.4.20 FLAMMABLE SOLIDS
(Classified in Accordance with Appendix B.7)

Pictogram
Flame

Hazard category	Signal word	Hazard statement
1	Danger	Flammable solid
2	Warning	Flammable solid

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Ground/Bond container and receiving equipment.** - *if electrostatically sensitive material is for reloading*. **Use explosion-proof electrical/ventilating/ lighting/... /equipment.** ... Chemical manufacturer, importer, or distributor to specify other equipment. - *if dust clouds can occur*. **Wear protective gloves/eye protection/face protection** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*.		

C.4.21 SELF-REACTIVE SUBSTANCES AND MIXTURES
(Classified in Accordance with Appendix B.8)

Pictogram
Exploding bomb

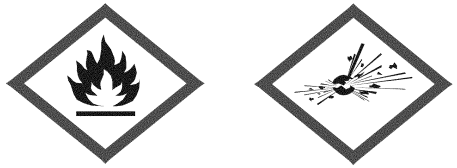
Hazard category	Signal word	Hazard statement
Type A	Danger	Heating may cause an explosion

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep/Store away from clothing/…/combustible materials.** **...** Chemical manufacturer, importer, or distributor to specify other incompatible materials. **Keep only in original container.** **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk.* **In case of fire: Evacuate area. Fight fire remotely due to the risk of explosion.**	**Store in a well-ventilated place. Keep cool.** **Store at temperatures not exceeding …°C/…°F.** ... Chemical manufacturer, importer, or distributor to specify temperature. **Store away from other materials.**	**Dispose of contents/container to...** … in accordance with local/regional/national/international regulations (to be specified).

C.4.21 SELF-REACTIVE SUBSTANCES AND MIXTURES (CONTINUED)
(Classified in Accordance with Appendix B.8)

Hazard category	Signal word	Hazard statement
Type B	Danger	Heating may cause a fire or explosion

Pictograms
Exploding bomb and flame



Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep/Store away from clothing/.../combustible materials.** ... Chemical manufacturer, importer, or distributor to specify other incompatible materials. **Keep only in original container.** **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish.** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*. **In case of fire: Evacuate area. Fight fire remotely due to the risk of explosion.**	**Store in a well-ventilated place. Keep cool.** **Store at temperatures not exceeding …°C/…°F.** ... Chemical manufacturer, importer, or distributor to specify temperature. **Store away from other materials.**	**Dispose of contents/container to**... …in accordance with local/regional/national/international regulations (to be specified).

C.4.21 SELF-REACTIVE SUBSTANCES AND MIXTURES(CONTINUED)
(Classified in Accordance with Appendix B.8)

Hazard category	Signal word	Hazard statement
Type C	Danger	Heating may cause a fire
Type D	Danger	Heating may cause a fire
Type E	Warning	Heating may cause a fire
Type F	Warning	Heating may cause a fire

Pictogram
Flame

Precautionary statements

Prevention	Response	Storage	Disposal
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Keep/Store away from clothing/…/combustible materials.** …Chemical manufacturer, importer, or distributor to specify other incompatible materials. **Keep only in original container.** **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk.*	**Store in a well-ventilated place. Keep cool.** **Store at temperatures not exceeding …°C/…°F.** ...Chemical manufacturer, importer, or distributor to specify temperature. **Store away from other materials.**	**Dispose of contents/container to...** …in accordance with local/regional/national/international regulations (to be specified).

C.4.22 PYROPHORIC LIQUIDS
(Classified in Accordance with Appendix B.9)

Hazard category	Signal word	Hazard statement
1	Danger	Catches fire spontaneously if exposed to air

Pictogram
Flame

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition sources(s). **Do not allow contact with air.** **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**If on skin: Immerse in cool water/wrap with wet bandages** **In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk.*	**Store contents under ...** ... Chemical manufacturer, importer, or distributor to specify appropriate liquid or inert gas.	

C.4.23 PYROPHORIC SOLIDS
(Classified in Accordance with Appendix B.10)

Pictogram
Flame

Hazard category	Signal word	Hazard statement
1	Danger	Catches fire spontaneously if exposed to air

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat/sparks/open flames/hot surfaces. - No smoking. Chemical manufacturer, importer, or distributor to specify applicable ignition source(s). **Do not allow contact with air.** **Wear protective gloves/eye protection/face protection** Chemical manufacturer, importer, or distributor to specify type of equipment.	**Brush off loose particles from skin. Immerse in cool water/wrap in wet bandages.** **In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*.	**Store contents under ...** …Chemical manufacturer, importer, or distributor to specify appropriate liquid or inert gas.	

C.4.24 SELF-HEATING SUBSTANCES AND MIXTURES
(Classified in Accordance with Appendix B.11)

Hazard category	Signal word	Hazard statement
1	Danger	Self-heating; may catch fire
2	Warning	Self-heating in large quantities; may catch fire

Pictogram
Flame

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep cool. Protect from sunlight. **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.		**Maintain air gap between stacks/pallets.** **Store bulk masses greater than … kg/…lbs at temperatures not exceeding …°C/…°F.** ... Chemical manufacturer, importer, or distributor to specify mass and temperature. **Store away from other materials.**	

C.4.25 SUBSTANCES AND MIXTURES WHICH, IN CONTACT WITH WATER, EMIT FLAMMABLE GASES (Classified in Accordance with Appendix B.12)

Pictogram
Flame

Hazard category	Signal word	Hazard statement
1	Danger	In contact with water releases flammable gases, which may ignite spontaneously
2	Danger	In contact with water releases flammable gas

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Do not allow contact with water. **Handle under inert gas. Protect from moisture.** **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**Brush off loose particles from skin and immerse in cool water/wrap in wet bandages.** **In case of fire: Use ... to extinguish** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*.	**Store in a dry place. Store in a closed container.**	**Dispose of contents/container to...** …in accordance with local/regional/national/ international regulations (to be specified).

C.4.25 SUBSTANCES AND MIXTURES WHICH, IN CONTACT WITH WATER, EMIT FLAMMABLE GASES (CONTINUED)

(Classified in Accordance with Appendix B.12)

Hazard category	Signal word	Hazard statement
3	Warning	In contact with water releases flammable gas

Pictogram
Flame

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Handle under inert gas. Protect from moisture. **Wear protective gloves/eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment.	**In case of fire: Use ... to extinguish.** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*.	**Store in a dry place. Store in a closed container.**	**Dispose of contents/container to...** ... in accordance with local/regional/national/international regulations (to be specified).

C.4.26 OXIDIZING LIQUIDS
(Classified in Accordance with Appendix B.13)

Hazard category	Signal word	Hazard statement
1	Danger	May cause fire or explosion; strong oxidizer

Pictogram
Flame over circle

Precautionary statements			
Prevention	**Response**	**Storage**	**Disposal**
Keep away from heat. **Keep/Store away from clothing and other combustible materials.** **Take any precaution to avoid mixing with combustibles/...** ... Chemical manufacturer, importer, or distributor to specify other incompatible materials. **Wear protective gloves /eye protection/face protection.** Chemical manufacturer, importer, or distributor to specify type of equipment. **Wear fire/flame resistant/retardant clothing.**	**If on clothing: Rinse immediately contaminated clothing and skin with plenty of water before removing clothes.** **In case of major fire and large quantities: Evacuate area. Fight fire remotely due to the risk of explosion.** **In case of fire: Use ... to extinguish.** ... Chemical manufacturer, importer, or distributor to specify appropriate media. - *if water increases risk*.		**Dispose of contents/container to...** …in accordance with local/regional/national/international regulations (to be specified).

C.4.26 OXIDIZING LIQUIDS (CONTINUED)
(Classified in Accordance with Appendix B.13)

Hazard category	Signal word	Hazard statement
2	Danger	May intensify fire; oxidizer
3	Warning	May intensify fire; oxidizer

Pictogram
Flame over circle

C.4.30 Label elements for OSHA defined hazards

Hazard	Signal word	Hazard statement	Pictogram
Pyrophoric Gas	Danger	Catches fire spontaneously if exposed to air	Flame
Simple Asphyxiant	Warning	May displace oxygen and cause rapid suffocation	*No Pictogram*
Combustible Dust[2]	Warning	May form combustible dust concentrations in air	*No Pictogram*

[2] *The chemical manufacturer or importer shall label chemicals that are shipped in dust form, and present a combustible dust hazard in that form when used downstream, under paragraph (f)(1); 2) the chemical manufacturer or importer shipping chemicals that are in a form that is not yet a dust must provide a label to customers under paragraph (f)(4) if, under normal conditions of use, the chemicals are processed in a downstream workplace in such a way that they present a combustible dust hazard; and 3) the employer shall follow the workplace labeling requirements under paragraph (f)(6) where combustible dust hazards are present.*

Appendix D to § 1910.1200—Safety Data Sheets (Mandatory)

A safety data sheet (SDS) shall include the information specified in Table D.1 under the section number and heading indicated for sections 1–11 and 16. If no relevant information is found for any given subheading within a section, the SDS shall clearly indicate that no applicable information is available. Sections 12–15 may be included in the SDS, but are not mandatory.

TABLE D.1—MINIMUM INFORMATION FOR AN SDS

Heading	Subheading
1. Identification	(a) Product identifier used on the label; (b) Other means of identification; (c) Recommended use of the chemical and restrictions on use; (d) Name, address, and telephone number of the chemical manufacturer, importer, or other responsible party; (e) Emergency phone number.
2. Hazard(s) identification	(a) Classification of the chemical in accordance with paragraph (d) of § 1910.1200; (b) Signal word, hazard statement(s), symbol(s) and precautionary statement(s) in accordance with paragraph (f) of § 1910.1200. (Hazard symbols may be provided as graphical reproductions in black and white or the name of the symbol, e.g., flame, skull and crossbones); (c) Describe any hazards not otherwise classified that have been identified during the classification process; (d) Where an ingredient with unknown acute toxicity is used in a mixture at a concentration ≥1% and the mixture is not classified based on testing of the mixture as a whole, a statement that X% of the mixture consists of ingredient(s) of unknown acute toxicity is required.
3. Composition/information on ingredients	Except as provided for in paragraph (i) of § 1910.1200 on trade secrets: For Substances (a) Chemical name; (b) Common name and synonyms; (c) CAS number and other unique identifiers; (d) Impurities and stabilizing additives which are themselves classified and which contribute to the classification of the substance. For Mixtures In addition to the information required for substances: (a) The chemical name and concentration (exact percentage) or concentration ranges of all ingredients which are classified as health hazards in accordance with paragraph (d) of § 1910.1200 and (1) Are present above their cut-off/concentration limits; or (2) Present a health risk below the cut-off/concentration limits. (b) The concentration (exact percentage) shall be specified unless a trade secret claim is made in accordance with paragraph (i) of § 1910.1200, when there is batch-to-batch variability in the production of a mixture, or for a group of substantially similar mixtures (*See* A.0.5.1.2) with similar chemical composition. In these cases, concentration ranges may be used. For All Chemicals Where a Trade Secret is Claimed Where a trade secret is claimed in accordance with paragraph (i) of § 1910.1200, a statement that the specific chemical identity and/or exact percentage (concentration) of composition has been withheld as a trade secret is required.
4. First-aid measures	(a) Description of necessary measures, subdivided according to the different routes of exposure, i.e., inhalation, skin and eye contact, and ingestion; (b) Most important symptoms/effects, acute and delayed. (c) Indication of immediate medical attention and special treatment needed, if necessary.
5. Fire-fighting measures	(a) Suitable (and unsuitable) extinguishing media. (b) Specific hazards arising from the chemical (e.g., nature of any hazardous combustion products). (c) Special protective equipment and precautions for fire-fighters.
6. Accidental release measures	(a) Personal precautions, protective equipment, and emergency procedures. (b) Methods and materials for containment and cleaning up.
7. Handling and storage	(a) Precautions for safe handling. (b) Conditions for safe storage, including any incompatibilities.
8. Exposure controls/personal protection	(a) OSHA permissible exposure limit (PEL), American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value (TLV), and any other exposure limit used or recommended by the chemical manufacturer, importer, or employer preparing the safety data sheet, where available. (b) Appropriate engineering controls. (c) Individual protection measures, such as personal protective equipment.
9. Physical and chemical properties	(a) Appearance (physical state, color, etc.); (b) Odor; (c) Odor threshold; (d) pH; (e) Melting point/freezing point; (f) Initial boiling point and boiling range; (g) Flash point; (h) Evaporation rate; (i) Flammability (solid, gas); (j) Upper/lower flammability or explosive limits;

TABLE D.1—MINIMUM INFORMATION FOR AN SDS—Continued

Heading	Subheading
	(k) Vapor pressure; (l) Vapor density; (m) Relative density; (n) Solubility(ies); (o) Partition coefficient: n-octanol/water; (p) Auto-ignition temperature; (q) Decomposition temperature; (r) Viscosity.
10. Stability and reactivity	(a) Reactivity; (b) Chemical stability; (c) Possibility of hazardous reactions; (d) Conditions to avoid (e.g., static discharge, shock, or vibration); (e) Incompatible materials; (f) Hazardous decomposition products.
11. Toxicological information	Description of the various toxicological (health) effects and the available data used to identify those effects, including: (a) Information on the likely routes of exposure (inhalation, ingestion, skin and eye contact); (b) Symptoms related to the physical, chemical and toxicological characteristics; (c) Delayed and immediate effects and also chronic effects from short- and long-term exposure; (d) Numerical measures of toxicity (such as acute toxicity estimates). (e) Whether the hazardous chemical is listed in the National Toxicology Program (NTP) Report on Carcinogens (latest edition) or has been found to be a potential carcinogen in the International Agency for Research on Cancer (IARC) Monographs (latest edition), or by OSHA.
12. Ecological information (Non-mandatory)	(a) Ecotoxicity (aquatic and terrestrial, where available); (b) Persistence and degradability; (c) Bioaccumulative potential; (d) Mobility in soil; (e) Other adverse effects (such as hazardous to the ozone layer).
13. Disposal considerations (Non-mandatory)	Description of waste residues and information on their safe handling and methods of disposal, including the disposal of any contaminated packaging.
14. Transport information (Non-mandatory)	(a) UN number; (b) UN proper shipping name; (c) Transport hazard class(es); (d) Packing group, if applicable; (e) Environmental hazards (e.g., Marine pollutant (Yes/No)); (f) Transport in bulk (according to Annex II of MARPOL 73/78 and the IBC Code); (g) Special precautions which a user needs to be aware of, or needs to comply with, in connection with transport or conveyance either within or outside their premises.
15. Regulatory information (Non-mandatory)	Safety, health and environmental regulations specific for the product in question.
16. Other information, including date of preparation or last revision.	The date of preparation of the SDS or the last change to it.

Appendix F to § 1910.1200—Guidance for Hazard Classifications Re: Carcinogenicity (Non-Mandatory)

The mandatory criteria for classification of a chemical for carcinogenicity under HCS (§ 1910.1200) are found in Appendix A.6 to this section. This non-mandatory Appendix provides additional guidance on hazard classification for carcinogenicity. Part A of Appendix F includes background guidance provided by GHS based on the Preamble of the International Agency for Research on Cancer (IARC) ''Monographs on the Evaluation of Carcinogenic Risks to Humans'' (2006). Part B provides IARC classification information. Part C provides background guidance from the National Toxicology Program (NTP) ''Report on Carcinogens'' (RoC), and Part D is a table that compares GHS carcinogen hazard categories to carcinogen classifications under IARC and NTP, allowing classifiers to be able to use information from IARC and NTP RoC carcinogen classifications to complete their classifications under the GHS, and thus the HCS.

Part A: Background Guidance [1]

As noted in Footnote 6 of Appendix A.6. to this section, the GHS includes as guidance for classifiers information taken from the Preamble of the International Agency for Research on Cancer (IARC) ''Monographs on the Evaluation of Carcinogenic Risks to Humans'' (2006), providing guidance on the evaluation of the strength and evidence of carcinogenic risks to humans. This guidance also discusses some additional considerations in classification and an approach to analysis, rather than hard-and-fast rules. Part A is consistent with Appendix A.6, and should help in evaluating information to determine carcinogenicity.

Carcinogenicity in humans:

The evidence relevant to carcinogenicity from studies in humans is classified into one of the following categories:

(a) Sufficient evidence of carcinogenicity: A causal relationship has been established between exposure to the agent and human cancer. That is, a positive relationship has been observed between the exposure and cancer in studies in which chance, bias and confounding could be ruled out with reasonable confidence.

(b) Limited evidence of carcinogenicity: A positive association has been observed between exposure to the agent and cancer for which a causal interpretation is considered by the Working Group to be credible, but chance, bias or confounding could not be ruled out with reasonable confidence.

In some instances, the above categories may be used to classify the degree of evidence related to carcinogenicity in specific organs or tissues.

Carcinogenicity in experimental animals:

The evidence relevant to carcinogenicity in experimental animals is classified into one of the following categories:

[1] *The text of Appendix F, Part A, on the IARC Monographs, is paraphrased from the 2006 Preamble to the ''Monographs on the Evaluation of Carcinogenic Risks to Humans''; the Classifier is referred to the full IARC Preamble for the complete text. The text is not part of the agreed GHS text on the harmonized system developed by the OECD Task Force-HCL.*

(a) Sufficient evidence of carcinogenicity: A causal relationship has been established between the agent and an increased incidence of malignant neoplasms or of an appropriate combination of benign and malignant neoplasms in two or more species of animals or two or more independent studies in one species carried out at different times or in different laboratories or under different protocols. An increased incidence of tumors in both sexes of a single species in a well-conducted study, ideally conducted under Good Laboratory Practices, can also provide sufficient evidence.

Exceptionally, a single study in one species and sex might be considered to provide sufficient evidence of carcinogenicity when malignant neoplasms occur to an unusual degree with regard to incidence, site, type of tumor or age at onset, or when there are strong findings of tumors at multiple sites.

(a) Limited evidence of carcinogenicity: The data suggest a carcinogenic effect but are limited for making a definitive evaluation because, e.g. the evidence of carcinogenicity is restricted to a single experiment; there are unresolved questions regarding the adequacy of the design, conduct or interpretation of the studies; the agent increases the incidence only of benign neoplasms or lesions of uncertain neoplastic potential; or the evidence of carcinogenicity is restricted to studies that demonstrate only promoting activity in a narrow range of tissues or organs.

Guidance on How To Consider Important Factors in Classification of Carcinogenicity (See Reference Section)

The weight of evidence analysis called for in GHS and the HCS (§ 1910.1200) is an integrative approach that considers important factors in determining carcinogenic potential along with the strength of evidence analysis. The IPCS ''*Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis''* (2001), International Life Sciences Institute (ILSI) ''*Framework for Human Relevance Analysis of Information on Carcinogenic Modes of Action''* (Meek, *et al.,* 2003; Cohen *et al.,* 2003, 2004), and Preamble to the IARC Monographs (2006; Section B.6. (Scientific Review and Evaluation; Evaluation and Rationale)) provide a basis for systematic assessments that may be performed in a consistent fashion. The IPCS also convened a panel in 2004 to further develop and clarify the human relevance framework. However, the above documents are not intended to dictate answers, nor provide lists of criteria to be checked off.

Mode of Action

Various documents on carcinogen assessment all note that mode of action in and of itself, or consideration of comparative metabolism, should be evaluated on a case-by-case basis and are part of an analytic evaluative approach. One must look closely at any mode of action in animal experiments, taking into consideration comparative toxicokinetics/toxicodynamics between the animal test species and humans to determine the relevance of the results to humans. This may lead to the possibility of discounting very specific effects of certain types of substances. Life stage-dependent effects on cellular differentiation may also lead to qualitative differences between animals and humans. Only if a mode of action of tumor development is conclusively determined not to be operative in humans may the carcinogenic evidence for that tumor be discounted. However, a weight of evidence evaluation for a substance calls for any other tumorigenic activity to be evaluated, as well.

Responses in Multiple Animal Experiments

Positive responses in several species add to the weight of evidence that a substance is a carcinogen. Taking into account all of the factors listed in A.6.2.5.2 and more, such chemicals with positive outcomes in two or more species would be provisionally considered to be classified in GHS Category 1B until human relevance of animal results are assessed in their entirety. It should be noted, however, that positive results for one species in at least two independent studies, or a single positive study showing unusually strong evidence of malignancy may also lead to Category 1B.

Responses Are in One Sex or Both Sexes

Any case of gender-specific tumors should be evaluated in light of the total tumorigenic response to the substance observed at other sites (multi-site responses or incidence above background) in determining the carcinogenic potential of the substance.

If tumors are seen only in one sex of an animal species, the mode of action should be carefully evaluated to see if the response is consistent with the postulated mode of action. Effects seen only in one sex in a test species may be less convincing than effects seen in both sexes, unless there is a clear patho-physiological difference consistent with the mode of action to explain the single sex response.

Confounding Effects of Excessive Toxicity or Localized Effects

Tumors occurring only at excessive doses associated with severe toxicity generally have doubtful potential for carcinogenicity in humans. In addition, tumors occurring only at sites of contact and/or only at excessive doses need to be carefully evaluated for human relevance for carcinogenic hazard. For example, forestomach tumors, following administration by gavage of an irritating or corrosive, non-mutagenic chemical, may be of questionable relevance. However, such determinations must be evaluated carefully in justifying the carcinogenic potential for humans; any occurrence of other tumors at distant sites must also be considered.

Tumor Type, Reduced Tumor Latency

Unusual tumor types or tumors occurring with reduced latency may add to the weight of evidence for the carcinogenic potential of a substance, even if the tumors are not statistically significant.

Toxicokinetic behavior is normally assumed to be similar in animals and humans, at least from a qualitative perspective. On the other hand, certain tumor types in animals may be associated with toxicokinetics or toxicodynamics that are unique to the animal species tested and may not be predictive of carcinogenicity in humans. Very few such examples have been agreed internationally. However, one example is the lack of human relevance of kidney tumors in male rats associated with compounds causing α2u-globulin nephropathy (IARC, Scientific Publication N° 147 [2]). Even when a particular tumor type may be discounted, expert judgment must be used in assessing the total tumor profile in any animal experiment.

Part B: International Agency for Research on Cancer (IARC) [3]

IARC Carcinogen Classification Categories:

Group 1: The agent is *carcinogenic to humans*

This category is used when there is *sufficient evidence of carcinogenicity* in humans. Exceptionally, an agent may be placed in this category when evidence of carcinogenicity in humans is less than *sufficient* but there is *sufficient evidence of carcinogenicity* in experimental animals and strong evidence in exposed humans that the agent acts through a relevant mechanism of carcinogenicity.

Group 2:

This category includes agents for which, at one extreme, the degree of evidence of carcinogenicity in humans is almost *sufficient,* as well as those for which, at the other extreme, there are no human data but for which there is evidence of carcinogenicity in experimental animals. Agents are assigned to either Group 2A (*probably carcinogenic to humans*) or Group 2B (*possibly carcinogenic to humans*) on the basis of epidemiological and experimental evidence of carcinogenicity and mechanistic and other relevant data. The terms *probably carcinogenic* and *possibly carcinogenic* have no quantitative significance and are used simply as descriptors of different levels of evidence of human carcinogenicity, with *probably carcinogenic* signifying a higher level of evidence than *possibly carcinogenic.*

Group 2A: The agent is *probably carcinogenic to human.*

This category is used when there is *limited evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals. In some cases, an agent may be classified in this category when there is *inadequate evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals and strong evidence that the carcinogenesis is mediated by a mechanism that also operates in humans. Exceptionally, an agent may be classified in this category solely on the basis of *limited evidence of carcinogenicity* in humans. An agent may be assigned to this category if it clearly belongs, based on mechanistic considerations, to a class of agents for which one or more members have been classified in Group 1 or Group 2A.

[2] *While most international agencies do not consider kidney tumors coincident with α2u-globulin nephropathy to be a predictor of risk in humans, this view is not universally held. (See: Doi et al., 2007).*

[3] *Preamble of the International Agency for Research on Cancer (IARC) ''Monographs on the Evaluation of Carcinogenic Risks to Humans'' (2006).*

Group 2B: The agent is *possibly carcinogenic to humans.*

This category is used for agents for which there is *limited evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals. It may also be used when there is *inadequate evidence of carcinogenicity* in humans but there is *sufficient evidence of carcinogenicity* in experimental animals. In some instances, an agent for which there is *inadequate evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals together with supporting evidence from mechanistic and other relevant data may be placed in this group. An agent may be classified in this category solely on the basis of strong evidence from mechanistic and other relevant data.

Part C: National Toxicology Program (NTP), ''Report on Carcinogens'', Background Guidance

NTP Listing Criteria [4]*:*

The criteria for listing an agent, substance, mixture, or exposure circumstance in the Report on Carcinogens (RoC) are as follows:

Known To Be A Human Carcinogen: There is sufficient evidence of carcinogenicity from studies in humans [5] that indicates a causal relationship between exposure to the agent, substance, or mixture, and human cancer.

Reasonably Anticipated To Be A Human Carcinogen: There is limited evidence of carcinogenicity from studies in humans that indicates that a causal interpretation is credible, but that alternative explanations, such as chance, bias, or confounding factors, could not adequately be excluded,

or

there is sufficient evidence of carcinogenicity from studies in experimental animals that indicates there is an increased incidence of malignant and/or a combination of malignant and benign tumors in multiple species or at multiple tissue sites, or by multiple routes of exposure, or to an unusual degree with regard to incidence, site, or type of tumor, or age at onset,

or

there is less than sufficient evidence of carcinogenicity in humans or laboratory animals; however, the agent, substance, or mixture belongs to a well-defined, structurally-related class of substances whose members are listed in a previous Report on Carcinogens as either known to be a human carcinogen or reasonably anticipated to be a human carcinogen, or there is convincing relevant information that the agent acts through mechanisms indicating it would likely cause cancer in humans.

Conclusions regarding carcinogenicity in humans or experimental animals are based on scientific judgment, with consideration given to all relevant information. Relevant information includes, but is not limited to, dose response, route of exposure, chemical structure, metabolism, pharmacokinetics, sensitive sub-populations, genetic effects, or other data relating to mechanism of action or factors that may be unique to a given substance. For example, there may be substances for which there is evidence of carcinogenicity in laboratory animals, but there are compelling data indicating that the agent acts through mechanisms that do not operate in humans and would therefore not reasonably be anticipated to cause cancer in humans.

Part D: Table Relating Approximate Equivalences Among IARC, NTP RoC, and GHS Carcinogenicity Classifications

The following table may be used to perform hazard classifications for carcinogenicity under the HCS (§ 1910.1200). It relates the approximated GHS hazard categories for carcinogenicity to the classifications provided by IARC and NTP, as described in Parts B and C of this Appendix.

APPROXIMATE EQUIVALENCES AMONG CARCINOGEN CLASSIFICATION SCHEMES

IARC	GHS	NTP RoC
Group 1	Category 1A	Known.
Group 2A	Category 1B	Reasonably Anticipated.
Group 2B	Category 2	(See Note 1).

Note 1:

1. *Limited evidence of carcinogenicity from studies in humans (corresponding to IARC 2A/GHS 1B);*
2. *Sufficient evidence of carcinogenicity from studies in experimental animals (again, essentially corresponding to IARC 2A/GHS 1B);*
3. *Less than sufficient evidence of carcinogenicity in humans or laboratory animals; however:*

c. *The agent, substance, or mixture belongs to a well-defined, structurally-related class of substances whose members are listed in a previous RoC as either ''Known'' or ''Reasonably Anticipated'' to be a human carcinogen, or*

d. *There is convincing relevant information that the agent acts through mechanisms indicating it would likely cause cancer in humans.*

■ 33. Amend § 1910.1450 as follows:

■ A. Remove the definitions of *Combustible liquid, Compressed gas, Explosive, Flammable, Flashpoint, Organic peroxide, Oxidizer, Unstable (reactive),* and *Water-reactive* from paragraph (b);

■ B. Revise the definitions of *Hazardous chemical, Physical hazard, and Reproductive toxins* in paragraph (b);

■ C. Add definitions of *Health hazard* and *Mutagen* in alphabetical order in paragraph (b);

[4] *See: http://ntp.niehs.nih.gov/go/15209.*

[5] *This evidence can include traditional cancer epidemiology studies, data from clinical studies, and/or data derived from the study of tissues or cells from humans exposed to the substance in question that can be useful for evaluating whether a relevant cancer mechanism is operating in people.*

■ D. In paragraphs (f)(3)(v), (h)(1) introductory text, (h)(1)(ii) and (h)(2)(iii), remove the phrases ''Material Safety Data Sheets'' and ''material safety data sheets'' and add in their place ''safety data sheets'';

■ E. In Appendix A to § 1910.1450, in the Table of Contents (item ''G'') remove ''Material Safety Data Sheets'' and add in its place ''Safety Data Sheets'';

■ F. In Appendix A to § 1910.1450, revise the heading ''G. Material Safety Data Sheets'' and revise the text following the heading.

The revisions read as follows:

§ 1910.1450 Occupational exposure to hazardous chemicals in laboratories.

* * * * *

(b) * * *

Hazardous chemical means any chemical which is classified as health hazard or simple asphyxiant in accordance with the Hazard Communication Standard (§ 1910.1200).

Health hazard means a chemical that is classified as posing one of the following hazardous effects: Acute toxicity (any route of exposure); skin corrosion or irritation; serious eye damage or eye irritation; respiratory or skin sensitization; germ cell mutagenicity; carcinogenity; reproductive toxicity; specific target organ toxicity (single or repeated exposure); aspiration hazard. The criteria for determining whether a chemical is classified as a health hazard are detailed in Appendix A of the Hazard Communication Standard (§ 1910.1200) and § 1910.1200(c) (definition of ''simple asphyxiant'').

* * * * *

Mutagen means chemicals that cause permanent changes in the amount or structure of the genetic material in a cell. Chemicals classified as mutagens in accordance with the Hazard Communication Standard (§ 1910.1200) shall be considered mutagens for purposes of this section.

* * * * *

Physical hazard means a chemical that is classified as posing one of the following hazardous effects: Explosive; flammable (gases, aerosols, liquids, or solids); oxidizer (liquid, solid, or gas); self reactive; pyrophoric (gas, liquid or solid); self-heating; organic peroxide; corrosive to metal; gas under pressure; in contact with water emits flammable gas; or combustible dust. The criteria for determining whether a chemical is classified as a physical hazard are in Appendix B of the Hazard Communication Standard (§ 1910.1200) and § 1910.1200(c) (definitions of ''combustible dust'' and ''pyrophoric gas'').

* * * * *

Reproductive toxins mean chemicals that affect the reproductive capabilities including adverse effects on sexual function and fertility in adult males and females, as well as adverse effects on the development of the offspring. Chemicals classified as reproductive toxins in accordance with the Hazard Communication Standard (§ 1910.1200) shall be considered reproductive toxins for purposes of this section.

* * * * *

Appendix A to § 1910.1450—National Research Council Recommendations Concerning Chemical Hygiene in Laboratories (Non-Mandatory)

* * * * *

G. Safety Data Sheets

Safety data sheets are presented in ''Prudent Practices'' for the chemicals listed below. (Asterisks denote that comprehensive safety data sheets are provided).

* * * * *

PART 1915—OCCUPATIONAL SAFETY AND HEALTH STANDARDS FOR SHIPYARD EMPLOYMENT

■ 34. Revise the authority citation for part 1915 to read as follows:

Authority: Section 41, Longshore and Harbor Workers' Compensation Act (33 U.S.C. 941); Sections. 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31160), 4–2010 (75 FR 55355), or 1–2012 (77 FR 3912), as applicable; 29 CFR Part 1911.

Section 1915.100 also issued under 49 U.S.C. 1801–1819 and 5 U.S.C. 553.

Sections 1915.120 and 1915.152 of 29 CFR also issued under 29 CFR part 1911.

Subpart Z—[Amended]

■ 35. Revise § 1915.1001 paragraphs (i)(3), (k)(7), and (k)(8) to read as follows:

§ 1915.1001 Asbestos.

* * * * *

(i) * * *

(3) The employer shall ensure that contaminated clothing is transported in sealed impermeable bags, or other closed, impermeable containers, and labeled in accordance with paragraph (k) of this section.

* * * * *

(k) * * *

(7) *Hazard communication.* (i) Labels shall be affixed to all products containing asbestos and to all containers containing such products, including waste containers. Where feasible, installed asbestos products shall contain a visible label.

(ii) *General.* The employer shall include asbestos in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of asbestos and safety data sheets, and is trained in accordance with the provisions of the HCS and paragraph (k)(9) of this section. The employer shall ensure that at least the following hazards are addressed: Cancer and lung effects.

(iii) *Labels.* (A) The employer shall ensure that labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers bear the following information:

DANGER
CONTAINS ASBESTOS FIBERS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
DO NOT BREATHE DUST
AVOID CREATING DUST

(B)(*1*) Prior to June 1, 2015, employers may include the following information on raw materials, mixtures or labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers in lieu of the labeling requirements in paragraphs (k)(7)(ii) and (k)(7)(iii)(A) of this section:

DANGER
CONTAINS ASBESTOS FIBERS
AVOID CREATING DUST
CANCER AND LUNG DISEASE HAZARD

(*2*) Labels shall also contain a warning statement against breathing asbestos fibers.

(iv) The provisions for labels required in paragraph (k)(7) of this section do not apply where:

(A) Asbestos fibers have been modified by a bonding agent, coating, binder, or other material, provided that the manufacturer can demonstrate that, during any reasonably foreseeable use, handling, storage, disposal, processing, or transportation, no airborne concentrations of asbestos fibers in excess of the permissible exposure limit and/or excursion limit will be released, or

(B) Asbestos is present in a product in concentrations less than 1.0 percent.

(8) *Signs.* (i) Warning signs that demarcate the regulated area shall be provided and displayed at each location where a regulated area is required to be established by paragraph (e) of this section. Signs shall be posted at such a distance from such a location that an

employee may read the signs and take necessary protective steps before entering the area marked by the signs.

(ii) The warning signs required by this paragraph (k)(8) shall bear the following legend:

DANGER
ASBESTOS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
AUTHORIZED PERSONNEL ONLY

(iii) In addition, where the use of respirators and protective clothing is required in the regulated area under this section, the warning signs shall include the following:

WEAR RESPIRATORY PROTECTION
AND PROTECTIVE CLOTHING IN THIS
AREA

(iv) The employer shall ensure that employees working in and contiguous to regulated areas comprehend the warning signs required to be posted by paragraph (k)(8) of this section. Means to ensure employee comprehension may include the use of foreign languages, pictographs, and graphics.

(v) When a building/vessel owner or employer identifies previously installed PACM and/or ACM, labels or signs shall be affixed or posted so that employees will be notified of what materials contain PACM and/or ACM. The employer shall attach such labels in areas where they will clearly be noticed by employees who are likely to be exposed, such as at the entrance to mechanical room/areas. Signs required by paragraph (k)(6) of this section may be posted in lieu of labels, so long as they contain information required for labeling. The employer shall ensure, to the extent feasible, that employees who come in contact with these signs or labels can comprehend them. Means to ensure employee comprehension may include the use of foreign languages, pictographs, graphics, and awareness training.

(vi) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (k)(8)(ii) of this section:

DANGER
ASBESTOS
CANCER AND LUNG DISEASE HAZARD
AUTHORIZED PERSONNEL ONLY

(vii) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (k)(8)(iii) of this section:

RESPIRATORS AND PROTECTIVE
CLOTHING ARE REQUIRED IN THIS
AREA

* * * * *

■ 36. Revise § 1915.1026 paragraphs (g)(2)(iv) and (j)(1), to read as follows:

§ 1915.1026 Chromium (VI).

* * * * *

(g) * * *

(2) * * *

(iv) The employer shall ensure that bags or containers of contaminated protective clothing or equipment that are removed from change rooms for laundering, cleaning, maintenance, or disposal are labeled in accordance with the requirements of the Hazard Communication Standard, § 1910.1200.

* * * * *

(j) * * *

(1) *Hazard communication.* The employer shall include chromium (VI) in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of chromium (VI) and safety data sheets, and is trained in accordance with the provisions of HCS and paragraph (j)(2) of this section. The employer shall ensure that at least the following hazards are addressed: Cancer; skin sensitization; and eye irritation.

* * * * *

PART 1926—SAFETY AND HEALTH REGULATIONS FOR CONSTRUCTION

Subpart D—[Amended]

■ 37. The authority citation for subpart D is revised to read as follows:

Authority: Section 107 of the Contract Work Hours and Safety Standards Act (40 U.S.C. 3704); Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, and 657); and Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355), or 1–2012 (77 FR 3912) as applicable; and 29 CFR part 1911.

Sections 1926.58, 1926.59, 1926.60, and 1926.65 also issued under 5 U.S.C. 553 and 29 CFR part 1911.

Section 1926.61 also issued under 49 U.S.C. 1801–1819 and 6 U.S.C. 553.

Section 1926.62 also issued under section 1031 of the Housing and Community Development Act of 1992 (42 U.S.C. 4853).

Section 1926.65 also issued under section 126 of the Superfund Amendments and Reauthorization Act of 1986, as amended (reprinted at 29 U.S.C.A. 655 Note), and 5 U.S.C. 553.

■ 38. Revise § 1926.60 paragraphs (l)(1) and (l)(2) to read as follows:

§ 1926.60 Methylenedianiline.

* * * * *

(l) * * *

(1) *Hazard communication.* The employer shall include Methylenedianiline (MDA) in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of MDA and safety data sheets, and is trained in accordance with the provisions of HCS and paragraph (l)(3) of this section. The employer shall ensure that at least the following hazards are addressed: Cancer; liver effects; and skin sensitization.

(2) *Signs and labels*— (i) *Signs.* (A) The employer shall post and maintain legible signs demarcating regulated areas and entrances or access-ways to regulated areas that bear the following legend:

DANGER
MDA
MAY CAUSE CANCER
CAUSES DAMAGE TO THE LIVER
RESPIRATORY PROTECTION AND
PROTECTIVE CLOTHING MAY BE
REQUIRED IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(B) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (l)(2)(i)(A) of this section:

DANGER
MDA
MAY CAUSE CANCER
LIVER TOXIN
AUTHORIZED PERSONNEL ONLY
RESPIRATORS AND PROTECTIVE
CLOTHING MAY BE REQUIRED TO BE
WORN IN THIS AREA

(ii) *Labels.* (A) The employer shall ensure that labels or other appropriate forms of warning are provided for containers of MDA within the workplace. The labels shall comply with the requirements of § 1910.1200(f) and shall include at least the following information for pure MDA and mixtures containing MDA:

DANGER
CONTAINS MDA
MAY CAUSE CANCER
CAUSES DAMAGE TO THE LIVER

(B) Prior to June 1, 2015, employers may include the following information workplace labels in lieu of the labeling requirements in paragraph (l)(2)(ii)(A) of this section:

(*1*) For Pure MDA:

DANGER
CONTAINS MDA
MAY CAUSE CANCER
LIVER TOXIN

(*2*) For mixtures containing MDA:

DANGER
CONTAINS MDA
CONTAINS MATERIALS WHICH MAY
CAUSE CANCER

LIVER TOXIN
* * * * *

■ 39. Amend § 1926.62 by revising paragraph (g)(2)(vii), the heading of paragraph (l), paragraph (l)(1)(i), and paragraph (m), and Appendix B to § 1926.62 section XI, to read as follows:

§ 1926.62 Lead.

* * * * *

(g) * * *

(2) * * *

(vii)(A) The employer shall ensure that the containers of contaminated protective clothing and equipment required by paragraph (g)(2)(v) of this section are labeled as follows:

DANGER: CLOTHING AND EQUIPMENT CONTAMINATED WITH LEAD. MAY DAMAGE FERTILITY OR THE UNBORN CHILD. CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM. DO NOT EAT, DRINK OR SMOKE WHEN HANDLING. DO NOT REMOVE DUST BY BLOWING OR SHAKING. DISPOSE OF LEAD CONTAMINATED WASH WATER IN ACCORDANCE WITH APPLICABLE LOCAL, STATE, OR FEDERAL REGULATIONS.

(B) Prior to June 1, 2015, employers may include the following information on bags or containers of contaminated protective clothing and equipment required by paragraph (g)(2)(v) in lieu of the labeling requirements in paragraph (g)(2)(vii)(A) of this section:

Caution: Clothing contaminated with lead. Do not remove dust by blowing or shaking. Dispose of lead contaminated wash water in accordance with applicable local, state, or federal regulations.

* * * * *

(l) *Communication of hazards.*

(1) * * *

(i) *Hazard communication.* The employer shall include lead in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of lead and safety data sheets, and is trained in accordance with the provisions of HCS and paragraph (l) of this section. The employer shall ensure that at least the following hazards are addressed:

(A) Reproductive/developmental toxicity;

(B) Central nervous system effects;

(C) Kidney effects;

(D) Blood effects; and

(E) Acute toxicity effects.

* * * * *

(m) *Signs.*

(1) *General.*

(i) The employer shall post the following warning signs in each work area where an employee's exposure to lead is above the PEL.

DANGER
LEAD WORK AREA
MAY DAMAGE FERTILITY OR THE UNBORN CHILD
CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM
DO NOT EAT, DRINK OR SMOKE IN THIS AREA

(ii) The employer shall ensure that no statement appears on or near any sign required by this paragraph (m) that contradicts or detracts from the meaning of the required sign.

(iii) The employer shall ensure that signs required by this paragraph (m) are illuminated and cleaned as necessary so that the legend is readily visible.

(iv) The employer may use signs required by other statutes, regulations or ordinances in addition to, or in combination with, signs required by this paragraph (m).

(v) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (m)(1)(i) of this section:

WARNING
LEAD WORK AREA
POISON
NO SMOKING OR EATING

* * * * *

Appendix B to § 1926.62—Employee Standard Summary

* * * * *

XI. Signs—Paragraph (M)

The standard requires that the following warning sign be posted in work areas when the exposure to lead is above the PEL:

DANGER
LEAD WORK AREA
MAY DAMAGE FERTILITY OR THE UNBORN CHILD
CAUSES DAMAGE TO THE CENTRAL NERVOUS SYSTEM
DO NOT EAT, DRINK OR SMOKE IN THIS AREA

Prior to June 1, 2016, employers may use the following legend in lieu of that specified above:

WARNING
LEAD WORK AREA
POISON
NO SMOKING OR EATING

* * * * *

■ 40. Revise § 1926.64 paragraphs (a)(1)(ii) introductory text, (a)(1)(ii)(B), and (d)(1)(vii), and the note following paragraph (d)(1)(vii), to read as follows:

§ 1926.64 Process safety management of highly hazardous chemicals.

* * * * *

(a) * * *

(1) * * *

(ii) A process which involves a Category 1 flammable gas (as defined in § 1910.1200(c)) or flammable liquid with a flashpoint below 100 °F (37.8 °C) on site in one location, in a quantity of 10,000 pounds (4535.9 kg) or more except for:

* * * * *

(B) Flammable liquids with a flashpoint below 100 °F (37.8 °C) stored in atmospheric tanks or transferred that are kept below their normal boiling point without benefit of chilling or refrigeration.

* * * * *

(d) * * *

(1) * * *

(vii) Hazardous effects of inadvertent mixing of different materials that could foreseeably occur.

Note to paragraph (d)(1): Safety data sheets meeting the requirements of § 1910.1200(g) may be used to comply with this requirement to the extent they contain the information required by this paragraph (d)(1).

* * * * *

■ 41. Amend § 1926.65 paragraph (a)(3) by revising the definition of ''Health hazard'' to read as follows:

§ 1926.65 Hazardous waste operations and emergency response.

(a) * * *

(3) * * *

Health hazard means a chemical or a pathogen where acute or chronic health effects may occur in exposed employees. It also includes stress due to temperature extremes. The term *health hazard* includes chemicals that are classified in accordance with the Hazard Communication Standard, § 1910.1200, as posing one of the following hazardous effects: acute toxicity (any route of exposure); skin corrosion or irritation; serious eye damage or eye irritation; respiratory or skin sensitization; germ cell mutagenicity; carcinogenicity; reproductive toxicity; specific target organ toxicity (single or repeated exposure); aspiration toxicity or simple asphyxiant. (*See* Appendix A to § 1910.1200—Health Hazard Criteria (Mandatory) for the criteria for determining whether a chemical is classified as a health hazard.)

* * * * *

Subpart F—[Amended]

■ 42. Revise the authority citation for subpart F to read as follows:

Authority: Section 107 of the Contract Work Hours and Safety Standards Act (40 U.S.C. 3704); Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736),1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (62 FR 50017), 5–2002 (67 FR 650008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355), or 1–2012

(77 FR 3912), as applicable; and 29 CFR part 1911.

* * * * *

■ 43. Amend § 1926.152 as follows:
■ A. Revise the section heading;
■ B. Remove the words ''and combustible'' from the first sentence in paragraph (a)(1), the heading of paragraph (b), and paragraphs (b)(2) introductory text, (b)(4)(viii), (h) introductory text, and (h)(1);
■ C. Remove the words ''or combustible'' wherever it appears in paragraphs (a)(2), (b)(1), (b)(4)(iii), (b)(5), and (c)(3);
■ D. Remove the words ''or combustible'' in paragraphs (d) (the heading), (d)(1), (d)(4), (e)(1), (e)(3), (f)(2), (g)(1), and (g)(8);
■ E. Remove the words ''or combustible'' wherever it appears in paragraphs (i)(1)(i)(D) and (F), (i)(1)(iii)(D), (i)(2)(ii)(A), (D), and (F), (i)(2)(vii)(B)(*2*), (i)(4)(iv)(C), (i)(5)(vi)(A), (D), (G), (V) introductory text, and (i)(5)(vi)(V)(*1*); (j)(1)(i), (j)(2)(ii), (j)(5), and (k)(4);
■ F. Amend the fifth sentence of paragraph (b)(4)(vi) by adding the words ''Category 1, 2, or 3'' before the words ''flammable liquids'';
■ G. Amend paragraphs (e)(2), (e)(5), (g)(7)(i), and (g)(7)(ii), by adding the words ''Category 1, 2, or 3'' before the words ''flammable liquids'' ;
■ H. Amend paragraphs (f)(1) and (f)(3) by removing the words ''Flammable liquids'' and adding in their place the words ''Category 1, 2, or 3 flammable liquids'';
■ I. Revise paragraphs (b)(2)(iii), (b)(3), (h) introductory text, (i)(2)(iv)(F) and (G), (i)(2)(vi)(B), (i)(2)(viii)(E), (i)(3)(i), (i)(3)(iv)(A) and (C), (i)(3)(v)(D), and (i)(4)(iv)(E);
■ J. Revise Table F–19 and paragraph (k)(3)(iv).

The revisions read as follows:

§ 1926.152 Flammable liquids.

* * * * *

(b) * * *

(2) * * *

(iii) Cabinets shall be labeled in conspicuous lettering, ''Flammable-Keep Away from Open Flames.''

(3) Not more than 60 gallons of Category 1, 2 and/or 3 flammable liquids or 120 gallons of Category 4 flammable liquids shall be stored in any one storage cabinet. Not more than three such cabinets may be located in a single storage area. Quantities in excess of this shall be stored in an inside storage room.

* * * * *

(h) *Scope.* This section applies to the handling, storage, and use of flammable liquids with a flashpoint at or below 199.4 °F (93 °C). This section does not apply to:

* * * * *

(i) * * *

(2) * * *

(iv) * * *

(F) Tanks and pressure vessels storing Category 1 flammable liquids shall be equipped with venting devices that shall be normally closed except when venting to pressure or vacuum conditions. Tanks and pressure vessels storing Category 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be equipped with venting devices that shall be normally closed except when venting under pressure or vacuum conditions, or with approved flame arresters.

Exemption: Tanks of 3,000 bbls (barrels) (84 m(3)) capacity or less containing crude petroleum in crude-producing areas; and, outside aboveground atmospheric tanks under 1,000 gallons (3,785 L) capacity containing other than Category 1 flammable liquids may have open vents. (*See* paragraph (i)(2)(vi)(B) of this section.)

(G) Flame arresters or venting devices required in paragraph (i)(2)(iv)(F) of this section may be omitted for Category 2 flammable liquids or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C) where conditions are such that their use may, in case of obstruction, result in tank damage.

* * * * *

(vi) * * *

(B) Where vent pipe outlets for tanks storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), are adjacent to buildings or public ways, they shall be located so that the vapors are released at a safe point outside of buildings and not less than 12 feet (3.658 m) above the adjacent ground level. In order to aid their dispersion, vapors shall be discharged upward or horizontally away from closely adjacent walls. Vent outlets shall be located so that flammable vapors will not be trapped by eaves or other obstructions and shall be at least 5 feet (1.52 m) from building openings.

(viii) * * *

(E) For Category 2 flammable liquids or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasolines, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity. A fill pipe entering the top of a tank shall terminate within 6 inches (15.24 cm) of the bottom of the tank and shall be installed to avoid excessive vibration.

* * * * *

(3) * * *

(i) *Location.* Evacuation for underground storage tanks shall be made with due care to avoid undermining of foundations of existing structures. Underground tanks or tanks under buildings shall be so located with respect to existing building foundations and supports that the loads carried by the latter cannot be transmitted to the tank. The distance from any part of a tank storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), to the nearest wall of any basement or pit shall be not less than 1 foot (0.304 m), and to any property line that may be built upon, not less than 3 feet (0.912 m). The distance from any part of a tank storing Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids to the nearest wall of any basement, pit or property line shall be not less than 1 foot (0.304 m).

* * * * *

(iv) * * *

(A) Location and arrangement of vents for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C). Vent pipes from tanks storing Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be so located that the discharge point is outside of buildings, higher than the fill pipe opening, and not less than 12 feet (3.658 m) above the adjacent ground level. Vent pipes shall discharge only upward in order to disperse vapors. Vent pipes 2 inches (5.08 cm) or less in nominal inside diameter shall not be obstructed by devices that will cause excessive back pressure. Vent pipe outlets shall be so located that flammable vapors will not enter building openings, or be trapped under eaves or other obstructions. If the vent pipe is less than 10 feet (3.04 m) in length, or greater than 2 inches (5.08 cm) in nominal inside diameter, the outlet shall be provided with a vacuum and pressure relief device or there shall be an approved flame arrester located in the vent line at the outlet or within the approved distance from the outlet.

* * * * *

(C) Location and arrangement of vents for Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4 flammable liquids. Vent pipes from tanks storing Category 3 flammable liquids with a flashpoint at or above 100 °F (37.8 °C) or Category 4

flammable liquids shall terminate outside of the building and higher than the fill pipe opening. Vent outlets shall be above normal snow level. They may be fitted with return bends, coarse screens or other devices to minimize ingress of foreign material.

* * * * *

(v) * * *

(D) For Category 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasolines, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity by terminating within 6 inches (15.24 cm) of the bottom of the tank.

* * * * *

(4) * * *

(iv) * * *

(E) For Category 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), other than crude oils, gasolines, and asphalts, the fill pipe shall be so designed and installed as to minimize the possibility of generating static electricity by terminating within 6 inches (15.24 cm) of the bottom of the tank.

* * * * *

(k) * * *

(3) * * *

* * * * *

BILLING CODE 4510–26–P

TABLE F-19 - ELECTRICAL EQUIPMENT HAZARDOUS AREAS - SERVICE STATIONS

Location	Class I Group D division	Extent of classified area
Underground tank:		
Fill opening	1	Any pit, box or space below grade level, any part of which is within the Division 1 or 2 classified area.
	2	Up to 18 inches (45.72 cm) above grade level within a horizontal radius of 10 feet (3.04 m) from a loose fill connection and within a horizontal radius of 5 feet (1.52 m) from a tight fill connection.
Vent - Discharging upward	1	Within 3 feet (0.912 m) of open end of vent, extending in all directions.
	2	Area between 3 feet (0.912 m) and 5 feet (1.52 m) of open end of vent, extending in all directions.
Dispenser:		
Pits	1	Any pit, box or space below grade level, any part of which is within the Division 1 or 2 classified area.
Dispenser enclosure	1	The area 4 feet (1.216 m) vertically above base within the enclosure and 18 inches (45.72 cm) horizontally in all directions.
Outdoor	2	Up to 18 inches (45.72 cm) above grade level within 20 feet (6.08 m) horizontally of any edge of enclosure.
Indoor:		
With mechanical ventilation.	2	Up to 18 inches (45.72 cm) above grade level within 20 feet (6.08 m) horizontally of any edge of enclosure.
With gravity ventilation	2	Up to 18 inches (45.72 cm) above grade or floor level within 25 feet (7.6 m) horizontally of any edge of enclosure.
Remote pump - Outdoor	1	Any pit, box or space below grade level if any part is within a horizontal distance of 10 feet (3.04 m) from any edge of pump.
	2	Within 3 feet (0.912 m) of any edge of pump, extending

		in all directions. Also up to 18 inches (45.72 cm) above grade level within 10 feet (3.04 m) horizontally from any edge of pump.
Remote pump - Indoor.....	1	Entire area within any pit.
	2	Within 5 feet (1.52 m) of any edge of pump, extending in all directions. Also up to 3 feet (3.04 m) above floor or grade level within 25 feet (6.08 m) horizontally from any edge of pump.
Lubrication or service room.	1	Entire area within any pit.
	2	Area up to 18 inches (45.72 cm) above floor or grade level within entire lubrication room.
Dispenser for Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 ° F (37.8 ° C)	2	Within 3 feet (0.912 m) of any fill or dispensing point, extending in all directions.
Special enclosure inside building per 1910.106(f)(1)(ii).	1	Entire enclosure.
Sales, storage and rest rooms.....	(1)	If there is any opening to these rooms within the extent of a Division 1 area, the entire room shall be classified as Division 1.

(1) Ordinary.

* * * * *

BILLING CODE 4510–26–C

(iv) Piping handling Category 1 or 2 flammable liquids, or Category 3 flammable liquids with a flashpoint below 100 °F (37.8 °C), shall be grounded to control stray currents.

* * * * *

■ 44. Amend § 1926.155 as follows:

■ A. Remove and reserve paragraph (c);

■ B. Revise paragraphs (h) and (i)(1) and (2).

The revisions read as follows:

§ 1926.155 Definitions applicable to this subpart.

* * * * *

(h) *Flammable liquid* means any liquid having a vapor pressure not exceeding 40 pounds per square inch (absolute) at 100 °F (37.8 °C) and having a flashpoint at or below 199.4 °F (93 °C). Flammable liquids are divided into four categories as follows:

(1) Category 1 shall include liquids having flashpoints below 73.4 °F (23 °C) and having a boiling point at or below 95 °F (35 °C).

(2) Category 2 shall include liquids having flashpoints below 73.4 °F (23 °C) and having a boiling point above 95 °F (35 °C).

(3) Category 3 shall include liquids having flashpoints at or above 73.4 °F (23 °C) and at or below 140 °F (60 °C).

(4) Category 4 shall include liquids having flashpoints above 140 °F (60 °C) and at or below 199.4 °F (93 °C).

(i) * * *

(1) The flashpoint of liquids having a viscosity less than 45 Saybolt Universal Second(s) at 100 °F (37.8 °C) and a flashpoint below 175 °F (79.4 °C) shall be determined in accordance with the Standard Method of Test for Flash Point by the Tag Closed Tester, ASTM D–56–69 (incorporated by reference; *See* § 1926.6), or an equivalent method as defined by § 1910.1200 appendix B.

(2) The flashpoints of liquids having a viscosity of 45 Saybolt Universal Second(s) or more at 175 °F (79.4 °C) or higher shall be determined in accordance with the Standard Method of Test for Flash Point by the Pensky Martens Closed Tester, ASTM D–93–69 (incorporated by reference; *See* § 1926.6), or an equivalent method as defined by § 1910.1200 appendix B.

* * * * *

Subpart Z—[Amended]

■ 45. Revise the authority citation for subpart Z to read as follows:

Authority: Section107 of the Contract Work Hours and Safety Standards Act (40 U.S.C. 3704); Sections 4, 6, and 8 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); and Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736), 1–90 (55 FR 9033), 6–96 (62 FR 111), 3–2000 (65 FR 50017), 5–2002 (67 FR 65008), 5–2007 (72 FR 31159), 4–2010 (75 FR 55355), or 1–2012 (77 FR 3912) as applicable; and 29 CFR part 1911.

Section 1926.1102 not issued under 29 U.S.C. 655 or 29 CFR part 1911; also issued under 5 U.S.C. 553.

■ 46. Amend § 1926.1101 as follows:
■ A. Redesignate paragraph (k)(1) as (k)(1)(i) and add a new heading to paragraph (k)(1);
■ B. Add new paragraphs (k)(1)(ii), (k)(7)(ii)(C), (k)(7)(ii)(D), and (k)(8)(iv);
■ C. Amend paragraphs (k)(2)(i) and (k)(3)(i) by removing the references to ''(k)(1)'' and adding in their place ''(k)(1)(i)'';
■ D. Revise paragraphs (k)(7)(ii)(A) and (B), and (k)(8)(ii) and (iii);

The revisions read as follows:

§ 1926.1101 Asbestos.

* * * * *

(k) * * *

(1) *Hazard communication.*

* * * * *

(ii) The employer shall include asbestos in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of asbestos and safety data sheets, and is trained in accordance with the provisions of HCS and paragraphs (k)(9) and (10) of this section. The employer shall provide information on at least the following hazards: Cancer and lung effects.

* * * * *

(7) * * *

(ii) * * *

(A) The warning signs required by paragraph (k)(7) of this section shall bear the following information.

DANGER
ASBESTOS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
AUTHORIZED PERSONNEL ONLY

(B) In addition, where the use of respirators and protective clothing is required in the regulated area under this section, the warning signs shall include the following:

WEAR RESPIRATORY PROTECTION AND PROTECTIVE CLOTHING IN THIS AREA

(C) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (k)(7)(ii)(A) of this section:

DANGER
ASBESTOS
CANCER AND LUNG DISEASE HAZARD
AUTHORIZED PERSONNEL ONLY

(D) Prior to June 1, 2016, employers may use the following legend in lieu of that specified in paragraph (k)(7)(ii)(B) of this section:

RESPIRATORS AND PROTECTIVE CLOTHING ARE REQUIRED IN THIS AREA

* * * * *

(8) * * *

(ii) The employer shall ensure that such labels comply with paragraphs (k) of this section.

(iii) The employer shall ensure that labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers bear the following information:

DANGER
CONTAINS ASBESTOS FIBERS
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS
DO NOT BREATHE DUST
AVOID CREATING DUST

(iv) (A) Prior to June 1, 2015, employers may include the following information on raw materials, mixtures or labels of bags or containers of protective clothing and equipment, scrap, waste, and debris containing asbestos fibers in lieu of the labeling requirements in paragraphs (k)(8)(ii) and (k)(8)(iii) of this section:

DANGER
CONTAINS ASBESTOS FIBERS
AVOID CREATING DUST
CANCER AND LUNG DISEASE HAZARD

(B) Labels shall also contain a warning statement against breathing asbestos fibers.

* * * * *

■ 47. Revise § 1926.1126 paragraphs (g)(2)(iv) and (j)(1) to read as follows:

§ 1926.1126 Chromium (VI).

* * * * *

(g) * * *

(2) * * *

(iv) The employer shall ensure that bags or containers of contaminated protective clothing or equipment that are removed from change rooms for laundering, cleaning, maintenance, or disposal shall be labeled in accordance with the requirements of the Hazard Communication Standard, § 1910.1200.

* * * * *

(j) * * *

(1) *Hazard communication.* The employer shall include chromium (VI) in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of chromium and safety data sheets, and is trained in accordance with the provisions of § 1910.1200 and paragraph (j)(2) of this section. The employer shall provide information on at least the following hazards: Cancer; eye irritation; and skin sensitization.

* * * * *

■ 48. Revise § 1926.1127 paragraphs (i)(2)(iv), (k)(7), and (m)(1), (m)(2), and (m)(3), to read as follows:

§ 1926.1127 Cadmium.

* * * * *

(i) * * *

(2) * * *

(iv) The employer shall ensure that containers of contaminated protective clothing and equipment that are to be taken out of the change rooms or the workplace for laundering, cleaning, maintenance or disposal shall bear labels in accordance with paragraph (m)(3)(ii) of this section.

(k) * * *

(7) Waste, scrap, debris, bags, and containers, personal protective equipment and clothing contaminated with cadmium and consigned for disposal shall be collected and disposed of in sealed impermeable bags or other closed, impermeable containers. These bags and containers shall be labeled in accordance with paragraph (m)(3)(ii) of this section.

* * * * *

(m) * * *

(1) *Hazard communication.* The employer shall include cadmium in the program established to comply with the Hazard Communication Standard (HCS) (§ 1910.1200). The employer shall ensure that each employee has access to labels on containers of cadmium and safety data sheets, and is trained in accordance with the provisions of HCS and paragraph (m)(4) of this section. The employer shall provide information on at least the following hazards: Cancer; lung effects; kidney effects; and acute toxicity effects.

(2) *Warning signs.* (i) Warning signs shall be provided and displayed in regulated areas. In addition, warning signs shall be posted at all approaches to regulated areas so that an employee may read the signs and take necessary protective steps before entering the area.

(ii) Warning signs required by paragraph (m)(2)(i) of this section shall bear the following legend:

DANGER
CADMIUM
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS AND KIDNEYS
WEAR RESPIRATORY PROTECTION IN THIS AREA
AUTHORIZED PERSONNEL ONLY

(iii) The employer shall ensure that signs required by this paragraph (m)(2) are illuminated, cleaned, and maintained as necessary so that the legend is readily visible.

(iv) Prior to June 1, 2016, employers may use the following legend in lieu of

that specified in paragraph (m)(2)(ii) of this section:

DANGER
CADMIUM
CANCER HAZARD
CAN CAUSE LUNG AND KIDNEY DISEASE
AUTHORIZED PERSONNEL ONLY
RESPIRATORS REQUIRED IN THIS AREA

(3) *Warning labels.* (i) Shipping and storage containers containing cadmium or cadmium compounds shall bear appropriate warning labels, as specified in paragraph (m)(1) of this section.

(ii) The warning labels for containers of cadmium-contaminated protective clothing, equipment, waste, scrap, or debris shall include at least the following information:

DANGER
CONTAINS CADMIUM
MAY CAUSE CANCER
CAUSES DAMAGE TO LUNGS AND KIDNEYS
AVOID CREATING DUST

(iii) Where feasible, installed cadmium products shall have a visible label or other indication that cadmium is present.

(iv) Prior to June 1, 2015, employers may include the following information on shipping and storage containers containing cadmium, cadmium compounds, or cadmium-contaminated clothing, equipment, waste, scrap, or debris in lieu of the labeling requirements specified in paragraphs (m)(3)(i) and (m)(3)(ii) of this section:

DANGER
CONTAINS CADMIUM
CANCER HAZARD
AVOID CREATING DUST
CAN CAUSE LUNG AND KIDNEY DISEASE

Environmental Protection Agency

40 CFR Part 65

National Uniform Emission Standards for Storage Vessel and Transfer Operations, Equipment Leaks, and Closed Vent Systems and Control Devices; and Revisions to the National Uniform Emission Standards General Provisions; Proposed Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 65

[EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; EPA–HQ–OAR–2010–0871; FRL–9645–1]

RIN 2060–AR00

National Uniform Emission Standards for Storage Vessel and Transfer Operations, Equipment Leaks, and Closed Vent Systems and Control Devices; and Revisions to the National Uniform Emission Standards General Provisions

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The EPA is proposing National Uniform Emission Standards for Storage Vessels and Transfer Operations, Equipment Leaks and Control Devices, herein referred to as Uniform Standards. The EPA is also proposing supplemental revisions to the National Uniform Emission Standards General Provisions, which were proposed with the National Uniform Emission Standards for Heat Exchange Systems, signed by the EPA Administrator on November 30, 2011.

The proposed Uniform Standards would be referenced, as appropriate, in future revisions to new source performance standards and national emission standards for hazardous air pollutants for individual source categories that are part of the chemical manufacturing and refining industries that have storage vessels and transfer operations, equipment leaks or control devices used to control process vents from reactors, distillation and other operations, as well as from emissions from storage vessels, transfer operations and equipment leaks that are routed to control devices. Establishing these Uniform Standards is consistent with the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review,* issued on January 18, 2011. In the future, as we periodically review and, if necessary, revise new source performance standards and national emission standards for hazardous air pollutants, as required by the Clean Air Act, we can direct those rulemakings to the proposed Uniform Standards, provided the Uniform Standards meet the applicable statutory stringency requirements for the specific rulemaking. The proposed Uniform Standards would ensure consistency and streamline recordkeeping and reporting requirements for facilities with storage vessels and transfer operations, equipment leaks and process vents that must comply with multiple regulations.

DATES: *Comments.* Comments must be received on or before June 25, 2012.

Public Hearing. If anyone contacts the EPA by April 10, 2012 requesting to speak at a public hearing, the EPA will hold a public hearing on or about April 25, 2012.

ADDRESSES: *Comments.* Technical comments pertinent to the Uniform Standards should be identified as follows:

- Uniform Standards for Storage Vessels and Transfer Operations should be marked, ''Attention Docket ID No. EPA–HQ–OAR–2010–0871.''
- Uniform Standards for Equipment Leaks should be marked, ''Attention Docket ID No. EPA–HQ–OAR–2010–0869.''
- Uniform Standards for Control Devices should be marked, ''Attention Docket ID No. EPA–HQ–OAR–2010–0868.''
- Uniform Standards General Provisions or General Comments on the Uniform Standards should be marked, ''Attention Docket ID No. EPA–HQ–OAR–2010–0870.''

Submit your comments, identified by the appropriate Docket ID No., by one of the following methods:

- *http://www.regulations.gov.* Follow the on-line instructions for submitting comments.
- *http://www.epa.gov/oar/docket.html.* Follow the instructions for submitting comments on the EPA Air and Radiation Docket Web site.
- *Email:* Comments may be sent by electronic mail (email) to *a-and-r-docket@epa.gov,* Attention Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate).
- *Fax:* Fax your comments to: (202) 566–9744, Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate).
- *Mail:* Send your comments to: EPA Docket Center (EPA/DC), Environmental Protection Agency, Mailcode 2822T, 1200 Pennsylvania Ave. NW., Washington, DC 20460, Attention Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate). Please include a total of two copies. We request that a separate copy also be sent to the contact person identified below (see **FOR FURTHER INFORMATION CONTACT**). In addition, please mail a copy of your comments on the information collection provisions to the Office of Information and Regulatory Affairs, OMB, Attention: Desk Officer for EPA, 725 17th St. NW., Washington, DC 20503.
- *Hand Delivery:* Deliver your comments to: EPA Docket Center (EPA/DC), EPA West Building, Room 3334, 1301 Constitution Ave. NW., Washington, DC 20460, Attention Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate). Such deliveries are only accepted during the normal hours of operation (8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays), and special arrangements should be made for deliveries of boxed information.

Instructions: All submissions must include agency name and docket number for this rulemaking. Direct your comments to Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate). The EPA's policy is that all comments received will be included in the public docket and may be made available online at *http://www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *http://www.regulations.gov* or email. The *http://www.regulations.gov* Web site is an ''anonymous access'' system, which means the EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to the EPA without going through *http://www.regulations.gov,* your email address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, the EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If the EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, the EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption and be free of any defects or viruses.

Docket: All documents in the docket are listed in the *http://www.regulations.gov* index. Although listed in the index, some information is not publicly available, e.g., CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy form. Publicly available docket materials are available either electronically at *http://www.regulations.gov* or in hard copy at the EPA Docket Center, EPA/DC, EPA West Building, Room 3334, 1301 Constitution Ave. NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the EPA Docket Center is (202) 566–1742.

FOR FURTHER INFORMATION CONTACT: For information regarding the proposed General Provisions to the National Uniform Emission Standards, contact Brenda Shine, (919) 541–3608, Sector Policies and Programs Division (E143–01), Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711; Telephone number: (919) 541–3608; Fax number (919) 541–0246; email address: *shine.brenda@epa.gov.*

For information regarding the proposed National Uniform Emission Standards for Equipment Leaks, contact Jodi Howard, Sector Policies and Programs Division (E143–01), Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711; Telephone number: (919) 541–4607; Fax number (919) 541–0246; email address: *howard.jodi@epa.gov.*

For information regarding the proposed National Uniform Emission Standards for Storage Vessel and Transfer Operations, contact Nick Parsons, Sector Policies and Programs Division (E143–01), Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711; Telephone number: (919) 541–5372; Fax number (919) 541–0246; email address: *parsons.nick@epa.gov.*

For information regarding the proposed National Uniform Emission Standards For Control Devices, contact Andrew Bouchard, Sector Policies and Programs Division (E143–01), Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711; Telephone number: (919) 541–4036; Fax number (919) 541–0246; email address: *bouchard.andrew@epa.gov.*

Organization of This Document. The following outline is provided to aid in locating information in this preamble.

I. General Information
A. Does the proposed action apply to me?
B. What should I consider as I prepare my comments to the EPA?
C. Where can I get a copy of this document?
D. Public Hearing
II. Background Information for These Proposed Rules
A. What is the statutory authority and regulatory background for the proposed Uniform Standards?
B. What is the history and background of the proposed Uniform Standards?
C. What is the relationship between the Uniform Standards and the referencing subparts?
D. What are the purpose and benefits of the proposed Uniform Standards?
E. How were the proposed Uniform Standards developed?
F. What are the electronic data submittal requirements?
III. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Standards for Storage Vessel and Transfer Operations—Subpart I
A. Summary
B. Rationale
IV. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Emission Standards for Equipment Leaks—Subpart J
A. Summary
B. Rationale
V. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Emission Standards for Control Devices—Subpart M
A. Summary
B. Rationale
VI. Summary and Rationale for the Proposed Revision of 40 CFR Part 65 Uniform Standards General Provisions—Subpart H
A. Summary
B. Rationale
VII. Impacts of the Proposed Rule
A. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart I?
B. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart J?

C. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart M?
D. What are the cost impacts associated with the proposed reporting requirements for the Uniform Standards?
VIII. Statutory and Executive Order Reviews
A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review
B. Paperwork Reduction Act
C. Regulatory Flexibility Act
D. Unfunded Mandates Reform Act
E. Executive Order 13132: Federalism
F. Executive Order 13175: Consultation and Coordination with Indian Tribal Governments
G. Executive Order 13045: Protection of Children from Environmental Health Risks and Safety Risks
H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use
I. National Technology Transfer and Advancement Act
J. Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations

I. General Information

A. Does the proposed action apply to me?

Regulated Entities. The proposed rules would establish a series of national uniform emission standards for storage vessels and transfer operations, equipment leaks and control devices.

We expect, in future rulemaking actions, to propose that new source performance standards (NSPS) and national emission standards for hazardous air pollutants (NESHAP) for other source categories will also reference and require compliance with Uniform Standards, as appropriate, provided that the referencing subpart rulemakings demonstrate that the Uniform Standards meet the statutory stringency requirements that would apply to the referencing subpart source category, such as Clean Air Act (CAA) section 112(d), maximum achievable control technology (MACT), section 112(f), residual risk ample margin of safety (AMOS) and section 111(b), best systems of emission reduction (BSER). Examples of categories and entities potentially affected by the proposed Uniform Standards for Storage Vessels and Transfer Operations, Equipment Leaks and Control Devices include the following:

Category	NAICS [a] code	Examples of potentially regulated entities
Chemical Manufacturing	325	Manufacturing industries, particularly petrochemical, chemical, polymers, plastics and specialty chemicals manufacturing.
Refining	324	Petroleum refineries.

[a] North American Industry Classification System.

This table is not intended to be exhaustive; rather, it provides a guide for readers regarding entities the EPA anticipates are likely to be potentially affected by this action through future, separate rulemaking actions.

The table includes source categories currently subject to NESHAP under subparts in 40 CFR part 61 and 40 CFR part 63 and NSPS under subparts in 40 CFR part 60. The entities listed in the above table are not affected by this action unless and until the EPA proposes in a separate notice to apply a Uniform Standard to their source categories. As proposed in 40 CFR part 65, subparts H, I, J and M would apply to owners or operators expressly referenced to part 65 from future rulemakings that may result in new subparts or revisions to current subparts of 40 CFR parts 60, 61 or 63. The list of categories and entities potentially affected by this proposed action in the future is provided solely to inform owners and operators of facilities in those categories of the potential for future rulemaking and to solicit comments from these entities at this time. If, in future rulemakings, the EPA were to propose to apply these Uniform Standards to a particular source category, there would be another opportunity to comment on the application to a specific industry. Because the EPA believes that establishing Uniform Standards for types of emission points found in a variety of industries will be efficient for facilities, state, local and tribal governments and the public, we seek broad input at this time. In the future, you would determine whether your facility, company, business or organization would be regulated by a proposed action by examining the applicability criteria in the referencing subpart. If you have any questions regarding the applicability of this action to a particular entity, consult either the air permitting authority for the entity or your EPA regional representative, as listed in the referencing subpart.

B. What should I consider as I prepare my comments to the EPA?

1. Submitting CBI

Do not submit information that you consider to be CBI electronically through *http://www.regulations.gov* or email. Send or deliver information identified as CBI to only the following address: U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, U.S. EPA Mailroom (C404–02), Attention: Mr. Roberto Morales, Document Control Officer, 109 T.W. Alexander Drive, Research Triangle Park, NC 27711, Attention Docket ID No. EPA–HQ–OAR–2010–0868; EPA–HQ–OAR–2010–0869; EPA–HQ–OAR–2010–0870; or EPA–HQ–OAR–2010–0871 (as appropriate).

Clearly mark the part or all of the information that you claim to be CBI. For CBI information in a disk or CD–ROM that you mail to the EPA, mark the outside of the disk or CD–ROM as CBI and then identify electronically within the disk or CD–ROM the specific information that is claimed as CBI. In addition to one complete version of the comment that includes information claimed as CBI, a copy of the comment that does not contain the information claimed as CBI must be submitted for inclusion in the public docket. Information marked as CBI will not be disclosed except in accordance with procedures set forth in 40 CFR part 2.

If you have any questions about CBI or the procedures for claiming CBI, please consult the appropriate person identified in the **FOR FURTHER INFORMATION CONTACT** section.

2. Docket

The docket numbers for the proposed action regarding the Uniform Standards are as follows:

- Uniform Standards for Storage Vessels and Transfer Operations (40 CFR part 65, subpart I) is Docket ID No. EPA–HQ–OAR–2010–0871.
- Uniform Standards for Equipment Leaks (40 CFR part 65, subpart J) is Docket ID No. EPA–HQ–OAR–2010–0869.
- Uniform Standards for Control Devices (40 CFR part 65, subpart M) is Docket ID No. EPA–HQ–OAR–2010–0868.
- Uniform Standards General Provisions or general comments on the Uniform Standards (40 CFR part 65,

subpart H) is Docket ID No. EPA–HQ–OAR–2010–0870.

To ensure proper receipt by the EPA, be sure to identify the docket ID number(s) assigned to this action in the subject line on the first page of your response.

C. Where can I get a copy of this document?

In addition to being available in the docket, an electronic copy of this proposed action will also be available on the World Wide Web (WWW) through the Technology Transfer Network (TTN). Following signature, a copy of the proposed action will be posted on the TTN's policy and guidance page for newly proposed or promulgated rules at the following address: *http://www.epa.gov/ttn/oarpg/*. The TTN provides information and technology exchange in various areas of air pollution control.

D. Public Hearing

If a public hearing is held, it will be held at 10 a.m. at the EPA's Environmental Research Center Auditorium, Research Triangle Park, NC, or an alternate site nearby. Contact Ms. Janet Eck at (919) 541–7946 to request a hearing, to request to speak at a public hearing, to determine if a hearing will be held or to determine the hearing location. If no one contacts the EPA requesting to speak at a public hearing concerning this proposed rule by April 10, 2012, a hearing will not be held.

II. Background Information for These Proposed Rules

A. What is the statutory authority and regulatory background for the proposed Uniform Standards?

Consistent with the authority under CAA section 301(a)(1) and CAA sections 111 and 112, we are proposing to establish the Uniform Standards as a set of foundational requirements that may be considered and adopted by future rulemakings under CAA sections 111 and 112. Section 301(a)(1) of the CAA authorizes the Administrator ''to prescribe such regulations as are necessary to carry out his functions under [the CAA].'' The proposed Uniform Standards, if finalized, would provide a set of common control requirement subparts describing testing, monitoring, recordkeeping and reporting requirements that would, if appropriate, be referenced in future CAA 111 and 112 rulemakings. Future rulemakings would include CAA section 112(d) standards, based on MACT determinations and generally available control technology or management practice (GACT) determinations (for area sources), as well as CAA section 112(d)(6) reviews of existing standards and CAA section 112(f) revisions, which take into account the risk to public health remaining after application of the MACT-based standards. The proposed Uniform Standards could also be referenced during CAA section 111(b) rulemakings to establish NSPS for source categories, and as we periodically review and revise these standards, to reflect improvements in methods for reducing emissions. CAA section 111(b) standards require a level of control that historically has been referred to as ''Best Demonstrated Technology.'' In order to better reflect that CAA section 111 was amended in 1990 to clarify that ''best systems'' may or may not be ''technology,'' the EPA is now using the term ''best system of emission reduction'' or BSER.

As foundational requirements, the Uniform Standards would become applicable to a particular source category only if a subsequent rulemaking for that source category references the Uniform Standards. We have previously promulgated similar standards, such as the 40 CFR parts 60, 61 and 63 General Provisions (59 FR 12430, March 16, 1994) and the Consolidated Federal Air Rules (CAR) (65 FR 78267, December 14, 2000), which only become applicable to a source category when referenced by another rulemaking. In this preamble, we refer to subparts that would reference the Uniform Standards as ''referencing subparts.'' The authority for the referencing standards would be provided under the referencing subpart. The rationale for each determination that the Uniform Standards in proposed 40 CFR part 65, subparts H, I, J or M are equivalent to MACT, GACT, AMOS or BSER and comply with all other applicable statutory requirements would be presented in the rulemaking for the individual source category with an opportunity for public comment at that time.

The proposed Uniform Standards are also responsive to Executive Order 13563, *Improving Regulation and Regulatory Review,* which directs each federal agency to ''periodically review its existing significant regulations to determine whether any such regulations should be modified, streamlined, expanded, or repealed so as to make the agency's regulatory program more effective or less burdensome in achieving the regulatory objectives.'' The proposed Uniform Standards reflect the EPA's regulatory experience from previous NESHAP and NSPS rulemakings involving similar kinds of sources and emission points. They incorporate our review of the most current technology and emission reduction practices, as detailed in sections III through V of the preamble, and provide updated monitoring, recordkeeping and reporting requirements that may be referenced by future CAA 111 and 112 rulemakings.

The proposed Uniform Standards for Storage Tanks and Transfer Operations, Equipment Leaks and Control Devices would be codified under 40 CFR part 65 as subparts I, J and M. The General Provisions for the Uniform Standards and Uniform Standards for Heat Exchange Systems were previously proposed in a separate notice signed by the EPA Administrator on November 30, 2011 (77 FR 960, January 6, 2012) and would be codified under 40 CFR part 65 as subparts H and L, respectively. We are proposing supplemental requirements for the General Provisions (subpart H) to include new provisions applicable to all Uniform Standards, as well as new provisions applicable to individual Uniform Standards in subparts I, J and M. As discussed in section VI.A of this preamble, we are maintaining the previously proposed five sections of subpart H and adding eleven new sections. Of the five previously proposed sections, we are proposing to make substantive changes to three sections. The EPA will consider all comments pertaining to the Uniform Standards General Provisions (subpart H) that were submitted in response to the previous proposal (77 FR 960, January 6, 2012), and will address those comments as we address the comments on the supplemental provisions proposed in this action.

B. What is the history and background of the proposed Uniform Standards?

In a number of cases, the EPA has established CAA standards for different source categories that regulate the same kinds of emission points. Standards for a given type of emission point may require application of controls with similar control efficiencies and include similar design, component or operating standards, even though these emission points may be located at different types of sources or facilities. To avoid duplicative or disjointed requirements, and to promote consistency among technical requirements for similar emission points in different source categories, the EPA has established several common control requirement subparts describing testing, monitoring, recordkeeping and reporting requirements for certain emission points

and emission controls that can be referenced from multiple source categories. For instance, we promulgated standard requirements for selected emission points (*i.e.,* containers, surface impoundments, oil-water separators and organic-water separators, tanks, and individual drain systems) in individual subparts under the NESHAP for Off-Site Waste and Recovery Operations (61 FR 34158, July 1, 1996), and we promulgated subparts for selected emission points (*i.e.,* closed vent systems, control devices, recovery devices and routing to a fuel gas system or a process; equipment leaks; and storage vessels) as part of the Generic MACT program. The Generic MACT standards, which were promulgated under 40 CFR part 63, subparts SS, TT, UU and WW, were referenced in NESHAP requirements for individual source categories.

Consolidation of compliance requirements under these subparts allows for ease of reference, administrative convenience and consistency in the technical requirements of the air emission control requirements applied to similar emission points under different source category regulations. The 40 CFR part 63, subparts SS, TT, UU and WW are emission point- and emissions control-specific. They specify monitoring, recordkeeping and reporting requirements, but generally do not specify emissions reduction performance requirements or applicability thresholds. Instead, the referencing subpart specifies the emissions reduction performance requirements and applicability thresholds.

By establishing these emission point- and emissions control-specific subparts, other source category-specific regulations were able to reference a common set of design, operating, testing, inspection, monitoring, repair, recordkeeping and reporting requirements for air emissions controls. This reduced the potential for duplicative or conflicting technical requirements, and promoted consistency of the air emission requirements applied to similar emission points, while allowing specific emission standards to be set within the context of the source category-specific regulations. Additionally, creating emission point-specific and emissions control-specific subparts ensured that all regulations that cross-referenced these subparts could be amended in a consistent and timely manner, through one regulatory action.

We intend to establish, through the proposed Uniform Standards, a workable process for consolidation and a more efficient approach to rulemaking. The Uniform Standards have, in general, been modeled after the emission-point and emissions control-specific subparts of the Generic MACT. We are proposing the Uniform Standards in lieu of revising the Generic MACT because it is our intention to provide a set of common compliance monitoring, recordkeeping and reporting requirements that could be applied to emission points referenced from CAA 111 and 112 (NSPS and NESHAP, respectively) rulemakings. The Uniform Standards are designed to apply to chemical and refining facilities regulated under the authority of sections 111 and 112 of the CAA and who may currently be subject to regulation under 40 CFR parts 60, 61 and 63. The Generic MACT is currently referenced by NESHAP under the provisions of 40 CFR part 63 and section 112 of the CAA; revising the current Generic MACT to be referenced by sources regulated under NSPS could create confusion regarding regulatory authority. In addition, the Generic MACT currently affects a large number of source categories and referencing subparts; therefore, a large revision of the Generic MACT could potentially be more confusing for regulated sources. Thus, we are proposing to establish the Uniform Standards under 40 CFR part 65 and anticipate, through future notice-and-comment rulemaking, to cross-reference subparts I, J and M from source category emission standards within at least two different parts of title 40 of the CFR—parts 60 and 63, which establish NSPS and NESHAP standards, respectively. The process of revising individual referencing subparts to reference the Uniform Standards or develop new subparts that reference the Uniform Standards is a clear-cut process that allows for review of the needs of specific source categories.

C. What is the relationship between the Uniform Standards and the referencing subparts?

This action may affect other source categories with similar emission points if the EPA takes action in the future to propose to apply the Uniform Standards to one or more other source categories for storage vessels and transfer operations, equipment leaks or process vents. However, the EPA will determine applicability of these proposed Uniform Standards for another source category through notice-and-comment rulemaking. In such a rulemaking, we will explain that all or a portion of 40 CFR part 65, subparts H, I, J or M are consistent with the CAA requirements at issue for the specific authority in the rulemaking. For example, in the context of an NSPS rulemaking, we could determine that subpart J is BSER for the source category at issue or, alternatively, we could determine that different emission standards should apply, but that recordkeeping, reporting and other requirements of subpart J are appropriate.

We expect to see similar benefits for these Uniform Standards as we have seen for previous emission point- and emissions control-specific subparts, as described above, including the ability to reference a common set of standards for the same type of emission point located at sources within different source categories. This approach will maximize consistency between source categories for each type of emission point.

As with the common control requirement subparts previously promulgated, the proposed Uniform Standards would include technical requirements and would not, in most cases, specify source category-specific applicability thresholds or emissions reduction performance requirements, because these requirements are more properly established in source category-specific rules.

However, we are proposing applicability thresholds, compliance requirements and monitoring frequencies that would apply if the referencing subpart does not specify these parameters. In the rulemaking actions that revise or propose standards to cross-reference 40 CFR part 65, subparts I, J and M, we would address whether the referencing subpart should cross-reference subparts I, J and M in their entirety or cross-reference only a subset of subparts I, J and M. Moreover, we would determine whether the referencing (source category-specific) subpart should include more or less stringent requirements than subparts I, J and M.

As we revise or promulgate source category-specific standards that have emission points addressed by a uniform standard for storage vessels, transfer operations, equipment leaks and/or control devices, we would propose whether and to what extent we would reference the Uniform Standards in the proposed 40 CFR part 65, subparts I, J and M. In making that decision, we would consider the applicable CAA requirements, analyses of the individual source category and the similarity of emission characteristics and applicable controls. We would consider factors such as: (1) The volume and concentration of emissions; (2) the type of emissions; (3) the similarity of emission points; (4) the cost and

effectiveness of controls for one source category relative to the cost and effectiveness of controls for the other source category; (5) whether a source has unusual characteristics that might require different analytical methods; and (6) whether any of the sources have existing emission controls that are dissimilar and more stringent than controls required for similar sources outside the source category. These factors would be considered on a source category-specific basis to ensure that sources are appropriately similar, and that emissions control technologies and reductions demonstrated outside of a source category are achievable for new and existing sources in an applicable source category.

In future rulemakings, the referencing subpart would establish the source category-specific requirements, including the regulated materials, appropriate applicability thresholds or tiers, emissions limit requirements (including the format and units of measure) and other source category-specific requirements. Additionally, the referencing subpart would provide rationale for the use of surrogates, if the use of surrogates is appropriate for the source category; for example, the referencing subpart could establish limits on particulate matter (PM) to achieve control of non-volatile metallic hazardous air pollutants (HAP), yet refer to the Uniform Standards for monitoring, recordkeeping and reporting requirements. For any provisions of the Uniform Standards not cross-referenced by a source category-specific subpart, the requirement would be expressly addressed in the source category-specific (referencing) subpart. A portion of 40 CFR part 65, subparts I, J and/or M could be cross-referenced and exceptions could be made within the referencing subpart, as necessary, to ensure that the proposed requirements are appropriate to the source category in light of the applicable CAA requirements. For example, the referencing subpart could specify a monitoring frequency other than that contained in the Uniform Standards if we determine that a different monitoring frequency is appropriate for the regulated emission point in that source category. A referencing subpart with applicability thresholds, for instance, may only direct to a portion of the Uniform Standards or not direct to the Uniform Standards at all for certain thresholds. Because the proposed Uniform Standards could be referenced in this manner, we believe that the requirements in subparts I, J and M would not inhibit the flexibility to address source category-specific needs.

The rationale for each determination that the provisions of 40 CFR part 65, subparts H, I, J or M should be cross-referenced for an individual referencing subpart in light of the applicable CAA requirements, would be addressed in the rulemaking for the individual subpart at the time of proposal, and we would provide an opportunity for public comment at that time. A description of the analyses performed as part of that review would be presented in the rulemaking for the individual subpart and an opportunity for comment would be provided. We would also assess the costs, emission reduction, economic and other impacts as they relate to the specific source category at issue at that time.

In light of these considerations, we have determined that the proposed Uniform Standards would promote the EPA's ability to simplify, clarify and improve implementation of the rules with which source owners or operators must comply, consistent with the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review,* and resulting in a cost and burden reduction for both the public and private sector.

D. What are the purpose and benefits of the proposed Uniform Standards?

This action proposes the Uniform Standards for Storage Vessels and Transfer Operations (40 CFR part 65, subpart I), Equipment Leaks (40 CFR part 65, subpart J) and Control Devices (40 CFR part 65, subpart M), and revisions to the General Provisions for the Uniform Standards (40 CFR part 65, subpart H).

This action is based on the EPA's review of the current requirements for equipment leaks, storage tanks and transfer operations and control devices used to control process vents in light of over 20 years of regulatory implementation experience. The benefits of the proposed Uniform Standards include:

- Providing one-stop requirements for equipment leaks, storage tanks and control devices for the chemical manufacturing and refining industries;
- Providing strengthened control and monitoring requirements based on cost-effective advances in technology that could be considered for adoption in future rulemakings;
- Enhancing compliance and enforcement to ensure that the standards achieve the intended emissions reductions required for MACT, GACT or BSER; and
- Reduction of unnecessary and unproductive regulatory burden.

These benefits also support the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review.* Examples of the changes we are proposing that accomplish each of these objectives are below.

The proposed Uniform Standards provide the benefit of one-stop compliance, monitoring, recordkeeping and reporting requirements for specific emission points that would be referenced in future rulemakings for the chemical manufacturing and refining industries. The EPA desires to facilitate implementation and compliance by making requirements easier to understand, incorporating streamlined compliance approaches and applying these approaches across industry sectors. Currently, the chemical manufacturing and refining industries may be subject to multiple NSPS and NESHAP, including the Generic MACT (40 CFR part 63, subparts SS, TT, UU, and WW); the Miscellaneous Organic Chemical Manufacturing NESHAP (68 FR 63851, November 10, 2003) (MON); the Hazardous Organic NESHAP (59 FR 19402, April 22, 1994) (HON), the Organic Liquids Distribution (OLD) NESHAP (69 FR 5038, February 3, 2004); the Petroleum Refineries NESHAP (60 FR 43260, August 18, 1995); the Synthetic Organic Chemical Manufacturing Industry (SOCMI) rules (Standards of Performance for Volatile Organic Liquid Storage Vessels (52 FR 11429, April 8, 1987); Standards of Performance for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry (48 FR 48335, October 18, 1983); and SOCMI Reactor Processes (58 FR 45962, August 31, 1993)). Several of these rules cover similar emission points, such as storage tanks, transfer operations, equipment leaks or process vents that route to a control device. As a result, facilities subject to two or more of these rules may have overlapping or confusing compliance requirements for the same emission point. Additionally, facilities may have burdensome recordkeeping and reporting requirements for multiple subparts to which they are subject. The proposed Uniform Standards revise and streamline the compliance approach for future rulemakings by applying a set of control and compliance methods that may be referenced from multiple subparts. In particular, the proposed Uniform Standards are structured so that facilities regulated under NSPS and NESHAP could reference the same cost-effective monitoring, recordkeeping and reporting requirements for storage tanks,

transfer racks, equipment leaks and process vents that route to a control device, provided the Uniform Standards are determined to be appropriate for the NSPS and NESHAP source categories (see section II.C of this preamble). By providing a consistent set of compliance, monitoring, recordkeeping and reporting requirements, the proposed standards would reduce the burden to the chemical manufacturing and refining industries. Additionally, applying these common emission point-specific requirements provides the benefit of easing the enforcement burden for government agencies.

The proposed 40 CFR part 65, subparts I, J and M also provide the groundwork for future rulemakings as a set of strengthened control and monitoring requirements that may be considered for use in future referencing subparts to meet MACT, GACT, AMOS or BSER. The proposed standards are based on a consolidation of existing requirements, but have been augmented where appropriate based on our survey of available technology and a review of existing regulations for each emission point. For example, under the proposed Uniform Standards for Storage Vessels and Transfer Operations, we are proposing to specify situations when landing a floating roof is allowable and the amount of time that a storage vessel with a landed floating roof may be left standing idle. These changes reduce the amount of time during which volatile regulated materials are exposed to the atmosphere and may be released. To improve detection of leaks on fixed roof storage tanks and thereby minimize emissions, we are also proposing to require monitoring for leaks from closure devices, pressure/vacuum vents and other potential leak interfaces on fixed roof storage vessels using Method 21 of 40 CFR part 60, appendix A–7, or optical gas imaging instead of visual inspections for defects. We are also proposing to include different delay of repair provisions in the proposed Uniform Standards for Equipment Leaks which specify that if a valve or connector cannot be repaired within 15 days, ''low leak technology'' must be used to repair the equipment when it is technically feasible to do so. ''Low leak technology'' that is available and cost effective includes replacing the valve packing, flange gaskets or the entire valve or connector. These requirements provide additional emissions reductions and could be referenced by future rulemakings as a means to meet applicable CAA requirements. The proposed Uniform Standards for Control Devices include strengthened provisions that require owners and operators of closed vent systems to provide monitoring for each bypass for pressure relief devices (PRD), low leg drains, high point bleeds, analyzer vents and open-ended valves or lines. We are proposing that this equipment is subject to the bypass line requirements to have a flow monitor or a car seal on each bypass line that could divert a vent stream to the atmosphere, thereby minimizing emissions from these points. The proposed requirements under 40 CFR part 65, subparts I, J and M have been designed to reflect advanced practices and control methods and provide robust air emissions control. This allows us to consider these proposed standards as a basis for review in future rulemakings for source categories with similar emission points. Further discussion of these provisions and other strengthened requirements under the Uniform Standards are included in the discussions for each individual subpart in sections III, IV and V of this preamble.

The proposed Uniform Standards also provide the benefits of improved compliance and enforceability. We are proposing to facilitate implementation and compliance by clarifying current requirements that were vague or confusing. For example, current equipment leak rules require facilities to equip open-ended valves or lines with a cap, blind flange, plug or second valve to prevent emissions. We have retained that requirement in the proposed Uniform Standards for Equipment Leaks, but we have added a requirement to check that the cap, blind flange, plug or second valve is installed or closed properly using Method 21 of 40 CFR part 60, appendix A–7 at least once a year to ensure compliance with the standard. The EPA is also proposing to clarify requirements in the Uniform Standards that were confusing during implementation of previous rules, such as the monitoring requirements for small boilers and process heaters that are not part of a fuel gas system (see discussion in section V.B.3 of this preamble). As another example, the proposed Uniform Standards for Equipment Leaks include all the types of equipment for which sensory monitoring is required in one section, which makes clear that the sensory monitoring requirements for all applicable types of equipment are identical. In other current standards, these requirements are spread throughout the rule, and slight differences in wording make it difficult to tell if the requirements are supposed to be the same. These clarifications are intended to improve compliance and enforceability as the Uniform Standards are considered during CAA 111 and 112 rulemakings and incorporated into future referencing subparts. Further clarifications are discussed in the individual subparts in sections III, IV and V of this preamble.

The proposed Uniform Standards also provide benefits as they reduce unproductive burden within the chemical and refining sectors. For example, the proposed Uniform Standards for Equipment Leaks include provisions to use optical imaging to monitor for leaks (where appropriate and allowed by the referencing subpart) instead of instrument monitoring. Because the optical gas imaging device can monitor many more pieces of equipment than conducting instrument monitoring in the same period of time, these provisions are expected to reduce the cost of labor required to meet the proposed Uniform Standards for Equipment Leaks. In particular, we have focused on simplifying recordkeeping and reporting requirements throughout each proposed subpart. For example, under the proposed General Provisions, we have specified that certain reports that are required to be submitted will be done so electronically, as discussed in sections II.F and VI.B.7 of this preamble. We are also proposing a revised record retention policy that allows that records can be maintained in electronic format and accessible within 2 hours of a request for the 5-year record retention period. We have not included different retention periods for onsite and offsite records because the ability to maintain electronic records removes the need for specifying the storage location. An electronic record can be stored either onsite or offsite, but still be quickly accessible from onsite.

Furthermore, we have developed the proposed Uniform Standards in keeping with the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review,* issued January 18, 2011. Consistent with Executive Order 13563, the proposed standards are based on a thorough review of current regulations and reduce regulatory burden by consolidating and simplifying requirements, including eliminating duplicative requirements. These proposed standards further facilitate implementation and compliance by clarifying and improving current requirements, using new and streamlined compliance approaches and applying these approaches broadly. The proposed Uniform Standards also implement cost-effective control strategies without compromising environmental protection, and have

taken into consideration the latest control techniques. Finally, these standards provide a flexible, streamlined process for future rulemakings that will reduce burden and increase efficiency for both government regulators and industry.

E. How were the proposed Uniform Standards developed?

In keeping with previous emission point-specific and emissions control-specific subparts, we have structured the proposed Uniform Standards for 40 CFR part 65, subparts H, I, J and M to provide a common set of monitoring, testing, recordkeeping and reporting requirements. We intend the proposed Uniform Standards to provide common standards for environmental control that may be referenced from multiple regulations and that may be useful for a broad range of source categories. It is our view that the Uniform Standards will decrease inconsistencies between rulemakings for similar types of industries and reduce burden for both industry and government regulators.

In keeping with the requirements of Executive Order 13563, *Improving Regulation and Regulatory Review,* we reviewed the current Generic MACT standards of 40 CFR part 63, subparts SS, TT, UU, and WW; the MON (68 FR 63888, November 10, 2003); the HON (59 FR 19402, April 22, 1994); and other recent rules in the development of the proposed Uniform Standards. The Generic MACT standards of 40 CFR part 63, subparts SS, TT, UU, and WW were chosen as a starting point for the Uniform Standards because they were previously developed for the purpose of providing consistent requirements for storage vessels and transfer operations, equipment leaks and control devices used to control process vents that could be referenced by multiple NESHAP subparts, and they already incorporate technical improvements based on the EPA's experience with implementation of other subparts, such as the National Emission Standards for Petroleum Refineries (40 CFR part 60, subpart CC) and the HON. We augment these provisions in the proposed Uniform Standards by adding requirements from recent rulemakings, clarifying unclear requirements and incorporating alternative technologies and compliance approaches. As part of this process, we have investigated current practices and advances in technology and examined the cost effectiveness of applying certain technologies for control. Additionally, we reviewed the applicability determination index database, test reports, title V permit requirements, Office of Enforcement and Compliance Assurance experience and recent EPA decisions to identify cost-effective technological, monitoring and compliance approaches that would reduce burden across source categories. In this proposal, we are referring to the existing flare requirements in 40 CFR 63.11(b) of subpart A for flare compliance and are not proposing new flare requirements. We are continuing to gather data, review flare research papers and test reports, and investigate operating conditions that may influence the performance of a flare. Based on this information, we may in the future propose to add new flare requirements to the Uniform Standards.

As discussed in section II.B of this preamble, we expect that applying a common set of monitoring, testing and recordkeeping and reporting requirements to multiple source categories would be feasible because several source categories within the chemical and refining industries use similar process operations and have similar emission points. Specifically, various industries require the regulation of air emissions from storage vessel and transfer operations, equipment leaks and control devices. Although these industries may have variations in their process operations and the regulated materials used, these emission sources are generally amenable to similar methods for control and demonstration of compliance.

Our review of current regulations for storage vessel and transfer operations, equipment leaks and process vents found that these emission points often have similar requirements for the demonstration of compliance. In general, the mechanisms for release of emissions to the atmosphere from these emission points or emissions controls are similar, regardless of the specific regulated materials involved. With the knowledge of these similarities, we expect that compliance methods that have been determined to be cost effective for control of a specific amount of a given regulated material at one of the proposed emission points would generally be cost effective for the same regulated material at similar emission points, regardless of the source category. Specifically, the compliance methods proposed with the Uniform Standards have been developed with the consideration that they may be applied to emission points in a broad range of source categories. Although we considered how the proposed requirements would apply to petroleum refineries and chemical plants, we have structured the Uniform Standards to provide flexible compliance methods that could be useful for multiple industries. In determining the best and most cost-effective compliance methods, monitoring, and recordkeeping and reporting requirements for the proposed standards, we examined and drew guidance from current rules from many different source categories that contain storage vessel, transfer operations, equipment leaks, process vents, and a variety of control devices. These guiding rules are discussed further in sections III, IV and V of this preamble. While the current rules provide requirements for individual source categories with slight variations for the specific regulated materials and process methods used in the regulated industry, we propose that the Uniform Standards, which would consolidate consistent, cost-effective requirements from a wide range of compliance methods for the same emission points, could be easily and effectively applied to additional industries.

Because the proposed Uniform Standards are intended to supply general requirements for source category-specific subparts, we expect that as current NSPS and NESHAP are periodically reviewed for technology advancements, they may refer to the Uniform Standards for compliance monitoring, recordkeeping and reporting provisions. Review of both NSPS and NESHAP under the CAA authorizes us to consider the cost impacts of control. Therefore, in reviewing the current requirements for these emission points across source categories, we examined the cost effectiveness of the compliance methods. For example, we have considered the cost effectiveness of control methods for equipment leaks on a volatile organic compound (VOC) basis. The majority of the emissions from equipment leaks are the result of gases or vapors escaping through leaks, either because the process fluid itself is a gas or vapor or because the process fluid is a liquid that volatilizes easily. Therefore, VOC are a class of compounds that are representative of these types of emissions. The proposed Uniform Standards, as a whole, reflect our determination of the best and most cost-effective compliance and control options for the regulated materials generally expected at the proposed emission points.

To account for the differences between individual source categories, the proposed standards generally provide limited technical requirements for monitoring, testing, recordkeeping and reporting for the identified emission points. Overall, we have determined that the regulated materials, applicability requirements, emission

limits or control levels are best determined on a source category basis, as discussed in section II.C in this preamble, to reflect the specific needs of the source category. However, we are proposing applicability thresholds for the Uniform Standards for Storage Tanks (including size and vapor pressure) and control levels for the Uniform Standards for Equipment Leaks (including thresholds at which leaking equipment must be repaired, or ''leak definitions''). These thresholds are provided for consideration in future referencing subpart rulemakings, and would only apply if the referencing subpart does not specify an applicability threshold and/or control level. The referencing subpart may choose to refer to these thresholds in the Uniform Standards or may establish more appropriate thresholds for a specific source-category (overriding the Uniform Standards), as discussed in section II.C.

F. What are the electronic data submittal requirements?

Electronic reporting is becoming an increasingly common element of modern life (as evidenced by electronic banking and income tax filing), and the EPA is beginning to require electronic submittal of certain environmental data. Electronic reporting is already common in environmental data collection and many media offices at the EPA are reducing reporting burden for the regulated community by embracing electronic reporting systems as an alternative to paper-based reporting.

One of the major benefits of reporting electronically is standardization, to the extent possible, of the data reporting formats, which provides more certainty to users of the data required in specific reports. For example, electronic reporting software allows for more efficient data transmittal and the software's validation mechanism helps industry users submit fewer incomplete reports. This alone saves industry and regulatory agencies report processing resources and reduces transaction times. Standardization also allows for development of efficient methods to compile and store much of the documentation required to be reported under this rule.

We are proposing that certain reports required to be submitted through the Uniform Standards would be submitted electronically. These reports would include all performance test reports, continuous emission monitoring system (CEMS) performance evaluation reports, the 40 CFR part 65, subparts I and J portions of the Notification of Compliance Status, and semiannual periodic reports specified in 40 CFR part 65, subparts H, I, J and M. All other reports would be submitted in hard copy or other method mutually agreed to between the source and the delegated authority. We have reasoned that reporting elements that are descriptive and contain a high level of detail would not be easily incorporated into the electronic reporting system at this time. For a discussion of each of these various types of reports, see sections III, IV, V and VI of this preamble.

The availability of electronic reporting for sources subject to the Uniform Standards will provide efficiency, improved services, better accessibility of information and more transparency and accountability. Additionally, submittal of these required reports electronically provides significant benefits for regulatory agencies, industry and the public. The compliance data electronic reporting system is being developed such that once a facility's initial data entry into the system is established and a report is generated, subsequent data submittal would only consist of electronic updates to existing information in the system. Such a system would effectively reduce the burden associated with submittal of data and reports by reducing the time, costs and effort required to submit and update hard copies of documentation. State, local and tribal air pollution control agencies could also benefit from more streamlined and accurate electronic data submitted to them. Electronic reporting would allow for an electronic review process rather than a manual data assessment, making review and evaluation of the source-provided data and calculations easier and more efficient. Electronic reporting would also benefit the public by generating a more transparent review process and increasing the ease and efficiency of data accessibility. Furthermore, electronic reporting would reduce the burden on the regulated community by reducing the effort involved in data collection and reporting activities. With the complete information provided in electronic reports, we anticipate there will be a need for fewer and less substantial data collection requests in conjunction with prospective required residual risk assessments or technology reviews. We anticipate that using electronic reporting for the required reports will result in an overall reduction in reporting costs; specifically, we estimated potential savings in reporting costs for an existing chemical plant to be approximately $6,780 (or a 42-percent cost reduction in hard copy reporting required by existing rules). For further discussion of the economic and cost impacts of electronic reporting, see section VII.D of this preamble.

Another benefit of the proposed electronic data submittal is that these data will greatly improve the overall quality of existing and new emissions factors by supplementing the pool of emissions test data for establishing emissions factors and by ensuring that the factors are more representative of current industry operational procedures. A common complaint heard from industry and regulators is that emission factors are outdated or not representative of a particular source category. With timely receipt and incorporation of data from most performance tests, the EPA would be able to ensure that the updated emission factors become available to represent the most current range of operational practices.

We are proposing that data entry of these electronic reports would be through the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through the EPA's Central Data Exchange (CDX) (*www.epa.gov/cdx*). Data transmitted electronically through CEDRI will be stored in CDX as an official copy of record. Once you have accessed CEDRI, you will select the applicable subpart for the report that you are submitting. You will then select the report type being transmitted, enter the data into the form and click on the submit button. In some cases, such as with submittal of a Notification of Compliance Status Report, you will select the report type, enter basic facility information and then upload the report in a specified file format.

In addition, we believe that there will be utility in allowing other reporting forms to be developed and used in cases where the other reporting forms can provide an alternate electronic file consistent with the EPA's form output format. This approach has been used successfully to provide alternatives for other electronic forms (*e.g.,* income tax transmittal). The proposal to submit performance test data electronically to the EPA would apply only to those performance tests conducted using test methods that will be supported by the electronic reporting tool (ERT) which can be accessed at *http://www.epa.gov/ttn/chief/ert/index.html.* The ERT contains a specific electronic data entry form for most of the commonly used EPA reference methods. A listing of the pollutants and test methods supported by the ERT is available at the ERT Web site listed above. A generic form is also available for test methods that are not specifically supported by ERT and you may submit performance tests with non-

listed test methods using the generic form.

In CEDRI, the user must then upload the ERT file. CEDRI transmits a copy of the ERT project data file directly to WebFIRE, where the data are made available. Where performance test reports are transmitted, WebFIRE notifies the appropriate state, local or tribal agency contact that an ERT project data file was received from the source.

In summary, in addition to supporting regulation development, control strategy development and other air pollution control activities, having an electronic database populated with these reports would save industry, state, local, tribal agencies and the EPA significant time, money and effort while also improving the quality of emission inventories and, as a result, air quality regulations.

III. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Standards for Storage Vessel and Transfer Operations—Subpart I

A. Summary

We are proposing new Uniform Standards for control of emissions from storage vessels and transfer operations. These Uniform Standards would apply to a storage vessel or transfer operation only if that storage vessel or transfer operation is subject to a regulation that references such standards in proposed 40 CFR part 65, subpart I for control of air emissions from these sources. In section III of this preamble, the term ''we'' refers to the EPA and the term ''you'' refers to owners and operators of sources affected by the proposed standards. Additionally, ''subpart I'' refers to proposed 40 CFR part 65, subpart I. Section III.B provides our rationale for the proposed requirements.

1. What parts of my plant are affected by the proposed rule?

Proposed subpart I would apply to atmospheric storage vessels, pressurized vessels and transfer operations for which another subpart references such standards in this subpart for air emission control. Different vessel size and stored material maximum true vapor pressure (MTVP) thresholds are specified for the different control requirements for storage vessels. Different throughputs and transferred material MTVP thresholds are specified for the different control requirements for transfer operations. We are not proposing to specify a compliance timeline in this subpart, since the compliance period would depend upon the proposal and final rule effective dates of the referencing subpart; thus, the compliance timeline for implementing these standards, as specified in the referencing subpart, would apply for that source category.

As in current storage vessel rules, the proposed rule for storage vessels is based on design requirements, inspection requirements and emission standards. Current rules specify the size and vapor pressure thresholds that define which storage vessels must comply with the requirements. Similar thresholds are specified in proposed subpart I. As in current transfer operations rules, the proposed Uniform Standards for transfer operations are based on loading requirements, inspection requirements and emission standards. Current rules specify the size and vapor pressure thresholds that define which transfer operations must comply with the requirements. Similar thresholds are specified in proposed subpart I.

2. What are the proposed general requirements for complying with this subpart?

Your storage vessels and transfer operations would be subject to some or all of the requirements of subpart I when another subpart references the use of such requirements in subpart I for air emission control. In addition, you would be required to meet the general provisions applicable to 40 CFR part 65 (*i.e.,* subpart A of 40 CFR part 65) and the general provisions applicable to the referencing subpart (*i.e.,* subpart A of 40 CFR parts 60, 61 or 63).

Atmospheric storage vessels. Under proposed subpart I, you would be required to control emissions from each atmospheric storage vessel that contains regulated material (and is part of a regulated source subject to a referencing subpart). The type of control would depend on the size of the storage vessel and the MTVP of the stored regulated material. We are proposing four compliance approaches for each storage vessel that meets the capacity and MTVP thresholds presented in Table 1 of this preamble (and Table 1 of proposed subpart I). These approaches are: (1) Operate and maintain either an internal floating roof (IFR) or an external floating roof (EFR), provided the MTVP of the stored regulated material is less than 11.1 pounds per square inch absolute (psia); (2) operate and maintain a vapor balancing system on a fixed roof tank; (3) vent emissions from a fixed roof tank through a closed vent system to a control device according to the requirements in proposed 40 CFR part 65, subpart M; or (4) route emissions from a fixed roof tank to a fuel gas system. For each storage vessel that does not meet either set of thresholds described above, you would be required to operate and maintain a fixed roof (or you may elect to comply with the requirements for larger tanks that store regulated material with higher MTVP). Inspections and repair of defects and leaks would also be required for all storage vessels. Each of the four compliance approaches is discussed in further detail in sections III.A.4 through 7 of this preamble.

TABLE 1—CONTROL THRESHOLDS FOR ATMOSPHERIC STORAGE VESSELS

Comply with	If the storage capacity is	And the MTVP is
Requirements for fixed roof storage vessels in § 65.310	<20,000 gal, or	Any level.
	<40,000 gal, or	<1.9 psia.
	≥40,000 gal	<0.75 psia.
Any one of four compliance approaches specified in §§ 65.315, 65.320, 65.325 or 65.330.	≥20,000 gal, or	≥1.9 psia.
	≥40,000 gal	≥0.75 psia.

Transfer operations. If you own or operate a transfer rack that loads regulated material into transport vehicles (*i.e.,* cargo tanks or tank cars) or containers, you would have to control emissions from the transfer operations as specified in proposed subpart I. The specific control requirements would differ depending on the amount of regulated material transferred and the MTVP of the stored material. Details are discussed in sections III.A.9 and 10 of this preamble. The proposed rule does not specify requirements for loading regulated material into barges, which are currently regulated by the Marine Tank Vessel Loading Operations NESHAP (40 CFR part 63, subpart Y) and would remain so covered.

3. What are the proposed requirements for fixed roof atmospheric storage vessels that are small or store material that has a low vapor pressure?

For fixed roof atmospheric storage vessels that are smaller than 20,000 gallons, smaller than 40,000 gallons and store material with a MTVP less than 1.9 psia or greater than or equal to 40,000 gallons and store material with a MTVP less than 0.75 psia, you would have to meet specified equipment, operating, inspection and repair requirements. The proposed equipment requirements are to: (1) Install the fixed roof in a manner that would avoid creating open spaces between roof section joints or between the interface of the roof edge and the tank wall; and (2) equip each opening in the fixed roof with a closure device that, when secured in the closed position, allows no open spaces in the closure device or between the perimeter of the opening and the closure device. You would be required to operate the fixed roof with each closure device secured in the closed position except during those periods when access is needed. A conservation vent or similar device would be allowed to vent to the atmosphere when diurnal temperature changes or filling of the storage vessel cause pressure in the storage vessel to exceed the design range for the storage vessel (i.e., normal breathing and working emissions).

To demonstrate compliance with the equipment and operating requirements, you would be required to conduct initial and periodic monitoring of the fixed roof and its closure devices for leaks. For parts of the fixed roof that you determine are unsafe to monitor, you would have to develop a written plan in which you document why those parts are unsafe to monitor and that specifies a schedule for monitoring when it is safe to do so.

We are proposing two monitoring options. One option would be to use Method 21 of 40 CFR part 60, appendix A–7. This monitoring would be required annually, and you would detect a leak each time you obtain an instrument reading greater than 500 parts per million by volume (ppmv). The second option would be to use optical gas imaging. This monitoring would be required semiannually, and the instrument would have to be capable of detecting at least one of the compounds emitted from the storage vessel. A leak would be detected each time the instrument detects an image. This option also would reference a protocol for other requirements. We are currently developing the protocol and expect to propose it as appendix K to 40 CFR part 60. Public comment on the content of the proposed protocol will be requested in the **Federal Register** notice for the proposed protocol. In addition, we intend to provide an opportunity to comment on the application of appendix K to 40 CFR part 60 to the optical gas imaging provisions in these Uniform Standards. As discussed in section IV of this preamble, the protocol would also apply to optical gas imaging for equipment leaks. See section IV.A.5 of this preamble for a discussion of the information that we are planning to include in the protocol. Note, however, that the proposed bimonthly monitoring frequency for equipment leaks would not apply to monitoring of fittings on storage vessels.

If leaks are discovered in a storage vessel during an inspection, you have to either complete repairs or completely empty the storage vessel within 45 days, although you would be allowed up to two extensions of up to 30 days each. If you use an extension, you must maintain records that document your use of the extension. These records must indicate that alternative storage capacity was unavailable and list the actions you took in an effort to repair or empty the tank in the allowed period before the extension.

4. What are the proposed requirements to control atmospheric storage vessels with a floating roof (''floating roof approach'')?

If you elect to use a floating roof to control emissions from an atmospheric storage vessel that meets the size and MTVP thresholds for such control, you would have to comply with the proposed equipment, operating, inspection and repair requirements for floating roofs specified in this rule.

The proposed rule includes rim seal equipment requirements that are consistent with current rules. If you use an IFR, you would be required to equip the IFR with a liquid-mounted seal, mechanical shoe seal or two seals mounted one above the other. If you use an EFR, you would have to equip the EFR with a liquid-mounted seal and secondary seal, or with a mechanical shoe seal and secondary seal.

The proposed rule includes design and operation specifications for closure devices and other fittings for each type of opening through the deck of the floating roof. Most of these design and operational requirements for deck fittings are consistent with requirements in current rules. One difference is that the proposed rule explicitly specifies requirements for slotted ladder legs that are comparable to requirements for slotted guidepoles. Another difference is that the proposed rule defines automatic bleeder vents (vacuum breaker vent) to include both devices that are activated by pressure and vacuum differences across the floating roof and devices that are activated when an extension leg contacts the floor of the storage vessel. The proposed rule also includes additional control options for slotted guidepoles that were developed for the Storage Tank Emission Reduction Partnership Program (STERPP) (65 FR 19891, April 13, 2000).

The proposed rule would require that you equip each storage vessel with an alarm system that signals when the floating roof: (1) Is about to land on its legs or other support devices; or (2) is close to being overfilled. Each time the floating roof is landed, you would be required to estimate, record and report the amount of regulated material emitted during the time the roof was landed. Similarly, if the storage vessel is ever overfilled, you would be required to estimate, record and report the amount of regulated material spilled and emitted to the atmosphere.

The proposed rule would require that the floating roof be floating on the liquid surface at all times except for certain instances when the floating roof is being supported on leg supports or other support devices (landed). We are proposing to limit both the total amount of time and the circumstances under which the floating roof may be landed to: (1) During the initial fill; (2) when necessary for maintenance, inspection or to support a change to an incompatible liquid, provided you either begin refilling the storage vessel or begin actions to completely empty the storage vessel within 24 hours; (3) when actions to completely empty the storage vessel begin within 24 hours after the roof is landed in order to take the storage vessel out of service; or (4) if the vapors are routed through a closed vent system to a control device from the time the roof is landed until the roof is within 10 percent by volume of being refloated. Typically, once you begin refilling the storage vessel, you would not be allowed to suspend refilling or withdraw liquid until after the roof is refloated. The requirement for continuous refilling until the roof is refloated would not apply to a storage vessel that is used to store product from a batch process if the quantity of product from one batch is insufficient to refloat the roof, and the roof will be refloated when product from additional batches is added to the storage vessel. However, withdrawal of liquid from the storage vessel would still not be permitted until after the roof is refloated.

The proposed rule would require that you inspect the floating roof deck, deck fittings and rim seals. One option would be to conduct visual inspections, measure gaps in rim seals for an EFR and measure gaps between gaskets and the surfaces they are intended to seal for deck fittings on both IFR and EFR. The proposed rule also specifies that Method 21 of 40 CFR part 60, appendix A–7 may be used as an alternative to the deck fittings gap measurement requirements for either type of floating roof and the rim-seal gap measurements on EFR. Another proposed alternative to the deck fittings gap measurement requirements is optical gas imaging. Requirements for monitoring using optical gas imaging would be the same as discussed in section III.A.3 of this preamble for monitoring of fixed roofs. Monitoring using either optical gas imaging or Method 21 of 40 CFR part 60, appendix A–7 would be required while the floating roof is floating on the stored liquid. The proposed rule lists the conditions that would be considered inspection failure (*i.e.,* stored liquid on the floating roof; holes or tears in the primary or secondary seal; floating roof deck, deck fittings or rim seals that are not functioning as designed; failure to comply with the operational requirements; and excessive gaps).

The proposed rule includes inspection frequency requirements for both IFR and EFR. For IFR, you would have to inspect: (1) Before the initial fill of the storage vessel; (2) at least annually (tank top inspection only); and (3) each time the storage vessel is completely emptied and degassed (but no later than 10 years after the previous such inspection or no later than 5 years for IFR equipped with two rim seals). For EFR, you would have to inspect: (1) The primary and secondary rim seals and deck fittings within 90 days after the initial fill of the storage vessel; (2) the secondary seal, deck fittings and EFR at least annually; and (3) the primary seal no later than 5 years after the previous primary seal gap inspection. Delays in IFR and EFR inspection would be allowed if the storage vessel is out of service on the date 5 or 10 years after the last inspection, as applicable, provided the inspection is conducted prior to filling the storage vessel.

If you determine that it is unsafe to perform the EFR inspections specified in the rule, you would have to either perform the inspections no later than 30 days after making this determination, or remove the storage vessel from service no later than 45 days after making this determination. You may use up to two extensions (up to 30 days each) if the storage vessel cannot be emptied within 45 days, provided you document this decision, explain why it was unsafe to perform the inspection, document that alternative storage capacity is unavailable and provide a schedule of actions taken in an effort to completely empty the storage vessel during the extension period. Not completely emptying the storage vessel before the end of the second extension period would be a deviation.

In the event of an inspection failure, the proposed rule requires repair to correct the failure. In addition, if at times when you are not specifically conducting an inspection as required by the proposed rule, but you notice a condition that constitutes an inspection failure, you would be required to make the necessary repairs just as if the condition had been noted during a scheduled inspection. If you performed the inspection while the storage vessel was not storing liquid, you would have to complete repairs before refilling the storage vessel with liquid. If you performed the inspection while the storage vessel was storing liquid, you would have to complete repairs or remove the vessel from service within 45 days, but you would be allowed up to two extensions (up to 30 days each), as long as you document your decision to use the extension. The documentation would include a description of the failure, documentation that alternative storage capacity is unavailable and a schedule of actions taken in an effort to either repair or completely empty the storage vessel before the end of the applicable extension period. Not repairing or completely emptying the storage vessel before the end of the second extension would be a deviation.

You have the option to request the substitution of an alternate device for any of the seals and fittings specified in the floating roof approach, as long as the alternate device has an emission factor less than or equal to the emission factor for the specified device and the emission factor for the alternate device was determined under tests that accurately simulated the conditions under which the device will operate (*e.g.,* wind speed, temperature, pressure and filling rates).

5. What are the proposed requirements for control of fixed roof atmospheric storage vessels if I use vapor balancing (''vapor balancing approach'')?

If you elect to control emissions from a fixed roof atmospheric storage vessel by using vapor balancing, you would have to comply with the proposed design, operating, monitoring and repair requirements for vapor balancing specified in this rule. You would have to operate, maintain and inspect the fixed roof, and repair leaks as specified in section III.A.3 of this preamble. Unlike current rules, the proposed rule contains no requirements for offsite facilities that clean and/or reload the transport vehicles and barges.

Under the proposed vapor balancing approach, you would have to design and operate the vapor balancing system to route the vapors displaced from storage vessel loading to the transport vehicle used to fill the storage vessel. Each transport vehicle would have to have a current certification of pressure testing conducted in accordance with U.S. Department of Transportation (DOT) requirements, and you would have to keep records of these certifications. Barges would have to be pressure tested annually in accordance with procedures in the proposed rule; these procedures are consistent with requirements in the Marine Tank Vessel Loading Operations NESHAP (40 CFR part 63, subpart Y) and the Benzene Transfer Operations NESHAP (40 CFR part 61, subpart BB). You would be required to maintain copies of documentation showing that the required testing was performed. The fixed roof would have to meet the design and operating requirements described in section III.A.3 of this preamble.

Under the proposed operating requirements, liquid may be unloaded only when the transport vehicle's vapor-collection equipment is connected to the storage vessel's vapor balancing system. Also, no PRD on the storage vessel, transport vehicle or barge may be open during loading, and PRD on the storage vessel would not be allowed to open at any time as a result of diurnal temperature changes (*i.e.,* breathing losses would not be allowed). You would have to set PRD on storage vessels no lower than 2.5 pounds per square inch gauge (psig) in order to prevent breathing losses, unless you provide a rationale for a lower value in your notification of compliance. In addition, you would have to keep records of the pressure relief vent settings that prevent breathing losses from the storage vessel. All vapor connections and lines on the storage vessel would have to be equipped with closures that seal upon disconnect.

Most of the proposed requirements for inspecting, monitoring and repairing equipment in the vapor balancing system and the fixed roof are the same as for closed vent systems as described in section III.A.6 of this preamble. The only difference is that for vapor balancing systems you may elect to

comply with the alternative monitoring frequencies for batch operations in proposed 40 CFR part 65, subpart J if your vapor balancing system operates less than 75 percent of the hours during the year.

6. What are the proposed requirements for control of fixed roof atmospheric storage vessels if I route emissions through a closed vent system to a control device (''closed vent system approach'')?

If you elect to vent emissions from a fixed roof storage vessel through a closed vent system to a control device, you would have to comply with the proposed equipment, operating, inspection and repair requirements specified in this rule for these systems.

If your storage vessel and closed vent system are not in vacuum service, you would have to operate, maintain and inspect the fixed roof, and repair leaks as specified in section III.A.3 of this preamble, except that normal breathing and working emissions would not be allowed to vent to the atmosphere. Monitoring would not be required if the storage vessel and closed vent system are in vacuum service, but you would be required to demonstrate that vacuum is maintained by installing a pressure monitoring device and alarm as specified in proposed 40 CFR part 65, subpart J.

For the closed vent system, you would have to comply with the bypass line requirements specified in proposed 40 CFR part 65, subpart M, and you would be required to comply with requirements for equipment in regulated material service in proposed 40 CFR part 65, subpart J. Either equipment controls (*e.g.,* caps on open ended lines) or leak detection and repair (LDAR) would be required, as specified in 40 CFR 65.420 through 65.427 of proposed subpart J, except that sensory monitoring in 40 CFR 65.428 of proposed subpart J would be allowed for connectors if your referencing subpart does not require instrument monitoring for connectors. Note that the option in proposed subpart J to conduct sensory monitoring for equipment in regulated material service less than 300 hours per year (hr/yr) would not apply to equipment in the closed vent system. The proposed leak detection monitoring methods include either Method 21 of 40 CFR part 60, appendix A–7, or optical gas imaging in accordance with proposed 40 CFR 65.450 (provided your referencing subpart specifies that optical gas imaging is allowed for LDAR). Required monitoring and inspections would have to be conducted either when an affected storage vessel is being filled or at any other time the equipment in the closed vent system is in regulated material service. Any other potential sources of vapor leakage (*e.g.,* an access hatch) that are not defined as equipment would be subject to sensory monitoring and related repair requirements as specified in 40 CFR 65.428 and 65.430 of proposed subpart J.

For a non-flare control device, you would be required to comply with the provisions in proposed 40 CFR part 65, subpart M for the applicable control device and reduce regulated organic material emissions by at least 95 percent by weight or to an outlet concentration of regulated material less than 20 ppmv. To demonstrate initial compliance with this emission limit, proposed subpart I would allow you to conduct a design evaluation as an alternative to the performance test (note that the performance test is the default requirement in proposed subpart M). You would be required to comply with the provisions in 40 CFR 63.11(b) of subpart A for flares used to comply with the referencing subpart.

For those periods when you conduct planned routine maintenance of the control devices for your storage vessels, the proposed rule would require that you add no material to the storage vessel during those periods and limit the periods to a total of no more than 360 hr/yr. If you need more than 240 hr/yr, you would have to keep a record that explains why the extension was needed and describes how you minimized the amount of time beyond 240 hours. In addition, you would need to keep records of when the planned routine maintenance periods begin and end and the type of maintenance performed.

7. What are the proposed requirements for control of fixed roof atmospheric storage vessels if I route emissions to a fuel gas system (''fuel gas system approach'')?

If you elect to control storage vessel emissions by routing displaced vapor to a fuel gas system, you would be required to comply with the requirements for fuel gas systems, as specified in proposed 40 CFR part 65, subpart M. Specifically, you would be required to: (1) Submit a statement in your Notification of Compliance Status that the emission stream is connected to the fuel gas system; (2) meet the requirements for equipment in regulated material service in proposed 40 CFR part 65, subpart J for all equipment in the fuel gas system; (3) comply with proposed 40 CFR 65.724 for any small boilers or process heaters in the fuel gas system; and (4) not route halogenated streams to the fuel gas system. In addition, you would be required to operate, maintain and inspect the fixed roof, and repair leaks as specified in section III.A.3 of this preamble. The proposed procedures for inspecting or monitoring the equipment also are the same as for equipment in a closed vent system as described in section III.A.6 of this preamble.

8. What are the proposed requirements for pressure vessels?

The proposed rule defines a pressure vessel as a storage vessel that is designed not to vent to the atmosphere as a result of compression of the vapor headspace in the vessel during filling of the vessel to its design capacity. The proposed rule would require all openings in a pressure vessel to be equipped with closure devices. In addition, you would be required to conduct annual performance tests using either Method 21 of 40 CFR part 60, appendix A–7, or optical gas imaging to show pressure vessels operate with an instrument reading less than 500 ppmv (for Method 21 of 40 CFR part 60, appendix A–7) or no emissions are imaged by the instrument (for optical gas imaging). Each time you obtain an instrument reading equal to or greater than 500 ppmv (for Method 21 of 40 CFR part 60, appendix A–7) or emissions are imaged (for optical gas imaging), it would be a deviation of the emission limit, and you would be required to estimate, record and report the amount of regulated material emissions during the time the pressure vessel is out of compliance with the emission limit.

The proposed rule would require that all purge streams be routed through a closed vent system to a control device that reduces regulated material emissions by at least 98 percent or to an outlet concentration less than 20 ppmv. Inert material purging is a short duration maintenance procedure required by good engineering practice to ensure proper operation of this type of storage system. The closed vent system would be subject to the same bypass line requirements and monitoring and inspection requirements as for a closed vent system that conveys emissions from an atmospheric storage vessel to a control device; see section III.A.6 of this preamble for details. The proposed compliance requirements for a control device would be the same as for a control device that controls emissions from an atmospheric storage vessel; see section III.A.6 of this preamble for details.

9. What are the proposed requirements for control of transfer operations to load transport vehicles?

For each transfer rack that you use to load transport vehicles, you would be required to transfer the regulated material to the transport vehicles using submerged loading or bottom loading.

In addition, you would be required to control displacement emissions of regulated materials from the transport vehicles if you transfer more than 35 million gallons per year (gal/yr) of liquids with a weighted average MTVP greater than 4 psia. The proposed rule includes three compliance approaches for these emissions. One approach is to route the displaced emissions from the transport vehicle through a closed vent system to any combination of control devices. In this case, the proposed requirements are the same as those proposed for closed vent systems and control devices used to control emissions from storage vessels; see section III.A.6 of this preamble for details.

A second approach is to route the displaced emissions from the transport vehicle to a fuel gas system. Again, the proposed requirements are the same as the proposed requirements for storage vessels that are controlled by routing emissions to a fuel gas system.

The third approach is to design and operate a vapor balancing system to route vapors that are displaced from loading regulated liquids into transport vehicles back to the storage vessel or to another storage vessel that is connected to a common header. The proposed vapor balancing approach includes the following requirements: (1) Designing the vapor balancing system to prevent any regulated material vapors collected at one transfer rack from passing to another transfer rack; (2) equipping all vapor connections and lines in the vapor-collection equipment and vapor balancing system with closures that seal upon disconnect; (3) ensuring PRD in the system do not open while the transport vehicle is being filled with regulated material; (4) conducting the same LDAR procedures for equipment in the vapor balancing system as for equipment in a closed vent system; and (5) complying with the same bypass line requirements as in the proposed requirements for closed vent systems. You would not be allowed to use the vapor balancing approach if the applicable storage vessel has a floating roof.

Each transport vehicle that you load with regulated material that has a MTVP of regulated material greater than 4 psia would be required to pass an annual vapor tightness test conducted using Method 27 of 40 CFR part 60, appendix A–8. All other transport vehicles that you load with regulated material must either pass an annual vapor tightness test conducted using Method 27 of 40 CFR part 60, appendix A–8 or have a current certification in accordance with DOT pressure test requirements for cargo tanks or tank cars. You would be required to keep records of the DOT certifications and tests conducted using Method 27 of 40 CFR part 60, appendix A–8. You also would be required to take actions to assure that your vapor balancing system, closed vent system or fuel gas system is connected to the transport vehicle's vapor-collection equipment during each transfer of regulated material to transport vehicles.

10. What are the proposed requirements for control of transfer operations to load containers?

For each transfer of regulated material to a container at a transfer rack that loads only containers, you would be required, at a minimum, to use either submerged fill or fitted opening/transfer line purging. Whenever a container contains a regulated material, you would also be required to install and secure all covers and closure devices in the closed position, except when you need to access the container (e.g., for adding or removing material, sampling or cleaning). You would also be required to demonstrate annually that containers, 55 gallons and larger, that are loaded and then used for onsite storage are vapor tight by using one of two approaches. One approach is to use Method 27 of 40 CFR part 60, appendix A–8, under the same test conditions specified for testing transport vehicles, and the second approach is to monitor each potential leak interface on the container for leaks using Method 21 of 40 CFR part 60, appendix A–7. When monitoring using Method 21 of 40 CFR part 60, appendix A–7, an instrument reading greater than 500 ppmv would constitute a leak that you would be required to repair within 15 days.

We are proposing three more effective compliance approaches that you may elect to comply with as an alternative to conducting submerged filling. The first approach is to route emissions through a closed vent system to a control device in accordance with the same requirements that apply to closed vent systems and control devices that are used to control emissions from transfers to transport vehicles. The second approach is to design and operate a vapor balancing system that routes displaced vapors back to the storage vessel from which the transferred liquid originated. The requirements would be the same as for the vapor balancing approach for controlling emissions from transfers to transport vehicles. For example, vapor connection and lines in the vapor-collection equipment and vapor balancing system would have to be equipped with closures that seal upon disconnect. Any PRD on the container would have to remain closed while the container is being filled, and you would be required to comply with the same bypass line requirements and LDAR requirements for equipment in the vapor balancing system that are being proposed for closed vent systems. The third approach is to conduct the transfer operations inside a permanent total enclosure (meeting the criteria specified in 40 CFR 52.741, appendix B) that is vented through a closed vent system to a control device. The requirements for the closed vent system and control device would be the same as in the first approach described above.

11. What are the proposed recordkeeping and reporting requirements?

Recordkeeping. Proposed subpart I would require records related to both storage vessels and transfer operations. For each storage vessel that contains a regulated material, you would be required to record the vessel dimensions, storage capacity and type of stored material. In addition, proposed subpart I would require records related to each type of storage vessel and each compliance approach. Many of these records would require documentation of the dates and results of inspections (for fixed roofs, floating roofs, closed vent systems, fuel gas systems and vapor balancing systems), including descriptions of repairs or actions taken to remedy leaks or inspection failures.

Other records related to storage vessels would require documentation of: (1) The start and end dates of floating roof landing events and the procedure used to refloat the roof; (2) decisions to use extensions for inspections and repair/removal from service; (3) dates of each overfill event; (4) DOT certifications of vapor tightness tests for transport vehicles used to comply with the vapor balancing approach; (5) vapor tightness test results for barges used to comply with the vapor balancing approach; (6) date and time when periods of planned routine maintenance of a control device begin and end; and (7) identification of each potential source of vapor leakage in a closed vent system that is not defined as a piece of ''equipment.'' If you comply with closed vent system and control device requirements or fuel gas system

requirements specified in proposed 40 CFR part 65, subpart M, you would also be required to keep applicable records as specified in proposed subpart M. Similarly, if you comply with equipment monitoring requirements for a closed vent system or fuel gas system, or if you operate a closed vent system in vacuum service, you would be required to keep records that are related to these provisions, as specified in proposed 40 CFR part 65, subpart J. If you comply with the vapor balancing approach, you would be required to keep a record of the setting on the PRD that prevents breathing losses from the storage vessel. You would also be required to keep records of your estimates of emissions from: (1) Each spill caused by overfilling a storage vessel; (2) a storage vessel while the floating roof is landed; and (3) a pressure vessel that does not comply with the required emission limit.

For transfer operations, you would be required to keep records of vapor tightness tests of transport vehicles that are loaded with liquid that has a regulated material vapor pressure greater than 4 psia and DOT certifications of vapor tightness tests for other transport vehicles that are loaded with regulated material. If you comply with the approach to route emissions through a closed vent system to a control device or the fuel gas system approach, you would be required to keep records of monitoring, inspections and leak repairs, as specified in proposed 40 CFR part 65, subpart J, and you would be required to comply with the recordkeeping requirements specified in proposed 40 CFR part 65, subpart M, for the applicable control device. If you comply with the approach to load containers inside an enclosure, you would be required to keep records of the most recent calculations and measurements performed to verify that the enclosure meets the criteria of a permanent total enclosure, as specified in 40 CFR 52.741, appendix B.

Notification of Compliance Status. In the Notification of Compliance Status required by the referencing subpart and proposed 40 CFR part 65, subpart H, you would be required to include the identification of each storage vessel, its storage capacity and the liquid stored in the storage vessel. You would also be required to include identification of each transfer rack that loads regulated material into transport vehicles or containers. In addition, if you comply with the vapor balancing approach for a storage vessel (*i.e.,* proposed 40 CFR 65.320), and any PRD on that storage vessel is set to relieve at less than 2.5 psig, you would be required to provide rationale for why that setting is sufficient to prevent breathing losses from the storage vessel. Finally, if you comply with any provisions in 40 CFR part 65, subpart J or 40 CFR part 65, subpart M of the Uniform Standards, you must comply with any notification requirements related to those provisions that are specified in subpart J or subpart M.

Semiannual periodic report. Semiannual periodic reports must include: (1) Documentation of the date when a storage vessel was emptied or repaired if the action was not conducted before the end of a second extension period, as required in proposed 40 CFR 65.310(d) or 65.315(d); (2) storage vessel identification and the start and end dates of each floating roof landing that does not meet one of the criteria in proposed 40 CFR 65.315(b)(1); (3) a copy of the inspection report for a pressure vessel when you obtain an instrument reading greater than 500 ppmv when using Method 21 of 40 CFR part 60, appendix A–7, or an image of emissions when monitoring using optical gas imaging; and (4) any information required in semiannual periodic reports by proposed 40 CFR part 65, subpart J or proposed 40 CFR part 65, subpart M related to provisions in those subparts with which you comply.

Annual periodic reports. Annual periodic reports required by the referencing subpart must include the following information: (1) Inspection results for fixed and floating roofs when a failure or leak is detected; (2) estimated emissions each time a floating roof is landed; (3) estimated emissions each time a storage vessel is overfilled; (4) estimated emissions each time a pressure vessel fails a performance test; and (5) any information required in annual periodic reports by proposed 40 CFR part 65, subpart J or proposed 40 CFR part 65, subpart M related to provisions in those subparts with which you comply.

Other reports. We are proposing that you notify the Administrator at least 30 days prior to each planned inspection of rim seals and deck fittings in storage vessels. If an inspection is unplanned and you could not have known about the inspection 30 days in advance, then you would be required to notify the Administrator at least 7 days before the inspection. A delegated state or local agency may waive the requirement for notification of inspections.

B. Rationale

We developed the proposed requirements in subpart I based on a review of requirements in current federal and state rules, a survey of technology for controlling and monitoring emissions from storage vessels and transfer operations and an analysis of the cost impacts of various compliance approaches.

The rules listed in Table 2 of this preamble include many provisions that we have developed as the most effective provisions for controlling emissions from storage vessels and transfer operations. These provisions form the backbone of proposed subpart I. In addition, the Generic MACT subparts were already organized to be referenced from source category-specific subparts. One difference between the Generic MACT rules and the proposed rule is how the storage vessel and transfer rack operating condition thresholds for a particular control requirement are specified. The Generic MACT relies on the referencing subpart to specify the range of characteristics that a storage vessel or transfer rack must possess to be subject to a particular control requirement. Conversely, proposed subpart I specifies both the thresholds and control requirements that would apply to storage vessels and transfer racks at any facility that is subject to a referencing subpart that incorporates those Uniform Standards provisions. If, while developing a referencing subpart, we identify a reason to select a different threshold for that source category (such as a difference driven by a prior MACT, AMOS or BSER decision for that subcategory), we would specify that threshold in the referencing subpart and indicate it applies in place of the threshold specified in proposed subpart I. The proposed subpart I thresholds and corresponding control requirements were determined based on the survey of technology and the cost impacts analysis; typically, the proposed requirements represent the best level of emission reduction for which we determined the costs are reasonable for model storage vessels and transfer racks.

Another overarching difference between proposed subpart I and the Generic MACT subparts is that proposed subpart I was organized to be consistent with the ''plain language'' format that we have adopted since the Generic MACT rules were promulgated. The following sections describe the rationale for the proposed provisions in subpart I.

TABLE 2—RULES USED TO DEVELOP REQUIREMENTS IN PROPOSED SUBPART I

Provisions in proposed subpart I	Current rule used as starting point for the proposed provisions
Floating roofs	National Emission Standards for Storage Vessels (Tanks)—Control Level 2 (40 CFR part 63, subpart WW; ''Generic MACT for Tanks Level 2'')
Fixed roofs	National Emission Standards for Tanks—Level 1 (40 CFR part 63, subpart OO; ''Generic MACT for Tanks Level 1'')
Vapor balancing	National Emission Standards for Hazardous Air Pollutants: Miscellaneous Organic Chemical Manufacturing (40 CFR part 63, subpart FFFF; ''MON'')
Pressure vessels	National Emission Standards for Hazardous Air Pollutants from Off-Site Waste and Recovery Operations (40 CFR part 63, subpart DD)
Transfer to transport vehicles	National Emission Standards for Hazardous Air Pollutants: Organic Liquids Distribution (Non-Gasoline) (40 CFR part 63, subpart EEEE; ''OLD NESHAP'')
Transfer to containers	National Emission Standards for Containers (40 CFR part 63, subpart PP; ''Generic MACT for Containers'')

1. How is the EPA proposing to define the term ''storage vessel?''

We are proposing a definition of ''storage vessel'' that is generally consistent with the definition in the Generic MACT for Tanks Level 2, in that it means ''a stationary unit that [* * *] is designed to hold an accumulation of liquids or other materials.'' The definition also contains many of the same elements as definitions in many rules in 40 CFR part 63. For example, the proposed definition excludes vessels permanently attached to a motor vehicle, vessels containing regulated material only as impurities and wastewater tanks. Differences between the proposed definition and the definition in the Generic MACT for Tanks Level 2 and most other rules in 40 CFR part 63 are that the proposed definition specifically excludes process tanks, and it does not exclude pressure vessels. We excluded process tanks from the proposed definition because such vessels are in operation only when the process is operating, and they generally operate at process temperatures without the potential for significant emissions due to diurnal temperature changes. As a result, their emissions are more like other process vent emissions than storage tank emissions. We are proposing to include pressure vessels as a subset of storage vessels because we are proposing requirements for pressure vessels that differ from the requirements for atmospheric storage vessels. Proposed 40 CFR part 65, subpart H also defines both ''pressure vessel'' and ''atmospheric storage vessel.''

We request comment on the clarity of this definition and the effect it would have if it were to apply in place of the current definitions in rules that could someday reference proposed subpart I for storage vessel requirements. In particular, we are interested in identification of any types of materials stored that could become subject to a rule that are not currently subject under a current rule's definition.

2. How did the EPA determine the applicability thresholds and control approaches for atmospheric storage vessels?

As discussed in section III.A.2 of this preamble, any one of four specified compliance approaches would be required to control emissions from each atmospheric storage vessel that exceeds any pair of tank capacity and regulated material MTVP thresholds in Table 1 of proposed subpart I. Emissions from all other storage vessels that contain regulated material would have to be controlled using either any of these same four approaches or by equipping the storage vessel with a fixed roof that meets specified design and operation criteria.

As part of our survey of technology, we estimated impacts for several control options for typical fixed roof storage vessels and EFR storage vessels. One purpose of the analysis was to determine applicable thresholds above which the costs for each control option are reasonable. Consistent with requirements in current rules, the thresholds we examined were the vessel size and the vapor pressure of the stored material.

All of the control options that we evaluated involved variations in the requirements for floating roofs or changes to the storage vessel. We focused on floating roof controls because these are the most common controls currently in use, and the only feasible options for baseline EFR storage vessels. We did not estimate costs for the other compliance approaches for fixed roof storage vessels for various reasons. We did not estimate the costs to connect fixed roof storage vessels to a closed vent system and control device because these costs have been shown in previous analyses to exceed the costs of floating roofs (*e.g.,* see EPA–450/3–81–003a, EPA–450/3–80–025 or the memorandum titled *MACT Floor, Regulatory Alternatives, and Nationwide Impacts for Storage Tanks at Miscellaneous Organic Chemical Manufacturing Facilities,* in item II–B–28 in docket A–96–04). Many atmospheric fixed roof storage vessels are designed to operate at pressure much lower than the 2.5 psig set pressure for PRD that is required in vapor balancing options. Therefore, we did not estimate costs for vapor balancing because this approach is technically feasible for only a subset of atmospheric storage vessels. We did not estimate costs for routing storage vessel emissions to a fuel gas system because this option would not be available at some facilities. Furthermore, the performance of these other control techniques is expected to be the same or only marginally superior to the performance of IFR, particularly for larger storage vessels and storage vessels storing material with higher vapor pressures.

In the impacts analysis for fixed roof storage vessels, Control Option ST1 was installation of a typical IFR with typical rim seals and deck fittings, except that we varied the type of guide pole (none, solid and slotted). We assumed typical IFR are constructed from bolted aluminum panels, that the deck floats on pontoons and that the rim seal is a mechanical shoe seal. Based on information in AP–42 chapter 7, we assumed that even without a regulatory driver, roof legs, sample wells, stub drains and vacuum breakers typically are controlled in a manner consistent with the requirements in current rules such as 40 CFR part 63, subpart WW. Control Option ST2 was to upgrade other fittings, as necessary, with gasketed covers, wipers and other features needed to meet requirements in current rules such as subpart WW. Additional controls were applied under control Option ST2 only for column wells, ladder wells, guidepoles,

automatic gauge float wells and access hatches. Current rules allow a variety of control options for slotted guidepoles. In this analysis, we assumed for Option ST2 that controlled slotted guidepoles in IFR storage vessels are equipped with a gasketed cover, pole sleeve and pole wiper. Note that Control Option ST2 is also a control option for a storage vessel that is currently equipped with a typical IFR.

We assumed the baseline EFR storage vessel is equipped with a single rim seal (mechanical shoe) and typical fittings, except that we varied the type of guide pole (either solid or slotted). For such vessels, Control Option ST3 was to install a secondary rim seal, which we assumed would be rim-mounted. Control Option ST4 was to upgrade fittings, like in Control Option ST2 for fixed roof storage vessels. In this case, additional controls were applied under Control Option ST4 only for guidepoles and automatic gauge float wells because other fittings typically would be controlled to current regulatory levels in the absence of a regulatory driver. For this analysis we assumed that controlled slotted guidepoles in EFR storage vessels are equipped with gasketed covers and flexible enclosures. Proposed subpart I would allow a variety of compliance approaches for slotted guidepoles; we elected to evaluate a flexible enclosure in the impacts analysis because it shows a net cost savings even for the most costly approach. Control Option ST5 was to install a dome over storage vessels that meet the Control Option ST4 requirements.

We estimated baseline and controlled emissions using the AP–42 procedures. Inputs for the analysis included meteorological conditions for Houston, Texas, and typical throughputs obtained from a survey of the chemical manufacturing industry (see EPA–450/3–80–025). Costs were obtained from vendors. Table 3 of this preamble summarizes the cost- effectiveness estimates of the two control options for three sizes of model fixed roof storage vessels storing materials with a range of vapor pressures. Table 4 of this preamble shows the cost-effectiveness estimates of the three control options for model EFR storage vessels. Table 4 of this preamble also shows that the cost of Control Option ST5 (adding a dome over an EFR storage vessel that is already complying with Control Options ST3 and ST4) are unreasonable for all model vessels in the analysis; therefore, we rejected this control option from further consideration. Although we evaluated a variety of guide pole scenarios, as discussed above, the results in Table 3 of this preamble are for model storage vessels with a solid guide pole, and the results in Table 4 of this preamble are for model storage vessels with a slotted guide pole; the results for the other guide pole scenarios were not significantly different, and they would not lead to different conclusions. See the memorandum titled *Survey of Control Technology for Storage Vessels and Analysis of Impacts for Storage Vessel Control Options,* in the docket for proposed subpart I for a more detailed discussion of how these impacts were developed.

TABLE 3—ESTIMATED COST EFFECTIVENESS OF CONTROL OPTIONS ST1 AND ST2 FOR MODEL FIXED ROOF STORAGE VESSELS

Model storage vessel size (gal)	Cost effectiveness[a] ($/ton)			
	Vapor pressure at 25 degrees Celsius (psia)			
	0.5	0.75	1.9	3.0
Control Option ST1				
20,000	16,300	8,800	2,100	1,100
40,000	6,300	3,300	1,300	730
200,000	1,100	600	140	70
Control Option ST2				
20,000	18,900	12,000	4,200	2,500
40,000	17,900	11,800	4,600	2,900
200,000	19,000	12,000	4,200	2,500

[a] The cost-effectiveness values for Control Option ST2 are incremental relative to Control Option ST1.

TABLE 4—ESTIMATED COST EFFECTIVENESS OF CONTROL OPTIONS ST3, ST4 AND ST5 FOR MODEL EFR STORAGE VESSELS

Model storage vessel size (gal)	Cost effectiveness ($/ton)[a]			
	Vapor pressure at 25 degrees Celsius (psia)			
	0.5	0.75	1.9	3.0
Control Option ST3				
20,000	13,500	9,200	3,800	2,500
40,000	13,000	8,600	3,300	2,100
200,000	10,500	6,800	2,600	1,600
Control Option ST4				
20,000	(450)	(580)	(760)	(800)
40,000	(360)	(510)	(720)	(780)
200,000	(5)	(260)	(610)	(700)

TABLE 4—ESTIMATED COST EFFECTIVENESS OF CONTROL OPTIONS ST3, ST4 AND ST5 FOR MODEL EFR STORAGE VESSELS—Continued

Model storage vessel size (gal)	Cost effectiveness ($/ton) [a]			
	Vapor pressure at 25 degrees Celsius (psia)			
	0.5	0.75	1.9	3.0
Control Option ST5				
20,000	100,000	71,000	32,000	21,000
40,000	110,000	74,000	31,000	20,000
200,000	120,000	78,000	33,000	21,000

[a] The cost-effectiveness values for Control Option ST4 are incremental relative to Control Option ST3, and the cost-effectiveness values for Control Option ST5 are incremental relative to Control Option ST4.

Current rules specify requirements comparable to the combined requirements in Control Options ST1, ST2, ST3 and ST4 for atmospheric storage vessels, but the size and vapor pressure thresholds in the rules vary. For comparison purposes, the HON requires control of emissions from storage vessels with a capacity of at least 40,000 gallons that store material with a vapor pressure of at least 0.75 psia, and storage vessels with a capacity of at least 20,000 gallons that store material with a vapor pressure of at least 1.9 psia. Tables 3 and 4 of this preamble show the incremental cost impacts for storage vessels at these thresholds range from a cost savings for Control Option ST4 to $12,000/ton for storage vessels storing material with a vapor pressure of 0.75 psia under Control Option ST2.

Although cost effectiveness is an important consideration in establishing thresholds for proposed subpart I, we also considered the practicality of setting thresholds less stringent than the thresholds in the HON and other current rules. This would be impractical because, when those rules are amended to reference the Uniform Standards, they would have to override such thresholds in order to satisfy statutory MACT, AMOS and other regulatory requirements. Therefore, we have decided to propose the thresholds that are used in the HON (see Table 1 of this preamble). These thresholds are widely applicable because many current rules reference the HON, and we think they represent the best choice as defaults for the Uniform Standards. We request comment on this decision.

For most chemical manufacturing facilities, the costs to comply with the combined requirements of Control Options ST1, ST2, ST3 and ST4 for atmospheric storage vessels above the proposed thresholds are expected to be zero or minimal because they are already subject to current rules that have the same or similar thresholds and control requirements. However, many storage vessels at petroleum refineries are subject to 40 CFR part 63, subpart CC, which does not require control of deck fittings (*i.e.,* Control Options ST2 and ST4). Based on information provided by petroleum refiners in response to an information request, we determined that nationwide there are approximately 2,400 storage vessels with an EFR and 1,400 storage vessels with an IFR that meet or exceed the proposed thresholds in Table 1 of this preamble and about 60 percent of these storage vessels have slotted guidepoles (see the petroleum refinery database in Docket ID No. EPA–HQ–OAR–2010–0682). About 50 percent of the IFR storage vessels that have slotted guidepoles are controlled, and about two-thirds of the EFR storage vessels that have slotted guidepoles are controlled. We assumed all of the other fittings have typical controls (*i.e.,* consistent with Control Options ST1 and ST3). We also assumed each EFR is equipped with two rim seals, as required in 40 CFR part 63, subpart CC, and in Control Option ST3. To estimate current annual emissions, we first represented each storage vessel with one of four model sizes. Each model storage vessel also was assigned one of four model liquids, depending on the reported vapor pressure of the actual stored liquid. Storage vessels containing liquids with the lowest vapor pressures were represented with methyl ethyl ketone. The other storage vessels were organized into three groups, each of which was represented with a different grade of gasoline.

We estimated the current and controlled emissions for each model-refinery storage vessel using the AP–42 procedures and other assumptions, as described above in the discussion of the analysis to establish thresholds for control. We estimated costs to upgrade fittings for each storage vessel using the same information that we used in the analysis to establish thresholds for control. We also applied a product recovery credit of $500/ton of VOC to the prevented emissions. The emission reductions associated with upgrading the deck fittings on EFR storage vessels, particularly slotted guidepoles, resulted in a product recovery credit that exceeded the estimate of all costs associated with Control Options ST2 and ST4. Thus, the nationwide impacts of the control options for petroleum refineries is a cost savings of about $350/ton of VOC controlled. See the memorandum titled *Survey of Control Technology for Storage Vessels Analysis of Impacts for Storage Vessel Control Options,* in the docket for proposed subpart I for additional discussion of how these impacts were developed.

3. How did the EPA determine the control and compliance requirements for fixed roof atmospheric storage vessels?

All atmospheric storage vessels below the capacity and MTVP thresholds noted in section III.A.2 of this preamble would have to be equipped with a fixed roof. Although most current rules do not specify standards for such storage vessels, we expect that storage vessels at facilities that may in the future be subject to rules that reference the Uniform Standards already meet this proposed requirement. Thus, we do not expect any cost or emission impacts to meet this requirement. We request comment on the accuracy of this assumption.

The design and operating requirements that we are proposing for fixed roofs are based on the requirements in the Generic MACT for Tanks Level 1. However, we are proposing the seven changes to the requirements in the Generic MACT for Tanks Level 1, described below, to control more effectively fugitive emissions, simplify requirements and enhance consistency with requirements for storage vessels that may be subject to other sections in proposed subpart I.

First, we are not proposing to specify suitable materials for the fixed roof and closure devices. We decided that these decisions are best left to you and the storage vessel manufacturer. You would have the flexibility to choose whatever materials work best in your situation, provided you meet the design and operational requirements in proposed subpart I.

Second, like the Generic MACT for Tanks Level 1, proposed subpart I would allow opening of a closure device or removal of the roof when needed to provide access. The Generic MACT for Tanks Level 1 specifies that the closure devices may be opened to provide access for ''performing routine inspection, maintenance, or other activities needed for normal operations'' and ''to remove accumulated sludge or other residues from the bottom of the tank.'' In proposed subpart I, we use an edited version of these statements to clarify that the opening is allowed for ''manual operations that require access such as inspections, maintenance, sampling, and cleaning.'' A related difference between the Generic MACT for Tanks Level 1 and the proposed rule is that the proposed rule does not explicitly state that the closure device must be secured in the closed position or the roof reinstalled when the activity that requires access is complete. Such a statement is unnecessary, because the inverse of the provision allows openings when access is needed. The proposed rule clearly states that closure devices must be closed at all times except when access is needed.

Third, as in the Generic MACT for Tanks Level 1, proposed subpart I would allow you to route emissions from an opening through a closed vent system to a control device as an alternative to equipping the opening with a closure device. However, the Generic MACT for Tanks Level 1 does not specify compliance procedures for this control option. To ensure that emission reductions are consistent and quantifiable when a control device is used, we are proposing to require compliance with the procedures in proposed 40 CFR 65.325 for closed vent systems and control devices.

Fourth, the Generic MACT for Tanks Level 1 specifies at 40 CFR 63.902(c)(3) that opening of a safety device is allowed at any time. This provision was not included in proposed subpart I because the referencing subparts will address malfunctions.

Fifth, we are proposing delay of repair provisions that differ from the requirements in the Generic MACT for Storage Tanks Level 1. The primary difference between the Generic MACT for Storage Tanks Level 1 and proposed subpart I is the time allowed to complete repair. The Generic MACT for Tanks Level 1 allows delay as long as the owner or operator demonstrates that alternative tank capacity is not available to accept the regulated material from the tank that needs to be repaired, whereas the proposed rule would allow a maximum delay of 105 days (45 days plus up to two extensions of up to 30 days each). We have determined that 105 days is sufficient time to empty the tank, either to other existing tanks on site or to temporary storage, if necessary. Furthermore, current rules (and proposed subpart I) already include such requirements for repair of any floating roof, and applying the same requirements for fixed roof storage tanks would promote consistency and reduce the likelihood of inadvertent compliance errors. Sixth, we are proposing to require periodic monitoring of each potential source of vapor leakage from the fixed roof and fittings on the roof instead of annual visual inspections for defects. The monitoring could be conducted annually using Method 21 of 40 CFR part 60, appendix A–7 or semiannually using optical gas imaging (after promulgation of the protocol that we are developing for 40 CFR part 60, appendix K). See sections III.A.3 and IV.A.5 of this preamble for discussions of the protocol. Repairs would be required for each leak. A leak would be defined as any instrument reading greater than 500 ppmv when monitoring using Method 21 of 40 CFR part 60, appendix A–7, or any emissions imaged when using an optical gas imaging instrument. We are proposing this monitoring change to better control fugitive emissions. As documented in the docket for proposed subpart I, EPA inspectors have often found significant leaks from fittings by sensory means (particularly olfactory) and optical gas imaging when visual inspections indicate the gaskets and other elements of closure devices appear to be sound, and the conservation vent is not actively releasing to relieve increased pressure caused by diurnal temperature changes or filling the storage vessel (see the memorandum titled *Leaks Observed From Fixed Roof and Floating Roof Fittings,* in the docket for proposed subpart I).

The estimated annual costs, emission reductions and cost-effectiveness values for the three monitoring options are shown in Table 5 of this preamble. The estimated cost-effectiveness values for monitoring using either optical gas imaging or Method 21 of 40 CFR part 60, appendix A–7 are less than $230/ton per storage vessel, which we determined is reasonable. Note that the emission reductions for these two options are relative to estimated uncontrolled emissions. We lack the data needed to attempt to quantify the reductions for the visual inspections option, but we expect the reductions to be significantly less than for the other two options given the results of agency inspections noted above.

The impacts were estimated for a representative fixed roof storage vessel with eight fittings on the roof (an access hatch, gauge hatch, conservation vent, emergency pressure relief vent and four other miscellaneous types of valves and instruments). Costs were estimated assuming a visual inspection takes an average of 30 minutes and the other monitoring options take between 40 minutes and an hour, depending on the size of the facility at which the storage vessel is located. Based on the results of agency inspections, we estimated that initial optical gas imaging would find about 0.5 leaking fittings per storage vessel, and that monitoring with Method 21 of 40 CFR part 60, appendix A–7, would find an average of about 1 leaking fitting per storage vessel. We assumed that subsequent monitoring would find about 5-percent leaking fittings if optical gas imaging is conducted semiannually and monitoring with Method 21 of 40 CFR part 60, appendix A–7, is conducted annually. As in equipment leak analyses, repair costs were estimated assuming 75 percent of the leaks could be eliminated by a simple adjustment to the fitting and that 25 percent of the fittings would require a more extensive repair or replacement. Recordkeeping costs were estimated assuming 1 hr/yr to document the results of visual inspections and 0.5 hr/yr to document the results of the other monitoring options. Reporting costs were estimated assuming 0.5 hour per reporting period, to include records in annual periodic reports of inspections of each storage vessel for which a leak was found, and that 40 percent of the storage vessels have one leaking fitting each year (*i.e.,* 5 percent of the fittings are found to be leaking, and each tank has an average of eight fittings). Uncontrolled emissions for the conservation vent, emergency pressure relief vent and miscellaneous valves were estimated using average emission factors from the *Protocol for Equipment Leaks Emission Estimates* (EPA–453/R–95–017) for such equipment in the SOCMI. Uncontrolled emissions for access hatches and gauge hatches were approximated using AP–42 factors for such fittings on EFR

(unbolted, gasketed cover for access hatches and gasketed, weighted mechanical actuation gauge hatches). Controlled emissions were estimated assuming the percent reduction in emissions equals the percent reduction in the number of fittings found to be leaking.

TABLE 5—ESTIMATED IMPACTS OF MONITORING OPTIONS FOR FIXED ROOF STORAGE VESSELS

Monitoring option	Total annual cost ($/yr)	Emission reduction relative to uncontrolled (tpy)	Cost effectiveness ($/ton)	Incremental cost effectiveness ($/ton)
Visual	120	unknown	unknown	N/A
EPA Method 21	170	1.1	150	unknown
Optical gas imaging	260	1.1	230	undefined

tpy means tons per year.
N/A means not applicable.

We request comment, with supporting rationale, on all aspects of the proposed requirements for fixed roof storage vessels that store regulated material. We are particularly interested in comment on the proposed monitoring requirements. For example, itemized cost estimates, data on mass emissions from leaks and information about the types of initial repairs that would be needed and the expected frequency of replacements would be useful. Comparisons of results obtained using both Method 21 of 40 CFR part 60, appendix A–7, and optical gas imaging are requested.

4. How did the EPA determine the proposed requirements for atmospheric storage vessels that are controlled using an IFR or EFR?

As noted in section III.A.2 of this preamble, we are proposing four different compliance approaches for atmospheric storage vessels that exceed specified capacity and MTVP thresholds. One of these approaches is to use a floating roof. The requirements that we are proposing for this approach in proposed 40 CFR 65.315 are essentially the same as the requirements in the Generic MACT for Tanks Level 2. We are proposing additional requirements and clarifications as described below.

Rim seal design. The Generic MACT for Tanks Level 2 specifies alternative rim seal configurations for IFR and EFR storage vessels at 40 CFR 63.1063(a)(1)(i) and (ii). However, if certain conditions are met, 40 CFR 63.1063(a)(1)(i)(D) and (ii)(C) specify that full compliance with these configurations is not required for existing tanks until the next time the storage vessel is completely emptied and degassed or 10 years after promulgation of the referencing subpart, whichever occurs first. The storage vessel provisions in 40 CFR 63.119(b) and (c) of the HON contain the same provision. We are not proposing this delayed compliance provision because we expect most rules that reference the Uniform Standards will be amended versions of current rules, and these amended rules will not reference the Uniform Standards until more than 10 years after their original promulgation. Thus, all existing storage vessels that are subject to a referencing subpart should already be equipped with the required rim seals before they become subject to the Uniform Standards.

One of the objectives of rim seals is to help fill the annular space between the rim of the floating roof and the wall of the storage vessel thereby minimizing evaporative losses from this area. To meet this objective, rim seals must be constructed of a material that is impermeable to the stored material or any components of the stored material. A rim seal that is saturated with (or has been plasticized by) stored liquid would constitute an inspection failure because the rim seal would not be functioning as designed. In proposed subpart I, this requirement is specified in section 65.315(c)(1)(iii). We request comment on whether explicitly stating in subpart I that rim seal material saturated with (or plasticized by) stored liquid constitutes an inspection failure would help clarify this requirement. We also request comment on other possible approaches for clarifying this requirement. In addition, we are interested in strategies that could minimize repeated use of seal materials that are demonstrated to be less reliable than others. For example, we request comment on the feasibility and potential effectiveness of requiring more frequent inspections if a seal that failed during the first 5 years of use is replaced with a seal made from the same material.

Sample well requirements. The Generic MACT for Tanks Level 2 specifies at 40 CFR 63.1063(a)(2)(v) that each sample well and each deck drain that empties into the stored liquid may be equipped with a slit fabric seal or similar device that covers at least 90 percent of the opening instead of a deck cover. In other rules, such as the CAR, the HON and Standards of Performance for Volatile Organic Liquid Storage Vessels (Including Petroleum Liquid Storage Vessels) for Which Construction, Reconstruction, or Modification Commenced After July 23, 1984 (40 CFR part 60, subpart Kb; ''NSPS Kb''), the option for sample wells to use a slit fabric cover applies only for IFR. Therefore, to clarify the requirement, we are proposing to split the requirements for sample wells and deck drains into two paragraphs in subpart I. As an alternative to using a gasketed deck cover, proposed 40 CFR 65.315(a)(3)(v) specifies that sample wells in IFR may be equipped with a slit fabric seal (or similar device) that covers at least 90 percent of the opening. Proposed 40 CFR 65.315(a)(3)(vi) specifies that each opening for a deck drain (in any floating roof) that empties into the stored liquid must be equipped with a slit fabric (or similar device) that covers at least 90 percent of the opening.

Control requirements for guidepoles. The Generic MACT for Tanks Level 2 specifies in 40 CFR 63.1063(a)(2)(vii) that each unslotted guide pole shall be equipped with a gasketed cap on the top of the guide pole. We are proposing an alternative to this provision for proposed 40 CFR 65.315(a)(3)(viii) to indicate that a welded cap is an acceptable alternative to a gasketed cap for anti-rotational devices. The cap may be welded on an unslotted guide pole because such a guide pole is not used for gauging the liquid level. Emissions reductions are expected to be the same for both types of caps.

As part of the STERPP, we offered to enter into agreements with companies that have installed or will install controls to reduce their slotted guide pole emissions from storage vessels that

are subject to Standards of Performance for Storage Vessels for Petroleum Liquids for Which Construction, Reconstruction, or Modification Commenced After May 18, 1978, and Prior to July 23, 1984 (40 CFR part 60, subpart Ka) or NSPS Kb. During development of the program, we identified two additional slotted guide pole control options that are not included in the Generic MACT for Tanks Level 2. The STERPP included these options because their performance was determined to be comparable to the performance of other control options already specified in the rules. One of the new options is to use a flexible enclosure device that completely encloses the slotted guide pole and a cover on the top of the guide pole. The second new option is to install an internal guide pole sleeve, a pole wiper and a cover on the top of the guide pole. We are proposing to include both of these options in proposed 40 CFR 65.315(a)(3)(ix). As discussed above for unslotted guidepoles, the cover may be either gasketed or welded. There is no cost impact associated with these control options because these options are providing compliance flexibility without imposing new requirements.

Control requirements for slotted ladder legs. Many IFR tanks have a ladder with one slotted leg so that the leg can also be used for gauging and/or sampling. Current rules specify that ladder wells must have gasketed sliding deck covers, and slotted guidepoles must be controlled using any one of several techniques. However, current rules do not explicitly specify requirements for slotted ladder legs. Therefore, we are proposing to require any one of three options for this type of fitting. One option is to use a pole float in the slotted leg and pole wipers for both legs. A second option is to use a ladder sleeve and pole wipers for both legs. The third option is to use a flexible device that completely encloses the ladder and either a gasketed or welded cap on the top of the slotted leg. Each option also includes the requirement to have a gasketed sliding deck cover. These controls are similar to the controls for slotted guidepoles, and they have been accepted in equivalency determinations for numerous storage vessels that are subject to current rules. Thus, the costs to comply with proposed subpart I would be the same as costs to comply with current rules.

Delayed compliance date for deck fitting requirements. The Generic MACT for Tanks Level 2 specifies in 40 CFR 63.1063(a)(2)(ix) that deck fitting requirements do not apply for an existing IFR or EFR until the next time the storage vessel is completely emptied and degassed or 10 years after the promulgation date of the referencing subpart, whichever occurs first. We have not included this provision in proposed subpart I for the same reason described above regarding a similar provision for rim seals (i.e., all existing storage tanks that may in the future be subject to rules that reference the Uniform Standards should have already complied with the deck fitting requirements before they become subject to the Uniform Standards).

Operational requirements. The Generic MACT for Tanks Level 2 requires that the floating roof float on the stored liquid surface at all times, except for times when the floating roof is supported by its leg supports or other support devices such as hangers from the fixed roof (''landings''). Once the floating roof lands, ''the process of filling to the point of refloating the floating roof shall be continuous and shall be performed as soon as practical'' (40 CFR 63.1063(b)(2)), and you must keep records of the date the roof landed and the date it was refloated (40 CFR 63.1065(c)). The language at 40 CFR 63.1063(b)(2) is similar to the language in the CAR (40 CFR 65.43(b) and 65.44(b)), and the preamble to the CAR has clarified that the intent of this language is ''to prevent the liquid level [in the storage vessel] from rising and falling while the roof is resting on the supports'' (63 FR 57768, October 28, 1998). However, neither the Generic MACT for Tanks Level 2 nor the CAR place any limits on the number of landings or the amount of time that a floating roof may be landed. The lack of limits is a concern because the standing idle emissions can be significant, especially relative to the emissions and emissions reductions for deck fittings while the roof is floating. For example, Table 6 of this preamble presents estimated emissions from typical gasoline storage tanks equipped with an EFR and standing idle for 2 or 5 days. These emissions were estimated using AP–42 procedures for a storage vessel in Corpus Christi, Texas. The landed height of the roof was assumed to be 5 feet above the floor of the storage vessel, and the liquid level was assumed to be 0.75 feet above the floor of the storage vessel.

TABLE 6—ESTIMATED STANDING IDLE EMISSIONS FROM GASOLINE STORAGE VESSELS THAT ARE EQUIPPED WITH AN EFR

Size of storage vessel (gal)	Stored contents	Number of days standing idle	Estimated standing idle emissions (lb)
2,000,000	gasoline	2	830
		5	2,100
7,000,000	gasoline	2	1,500
		5	3,900

Other rules (e.g., NSPS Kb) allow floating roof landings only if the storage vessel is being completely emptied, and both the emptying and refilling processes must be continuous and as rapid as possible. This requirement has been interpreted as requiring the storage vessel to be emptied each time the floating roof lands. However, as we clarified in the preamble to the CAR (63 FR 57768), emptying the storage vessel every time the roof lands is undesirable because it increases the vapor space, which in turn increases emissions. Thus, emptying the storage vessel when landings are inadvertent or other times when emptying is not needed for operational reasons is counterproductive.

To minimize emissions from landings and clarify the requirements, we are proposing several differences relative to the requirements in current rules. For example, instead of requiring the floating roof to be floating on the liquid surface at all times except when it is landed on its supports, we are proposing to list specific situations under which the floating roof is not required to be floating on the stored liquid (proposed 40 CFR 65.315(b)(1)). We are proposing to allow the roof to be landed during the

initial fill because the landed height is typically several feet above the floor of the storage vessel. We are not proposing to require control of emissions in displaced gases during the initial fill because the average concentration of regulated materials in the vapor space over the course of the fill is relatively low, and the costs to vent such emissions to a control device are not reasonable. Like current rules, however, the proposed rule typically would require filling to the point of refloating the roof to be conducted continuously and as rapidly as practicable to minimize the amount of time a vapor space is present below the floating roof. The only exception to the proposed requirement for continuous filling until the roof is refloated would be for storage vessels that are used to store product from batch processes. The exemption would apply if the quantity of product from one batch is insufficient to refloat the roof, but sufficient product from additional batches to refloat the roof will be added before any material is withdrawn from the storage vessel.

We also recognize that landings are required in order to take the storage vessel out of service, and they are often required in order to perform inspections, maintenance or before filling the storage vessel with a liquid that is incompatible with the liquid currently stored in the storage vessel. Therefore, we are proposing to allow roof landings in these situations, provided the time spent standing idle is limited to no more than 24 hours. After 24 hours, you would be required to either begin actions to completely empty (and clean, if necessary) or refill the storage vessel. These requirements clarify that you would not be required to empty a storage vessel when the storage vessel does not need to be empty in order to conduct maintenance or inspections. The limited number of situations when landings are allowed is intended to eliminate unnecessary or convenience landings, and the 24-hour limit is intended to prevent emissions from unnecessary time spent standing idle. We request comment on the suitability of the 24-hour limit. In particular, we request comment on specific situations where a storage vessel does not need to be completely emptied to perform maintenance or inspection, but the maintenance or inspection activity cannot be completed in less than 24 hours. We also request comment on the proposed list of circumstances under which floating roof landings would be allowed, in particular whether there are other circumstances that would require a floating roof landing or whether the list allows landings in situations where they are unnecessary.

We are also proposing to allow landings if you elect to route emissions through a closed vent system to a control device that reduces emissions by at least 90 percent while the roof is landed because this control technique will also reduce standing loss emissions relative to uncontrolled landings. To prevent liquid from being drawn into the closed vent system, control would be required only when the liquid fills less than 90 percent of the volume under the landed roof. We are not proposing to require control of displaced emissions during refill after these events because the cost to control, considering the estimated emissions reduction, would not be reasonable except for very large storage vessels that store highly volatile material. We request comment on the technical feasibility and cost of this control option. In particular, we are interested in test data showing the gas flow rate and inlet mass emissions to a control device that was used as we proposed; please also provide related supporting information, such as the diameter of the storage vessel, the height of the landed roof, the average height of the liquid, the type of material stored and the pressure drop across the floating roof. We also request comment on whether the rule should limit the number of days operating in this manner so that the total controlled emissions do not exceed the standing idle emissions from one day. We also request comment on whether any facilities would have no choice but to comply with this control option because it would not be possible to limit landings to the situations described in the paragraph above; please provide a description of any such facilities and explain why limiting landings would not be possible.

Proposed subpart I would require you to estimate regulated material standing idle emissions from each landing and to submit the results in your next periodic report. As in the Generic MACT for Tanks Level 2, you would also be required to keep records documenting the start and end times of all roof landing events. We have determined that maintaining information on the occurrence, time span and quantity of standing idle emissions for landings is needed to demonstrate compliance with the proposed limits on when landings are allowed. This information will also help inform decisions about where to target compliance inspections. We request comment on the feasibility and burden of estimating emissions from landings.

Monitoring and alarm systems. Under the proposed rule, an inadvertent landing of a floating roof would be a deviation of the operating requirements described above. To minimize the number of unintended landings of floating roofs (and the additional emissions generated as a result), we are proposing to require that you equip each affected storage vessel with a system that provides a visual or audible signal when the floating roof is about to land on its legs (or other support devices). This monitoring is intended to alert you in time to take action to prevent an inadvertent landing and the resulting deviation. We are soliciting comment on the prevalence of such monitoring systems in use with existing storage vessels and the burden to add them to storage vessels that are not already so equipped. We estimated the cost to plan, purchase and install the required monitors to be about $2,000 per storage vessel. We estimated the annual costs, including costs to estimate emissions for each landing and related recordkeeping and reporting, to be about $900/year per storage vessel. These estimates assume each floating roof will be landed an average of two times per year, and that one of the landings will be inadvertent.

IFR and EFR inspections. The proposed inspection requirements are consistent with the inspection requirements in 40 CFR 63.1063(c) and (d), except for the six proposed changes discussed below. First, in an effort to improve clarity, we are proposing to tabulate many of the inspection and frequency requirements (see Tables 2 and 3 in proposed subpart I). The intent is not to change the requirements except as discussed below.

Second, we are proposing to specify how an inspector is to demonstrate when a gap constitutes an inspection failure for a deck fitting. The Generic MACT for Tanks Level 2 specifies at 40 CFR 63.1063(d)(1)(v) that a gap of more than ⅛ inch between any deck fitting gasket, seal or wiper, and the surface that it is intended to seal is an inspection failure. The Generic MACT for Tanks Level 2 does not, however, explicitly specify how an inspector is to determine whether gaps exceed this amount. Therefore, we are proposing to specify in proposed 40 CFR 65.315(c)(2)(i) that an inspector must use a ⅛-inch diameter probe, and each location where the probe passes freely constitutes a gap. This procedure is consistent with the currently specified procedure for monitoring rim seal gaps in EFR tanks.

Third, we are proposing an editorial change to the language from 40 CFR 63.1063(d)(1)(v) that is incorporated in

40 CFR 65.315(c)(2)(i). In the Generic MACT for Tanks Level 2, 40 CFR 63.1063(d)(1)(v) specifies that the gap limit for deck fittings applies to ''any deck fitting gasket, seal, or wiper.'' The use of the word ''seal'' in this sentence may be misinterpreted as meaning the provision applies to rim seals because the design requirements for deck fittings refer only to gaskets and wipers. Therefore, to eliminate confusion and improve clarity, we are proposing in 40 CFR 65.315(c)(2)(i) to specify that the gap limit applies to each deck fitting gasket or wiper.

Fourth, to increase compliance flexibility and possibly emissions reductions, we are proposing to allow optical gas imaging or monitoring using Method 21 of
40 CFR part 60, appendix A–7 as an alternative to measuring rim seal gaps for EFR and deck fitting gaps for both IFR and EFR. The monitoring would be required on the same schedule as the otherwise applicable gap measurement requirements. An inspection failure would occur if you obtain an instrument reading greater than 500 ppmv when monitoring using Method 21 of 40 CFR part 60, appendix A–7, or when you obtain an image of emissions when using optical gas imaging. Conditions causing an inspection failure would have to be repaired. To ensure consistent and reliable results when using optical gas imaging, we are also proposing two additional requirements: (1) Optical gas imaging would be allowed only if at least one compound in the emissions from the storage vessel can be detected by the optical gas imaging instrument and (2) monitoring would be required in accordance with a new protocol for optical gas imaging. As discussed in sections III.A.3 and III.A.4 of this preamble, we are currently developing a protocol for using optical gas imaging instruments, and we expect that the protocol will be proposed as appendix K in 40 CFR part 60. We anticipate that compliance with either of the proposed monitoring alternatives would result in lower emissions than compliance with the conventional gap measurement requirements because agency personnel using an optical gas imaging instrument have often seen images of emissions from seals and fittings that appear to be in good condition upon visual inspection (see the memorandum titled *Leaks Observed from Fixed Roof and Floating Roof Fittings,* in the docket for proposed subpart I). We have not estimated cost effectiveness to conduct optical gas imaging or monitoring using Method 21 of 40 CFR part 60, appendix A–7, because such monitoring is only an alternative to gap measurements, not a requirement. However, monitoring costs and burden for optical gas imaging may be lower if several fittings can be monitored simultaneously. We request comment on the technical feasibility, performance and costs of both proposed alternatives to gap measurement requirements.

Fifth, we are proposing to require inspections of an EFR deck and fittings annually rather than at least every 10 years, as specified in the Generic MACT for Tanks Level 2. The Generic MACT for Tanks Level 2 requires annual secondary seal gap measurements, but complete inspections of the EFR, rim seals and deck fittings are required only when the storage vessel is completely emptied and degassed, or every 10 years, whichever occurs first. A commenter on the proposed changes to storage vessel requirements in 40 CFR part 63, subpart CC (73 FR 66694, November 10, 2008), which would have referenced the Generic MACT for Tanks Level 2, stated that the annual inspection for EFR should be expanded to include inspection of the roof and deck fittings as well as the secondary seal because defects in the roof or fittings are often clearly visible during the secondary seal inspections (see Docket Item No. EPA–HQ–OAR–2003–0146–0176). Furthermore, the commenter noted that, under the current rule, it is unclear whether any such defects noted during the annual inspection are to be repaired, reported or ignored until the next complete inspection. Upon review, we have determined that annual inspections of the EFR deck and fittings are reasonable because: (1) An inspection for other failures can readily be accomplished each time an inspector is measuring secondary seal gaps; (2) conducting such failure inspections annually would more closely align the EFR inspection requirements with the current IFR inspection requirements; and (3) we estimated the additional burden and costs to be minimal. Measurement of gaps between deck fitting gaskets and the surfaces they are intended to seal is not required for IFR. However, given that EFR have a greater potential for emissions due to wind effects, we think the minimal additional time and cost to perform such measurements of EFR fittings is reasonable in light of the potential for reduced emissions. We estimated the additional labor costs for visual inspections, measurement of deck fitting gasket gaps and associated recordkeeping to be about $100/year. The additional burden was estimated to be about 2 hours per storage vessel.

As noted above, we are proposing to allow monitoring using Method 21 of 40 CFR part 60, appendix A–7 and optical gas imaging as alternatives to gap measurement requirements. We estimated the costs and burden to conduct annual monitoring of EFR deck fittings using Method 21 of 40 CFR part 60, appendix A–7 to be about the same as for annual to measurement of gaps at each fitting because an inspector has to check each fitting individually in both cases. Theoretically, costs and burden to conduct optical gas imaging could be slightly less (assuming the facility is using a camera that has already been purchased for monitoring equipment leaks) because several emission points can be monitored simultaneously with an optical gas imaging instrument, but we assumed the same amount of time because time is needed to prepare the camera and to obtain images from multiple locations. See the memorandum titled *Survey of Control Technology for Storage Vessels and Analysis of Impacts for Storage Vessel Control Options,* in the docket for proposed subpart I for additional discussion of how these costs and burden estimates were developed. We request comments that assess the effectiveness and burden of the proposed annual EFR inspections relative to the inspection requirements in the Generic MACT for Tanks Level 2.

We are also proposing to clarify that repair is required any time a condition that constitutes an inspection failure is noted, regardless of whether it was noted as part of a scheduled inspection. Although not stated explicitly, current rules imply that repair is required any time an inspection failure is noted because they state that inspections must be conducted at least once during a specified time period. Any time a condition that constitutes an inspection failure is noted is effectively an inspection, whether or not it was scheduled.

Finally, we are proposing changes to clarify the required frequency of inspections because we received comments on proposed amendments to 40 CFR part 63, subpart CC, that the current requirements could be subject to different interpretations (see docket item EPA–HQ–OAR–2003–0146–0176). For example, the requirement to conduct inspections ''every 10 years'' could mean in every tenth calendar year, no later than the date 10 years after the previous inspection or in the same month every 10 years. The same uncertainties also apply to the inspection requirements that must be

conducted once per year or every 5 years. We have also been asked when the inspection must be conducted if the storage vessel is out of service on the date when the inspection must be completed. To address these questions, we are proposing to replace the requirements for inspections at least once per year with a requirement to conduct inspections at least annually. The proposed General Provisions in 40 CFR part 65, subpart H specify that ''annually'' means once per calendar year, and successive occurrences of such events must be separated by at least 120 days. For the inspections that are required at least every 5 years and every 10 years under the Generic MACT for Tanks Level 2, we are proposing to require that the inspection typically must be conducted before the date 5 years (or 10 years) after the last inspection. The only exception is that an inspection may be delayed if the storage vessel is out of service on that date, but in such cases, the inspection must be conducted before the storage vessel is refilled.

Repairs. The proposed requirements to repair conditions that caused inspection failures are similar to the requirements at 40 CFR 63.1063(e) in the Generic MACT for Tanks Level 2. We are proposing three changes to clarify the requirements. As discussed above, the first change clarifies that all conditions that cause an inspection failure, regardless of whether they were identified during a scheduled inspection, must be repaired.

The second change would clarify terminology. The applicable repair requirements in 40 CFR 63.1063(e) differ depending on whether or not the inspection was conducted while the storage vessel was storing liquid. These requirements could be subject to inconsistent interpretations because the term ''storing liquid'' is not defined in the rule. The intent of the language was to apply different procedures depending on whether or not the storage vessel was completely empty when the inspection was conducted. The term ''completely empty'' is defined in the rule. Therefore, rather than define ''storing liquid,'' we are proposing to replace that term with the term ''completely empty'' to clarify the requirements.

The third change would clarify the recordkeeping requirements when you use an extension to delay repair or emptying of a storage vessel beyond 45 days. The current requirements in 40 CFR 63.1063(e) imply that documentation of extensions is to be prepared before you use an extension and could be misinterpreted as requiring a request for approval to use an extension. Section 63.1067 of the Generic MACT for Tanks Level 2 also specifies that this documentation be submitted in periodic reports. We have determined that approvals are not necessary; records that document the type of failure, the reasons why an extension was needed, the steps taken to either repair or completely empty the storage vessel during the extension and the date on which repairs were completed or the storage vessel was completely emptied are sufficient to demonstrate compliance. Furthermore, requesting approval via a periodic report is impractical because the schedule of such reports is unlikely to coincide with many extension periods. Therefore, to clarify the reporting requirements, the language in the proposed rule differs from the Generic MACT for Tanks Level 2 in that it clearly requires records of each decision to use an extension.

5. How did the EPA determine the proposed requirements for vapor balancing as a compliance approach for atmospheric storage vessels?

We are proposing that the second approach for atmospheric storage vessels is vapor balancing (proposed 40 CFR 65.320). Proposed subpart I would require the same design, operating, monitoring and repair requirements for the fixed roof and closure devices that would be required for the closed vent system approach. See section III.B.6 of this preamble for a discussion of our rationale for these requirements. The vapor balancing requirements that we are proposing are similar to requirements in several rules in 40 CFR part 63 (e.g., the MON), except for the following three changes. First, we are proposing to replace the requirement to conduct quarterly monitoring of pressure relief valves on storage vessels using Method 21 of 40 CFR part 60, appendix A–7, with a requirement to conduct applicable LDAR requirements for all equipment in the vapor balancing system. The proposed requirements are nearly identical to the proposed requirements for closed vent systems, as described in section III.B.6 of this preamble. The only difference is that you would have the option to reduce instrument monitoring frequencies (for types of equipment that must be monitored) consistent with the alternative for equipment in batch operations in proposed 40 CFR part 65, subpart J. We proposed this difference because it would be possible to determine the total operating hours for a vapor balancing system, but not for a closed vent system. We are not proposing to limit the monitoring requirement to PRD because such monitoring provides information only for that one piece of equipment. Conducting monitoring of the entire vapor balancing system while the storage vessel is being filled provides more information about the integrity of the entire system, and it is information collected while the system is actually operating and most likely to be emitting vapors.

The second difference from vapor balancing requirements in current rules is that the proposed rule would require design, operation, inspection and repair of openings and closure devices consistent with the requirements for fixed roofs in storage vessels that are controlled by routing emissions through a closed vent system to a control device, as described in section III.B.6 of this preamble. Although current rules and proposed subpart I require PRD be set at levels to prevent breathing losses, we determined that additional requirements are needed to minimize vapor leakage through the roof and fittings regardless of the method for controlling breathing and working losses.

The third difference from vapor balancing requirements in current rules is that the proposed rule would specify no requirements for offsite facilities that reload (and in some cases clean) the transport vehicle or barge. In current rules, these facilities are subject to the same control requirements as the facility that has the affected storage vessel. Both the vapor balancing and closed vent system options were included in current rules in 40 CFR part 63 because they were determined to be at least as effective as using floating roofs, which represented the MACT floors. Based on recent analyses, we determined that requiring control of offsite facilities as part of a vapor balancing option results in better overall control than the other options. Furthermore, the total emissions from a regulated source implementing vapor balancing and an uncontrolled offsite cleaning/reloading facility typically are about the same as the total emissions from both facilities when the regulated source implements the closed vent system approach. The performance of the closed vent system approach relative to vapor balancing will vary depending on the saturation level of the vapor space in the transport vehicle or barge when unloading of liquid to the storage vessel is complete. If the organic compound concentration in the vapor space of the transport vehicle or barge when transfer is complete is approximately the same as the concentration in the vapor space of the storage vessel, then the total mass of organic compounds in the transport

vehicle or barge (in both the vapor space and the liquid heel) would be the same under both approaches. Under these conditions, the performance of the two approaches is essentially the same, and control at the offsite cleaning/reloading facility as part of the vapor balancing approach is not needed to achieve the same level of control as the closed vent system approach. See the memorandum titled *Vapor Balancing Emissions Estimates for Storage Vessels,* in the docket for proposed subpart I for example calculations.

Another issue with the vapor balancing approach, as specified in current rules, is that it imposes a significant burden on the offsite facilities (assuming these facilities are not required to control transfer operations emissions under a rule that currently applies to their source category). Furthermore, because facilities outside the United States are not required to comply with this rule, a regulated source would not be allowed to use the vapor balancing approach if the transport vehicle is cleaned outside of the United States. Therefore, we have decided not to include control requirements for offsite facilities in proposed subpart I because we have determined that such requirements result in greater overall emissions reductions than other storage vessel control approaches. This additional control is not needed to meet regulatory requirements such as MACT in current rules because the performance of vapor balancing without offsite control is at least equivalent to the performance of other control approaches, including those that represent MACT in current rules. As a result, the offsite control requirement also imposes an unnecessary burden on the offsite facilities. Furthermore, the vapor balancing approach without offsite controls imposes clearly enforceable requirements on the regulated facility. We request comment on the differences between the proposed vapor balancing requirements and the vapor balancing requirements in current rules. In particular, we are interested in whether the proposed lack of requirements for offsite facilities could result in significantly higher total emissions under some conditions. We are also interested in test data or theoretical calculations of the organic compound saturation level or concentration in the vapor space of freely vented transport vehicles at the time when unloading of various liquids is complete.

6. How did the EPA determine the proposed requirements for control of atmospheric storage vessels when routing emissions through a closed vent system to a control device?

As discussed in section III.A.5 of this preamble, the proposed requirements are based on a combination of the procedures specified in 40 CFR part 65, subpart M and several additional requirements. As discussed in section V.B of this preamble, we have structured the proposed requirements in subpart M to be applicable to any emissions stream that is controlled by routing through a closed vent system to a control device. Referencing these provisions from proposed subpart I promotes consistency for all emissions streams that are routed through a closed vent system to a control device. It is also intended to simplify and reduce the burden of compliance and reduce the potential for inadvertent errors. However, we are also proposing several additional requirements to ensure appropriate control for storage vessels.

In addition to the proposed requirements in 40 CFR part 65, subpart M, we are proposing to require design and operation of the fixed roof and closure devices consistent with the proposed requirements for fixed roof storage vessels, as discussed in section III.B.3 of this preamble, except that breathing and working losses would have to be controlled rather than vented to the atmosphere. We are also proposing to require the same type of monitoring and repair of all potential sources of vapor leakage from the fixed roof and closure devices, as discussed in section III.B.3 of this preamble. We request comment on whether the proposed monitoring frequencies are reasonable and if any changes to operating procedures for the monitoring devices would ensure that the alternative monitoring methods provide similar results.

For equipment in a closed vent system, proposed 40 CFR part 65, subpart M references the compliance requirements in proposed 40 CFR part 65, subpart J. However, in subpart I we are proposing to reference only the bypass line requirements in proposed subpart M and reference directly the applicable equipment leak requirements in proposed subpart J. We selected this approach to specify more easily that certain options in proposed subpart J do not apply to equipment in a closed vent system that conveys emissions from a regulated storage vessel. Specifically, the alternative monitoring frequency requirements for equipment in batch operations would not be allowed for equipment in such closed vent systems because the closed vent system must be in service continuously. Similarly, the provision that specifies sensory monitoring for equipment in service less than 300 hr/yr would not be allowed for equipment in such closed vent systems because determining the amount of time the system actually is conveying emissions is not practical.

The applicable requirements in 40 CFR part 65, subpart J differ depending on whether the equipment is in regulated material service or if it contains or contacts fluid that contains regulated material at levels below the regulated material service threshold. Current rules typically require sensory monitoring of closed vent systems (only closed vent systems constructed of ductwork are subject to monitoring using Method 21 of 40 CFR part 60, appendix A–7). We are proposing instrument monitoring of closed vent systems in regulated material service to be consistent with the requirements for process lines that convey gaseous materials and to ensure that the emission streams reach the control device so that the required level of control is met. As an alternative to using Method 21 of 40 CFR part 60, appendix A–7, we are proposing to allow monitoring using an optical gas imaging device (after the protocol is promulgated, as discussed in section III.A.3 of this preamble), provided at least one compound in the emissions can be detected by the optical gas imaging instrument.

The proposed rule also specifies that all equipment in sections of closed vent systems that convey emissions from storage vessels that meet the thresholds for control (i.e., the thresholds specified in Table 1 of this preamble) are in regulated material service; no additional determination of the composition of gas streams in the closed vent system is required. This approach is being proposed because it provides an easy way for determining when equipment is in regulated material service and because the concentration of organic compounds in vapor that is in equilibrium with a liquid that has a vapor pressure of 0.75 psia (the minimum threshold for control) is approximately 50,000 ppmv, which after conversion to a weight basis, is comparable to or lower than typical 5 percent or 10 percent by weight thresholds in definitions of ''in organic HAP service'' or ''in VOC service'' in current rules. We request comment on other approaches that can accurately determine whether equipment is in regulated material service without imposing unreasonable burden.

Current rules for storage vessels generally require non-flare control devices to reduce organic compound emissions by at least 95 percent or to an outlet concentration of regulated material less than 20 ppmv. They also require at least a 99-percent reduction or outlet concentration less than 20 ppmv for acid gases or halogen atoms (the acid gases may be part of the emission stream directly from the storage vessel, or they may be generated by burning halogenated organic compounds in combustion control devices). These levels are achievable by storage vessels storing a wide range of materials in a wide range of source categories, and they are at least equivalent to the reductions that are achieved when using floating roofs. Thus, we are proposing to specify these required control levels in proposed subpart I rather than in each of the individual referencing subparts, thereby improving consistency and simplifying the referencing subparts. The use of flares to control organic emissions from storage vessels is another option that would be allowed in proposed subpart I; all requirements for flares are covered in 40 CFR 63.11(b) of subpart A.

Proposed 40 CFR part 65, subpart M specifies that control performance requirements will be specified in referencing subparts. Because proposed subpart I specifies the required reductions or outlet concentrations for non-flare control devices used to control emissions from storage vessels, subpart I (rather than the rule that references subpart I) would be the referencing subpart for the purpose of complying with proposed subpart M. Therefore, subpart I must specify the provisions for initial compliance determinations (*i.e.,* design evaluation or performance test), if applicable for storage vessels. We determined that design evaluations provide sufficiently accurate results for demonstrating compliance with the reductions required for storage vessels. Thus, we are proposing to specify in subpart I that initial compliance with requirements for non-flare control devices that control emissions from storage vessels may be demonstrated using a design evaluation instead of a performance test, which is the default in subpart M. However, any control devices that control other emissions (*e.g.,* process vents) in addition to storage vessel emissions, may still be required to conduct a performance test instead of a design evaluation, if another subpart references subpart M for the same control device.

As in current rules, we are proposing to require different standards for periods of planned routine maintenance of the control device. We are not proposing to require compliance with the same standard at all times because the cost of such a requirement would be unreasonable. Instead, we are proposing to prohibit the addition of material to the storage vessel during periods of planned routine maintenance and to limit the time of planned routine maintenance to less than 360 hr/yr. If you need more than 240 hr/yr, you would be required to keep a record documenting why 240 hours is insufficient and the steps you took to minimize the additional time for planned routine maintenance. In analyses for current rules, 240 hours has been determined as sufficient for most control device rebuilds.

7. How did the EPA determine the proposed requirements for control of atmospheric storage vessels when routing emissions to a fuel gas system?

For fuel gas systems that control emissions from storage vessels, proposed subpart I references the fuel gas system requirements in proposed 40 CFR part 65, subpart M and specifies a few additional requirements to ensure appropriate control for storage vessels. See section V.B.4 of this preamble for a discussion of the requirements in subpart M for fuel gas systems. Proposed subpart I also would require the same design operating, monitoring and repair requirements for the fixed roof and closure devices that would be required for the closed vent system approach. See section III.B.6 of this preamble for a discussion of our rationale for these requirements. Proposed subpart I also would require compliance with proposed 40 CFR part 65, subpart J for the equipment in the fuel gas system. As for the closed vent system approach, all equipment in sections of a fuel gas system that convey emissions from an affected storage vessel are in regulated material service and subject to the monitoring and other LDAR requirements for equipment in regulated material service. See section III.B.6 of this preamble for a discussion of the rationale for these requirements.

8. How did the EPA determine the proposed requirements for control for pressure vessels?

A pressure vessel is defined in the Uniform Standards as a storage vessel that is designed not to vent to the atmosphere as a result of compression of the vapor headspace in the vessel during filling of the vessel. We are proposing standards for all pressure vessels that contain any regulated material. We are not proposing thresholds for the following reasons. First, materials stored in a pressure vessel are likely to be highly volatile; thus, a low vapor pressure threshold would have little or no impact. Second, we do not expect the operating pressure or frequency of leaks to vary with the size of the storage vessel. Thus, the emissions for the same emission pathway would be the same regardless of the size of the storage vessel. Third, the fittings on the pressure vessel are comparable to the types of equipment (and in the same service as equipment) that would be subject to monitoring under proposed 40 CFR part 65, subpart J.

The proposed requirements for pressure vessels are to equip each opening with a closure device, operate without emissions to the atmosphere at any time, monitor annually all potential leak interfaces using Method 21 of 40 CFR part 60, appendix A–7 (or semiannually when using optical gas imaging), estimate and report emissions from periods when instrument readings exceed 500 ppmv or an image is detected and route purge streams to a control device. Closure devices are an operational necessity for pressure vessels, and they prevent emissions as well. We are proposing periodic monitoring requirements as a means to demonstrate compliance with the requirement to operate without emissions to the atmosphere. We have determined that estimating and reporting emissions is needed to help inform decisions about where to target compliance inspections and to ensure that the pressure vessels are properly operating with no vents to the atmosphere. The burden to conduct monitoring and associated recordkeeping and reporting is estimated to be about 2 hr/yr per storage vessel, at a cost of about $170/year for monitoring with Method 21 of 40 CFR part 60, appendix A–7. The burden is estimated to be about 3.5 hr/yr at a cost of about $260/year for monitoring with an optical gas imaging instrument. The differences in the proposed Uniform Standards are due primarily to the different monitoring frequencies.

We are proposing to include an alternative to the requirement of maintaining a closed system at all times. This alternative would allow you to purge inert materials that build up in the pressure vessel, provided the purge stream is routed through a closed vent system to a control device that achieves the same performance that is being proposed for atmospheric storage vessels (*i.e.,* reductions of at least 95 percent or to less than 20 ppmv or routed to a flare that meets the requirements in 40 CFR 63.11(b)). This

provision is consistent with an option for controlling emissions from pressure vessels that manage hazardous waste and are subject to the Standards for Owners and Operators of Hazardous Waste Treatment, Storage, and Disposal Facilities in 40 CFR 264.1084 and 40 CFR 265.1085. We are proposing this option in subpart I because it is consistent with and ensures control comparable to proposed requirements for atmospheric storage vessels.

9. How did the EPA determine the proposed requirements for overfill detection and alarms?

We are proposing to require you to equip each storage vessel with an overfill detection sensor. A consortium of international oil companies conducted a study that concluded 11 percent of sunken-roof accidents were caused by overfilling the storage vessel (see *2008 American Petroleum Institute (API) AST Conference,* in the docket for proposed subpart I). According to instrumentation industry representatives, overfill detection systems are currently available, and storage vessels designed to American Society of Mechanical Engineers (ASME) standards must be equipped with such monitoring and alarm systems. The proposed overfill monitoring requirement is intended to alert you to a potential overfill so that you can take action to prevent the overfill and, thus, avoid a deviation of design requirements. We estimated the average cost to plan, purchase and install the required monitor and alarm to be about $1,900 per storage vessel. We estimated the average annual cost of the proposed requirement, including recordkeeping and reporting, to be about $400/year per storage vessel. We expect that this requirement will add little burden because we understand that most storage vessels are already equipped with overfill monitoring and alarm systems. Therefore, we request comment with descriptions of any types of affected storage vessels that are not already equipped with overfill protection systems. We also request comment on whether additional design or operational requirements are needed to ensure successful implementation and enforcement of the proposed overfill monitoring requirement, and whether other types of monitoring could better prevent overfill and the resulting emissions.

10. How did the EPA determine the proposed requirements for control of transfer operations to load transport vehicles?

In the survey of technology for control of transfer operations that involve loading transport vehicles, we identified several compliance approaches. The most common is submerged loading (or bottom loading). We identified this compliance approach as Control Option TR1. We also identified four additional compliance approaches that are more effective than submerged loading alone: (1) Control Option TR2 is to route displaced emissions through a closed vent system to a flare; (2) Control Option TR3 is to route displaced emissions through a closed vent system to a control device that reduces regulated organic emissions by at least 98 percent or to less than 20 ppmv; (3) Control Option TR4 is to vapor balance the displaced emissions back to the storage vessel from which the transport vehicle is being loaded; and (4) Control Option TR5 is to route displaced emissions to a fuel gas system.

We estimated impacts only for Control Options TR1 and TR2. We did not estimate impacts for the other compliance approaches for several reasons. We did not estimate costs for Control Option TR3 because, as part of the analysis for the OLD NESHAP, we determined that flares are the most common and least costly control device for transfer racks. See the memorandum titled *Environmental and Cost Impacts of the Proposed OLD NESHAP,* in docket item EPA–HQ–OAR–2003–0138–0053 for the flare analysis. Although vapor balancing may be less costly than control using a flare in some cases, we did not estimate impacts for Control Option TR4 because vapor balancing requires no venting from the system while a transfer is occurring. This will require pressure settings in the system that may not be feasible for some atmospheric storage vessels. We also did not estimate impacts for Control Option TR5 because not all facilities have or could make use of a fuel gas system, and it would be impractical to install a fuel gas system to handle transfer emissions alone.

Regardless of the control option, vapor tightness testing of the transport vehicle is an approach for ensuring that emissions are conveyed to the intended destination. Finally, LDAR for the equipment in the transfer rack is an approach for controlling fugitive emissions from the transfer rack itself. Each of the control options and other compliance approaches and how they have been incorporated into proposed subpart I are discussed in the sections below.

Control Option TR1. According to AP–42 Chapter 5.2, splash loading results in a vapor-space saturation factor of 1.45, and submerged loading results in a saturation factor of 0.6. Reducing the saturation factor also reduces the concentration of organic compounds in the gases that are displaced when loading the transport vehicle. Thus, Control Option TR1 reduces transfer emissions by an estimated 60 percent relative to splash loading. As shown in Table 7 of this preamble, the costs for Control Option TR1 in light of the estimated emissions reductions also are reasonable for a wide range of transfer throughputs and average vapor pressures. In many cases, the switch to submerged loading would result in a cost savings. Thus, we are proposing that all transfers of regulated material to transport vehicles be conducted using submerged (or bottom) loading.

TABLE 7—ESTIMATED IMPACTS FOR SUBMERGED LOADING OF TRANSPORT VEHICLES

[Control option TR1]

Average vapor pressure of transferred material (psia)	Total transfer throughput at facility (million gal/yr)	Number of loading arms	Total annual costs ($/yr)	Emission reduction [a] (tpy)	Incremental cost effectiveness [a] ($/ton)
0.08	2	1	710	0.13	5,400
0.08	21	4	2,100	1.4	1,500
0.08	45	12	7,300	2.9	2,500
1	2	1	190	1.6	100
1	21	4	(12,100)	17	(710)
1	45	6	(28,000)	37	(770)
3	2	2	(2,700)	4.9	(560)
3	21	4	(43,000)	51	(840)

TABLE 7—ESTIMATED IMPACTS FOR SUBMERGED LOADING OF TRANSPORT VEHICLES—Continued

[Control option TR1]

Average vapor pressure of transferred material (psia)	Total transfer throughput at facility (million gal/yr)	Number of loading arms	Total annual costs ($/yr)	Emission reduction [a] (tpy)	Incremental cost effectiveness [a] ($/ton)
3	45	6	(94,000)	110	(860)

[a] Relative to uncontrolled (*i.e.,* splash loading).

The emissions estimates for the model facilities in Table 7 of this preamble were estimated using procedures in AP–42 Chapter 5.2, assuming the average transfer temperature is 60 °Farenheit and the average vapor molecular weight of transferred materials is 80. The total capital investment was scaled from a quote for converting a rack that has six arms from splash loading to submerged loading; this quote was provided by an industry trade association during development of the gasoline distribution area source rule (see docket item EPA–HQ–OAR–2006–0406–0060). Annual costs were developed for operation, maintenance and indirect costs such as capital recovery. We also included a product recovery credit for the emissions prevented by the change in loading procedures. See the memorandum titled *Survey of Control Technology for Transfer Operations and Analysis of Impacts for Transfer Operation Control Options,* in the docket for proposed subpart I for additional information regarding the development of these impacts.

Control Option TR2. In the impacts analysis for Control Option TR2, we evaluated the impacts for model facilities similar to those that we used in the analysis of submerged loading impacts. The resulting annual costs, emission reductions and incremental cost effectiveness relative to Control Option TR1 are shown in Table 8 of this preamble. See the memorandum titled *Survey of Control Technology for Transfer Operations and Analysis of Impacts for Transfer Operation Control Options,* in the docket for proposed subpart I for a more detailed discussion of how the impacts were developed.

TABLE 8—ESTIMATED IMPACTS TO CONTROL EMISSIONS FROM LOADING OF TRANSPORT VEHICLES USING A CLOSED VENT SYSTEM AND FLARE

[Control option TR2]

Total transfer throughput at facility (million gal/yr)	Average vapor pressure of transferred material (psia)	Number of loading arms	Total annual costs ($/yr)	Emission reduction [a] (tpy)	Incremental cost effectiveness [a] ($/ton)
15	1	6	94,000	8.5	11,100
	3	2	79,000	25.4	3,100
	6	6	94,000	50.7	1,900

	3	8	104,000	42.3	2,500
	6	8	104,000	84.5	1,200
45	1	6	94,000	25.4	3,700
	3	6	94,000	76.1	1,200
	6	12	131,000	152	860

[a] Relative to submerged loading.

Based on the results in Table 8 of this preamble, we determined that the costs of Control Option TR2 are reasonable when a facility transfers more than 35 million gal/yr of liquids that contain regulated material, and the weighted-average vapor pressure of the transferred liquids is a little over 3 psia. Using the monthly temperature data in AP–42 Chapter 7.1 to calculate vapor pressures for several cities shows the average true vapor pressure often is about 80 percent of the MTVP. Thus, we are proposing to require control of displaced emissions from transport vehicle loading at facilities that meet thresholds of at least 35 million gal/yr throughput and a weighted average MTVP of at least 4 psia.

As for storage vessels, some current rules specify thresholds for transfer operation control that are more stringent than the thresholds that we determined to be cost effective. For transfer operations, we decided not to propose any of the thresholds from current rules because few current rules require control of transfer operations, and the thresholds in these rules vary. We also have not conducted regulatory analyses for source categories that do not have control requirements for transfer operations. Therefore, we do not know what thresholds would be appropriate in those rules if they were to be amended to include requirements for transfer operations. At a minimum, the current analysis identifies the cost-effective thresholds that could be used as a starting point in more detailed analysis of requirements on a source category-specific basis.

In contrast to some current rules (*e.g.,* the HON), the proposed vapor pressure threshold is based on the MTVP instead of average vapor pressure. This is intended to reduce the compliance burden. If the temperature of the transferred material varies over the year, then significant calculations and recordkeeping is needed to document the vapor pressure for each transfer and the average over all transfers during the year. The burden grows as the number of materials transferred increases. We recognize that even determining the throughput-weighted MTVP could be burdensome for a rack that transfers numerous regulated materials. It also

requires you to project the total amount of various materials that you expect to transfer during the year so that you can determine whether there is a chance that you would exceed the thresholds. Basing the control threshold only on throughput as in some rules (*e.g.,* the OLD NESHAP) would be less burdensome, but control would be required regardless of the material transferred. Therefore, we request comment on the proposed thresholds for control and suggestions for alternative thresholds that would impose less compliance burden while still ensuring control of emissions when the cost of such control is reasonable.

Other compliance approaches. We are proposing to include several alternative compliance options with which you may elect to comply instead of using a flare. These alternatives are based on Control Options TR3, TR4 and TR5, and they are being included because their performance is the same as or possibly marginally better than the performance obtained by routing emissions through a closed vent system to a flare. We are proposing compliance procedures based on Control Options TR3 and TR5 that are the same as for the closed vent system and fuel gas system approaches for control of storage vessel emissions, except that monitoring or inspections would be required while a transport vehicle is being filled with regulated material. As in the requirements for storage vessels, we are proposing to allow you to demonstrate initial compliance with an emission limit using either a design evaluation or performance test regardless of the throughput. We are proposing this approach to minimize the compliance burden and because we have determined a design evaluation is sufficient given the relatively low level of emissions from transfer operations relative to other emission sources.

The option based on Control Option TR4 is similar to the vapor balancing approach in the OLD NESHAP and other rules in that it includes both design requirements and inspection requirements (*e.g.,* see 40 CFR 63.2346 and Tables 7 and 10 in 40 CFR part 63, subpart EEEE). Unlike current rules, however, we are also proposing to require the following specific design elements and operating procedures: (1) The vapor balancing system must be designed to prevent any regulated material vapors collected at one transfer rack from passing to another transfer rack; (2) all vapor connections in the system must be equipped with closures that seal upon disconnect; and (3) PRD in the system must remain closed while regulated material is loaded in the transport vehicle. Meeting these requirements will help ensure that the vapors displaced from loading transport vehicles with regulated materials are returned to the storage tank from which the liquids being loaded originated. The second and third requirements also are consistent with proposed requirements for vapor balancing systems to control emissions from storage vessels. Finally, we are proposing to require LDAR of equipment in the vapor balancing system consistent with the proposed requirements for equipment in closed vent systems. The vapor balancing system monitoring requirements vary widely in current rules. For example, no monitoring requirement is specified in the MON; the HON requires either annual visual inspections or annual monitoring using Method 21 of 40 CFR part 60, appendix A–7, depending on whether the system is constructed of hard-piping or ductwork; and the OLD NESHAP requires quarterly monitoring using Method 21 of 40 CFR part 60, appendix A–7. We are proposing requirements consistent with those for closed vent systems to streamline the compliance procedures and because a vapor balancing system serves essentially the same purpose as a closed vent system.

Transport vehicle tightness testing. As part of the compliance approaches that are based on Control Options TR2, TR3, TR4 and TR5, you would be required to transfer regulated materials only to transport vehicles that are determined to be vapor tight. We are proposing the vapor tightness requirement for transport vehicles that are loaded at affected transfer racks to ensure that the requirement to collect and convey emissions to control during transfer operations is effective. These requirements have the added benefit of minimizing emissions while the vehicle is in transport as well. To be considered vapor tight, each transport vehicle that is loaded with material that has a MTVP greater than 4 psia would be required to pass an annual vapor tightness test conducted using Method 27 of 40 CFR part 60, appendix A–8. All other transport vehicles would be required to have a current certification in accordance with DOT pressure test requirements in 49 CFR part 180 for cargo tanks or 49 CFR 173.31 for tank cars. These proposed requirements are similar to requirements in several current rules. For example, several gasoline distribution rules require testing of gasoline transport vehicles using Method 27 of 40 CFR part 60, appendix A–8 (*e.g.,* 40 CFR part 60, subpart XX, and 40 CFR part 63, subpart R). The OLD NESHAP requires EPA Method 27 testing for transport vehicles that are equipped with vapor-collection equipment, and other transport vehicles must meet the DOT certification requirements. In the preamble to the proposed OLD NESHAP, we noted that tank trucks in chemical service typically are not equipped with vapor-collection equipment (63 FR 15682, April 2, 2002). Although we are uncertain whether vapor-collection equipment is now more common on trucks used to transport chemicals than it was 10 years ago, we think it is appropriate that all vehicles used to transport materials with vapor pressure comparable to the vapor pressure of gasoline should be subject to the same vapor tightness requirements. The proposed MTVP threshold was set at 4 psia because this is about the minimum MTVP for any grade of gasoline. We request comment on the burden and costs of this proposed requirement to conduct vapor-tightness testing using Method 27 of 40 CFR part 60, appendix A–8. For example, we are interested in estimates of the number of vehicles that would have to be retrofitted with vapor-collection equipment, the costs of such retrofits and the fraction of the volume transported in such vehicles that exceeds the 4-psia threshold. In addition, since the MTVP of a given material varies depending on location, we request comment on whether a threshold based on another parameter would be easier to implement.

Finally, as in current rules, you would be required to take actions to assure that your closed vent system, vapor balancing system or fuel gas system is connected to the transport vehicle's vapor-collection equipment when regulated material is transferred. These requirements are intended to ensure that the displaced emissions are routed to the required control. Examples of actions to satisfy this requirement include training drivers in the hookup procedures and posting visible reminder signs at the affected transfer racks.

11. How did the EPA determine the proposed requirements for control of transfer operations to load containers?

In the survey of technology of emission controls for transfer racks that are used to load containers, we identified several control approaches that have each been included in one or more current rules. For example, one approach is to use controls such as submerged loading or fitted openings in conjunction with transfer line purging. We also identified operational practices to control emissions from containers that are storing transferred regulated

material (*e.g.,* maintaining covers and other closure devices in the closed position except when access to the container is necessary). We also identified three more effective compliance approaches: (1) Vapor balance displaced emissions back to a storage vessel; (2) locate the transfer rack inside an enclosure that meets the requirements for a Permanent or Temporary Total Enclosure in 40 CFR 52.741, appendix B, and exhaust the enclosure through a closed vent system to a control device; and (3) vent displaced emissions from the container itself through a closed vent system to a control device. In addition, vapor tightness testing can be conducted on containers, like transport vehicles.

For the impacts analysis, we evaluated two control options: Control Option TR6, which combines submerged fill with the operational practices of using closure devices on stored containers and Control Option TR7, which consists of venting displaced emissions through a closed vent system to a flare. We did not estimate impacts for the enclosure approach (Control Option TR8) because costs for the enclosure are expected to result in higher total costs than for Control Option TR7, and the control device might have to be larger to handle the airflow needed to meet the requirements in 40 CFR 52.741, appendix B. We did not estimate impacts for the vapor balancing approach (Control Option TR9) because we are not aware of any facility that is using this approach, and as with storage vessels, vapor balancing may not be feasible at all facilities due to allowable pressure limits for safe operation.

The impacts of Control Options TR6 and TR7 for a series of model transfer racks are presented in Table 9 of this preamble. The models cover a range of typical throughputs as reported by facilities that responded to an information collection request (ICR) for OLD operations (see the memorandum titled *Model Plants for the OLD Source Category,* in docket item EPA–HQ–OAR–2003–0138–0052 for site-specific throughputs). The models also span a wide range of average vapor pressures.

TABLE 9—ESTIMATED IMPACTS OF CONTROL OPTIONS TR6 AND TR7 FOR LOADING CONTAINERS AT A TRANSFER RACK

Average Reid vapor pressure of transferred material (psia)	Total transfer throughput at facility (million gal/yr)	Total annual costs ($/yr)	Emission reduction (tpy)	Cost effectiveness [a] ($/ton)
Control Option TR6				
1.5	0.1	700	0.016	43,000
1.5	5	(13)	0.81	(16)
3.37	0.1	680	0.036	19,000
3.37	5	(920)	1.8	(510)
8	0.1	630	0.12	5,500
8	5	(3,200)	0.016	(550)
Control Option TR7				
1.5	0.1	81,000	0.050	2,400,000
1.5	5	81,000	2.5	47,000
3.37	0.1	81,000	0.11	1,100,000
3.37	5	81,000	5.6	21,000
8	0.1	81,000	0.36	330,000
8	5	81,000	18	6,600

[a] Relative to uncontrolled for Control Option TR6 and relative to Control Option TR6 for Control Option TR7.

Capital costs for submerged fill were estimated assuming the capital costs for retrofitting one station that loads containers are about half of the costs for retrofitting one arm that loads transport vehicles. Annual costs for submerged fill were estimated using the same procedures as in the analysis for Control Option TR1. Costs for the closed vent and flare system were scaled from costs developed from vendor information in the analysis for the OLD analysis (see docket item EPA–HQ–OAR–2003–0138–0053).

Uncontrolled emissions were estimated using two approaches. One approach was to use the vehicle refueling equation presented in AP–42 chapter 5.2. This approach was used in the analysis for the OLD NESHAP because surveyed OLD facilities were using nozzles like those used at gasoline service stations. A problem with this approach is that it is not reliable at low vapor pressures. Specifically, as the vapor pressure approaches zero, the emissions are estimated to be negative. Therefore, we also estimated emissions using a second approach, which was to use the transfer rack loss equation in AP–42 chapter 5.2 (*i.e.,* the same approach that we used to estimate emissions from transport vehicles), but with one modification. It is not clear that the splash-loading factor in AP–42 is applicable for container loading given the much lower fill rate of containers. Therefore, we selected a saturation factor (*i.e.,* 0.88) that, when used in the transfer rack loss equation, produced the same emissions as the vehicle refueling equation when the Reid vapor pressure of transferred material is 3.37 psia (this is the vapor pressure used for models in the OLD analysis). Using this factor gave higher emissions estimates than the vapor refueling equation for Reid vapor pressures lower than 3.37 psia, and it gave higher emissions for Reid vapor pressures higher than 3.37 psia. To estimate controlled emissions for Control Option TR6, we assumed the saturation factor would be 0.6, as in the analysis for Control Option TR1. Thus, we assumed Control Option TR6 reduces emissions by 32 percent ([0.88 − 0.6]/[0.88] = 0.32). Controlled emissions for Control Option TR7 were assumed to be 2 percent of the emissions for Control Option TR6.

The results of this analysis show the cost impacts for Control Option TR6 are reasonable for throughputs greater than about 1 million gal/yr over the range of vapor pressures specified for the model transfer racks. The analysis also shows

the cost impacts of Control Option TR7 are unreasonable for all of the same model transfer racks. Thus, for transfer operations that include the loading of regulated material into containers, we are proposing that the Uniform Standards require submerged loading. In addition, when a loaded container contains regulated material and is maintained on site, all openings in the containers would have to be equipped with covers and closure devices, which you would have to maintain in the closed position except when access to the container is necessary (*e.g.,* for adding or removing material, sampling or cleaning).

We are also proposing other options that have equal or better performance that may be used instead of submerged loading, or that may be required, if justified, by referencing subparts. These other options include using fitted openings in conjunction with transfer line purging, which is specified in the Gasoline Distribution NESHAP (40 CFR part 63, subpart R). We are also proposing requirements for compliance approaches that are based on Control Options TR8 and TR9. These proposed requirements are a consolidated and streamlined version of the requirements in the Generic MACT for Containers and OLD NESHAP. If you use a closed vent system and control device, the control device would be required to reduce regulated material emissions by 95 percent, as in current rules. Inspection requirements for both closed vent systems and vapor balancing systems would be the same as for such systems used to convey emissions from loading of transport vehicles.

If you load a container 55 gallons or larger with material that has a MTVP greater than 4 psia and use the container for onsite storage of that material, then the container would be subject to either annual vapor tightness testing in accordance with Method 27 of 40 CFR part 60, appendix A–8, or annual monitoring of potential leak interfaces using Method 21 of 40 CFR part 60, appendix A–7. The leak definition for the EPA Method 21 testing would be 500 ppmv. These testing or monitoring requirements are needed to demonstrate that transferred materials with high vapor pressures are not emitted from storage. We request comment on the burden and costs of this proposed requirement to conduct vapor-tightness testing using Method 27 of 40 CFR part 60, appendix A–8. For example, we are interested in estimates of the number of containers that would have to be retrofitted with vapor-collection equipment, the costs of such retrofits and the fraction of the volume stored in such containers that exceeds the 4-psia threshold. In addition, since the MTVP of a given material varies, depending on location, we request comment on whether a threshold based on another parameter would be easier to implement.

12. How did the EPA determine the definitions of terms used in proposed subpart I?

As discussed in section VI.B.16 of this preamble, all definitions are located in proposed 40 CFR part 65, subpart H. Most of the definitions that are used in proposed subpart I are unchanged from the definitions in current rules, such as 40 CFR part 63, subpart WW and subpart EEEE. We are also proposing definitions for the terms ''barge,'' ''fittings'' and ''pressure vessel,'' which are not defined in current rules. The vapor balancing requirements for storage vessels specify that emissions from the storage vessel may be vapor balanced to a barge that is providing the liquid to fill the storage vessel. To clarify what type of vessel qualifies as a barge, we are proposing to define a barge as ''any vessel that transports regulated material liquids in bulk on inland waterways or at sea.''

We are proposing to add a definition for the term ''storage capacity.'' This term is intended to take the place of the term ''capacity'' that is defined in 40 CFR part 63, subpart WW. We are proposing the change to avoid possible confusion because the term capacity is also used in a different context in proposed 40 CFR part 65, subpart M. We are also modifying the definition to specify that storage capacity of a flat-bottomed storage vessel is determined by multiplying the internal cross-sectional area of the storage vessel by the internal height of the shell, but the calculation for storage vessels with a sloped bottom or cone-up or cone-down bottoms need to be adjusted to account for the fact that the floor is not flat.

We are proposing to include a definition for ''automatic bleeder vent (vacuum breaker vent).'' Vacuum breaker vents equalize the pressure across a landed floating roof when liquid is either being withdrawn or added below the landed roof. Current rules do not include a definition for such devices, but historically vacuum breaker devices have been a covered well opening with a leg attached to the underside of the cover. When the roof lands, the leg opens the vent by lifting the cover off the well. Recently, we learned of a new design that is activated by pressure or vacuum differences across the roof. Theoretical calculations have shown such vents should open only while the roof is landed, not while it is floating. Based on this analysis, we have decided to include both mechanically activated and pressure/vacuum activated devices in the proposed definition of ''automatic bleeder vent (vacuum breaker vent).'' We request additional information, in particular, any test data that either supports or contradicts the theoretical analysis.

Finally, we are proposing to use a new definition of ''maximum true vapor pressure'' that excludes the list of methods that may be used to determine MTVP. In proposed subpart I, this list has been moved to 40 CFR 65.306. We also added a new method to the list: *Test Method for Vapor Pressure of Reactive Organic Compounds in Heavy Crude Oil Using Gas Chromatography.* This method was developed because existing methods cannot be applied to heavy crude oils. We moved the list of methods to 40 CFR 65.306 because we are also proposing three additional changes to the procedures for determining MTVP that cannot be readily included in a definition. First, we are proposing to require testing to determine MTVP of mixtures (such as petroleum liquids) and to allow information from reference texts to be used only for pure compounds. We are proposing this change because we are concerned that the compositions of mixtures (*e.g.,* crude oils) vary considerably depending on their source and how they are handled before storage. Thus, average or generic values for a class of materials do not necessarily accurately represent the characteristics of the material in each storage vessel. Second, we are proposing to require new determinations each time a storage vessel is filled with a different type of material. This is an implied requirement in current rules, but this change clearly states the requirement. Third, because the composition of mixtures can vary (as noted above), we are proposing to require redetermination of the MTVP annually if stored materials are mixtures and previous testing has determined the MTVP is below the thresholds for control, as specified in Table 1 of proposed subpart I (and Table 1 of this preamble).

IV. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Emission Standards for Equipment Leaks—Subpart J

A. Summary

We are proposing new Uniform Standards for control of emissions from equipment leaks. These Uniform Standards for equipment leaks would

apply only to equipment that is subject to a regulation that references provisions in 40 CFR part 65, subpart J, for control of equipment leaks. We would only issue regulations that reference provisions of 40 CFR part 65, subpart J, once we have determined that those provisions meet applicable statutory requirements for a particular source category (*e.g.,* MACT, AMOS, BSER).

In section IV of this preamble, the term ''we'' refers to the EPA and the term ''you'' refers to owners and operators affected by the proposed standards. Section IV.A.1 of this preamble identifies the regulated sources under the proposed 40 CFR part 65, subpart J. Sections IV.A.2 through 4 of this preamble summarize the proposed standards for equipment leaks. Section IV.A.5 of this preamble summarizes the proposed standards for using an optical gas imaging instrument to detect leaks. Section IV.A.6 of this preamble summarizes the notification, reporting and recordkeeping requirements. Section IV.B of this preamble presents the rationale behind the development of the proposed standards.

1. What parts of my plant are affected by the proposed rule?

The proposed 40 CFR part 65, subpart J includes requirements for equipment in process units, closed vent systems and fuel gas systems, including valves, pumps, connectors, agitators, PRD, compressors, sampling connection systems, open-ended valves and lines, instrumentation systems and any other types of equipment specified by the referencing subpart that contain or contact regulated material (as defined by the referencing subpart). This subpart also includes requirements for closed-purge and closed-loop systems used to control emissions from certain types of equipment. Proposed 40 CFR part 65, subpart J does not include applicability provisions; instead, the referencing subpart would define what equipment in that source category is subject to the provisions of the Uniform Standards.

2. What are the proposed general requirements for complying with this subpart?

Your equipment would be subject to some or all of the requirements of 40 CFR part 65, subpart J when another subpart references the use of provisions of subpart J for air emission control. In addition, you would be required to meet the general provisions applicable to part 65 (*i.e.,* subpart H of 40 CFR part 65) and the general provisions applicable to the referencing subpart (*i.e.,* subpart A of 40 CFR parts 60, 61 or 63).

3. What are the types of techniques we are proposing to reduce emissions from equipment leaks?

Equipment leak standards consist of techniques to detect leaks based on sensory inspections, instrument monitoring or use of an optical gas imaging instrument, as applicable. Equipment design standards specify requirements regarding the use, design or operation of the equipment. Each of these techniques is summarized in this section.

Sensory monitoring. Sensory monitoring includes visual, audible, olfactory or any other sensory detection method used to determine a potential leak to the atmosphere. If you found indications of a potential leak, you would be required either to: (1) Repair the equipment such that the indications of a potential leak to the atmosphere are no longer evident; (2) determine that no bubbles are observed at potential leak sites during a leak check using a soap solution; or (3) conduct instrument monitoring as described in the next paragraph to determine if the instrument reading is above the applicable threshold (indicating that the equipment is leaking) and, if the equipment is leaking, repair the leak as described in section IV.A.4 of this preamble.

Instrument monitoring. Instrument monitoring would require you to check for leaks with a portable instrument in accordance with Method 21 of 40 CFR part 60, appendix A–7. A leak would be detected if you obtain an instrument reading above the threshold (*i.e.,* leak definition) specified in the applicable section of the proposed regulation. If you detect a leak, you would be required to repair the leak as described in section IV.A.4 of this preamble. The frequency at which you would be required to conduct instrument monitoring is specified for each type of equipment. For some equipment, the required monitoring frequency varies depending on the percentage of the equipment in the applicable process unit that was determined to be leaking in previous monitoring periods. In addition to following the procedures in Method 21 of 40 CFR part 60, appendix A–7, the proposed rule would require you to conduct a calibration drift assessment at the end of each monitoring day. The proposed rule also specifies procedures that would allow you to correct instrument readings for background concentrations of regulated materials.

Optical gas imaging. Another method of detecting leaks from equipment is to scan equipment using a device or system specially designed to use one of several types of remote sensing techniques, including optical gas imaging of infrared wavelengths, differential absorption light detection and ranging [DIAL], and solar occultation flux. The most common optical gas imaging instrument (also referred to as a ''camera'') is a passive system that creates an image based on the absorption of infrared wavelengths. A gas cloud containing certain hydrocarbons (*i.e.,* leaks) will show up as black or white plumes (depending on the instrument settings and characteristics of the leak) on the optical gas imaging instrument screen. This type of optical gas imaging instrument is the device on which our optical gas imaging provisions are based.

On December 22, 2008, we published an Alternative Work Practice (AWP) for LDAR that includes a combination of optical gas imaging and instrument monitoring techniques (73 FR 78199). The AWP provisions are located in the General Provisions in 40 CFR parts 60, 61 and 63, so any source subject to LDAR requirements in any current equipment leak rule may elect to comply with this AWP. (This includes the proposed Uniform Standards, as proposed 40 CFR part 65, subpart H specifies that those sections would continue to apply to the referencing subparts.) In addition, we are proposing the optical gas imaging-only provisions described in section IV.A.5 of this preamble. If specifically allowed by your referencing subpart, you would be allowed to use optical gas imaging rather than instrument monitoring to detect leaks from your equipment. You would be required to comply with the leak survey procedures for an optical gas imaging device that will be proposed in 40 CFR part 60, appendix K.

Equipment design. Proposed standards for some equipment consist of design features that either provide an additional barrier to emissions or provide for collection of otherwise discharged material for recycle, reuse or treatment. Where applicable, the specific requirements for each type of equipment and control level are described in section IV.A.4 of this preamble.

4. What are the specific equipment leak standards we are proposing?

As in current equipment leak rules, the proposed Uniform Standards for equipment leaks are based on a combination of standards, including

LDAR programs, equipment design standards and performance standards. In addition, we are proposing two alternative means of compliance that can be used only in specific situations. Many of these proposed equipment leak standards are consistent with current equipment leak standards. The discussion in this section IV.A of the preamble describes all elements of the proposed standards. Section IV.B of this preamble discusses how we developed the proposed provisions and describes how the proposed provisions are consistent with one or more previous rules or why we are introducing additional requirements unique to this proposal.

For most types of equipment, current rules specify separate requirements for equipment in different types of service (*e.g.,* gas and vapor service, light liquid service). The proposed Uniform Standards also follow this type of approach; for certain types of equipment (*e.g.,* valves), the proposed Uniform Standards include specific instrument monitoring requirements for equipment in gas and vapor service and equipment in light liquid service and specify specific sensory monitoring requirements for equipment in heavy liquid service. We are also proposing that the sensory monitoring requirements would apply to other equipment that meet certain criteria, such as equipment in regulated service less than 300 hr/yr and equipment that contains or contacts regulated material, but not in sufficient quantities to be operating in regulated material service.

Section IV.A.4 of this preamble describes proposed standards for specific types of equipment. After you identify indications of a potential leak using sensory monitoring or identify a leak using instrument monitoring, optical gas imaging or other method, the proposed rule would require you to repair the leaking equipment using procedures that also are summarized in section IV.A.4 of this preamble. Finally, alternative equipment leak standards that are provided in the proposed rule are summarized in section IV.A.4 of this preamble.

Proposed requirements for valves in gas and vapor service and valves in light liquid service. We are proposing that for valves in gas and vapor service and valves in light liquid service, you would be required to conduct instrument monitoring on a monthly basis for at least the first 2 months after initial startup. An instrument reading of 500 parts per million (ppm) or greater would indicate a leak requiring repair. Following the first 2 months, you would be required to conduct instrument monitoring at a frequency dependent upon the percentage of leaking valves within the process unit in those first 2 months (the proposed frequencies range from monthly if more than 2 percent of the valves were leaking to biennially if less than 0.25 percent of the valves were leaking). We are also proposing that you may use prior monitoring data in lieu of conducting initial monthly monitoring. For example, if your valves in gas and vapor service and valves in light liquid service are already subject to instrument monitoring and repair of leaks at 500 ppm or greater, you would be able to consider the monitoring data collected under your current rule to determine your monitoring frequency for the Uniform Standards.

We are also proposing provisions for subgrouping valves for monitoring purposes. We are proposing specific monitoring and repair requirements for valves located at a plant site with fewer than 250 total valves, valves for which the valve mechanism is not connected to a device that penetrates the valve housing (*e.g.,* most check valves), unsafe-to-monitor valves and difficult-to-monitor valves.

Proposed requirements for pumps in light liquid service. We are proposing monthly instrument monitoring for pumps in light liquid service. The instrument reading indicating a leak would vary based on the type of material being handled by that pump: 5,000 ppm or greater for pumps handling polymerizing monomers and 2,000 ppm or greater for all other pumps. In addition to instrument monitoring, you would be required to conduct a weekly visual inspection of all pumps in light liquid service for dripping liquids. If you found indications of liquids dripping, you would be required either to repair the pump seal, eliminating the indications of liquids dripping or to conduct instrument monitoring. If you elected to conduct instrument monitoring, the instrument reading that defines a leak requiring repair would be 5,000 ppm for a pump handling polymerizing monomers or 2,000 ppm for all other pumps.

We are also proposing specific monitoring and repair requirements for pumps equipped with a dual mechanical seal system that includes a barrier fluid system, pumps with no externally actuated shaft penetrating the pump housing, pumps located within the boundary of an unmanned plant site, unsafe-to-monitor pumps and difficult-to-monitor pumps.

Proposed requirements for connectors in gas and vapor service and connectors in light liquid service. If your referencing subpart specifically references proposed 40 CFR 65.422, you would be required to conduct instrument monitoring for connectors in gas and vapor service and connectors in light liquid service, and you would be required to conduct initial instrument monitoring within 12 months of the compliance date specified in a referencing subpart or 12 months after initial startup, whichever is later. We are also proposing to specify that if all the connectors in a process unit have been monitored for leaks prior to the compliance date specified in the referencing subpart, no initial monitoring is required, provided that either no process changes have been made since the prior monitoring or you can show that the results of the monitoring reliably demonstrate compliance despite process changes. Following the initial monitoring, you would be required to conduct instrument monitoring at a frequency between annually and every 8 years, depending on the percentage of leaking connectors within the process unit. An instrument reading of 500 ppm or greater would indicate a leak that would require repair. We are also proposing specific monitoring and repair requirements for unsafe-to-monitor connectors; difficult-to-monitor connectors; and inaccessible, ceramic or ceramic-lined connectors. Note that you would only be required to conduct instrument monitoring for connectors in gas and vapor service and connectors in light liquid service if your referencing subpart specifies that you must comply with proposed 40 CFR 65.422.

Proposed requirements for agitators in gas and vapor service and agitators in light liquid service. We are proposing monthly instrument monitoring for agitators in gas and vapor service and agitators in light liquid service. An instrument reading of 10,000 ppm or greater would indicate a leak that would require repair. In addition to instrument monitoring, you would be required to conduct weekly visual inspection of agitators. If you found indications of liquids dripping from the agitator seal, you would be required either to repair the agitator seal, eliminating the indications of liquids dripping or to conduct instrument monitoring. If you elected to conduct instrument monitoring, the instrument reading that defines a leak would be 10,000 ppm or greater. We are also proposing specific monitoring and repair requirements for agitators equipped with a dual mechanical seal system that includes a barrier fluid system, agitators with no externally actuated shaft penetrating the

agitator housing, agitators located within the boundary of an unmanned plant site, agitators obstructed by equipment or piping, unsafe-to-monitor agitators and difficult-to-monitor agitators.

Proposed requirements for PRD. Proposed 40 CFR 65.424 includes operational requirements and pressure release management requirements for all PRD in regulated material service. We are proposing that you operate PRD in gas or vapor service with an instrument reading less than 500 ppm above background. If your PRD includes or consists of a rupture disk, you would be required to install a replacement disk no later than 5 calendar days after each pressure release. In addition, after each pressure release from a PRD in gas or vapor service (regardless of the type of PRD), you would be required to conduct instrument monitoring to confirm that the instrument reading is less than 500 ppm no later than 5 calendar days after the PRD returns to regulated material service following a pressure release.

In addition, we are proposing provisions that would apply only if your referencing subpart specifies that no releases to the atmosphere are allowed from any PRD in regulated material service. We are proposing that for each such PRD, you would be required to install and operate a monitor capable of identifying a pressure release, recording the time and duration of each pressure release and notifying operators that a pressure release has occurred. We are also proposing that if the monitor is capable of monitoring concentration of any flow through the PRD, then you would not also be required to conduct separate instrument monitoring no later than 5 calendar days after the PRD returns to regulated material service following a pressure release to confirm that the instrument reading is less than 500 ppm. You would also be required to calculate, record and report the quantity of regulated material released during each pressure relief event. Note that your referencing subpart may include other requirements for releases to the atmosphere as well.

Proposed requirements for compressors. We are proposing two compliance options for compressors in regulated material service. The first would be to equip the compressor with a seal system that includes a barrier fluid system and that prevents leakage of process fluid to the atmosphere. You would determine, based on design considerations and operating experience, a criterion that indicates failure of the seal system, the barrier fluid system or both. You would also be required to equip the compressor with a sensor that would detect a failure of the seal system, the barrier fluid system or both. If a failure is indicated by either of those methods, a leak is detected, and you would be required to repair the leak. You would also be required to conduct sensory monitoring for all potential points of vapor leakage on the compressor other than the seal system.

The second option would be to designate that the compressor operates with an instrument reading of less than 500 ppm above background at all times. After you initially confirm that the compressor has an instrument reading less than 500 ppm, you would be required to conduct ongoing instrument monitoring at least annually to demonstrate that the compressor operates with an instrument reading of less than 500 ppm above background. If the instrument reading from any part of the compressor is 500 ppm above background or greater, the compressor would not be in compliance with proposed 40 CFR part 65, subpart J until the next instrument reading of less than 500 ppm above background.

Proposed requirements for sampling connection systems. We are proposing equipment design standards for sampling connection systems. You would be required to equip the sampling connection system with a closed-purge, closed-loop or closed vent system. You would be required to control purged process fluids by returning them to the process line, to a process, routing them to a control device, routing them to a fuel gas system or treating them in a waste management unit, a hazardous waste treatment facility or a device used to burn used oil for energy recovery (all of which would be required to meet specific standards). Gases displaced during filling of the sample container and gases remaining in the tubing or piping between the closed-purge system valve(s) and sample container valves(s) after the valves are closed and the sample container is disconnected are not considered to be purged process fluids and would not be required to be collected or captured. We are proposing to clarify that analyzer vents are considered sampling connection systems (and that CEMS are not considered analyzer vents). In-situ sampling systems and systems without purges would be exempt from these standards.

Proposed requirements for open-ended valves and lines in gas and vapor service and open-ended valves and lines in light liquid service. We are proposing equipment and operational standards for open-ended lines and open-ended valves. You would be required to equip open-ended valves and lines with a cap, blind flange, plug or second valve. The cap, blind flange, plug or second valve would be required to seal the open-ended valve or line at all times, except during operations requiring process fluid flow through the open-ended valve or line, during maintenance or during operations that require venting the line between block valves in a double block and bleed system. If the open-ended valve or line is equipped with a second valve, you would be required to close the valve on the process fluid end before closing the second valve.

In addition, you would be required to conduct annual instrument monitoring to demonstrate that the open-ended valve or line operates with an instrument reading of less than 500 ppm above background (*i.e.,* that the cap, blind flange, plug or second valve seals the open-ended valve or line at all times). If the instrument reading is 500 ppm above background or greater, the open-ended valve or line would not be in compliance with proposed 40 CFR part 65, subpart J until the next instrument reading of less than 500 ppm above background.

Open-ended valves and lines in an emergency shutdown system that are designed to open automatically in the event of a process upset would be exempt from the equipment design and instrument monitoring requirements. However, if your referencing subpart specifies that releases to the atmosphere from these types of open-ended valves and lines are not allowed, then any time an open-ended valve or line of this type does release to the atmosphere, it would not be in compliance with proposed 40 CFR part 65, subpart J. (Note that your referencing subpart may include other requirements for releases to the atmosphere as well.) In addition, open-ended valves and lines containing materials that would auto catalytically polymerize or would present an explosion, serious overpressure or other safety hazard if capped or equipped with a double block and bleed system would be exempt from the equipment and instrument monitoring requirements. Instead, you would be required to conduct sensory monitoring for these open-ended valves and lines.

Proposed requirements for equipment in closed vent systems and fuel gas systems. We are proposing operational standards for equipment in closed vent systems and fuel gas systems. You would be required to conduct annual instrument monitoring to demonstrate that each piece of equipment in a closed vent system or fuel gas system operates with an instrument reading of less than 500 ppm above background. If the

instrument reading is 500 ppm above background or greater, the equipment would not be in compliance with proposed 40 CFR part 65, subpart J until the next instrument reading of less than 500 ppm above background.

Proposed requirements for detecting leaks from other equipment. We are proposing that sensory monitoring would be the basic level of control for all equipment. Sensory monitoring would be required for all equipment that contains or contacts regulated material, but is not required to comply with the specific requirements in proposed 40 CFR 65.420 through 65.427. This would include: (1) Equipment at a plant site with less than 1,500 total pieces of equipment; (2) equipment that contains or contacts regulated material, but not in sufficient quantities to be operating in regulated material service; (3) equipment in regulated material service less than 300 hr/yr; (4) valves, pumps, connectors and agitators in heavy liquid service; (5) connectors not required by your referencing subpart to comply with 40 CFR 65.422; (6) instrumentation systems; (7) PRD in liquid service; (8) any equipment for which sensory monitoring is required specifically by a provision in proposed 40 CFR 65.420 through 65.427 (*e.g.,* potential points of vapor leakage on the compressor other than the seal system, open-ended valves and lines containing materials that would auto catalytically polymerize or would present an explosion, serious overpressure or other safety hazard if capped or equipped with a double block and bleed system); and (9) any other equipment, as specified by your referencing subpart. If you found indications of a potential leak, you would be required either to repair the equipment, eliminating the indications of the potential leak or conduct instrument monitoring to confirm whether there is a leak within 5 calendar days of detection. If you elected to conduct instrument monitoring, the instrument reading that defines a leak requiring repair is specified in proposed Table 1 to subpart J of 40 CFR part 65.

We are also proposing special requirements for equipment in vacuum service. You would be required to identify equipment operating in vacuum service. You would also be required to demonstrate that the equipment is operating in vacuum service by installing and maintaining a pressure gauge and alarm system that will alert an operator immediately and automatically when the equipment is not operating vacuum service. If the alarm were triggered, you would be required either to initiate procedures immediately to return the equipment to vacuum service or to begin to comply with the applicable requirements of proposed 40 CFR part 65, subpart J (*e.g.,* comply with the instrument monitoring requirements of proposed 40 CFR 65.420 for valves in gas and vapor service and valves in light liquid service).

Proposed repair requirements. We are proposing to specify that when the standards indicate that you are required to repair a leak, you would be required to do so as soon as practical, but not later than 15 calendar days after the leak is detected. You would also be required to make a first attempt at repair no later than 5 calendar days after the leak is detected. For leaks detected through instrument monitoring or optical gas imaging, repair would include instrument monitoring or optical gas imaging within the specified time frame to verify that the leak was repaired successfully.

We are also proposing to allow repairs to be delayed in a few specific situations. First, you would be allowed to delay repair if the repair is technically infeasible within 15 days of detection without a process unit shutdown. We are proposing to require repair of this equipment as soon as practical, but no later than the end of the next process unit shutdown or 5 years after detection, whichever is sooner. Any shutdown of 24 hours or longer would be considered the next process unit shutdown during which you would be required to repair the leak. Second, you would be allowed to delay repair if you determine that repair personnel would be exposed to an immediate danger as a consequence of complying with the repair requirement and you designate the equipment as unsafe-to-repair. Third, a delay in repair would be allowed for equipment that is isolated from the process and that does not remain in regulated material service. Fourth, for valves, connectors and agitators, delay of repair would be allowed if you demonstrate that emissions of purged material resulting from immediate repair would be greater than the fugitive emissions likely to result from delay of repair. When you do repair the valve, connector or agitator, you would be required to ensure the purged material is collected and destroyed, collected and routed to a fuel gas system or process or routed through a closed vent system to a control device. Finally, for pumps, you would be allowed to delay repair up to 6 months after the leak was detected if you demonstrate that repair would require a design change such as replacement of the existing seal design with a new seal system or a dual mechanical seal system, installing a pump with no external shaft or routing emissions through a closed vent system to a control device or to a fuel gas system. Regardless of the reason that you delay repair, you would be required to continue instrument monitoring on the appropriate schedule for that type of equipment.

If you delay repair of a valve or connector beyond 15 days, we are proposing to require that you repair the leaking equipment by replacing the leaking equipment with low leak technology unless it is not technically feasible to do so. You would have several types of ''low leak technologies'' from which to select. For valves, you could elect to repack the valve, replace the leaking valve with a valve designed to accommodate specific types of packing or replace the existing valve with a bellow seal valve. For connectors, you would have the option to replace the flange gasket or the entire connector. If you cannot replace the leaking equipment with low leak technology, then you would be required to explain why that replacement is technically infeasible in your annual periodic report and to keep records of the demonstration that replacement is technically infeasible. In addition, if that equipment leaks again in the future and you delay the repair beyond 15 days, you would be required to conduct a new analysis of the technical feasibility of using low leak technology (*i.e.,* you would not be allowed to just refer to the previous demonstration).

Proposed alternative standards. We are proposing to provide an alternative compliance option specifically for equipment in regulated material service in batch operations. If you conduct instrument monitoring for equipment in batch operations, we are proposing to provide alternative monitoring frequencies to accommodate non-continuous operation. In addition, each time you reconfigured the process components and transport piping in the batch operation for the production of a different product, you would be required to monitor the equipment in the reconfigured process for leaks within 30 days of beginning operation of the process.

5. What are the proposed standards for using an optical gas imaging device to detect leaks?

We anticipate that for some source categories, specific requirements for using an optical gas imaging device to detect leaks without accompanying instrument monitoring could be an

appropriate alternative to the requirements described in section IV.A.4 of this preamble. Therefore, we are proposing to allow the use of optical gas imaging as a standalone technique for detecting equipment leaks in regulated material service. These provisions for leak detection would be allowed as an alternative only if your referencing subpart includes a direct reference to proposed 40 CFR 65.450. At this time, we are allowing only limited use of optical gas imaging because we believe that this technique currently is not suitable for detection of leaking compounds in all industry sectors due to the limitation of the number of compounds that can be screened using this technology. However, we fully expect that the technology will improve over time and that the number of industry sectors allowed to use this option will increase in the future.

Additionally, we are currently developing a protocol for using optical gas imaging techniques. The protocol will be proposed to be promulgated as appendix K to 40 CFR part 60. Proposed 40 CFR 65.450 specifies that you must follow this protocol if you opt to use optical gas imaging in lieu of EPA Method 21. This protocol will outline specifications of the equipment that must be used, calibration techniques, procedures for conducting surveys and training requirements for optical gas imaging instrument operators. The protocol will not specify the instrument that must be used, but it will provide specifications and performance criteria that must be met. The protocol will contain techniques to verify that your instrument can image the most prevalent chemical in your process unit. Because field conditions greatly impact detection of the regulated material using optical gas imaging, the protocol will describe the impact that these field conditions may have on readings and how to address them, as well as when monitoring with this technique is inappropriate. These field conditions include distance to the target, complex thermal environments, position of the sun, background temperatures, humidity, wind speed, wind direction, angle to the target and time of day. The protocol will also address difficulties with identifying equipment and leaks in dense industrial areas.

We note that, to date, appendix K to 40 CFR part 60 has not been proposed for review and comment. When appendix K to 40 CFR part 60 is proposed, we will request comments on that appendix K. In addition, we intend to provide an opportunity to comment on the application of appendix K to 40 CFR part 60 to the optical gas imaging provisions in these Uniform Standards.

If you elect to comply with 40 CFR 65.450, then we are proposing that, unless your referencing subpart specifies otherwise, you would monitor your equipment bimonthly, and that the optical gas imaging instrument would be required to detect leaks at 60 grams per hour or greater. Any image that appears on the optical gas imaging instrument screen would be considered a leak requiring repair, regardless of the type of equipment leaking. You would be required to follow the repair requirements in proposed 40 CFR 65.432, except that the monitoring to verify repair would be monitoring using the optical gas imaging instrument rather than instrument monitoring. You would be allowed to delay repair of leaks under the same provisions as if you conducted instrument monitoring (proposed 40 CFR 65.432(d)), including leaks that are technically infeasible to repair without a process unit shutdown and leaks in unsafe-to-repair equipment.

6. What are the notification, reporting and recordkeeping requirements?

Notification of Compliance Status. We are proposing that the Notification of Compliance Status required by 40 CFR 65.225 would include: (1) The process unit, closed vent system or fuel gas system identification; (2) the number of each equipment type (*e.g.,* valves, pumps); (3) method of compliance with the standard for that equipment; and (4) whether you used monitoring data generated before the regulated source became subject to the referencing subpart to qualify for less frequent monitoring of valves and/or connectors. If your method of compliance is a closed vent system and control device or a fuel gas system, you would include the applicable information specified in proposed 40 CFR part 65, subpart M. In addition, if your referencing subpart required you to comply with 40 CFR 65.424(c) for PRD in regulated material service, you would be required to provide: (1) A description of the monitoring system to be implemented and (2) a description of the alarms or other methods by which operators will be notified of a release.

Semiannual periodic report. We are proposing that the semiannual periodic report required by 40 CFR 65.225 would include: (1) For compressors that you choose to operate at an instrument reading of less than 500 ppm, the date of an instrument reading of 500 ppm or greater and the date of the next instrument reading less than 500 ppm; (2) for PRD in gas or vapor service, any instrument reading of 500 ppm or greater more than 5 days after the PRD returns to service after a release; (3) for open-ended valves and lines, the date of an instrument reading of 500 ppm or greater and the date of the next instrument reading less than 500 ppm; (4) for PRD for which the referencing subpart states may not release to the atmosphere, information about each release, including duration of the release and an estimate of the quantity of substances released; (5) if your referencing subpart specifies that releases to the atmosphere from open-ended valves and lines in an emergency shutdown system that are designed to open automatically in the event of a process upset are not allowed, information about each release; (6) for equipment in closed vent systems and fuel gas systems, the date of an instrument reading of 500 ppm or greater and the date of the next instrument reading less than 500 ppm; and (7) for closed vent systems, control devices and fuel gas systems, the applicable information specified in proposed 40 CFR part 65, subpart M.

Annual periodic report. We are proposing that the annual periodic report would include a summary table showing: (1) The process unit identification; (2) the number of each type of equipment for which leaks were detected, either by instrument monitoring or by other method (*e.g.,* sensor on a compressor seal system); (3) the total number of valves and connectors monitored and the percent leaking; (4) the number of leaks for each type of equipment that were not repaired; and (5) the number of valves that are determined to be non-repairable. The annual periodic report also would include: (1) Information about instances of delayed repairs, including the demonstration that it was technically infeasible to replace a leaking valve or connector with low leak technology; (2) for PRD in gas and vapor service, confirmation that you conducted all required instrument monitoring to demonstrate that the instrument reading was less than 500 ppm no later than 5 calendar days after a PRD returned to regulated material service following a pressure release; (3) for compressors operated at an instrument reading of less than 500 ppm and open-ended valves and lines, confirmation that you conducted all required instrument monitoring to demonstrate that the instrument reading is less than 500 ppm; (4) for open-ended lines and valves, confirmation that you conducted all monitoring to demonstrate that the instrument reading is less than 500 ppm; (5) for equipment

in closed vent systems and fuel gas systems, confirmation that you conducted all monitoring to demonstrate that the instrument reading is less than 500 ppm; (6) for closed vent systems, control devices and fuel gas systems, the applicable information specified in proposed 40 CFR part 65, subpart M; (7) for regulated sources not included in the Notification of Compliance Status due to later compliance dates, the information required under the Notification of Compliance Status; and (8) any revisions to items reported in an earlier Notification of Compliance Status if the method of compliance has changed since the last report.

Recordkeeping. We are proposing that you would keep the following general records: (1) Equipment identification (including identification of unsafe- or difficult-to-monitor equipment) if the equipment is not physically tagged; (2) for unsafe- or difficult-to-monitor equipment, an explanation of why it is unsafe- or difficult-to-monitor and a planned monitoring schedule; (3) identification of compressors operating with an instrument reading of less than 500 ppm; (4) documentation of the determination that equipment is in heavy liquid service or is in regulated material service less than 300 hr/yr; (5) for equipment in vacuum service, records of any pressure alarms triggered and the duration the equipment was not in vacuum service; (6) monitoring instrument calibrations; (7) documentation and dates of monitoring events, leak detection, repairs and repair attempts, including documentation explaining why repair must be delayed and why a valve or connector could not be repaired using low leak technology, if applicable; and (8) the applicable records specified in proposed 40 CFR part 65, subpart M for closed vent systems, control devices and fuel gas systems used to comply with this subpart.

We are also proposing that you would keep the following records specific to equipment type: (1) For valves, the monitoring schedule for each process unit, documentation of the percent leaking calculation and documentation of valve subgrouping; (2) for pumps, documentation of visual inspections, documentation of dual mechanical seal pump visual inspections and documentation of the criteria that indicate failure of the seal system or the barrier fluid system; (3) for connectors, the start date and end date of each monitoring period for each process unit and documentation of the percent leaking calculation; (4) for agitators, documentation of visual inspections, documentation of dual mechanical seal agitator visual inspections and documentation of the criteria that indicate failure of the seal system or the barrier fluid system; (5) for PRD, the dates and results of each compliance test conducted for PRD in gas or vapor service after a pressure release and, if applicable, documentation of pressure releases (including duration and quantity of regulated material released); (6) for compressors, documentation of the criteria that indicate failure of the seal system or the barrier fluid system and, if applicable, the dates and results of each compliance test for compressors operating under the alternative compressor standard; (7) for sampling connection systems, documentation of the date and amount of each purge; (8) for open-ended lines and valves, the dates and results of each compliance test; and (9) for equipment in closed vent systems and fuel gas systems, the dates and results of each compliance test.

If you elect to perform instrument monitoring to demonstrate compliance for equipment in batch operations, you would record: (1) A list of equipment added to the batch operation since the last monitoring period; (2) the date and results of the monitoring for equipment added to a batch operation since the last monitoring period; (3) a statement that the inspection was performed if no leaking equipment is found; and (4) the proportion of the time during the calendar year that all the equipment in regulated material service in the batch operation is in use, including documentation that the equipment is in regulated material service the day you conduct monitoring.

For optical gas imaging, you would be required to keep: (1) Identification of the equipment and process units for which you choose to use the optical gas imaging instrument; (2) any records required to be kept by 40 CFR part 60, appendix K; (3) the video record used to document the leak survey results; and (4) the documentation of repairs and repair attempts otherwise required by proposed 40 CFR part 65, subpart J.

B. Rationale

The proposed equipment LDAR requirements in the Uniform Standards are based on a survey and analysis of emissions reduction techniques that considered current practices and advances in technology, as well as the emissions reduction impacts and the cost impacts for model plants implementing those practices and technologies. The options considered in this analysis were developed mostly based on current federal rules, such as the National Emission Standards for Equipment Leaks—Control Level 2 Standards (40 CFR part 63, subpart UU; ''Level 2 EL Generic MACT''), the Standards of Performance for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry for Which Construction, Reconstruction, or Modification Commenced After November 7, 2006 (40 CFR part 60, subpart VVa; ''NSPS VVa'') and the National Emission Standards for Organic Hazardous Air Pollutants for Equipment Leaks (40 CFR part 63, subpart H; ''HON''). Other options were developed from state and local rules and would be additional requirements not yet included in current federal regulations.

The proposed requirements for each type of equipment are the requirements that we determined are the most effective and reasonable for reducing emissions from equipment leaks after reviewing current rules and considering the costs and emissions reductions associated with each option. As noted previously in this preamble, we will determine the nationwide emissions reductions and cost impacts for any source category from which we propose to reference these Uniform Standards in the future to ensure those impacts continue to be reasonable on a nationwide basis, as well as meet any applicable statutory requirements (*e.g.,* MACT, AMOS, BSER). The remainder of section IV.B of this preamble summarizes how the results of the analysis led us to the proposed requirements; a more detailed description of the development of the analysis is available in the technical memorandum, *Analysis of Emissions Reduction Techniques for Equipment Leaks,* in Docket ID No. EPA–HQ–OAR–2010–0869.

1. What were the options considered in the analysis and what are the cost and VOC emissions reduction impacts of those options?

We developed six model plants—three to represent chemical manufacturing processes and three to represent petroleum refineries. The chemical manufacturing models represent a range of process sizes, from a simple process with about 1,200 total pieces of equipment to a complex process with nearly 13,000 total pieces of equipment. The refinery models also represent a range of sizes, from a simple topping refinery with a total of about 1,800 pieces of equipment to a complex refinery with over 43,000 total pieces of equipment. These models allowed us to consider the costs and VOC emissions

reduction impacts for processes of various sizes in multiple industries. We are aware that there are process units and facilities larger than our largest model; however, these models were intended to cover a range of sizes representing a majority of the process units and facilities potentially subject to 40 CFR part 65, subpart J. In addition, the options considered for the Uniform Standards that are affected by economies of scale will have a greater impact on smaller processes than larger processes. We note that for each subpart that we propose to reference the Uniform Standards in the future, we will estimate nationwide costs and emissions reductions on a source category-specific basis. In most cases, we expect that since we have developed representative models for this analysis of the Uniform Standards, we will be able to use these model plants as a basis for each source category-specific analysis. We will then use available data from each specific source category to adjust the models to represent that industry more accurately, which will provide a better estimate of the source category-specific nationwide costs and emissions.

As a first step, we decided to consider the impacts of implementing a LDAR program at an uncontrolled facility. While we expect that most equipment in regulated material service is already subject to a basic LDAR program, we wanted to evaluate the impacts of that program rather than simply assuming that a basic LDAR program is effective. We determined the costs and VOC emissions associated with implementing a basic LDAR program (hereafter referred to as the ''baseline'') for each of the six models. The elements that make up the baseline LDAR program are described in the following paragraphs.

Most current equipment leaks regulations include two types of leak detection methodologies: Instrument monitoring using Method 21 of 40 CFR part 60, appendix A–7, and sensory monitoring. Based on our review of the requirements and the applicability of current rules, including federal, state and local rules, we determined that baseline was implementation of a LDAR program equivalent to the requirements in the National Emission Standards for Equipment Leaks—Control Level 1 (40 CFR part 63, subpart TT; ''Level 1 EL Generic MACT'') and Standards of Performance for Equipment Leaks of VOC in the Synthetic Organic Compound Manufacturing Industry for which Construction, Reconstruction, or Modification Commenced After January 5, 1981 but Before November 7, 2006 (40 CFR part 60, subpart VV; ''NSPS VV''). These requirements include instrument monitoring using Method 21 of 40 CFR part 60, appendix A–7, for valves and agitators in gas and vapor service and for valves, pumps and agitators in light liquid service. The baseline leak definition for all of the above types of equipment is 10,000 ppm, and each piece of equipment must be monitored monthly, although valves may be transitioned to a less frequent monitoring schedule if they meet certain criteria (*e.g.,* the owner or operator may elect a reduced monitoring schedule if the percentage of valves leaking is equal to or less than 2.0 percent). The baseline requirements also include sensory monitoring for connectors; pumps, valves and agitators in heavy liquid service; PRD in liquid service; and instrumentation systems. Finally, the baseline requirements include instrument monitoring of PRD in gas and vapor service after a release to verify that the PRD is operating with an instrument reading of less than 500 ppm; equipping compressors with a seal system or maintaining them at or below an instrument reading of 500 ppm; handling of the process fluid collected through sampling connection systems properly; and equipping open-ended valves and lines with a cap, blind flange, plug, or a second valve.

We determined the cost and VOC emissions reduction impacts of the baseline LDAR program described above for each of the six models. We then calculated the cost effectiveness for the six models. The results of these calculations are shown in Table 10 of this preamble.

TABLE 10—BASELINE LDAR PROGRAM COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR MODEL PLANTS

Model		Uncontrolled VOC emissions (tpy)	Capital cost ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	Total VOC emissions reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	10	91,000	41,000	(2,900)	38,000	5.9	7,000
	2	79	460,000	130,000	(32,000)	98,000	63	2,000
	3	160	860,000	230,000	(62,000)	160,000	120	1,800
Petroleum Refinery Models	4	30	160,000	57,000	(14,000)	43,000	28	2,000
	5	270	960,000	260,000	(130,000)	140,000	250	1,000
	6	470	1,700,000	460,000	(210,000)	250,000	420	1,100

When we compared the cost effectiveness of the baseline conditions for each model to the number of pieces of equipment in the models, we found that implementing the baseline LDAR program is more cost effective for models with higher equipment counts. This is due to the fact that there are several costs in the analysis that are fixed regardless of the number of pieces of equipment, such as the cost of the monitoring instrument and the number of hours spent on administrative activities and preparing reports. In particular, we note that baseline is the least cost effective for the model with less than 1,500 pieces of equipment.

From baseline, we evaluated a total of five regulatory options, two for valves, two for pumps and one for connectors. In each of these options, we considered the impacts of increasing the stringency of one piece of the LDAR program, each option building on the one before it for that specific piece of equipment. We decided to develop the options in this manner to consider the effectiveness of each piece of the program separately and ensure that the LDAR program proposed for the Uniform Standards included the most appropriate pieces. The calculation methodologies used to develop the cost and emissions reduction impacts for each of the models are described in the technical memorandum, *Analysis of Emissions Reduction Techniques for Equipment Leaks,* in Docket ID No. EPA–HQ–OAR–2010–0869.

Throughout the rest of this section of the preamble, we present the impacts and cost effectiveness for each of the models. The costs and VOC emissions associated with each of the regulatory options were compared with the baseline costs and VOC emissions (or the previous option costs and VOC emissions, as appropriate) to determine the incremental costs and VOC emissions reduction impacts.

In Option 1 for valves, we considered the effect of lowering the leak definition from 10,000 ppm to 500 ppm for valves in gas and vapor service and valves in light liquid service. Table 11 of this preamble shows the incremental costs and VOC emissions reductions of lowering the leak definition from 10,000 ppm (baseline) to 500 ppm for valves in gas and vapor service and valves in light liquid service.

TABLE 11—MODEL PLANT COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR OPTION 1 FOR VALVES (LEAK DEFINITION OF 500 PPM) INCREMENTAL TO BASELINE

Model		Capital cost ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	VOC emissions reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	1,700	360	(350)	15	0.69	22
	2	6,200	1,300	(1,200)	97	2.4	40
	3	14,000	2,900	(2,500)	360	5.0	71
Petroleum Refinery Models	4	1,200	480	(210)	270	0.42	630
	5	13,000	5,400	(2,300)	3,000	4.7	650
	6	34,000	14,000	(5,900)	7,700	12	650

In Option 2 for valves, we considered further lowering the leak definition for valves in gas and vapor service and valves in light liquid service to 100 ppm. The leak definition of 100 ppm for valves is required in some state and local regulations, as well as consent decrees. However, we estimate that the incremental costs to reduce a ton of VOC emissions for this option increase significantly for all of the models compared to Option 1 for valves. Table 12 of this preamble shows the incremental costs and VOC emissions reductions of lowering the leak definition from 500 ppm (Option 1 for valves) to 100 ppm for valves in gas and vapor service and valves in light liquid service.

TABLE 12—MODEL PLANT COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR OPTION 2 FOR VALVES (LEAK DEFINITION OF 100 PPM) INCREMENTAL TO OPTION 1 FOR VALVES

Model		Capital cost ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	VOC emissions reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	3,800	960	(62)	900	0.12	7,300
	2	14,000	3,400	(360)	3,000	0.73	4,200
	3	31,000	7,500	(910)	6,600	1.8	3,600
Petroleum Refinery Models	4	5,300	2,900	(170)	2,800	0.33	8,400
	5	59,000	29,000	(1,500)	28,000	3.1	9,000
	6	150,000	83,000	(4,300)	79,000	8.7	9,100

In Option 1 for pumps, we considered the effect of lowering the leak definition from 10,000 ppm to 2,000 ppm for pumps in light liquid service. Table 13 of this preamble shows the incremental costs and VOC emissions reductions of lowering the leak definition from 10,000 ppm (baseline) to 2,000 ppm for pumps in light liquid service. The analysis showed that Option 1 for pumps is more cost effective for the chemical manufacturing models than for the refinery models.

TABLE 13—MODEL PLANT COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR OPTION 1 FOR PUMPS (LEAK DEFINITION OF 2,000 PPM) INCREMENTAL TO BASELINE

Model		Capital costs ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	VOC emissions reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	2,200	440	(130)	310	0.26	1,200
	2	5,900	1,200	(350)	830	0.70	1,200
	3	8,300	1,700	(490)	1,200	0.98	1,200
Petroleum Refinery Models	4	260	200	(15)	190	0.030	6,300
	5	2,300	1,800	(130)	1,600	0.26	6,300
	6	5,800	4,500	(330)	4,200	0.65	6,300

While this particular analysis showed that Option 1 for pumps is less cost effective for the refinery models, we note that there appear to be some anomalies in the values themselves. The large chemical manufacturing model (Model 3) and the small refinery model (Model 5) have a similar number of pumps, and the annualized costs (without VOC recovery credits) for these models is also very similar. However, the VOC recovery credit and VOC emissions reductions per year for Model 3 are over 3.5 times higher than those for Model 5. This trend is due to the fact that the calculated emissions factors for refinery pumps in this analysis range from about 2 to 5 times lower than the emissions factors for chemical manufacturing pumps. Part of that difference is expected and is due to the differences in the emissions equations in the *Protocol for Equipment Leak Emission Estimates* (EPA–453/R–95–017, November 1995). However, part of the difference is also due to the assumed distribution of leaking pumps in each sector. The distribution of leaking pumps at refineries was based on a study of quarterly monitoring of pumps in the 1990s (*Analysis of Refinery Screening Data,* prepared by Hal Taback Company for API, November 1997). It is possible that monthly monitoring data or data collected more recently would result in a different cost-effectiveness value for refinery pumps.

In Option 2 for pumps, we considered further lowering the leak definition for pumps in light liquid service to 500 ppm. The leak definition of 500 ppm for pumps appears in a few consent decrees. However, we estimated a significantly higher incremental cost to reduce a ton of VOC emissions for all of the models compared to Option 1 for pumps. Table 14 of this preamble shows the incremental costs and VOC emissions reductions of lowering the leak definition from 2,000 ppm (Option 1 for pumps) to 500 ppm for pumps in light liquid service.

TABLE 14—MODEL PLANT COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR OPTION 2 FOR PUMPS (LEAK DEFINITION OF 500 PPM) INCREMENTAL TO OPTION 1 FOR PUMPS

Model		Capital costs ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	VOC emissions Reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	1,000	370	(12)	350	0.024	15,000
	2	2,700	980	(32)	940	0.063	15,000
	3	3,700	1,400	(44)	1,300	0.088	15,000
Petroleum Refinery Models	4	140	440	(0.15)	440	0.00031	1,400,000
	5	1,200	3,800	(1.3)	3,800	0.0026	1,400,000
	6	3,000	9,600	(3.4)	9,600	0.0067	1,400,000

In Option 1 for connectors, we considered the impact of adding instrument monitoring for connectors in gas and vapor service and connectors in light liquid service as in Level 2 EL Generic MACT. In this option, the leak definition is 500 ppm. Connectors are monitored annually, but similar to valves, there are provisions for less frequent monitoring if the connectors meet certain conditions. When we evaluated the costs and emission reduction impacts relative to the number of connectors in the models, we again noticed that the option was more cost effective for models with the most connectors. Again, this trend is due to the fact that the number of hours spent on administrative activities and preparing reports is fixed regardless of the number of connectors. Table 15 of this preamble shows the incremental costs and VOC emissions reductions (from baseline) of requiring monitoring of connectors in gas and vapor service and connectors in light liquid service at a leak definition of 500 ppm.

TABLE 15—MODEL PLANT COSTS AND VOC EMISSIONS REDUCTION ESTIMATES FOR OPTION 1 FOR CONNECTORS (LEAK DEFINITION OF 500 PPM) INCREMENTAL TO BASELINE

Model		Capital costs ($)	Annualized costs without recovery credits ($)	VOC recovery credit ($)	Total annualized costs ($)	VOC emissions reduction (tpy)	Overall cost effectiveness ($/ton VOC)
Chemical Manufacturing Models	1	19,000	7,900	(510)	7,400	1.0	7,200
	2	66,000	16,000	(1,900)	14,000	3.7	3,700
	3	180,000	35,000	(5,200)	30,000	10	2,900
Petroleum Refinery Models	4	19,000	7,900	(200)	7,700	0.41	19,000
	5	170,000	34,000	(2,000)	32,000	4.0	8,000
	6	520,000	93,000	(6,100)	87,000	12	7,200

We also considered annual instrument monitoring for open-ended valves and lines. The requirement in nearly all equipment leak standards to equip open-ended valves and lines with a cap, blind flange, plug or a second valve is intended to essentially eliminate emissions from open-ended valves and lines. However, as we noted when we proposed amendments to NSPS VV (71 FR 65302, November 7, 2006), inspections conducted by enforcement agencies have found that many of these closure devices are leaking due to improper installation. Therefore, some states have begun to require instrument monitoring of open-ended valves and lines in addition to requiring a cap, blind flange, plug or a second valve. For example, in the Houston/Galveston/Brazoria area of

Texas, petroleum refining and SOCMI process units in which a highly-reactive volatile organic compound (HRVOC) is a raw material, intermediate, final product or in a waste stream are subject to the requirements of part 30, chapter 115, subchapter H, division 3 of the Texas Administrative Code. One of those requirements is quarterly monitoring of blind flanges, caps or plugs at the end of a pipe or line containing HRVOC and repair of leaks above 500 ppm (30 TAC 115.781(b)(3)). If the open-ended line is used for sampling of the process fluid and the cap, blind flange, plug or second valve is opened, then the instrument monitoring indicates whether the cap, blind flange, plug or second valve was re-closed properly after sampling. The monitoring will also indicate whether the open-ended valve is leaking.

We considered the cost of instrument monitoring for open-ended valves and lines separately from the other options in this analysis. Since the cap, blind flange, plug or a second valve is required to seal the open-ended valve or line and eliminate emissions, we do not expect that monitoring would achieve any additional emissions reduction. Rather, the instrument monitoring would ensure compliance with the requirement that the cap, blind flange, plug or second valve seal the open-ended valve or line. The nationwide cost of these monitors would be incorporated into the estimate of monitoring, recordkeeping and reporting burden for the referencing subpart. The costs for the model plants ranged from a capital cost of $810 and an annualized cost of $180 for the simple chemical manufacturing model to a capital cost of $23,000 and an annualized cost of $5,400 for the complex refinery model.

Similarly, we also estimated the costs of requiring electronic monitoring of PRD. This analysis was conducted separately from the options listed above because installation of electronic monitors is not expected to achieve additional emissions reductions. Rather, the electronic monitors would be used to notify operators when there is a pressure release and aid them in ensuring compliance with the requirement that there be no releases from the PRD. The nationwide cost of these monitors would be incorporated into the estimate of monitoring, recordkeeping and reporting burden for the referencing subpart. The costs for the model plants ranged from a capital cost of $11,000 and an annualized cost of $1,600 for the simple chemical manufacturing model to a capital cost of $130,000 and an annualized cost of $19,000 for the complex refinery model. We note that the requirement to install this type of monitor would only apply if a referencing subpart specifically referenced this section.

2. How did the EPA develop the proposed regulations based on the analysis of regulatory options?

The analysis of regulatory options described in section IV.B.1 of this preamble provided us with the information needed to determine the appropriate level of stringency for the requirements for the Uniform Standards for equipment leaks from valves, pumps and connectors. The next step was to determine the details for the proposed requirements, as well as determine what other provisions were appropriate to propose as part of the Uniform Standards. Rather than developing all-new regulatory language to describe these requirements, we reviewed the language provided in current equipment leaks regulations. We elected to use the Level 2 EL Generic MACT (40 CFR part 63, subpart UU) as a starting point for developing the Uniform Standards for equipment leaks. We determined that, as one of the most recently promulgated standards for equipment leaks, the Level 2 EL Generic MACT includes many of the provisions that we determined through the analysis described in section VI.B.I of this preamble are the appropriate level of control for the Uniform Standards. In addition, the Level 2 EL Generic MACT was already organized to be referenced from source category-specific subparts. The major overarching change that we made to the format of the Level 2 EL Generic MACT was to rearrange and rephrase all of the provisions to be consistent with our most recent ''plain English'' regulations.

We note that the Level 2 EL Generic MACT specifies certain types of equipment that are not subject to any of the requirements of that rule, such as equipment in lines with no process fluids. We have elected not to propose this specific provision in 40 CFR part 65, subpart J. Rather, we are proposing the requirements for detecting and repairing leaks in subpart J, and we expect that the referencing subpart will define clearly what equipment must comply with subpart J. Similarly, we are not proposing that equipment in vacuum service would be exempt from subpart J; instead, we are proposing the monitoring and recordkeeping requirements described in section IV.A.3 and section IV.B.5 of this preamble.

We also note that when reviewing the various equipment leak regulations, we noticed that while the requirements themselves are similar, the regulations are not consistent in defining a leak that must be repaired. As a specific example, the Level 2 EL Generic MACT specifies how to handle indications of liquids dripping that you find during a visual pump inspection, but it does not specifically say that indications of liquids dripping is a leak. Conversely, NSPS VVa specifically states that indications of liquids dripping is a leak and that removing the indications of liquids dripping is considered repair (although you are not required to conduct instrument monitoring to confirm repair in that case).

We believe that the standards are clearer if ''repair'' is defined based on the detection method used to identify the potential leak or leak. For example, for a leak detected using instrument monitoring, repair requires instrument monitoring to confirm that there is no longer a leak, while indications of a potential leak detected using sensory monitoring are considered repaired once you adjust or alter the equipment to eliminate the indications of a potential leak. Therefore, we are proposing in 40 CFR part 65, subpart H that ''repaired'' has different, specific meanings, depending on how the leak or potential leak is detected. We note that if you observe indications of a potential leak (*e.g.,* liquids dripping) during sensory monitoring and you elect to confirm the presence of a leak through instrument monitoring, you would be required to repair the leak only based on the instrument monitoring definition of ''repair'' (*i.e.,* not also based on the sensory monitoring definition of ''repair''). Although the Level 2 EL Generic MACT interpretation and language is different from the interpretation in NSPS VVa, we note that the substance of the proposed requirements is essentially the same as both these current rules.

We are clarifying in this preamble that the proposed option to maintain certain types of equipment (e.g., such as compressors, PRD, open-ended valves and lines, and equipment in closed vent systems and fuel gas systems) below 500 ppm above background is considered a performance standard and not a leak definition indicating a leak requiring repair. Therefore, the instrument monitoring that we are proposing for those types of equipment is to confirm that the performance standard is being met; it is not instrument monitoring to detect a leak. Additional details regarding these proposed requirements are provided in the equipment-specific paragraphs in section IV.B.4 of this preamble.

As we reviewed the regulatory language of current equipment leak rules, we noticed that the rules include definitions of some types of equipment (*e.g.,* connector, open-ended valve or line) but not others. We request comment on whether we should add definitions of ''valve,'' ''pump,'' ''agitator'' and ''compressor,'' as well as other terms that are used throughout the proposed Uniform Standards, but not defined (*e.g.,* ''dual mechanical seal system''). The intended purpose of adding definitions of these terms to 40 CFR part 65, subpart J, would not be to make the standards more or less stringent than current standards. Rather, the goal is to ensure that the standards are interpreted consistently. Therefore, comments on additional definitions should include proposed language for those definitions and describe how defining the term would result in interpretations that are more consistent.

The following sections describe the rationale for specific proposed provisions.

3. How did the EPA determine that the proposed compliance requirements of sensory monitoring for certain equipment are appropriate?

As we noted in section IV.B.1 of this preamble, most current equipment leaks regulations include requirements for sensory monitoring, as well as instrument monitoring using Method 21 of 40 CFR part 60, appendix A–7. Sensory monitoring has traditionally been required for certain equipment for which it is considered not cost effective to require instrument monitoring, such as equipment in heavy liquid service and equipment that is in use a very short time during the year. Our analysis of emissions reduction techniques showed that sensory monitoring is still necessary and appropriate for certain types of equipment. For the specific types of equipment listed in 40 CFR 65.428, we are proposing to require sensory monitoring equivalent to the monitoring required in the Level 2 EL Generic MACT, including equipment in heavy liquid service, equipment in regulated material service less than 300 hr/yr, PRD in light liquid service and instrumentation systems.

The list also includes equipment types that may not be specified in other rules. First, as noted in section IV.B.1 of this preamble, we determined that instrument monitoring at the baseline level (*i.e.,* 10,000 ppm leak definition) is the least cost effective for a plant site with less than 1,500 total pieces of equipment, so we are proposing to require only sensory monitoring for a plant site with less than 1,500 total pieces of equipment. Second, we are proposing to clarify that sensory monitoring is required for connectors in gas and vapor service and connectors in light liquid service if the referencing subpart does not require compliance with the instrument monitoring provisions for connectors (40 CFR 65.422). Third, we determined that sensory monitoring is necessary for any equipment that contains or contacts regulated material, but is not in regulated material service. For example, if a valve contains or contacts a light liquid process fluid with 3-percent regulated material (*i.e.,* less than the amount required to be defined as ''in light liquid service''), instrument monitoring is not cost effective and would not be required. However, if that valve leaks, there are emissions in that release that need to be addressed. We have determined that sensory monitoring is an appropriate standard in that case. Fourth, we are proposing that the list of equipment for which you are required to conduct sensory monitoring includes any equipment for which sensory monitoring is required by a provision in proposed 40 CFR 65.420 through 65.427. Throughout these sections of proposed 40 CFR part 65, subpart J, there are exceptions to the instrument monitoring requirements for specific types of equipment. This proposed requirement will help to ensure operators keep an eye out for these potential leaks without placing undue burden on the operators. The requirement to conduct sensory monitoring for specific types of equipment is discussed throughout the remainder of section IV.B.4 of this preamble. Finally, we are proposing sensory monitoring for other equipment, as required by the referencing subpart. This provision is included partly to provide some flexibility to the referencing subpart in defining the requirements for specific types of equipment (based on source category-specific and subpart-specific analyses) and partly to indicate that sensory monitoring should be the minimum requirement for any equipment not otherwise required to conduct instrument monitoring or meet a performance standard.

The change in format (*i.e.,* specifying types of equipment required to conduct sensory monitoring in one location and referencing one section for LDAR requirements) better indicates that the level of control for all these types of equipment is the same. In some current equipment leak regulations, these requirements are spread throughout the rule with minor variations in language, and it is not clear whether the monitoring and repair requirements are intended to be identical. In addition, as noted above, the change in format more clearly indicates that sensory monitoring is the minimum requirement for all types of equipment for which instrument monitoring is not required. While we expect that sensory monitoring will continue to be specified mostly for equipment in heavy liquid service and instrumentation systems, we recognize that if instrument monitoring is not currently required for other types of equipment in a specific source category, analyses may show that it is not appropriate to begin instrument monitoring in that specific source category. In that case, we wanted to ensure that it is clear that you would, at a minimum, continue conducting sensory monitoring for these pieces of equipment.

4. How did the EPA determine the proposed compliance requirements for specific types of equipment?

Based on the analysis described in section IV.B.1 of this preamble, we are proposing requirements mostly equivalent to the Level 2 EL Generic MACT, as well as instrument monitoring for open-ended valves and lines to ensure compliance with the proposed performance standard. We are also proposing several new requirements for delay of leak repair, including a requirement to install low leak technology when a leaking valve or connector is repaired more than 15 days after detection (*i.e.,* when repair of a leaking valve or connector has been delayed under 40 CFR 65.432(d)). We are also proposing several clarifications (relative to the Level 2 EL Generic MACT) and new requirements that are specific to certain types of equipment. This section includes rationale for those clarifications and requirements, as well as some rationale for requirements that we considered, but are not proposing.

Valves in gas and vapor service and valves in light liquid service. The requirements that we are proposing in 40 CFR 65.420 for valves in gas and vapor service and valves in light liquid service are essentially the same as the Level 2 EL Generic MACT, including the requirement to calculate the percent of valves leaking and the option to subgroup valves for monitoring purposes. The differences between the Level 2 EL Generic MACT and the proposed Uniform Standards are clarifications that are described in this section.

We are proposing to clarify how to determine monitoring frequency for valves in 40 CFR 65.420(a)(2)(i). In the

Level 2 EL Generic MACT, the decision point for the monitoring frequency determinations is expressed in terms such as ''less than the greater of 2 valves or 2 percent of the valves in a process unit.'' For these Uniform Standards, we are proposing language similar to the HON to clarify the terminology for this determination. We are not proposing any changes to the procedure itself. If the number of leaking valves is 2 percent of the valves or higher, you must either monitor monthly or, if the sum of the total valves leaking over the previous two monitoring periods is three or less, you must monitor at least quarterly.

We are also proposing to clarify that the provision for 250 or fewer valves in a process unit in the Level 2 EL Generic MACT is intended to ensure that monthly monitoring is not required and that quarterly is the most frequent monitoring required. Regardless of the number of valves in your process unit, you may monitor valves less frequently than quarterly if the percent leaking calculation qualifies that process unit for less frequent monitoring.

We are proposing to clarify that you are not required to conduct instrument monitoring for valves with a valve mechanism that is not connected to a device that penetrates the valve housing (*e.g.,* most check valves). As we stated in the background information document for NSPS VV (EPA–450/3–83–033a, November 1980), a valve that ''has no stem or subsequent packing gland * * * is not considered to be a potential source of fugitive emissions.'' Therefore, it is not necessary to conduct instrument monitoring to detect leaks, and we consider this proposed provision to be a clarification of our original intent. However, we are proposing to require you to conduct sensory monitoring to ensure that there are no fugitive emissions from other parts of these types of valves.

We are proposing to retain the requirement found in many current equipment leaks rules to limit the number of difficult-to-monitor valves in a new source to less than 3 percent of the valves in that source. The Uniform Standards would not define a new source; a new source would be defined by the referencing subpart. We are also proposing that you would not have to limit the number of difficult-to-monitor valves in a new source (as defined by the referencing subpart) if all of the difficult-to-monitor valves in that new source meet the description of low leak technology (see sections IV.A.4 and IV.B.5 of this preamble). We also considered requiring all valves in a new source to be designed to meet the description of low leak technology (not just those that you designate as difficult-to-monitor), unless it is technically infeasible to do so. If we included that provision in the Uniform Standards, we would consider removing the 3-percent restriction on difficult-to-monitor valves in a new source, since the potential for leaks from all of the valves would be reduced. We request comment on the proposed provision providing the option of designing difficult-to-monitor valves in a new source to meet the description of low leak technology, as well as the idea of requiring all valves in a new source to be designed to meet the description of low leak technology.

Finally, as we noted in section IV.B.1 of this preamble, we evaluated the impacts of lowering the leak definition from 500 ppm to 100 ppm for valves. Based on our analysis, we concluded that for this proposed rule, 500 ppm is the appropriate leak definition for valves. However, we note that our analysis was general and based on assumptions that may not be applicable to all source categories. We expect that when conducting the analysis to determine whether it is appropriate to reference these Uniform Standards from each source category, we will consider the appropriate leak definition for valves in that source category. If the analysis shows that referencing the Uniform Standards would be appropriate with a lower leak definition than 500 ppm for valves, then the referencing subpart could specify that lower leak definition and override the requirements in the Uniform Standards. We request comment and additional data supporting a different leak definition for valves in the Uniform Standard.

Pumps in light liquid service. The requirements that we are proposing in 40 CFR 65.421 for pumps in light liquid service are mostly the same as the Level 2 EL Generic MACT. Section IV.B.1 of this preamble presents the model plant impacts of lowering the leak definition from 10,000 ppm to 2,000 ppm for pumps in light liquid service. We also considered additional information when determining the appropriate level of control to propose. Specifically, data collected through an ICR for petroleum refineries (76 FR 5804, February 2, 2011) indicate that 93 percent of the pumps that are currently monitored for leaks are monitored at a leak definition of 2,000 ppm. We did reorganize the sections slightly and revise the language relative to the Level 2 EL Generic MACT to better indicate the similarity between the provisions for pumps and agitators. Other differences between the Level 2 EL Generic MACT and the proposed Uniform Standards are described in this section.

We are proposing to maintain the leak definition of 5,000 ppm for pumps handling polymerizing monomers. This leak definition was set nearly 20 years ago, during the development of the HON, based on the argument that since mechanical seals cannot be used on pumps handling polymerizing monomers, these pumps cannot achieve a 2,000-ppm leak performance level. We request comment and any available data either to support maintaining the 5,000-ppm leak definition for pumps handling polymerizing monomers or to support lowering the leak definition for pumps handling polymerizing monomers.

We are proposing to include the Level 2 EL Generic MACT requirements for weekly inspections of pumps subject to 40 CFR 65.421, including dual mechanical seal pumps. Like the Level 2 EL Generic MACT, we are proposing that if you find indications of liquids dripping during a weekly inspection, you could choose whether to repair the pump, eliminating those indications of liquids dripping or conduct instrument monitoring to determine if there is a leak. We are proposing to add a requirement that if you choose to repair the pump to eliminate the potential leak rather than conducting instrument monitoring, you would be required to do so before the next weekly inspection. This limit of time is similar to the 5 days allowed to repair equipment subject to sensory monitoring requirements. However, if we required repair within 5 days of detection and the next weekly inspection occurred less than 5 days after the inspection in which you observed the indications of liquids dripping (see the ''reasonable interval'' provisions in the General Provisions), then you would presumably continue to see the indications of liquids dripping that you are already planning to eliminate, and that weekly inspection would not provide any new information. We request comment on the amount of time provided to repair pumps with indications of liquids dripping.

We are also proposing an additional clarification regarding weekly inspections for pumps consistent with NSPS VVa. The aim of an LDAR program is to find and repair leaks. In some instances, the liquids found dripping from pumps are not leaks; for example, the liquids could simply be condensation from the atmosphere. Therefore, we are proposing to clarify in 40 CFR 65.421(c), consistent with NSPS VVa, that if you see liquids dripping during a weekly inspection, you choose to conduct instrument monitoring and

the instrument reading shows that the pump is not leaking, then for subsequent weekly inspections, you would not be required to conduct instrument monitoring when you find indications of liquids dripping, as long as the characteristics of the liquids dripping have not changed since the last weekly inspection. You would continue to conduct the weekly inspection, record the results, and conduct the monthly instrument monitoring, as required in proposed 40 CFR 65.421(a). Note, however, that if you repair the pump, then the clock would ''reset'' regarding the weekly inspections. In other words, if monthly instrument monitoring indicates that a leak has developed, then you would be required to repair the leak, and the next time you notice indications of liquids dripping during a weekly inspection, you would be required to choose whether to repair the potential leak or conduct instrument monitoring to determine if there is a leak.

We note that persistent liquids dripping may indicate an operation problem that should be addressed by maintenance. If indications of liquids dripping are noted for one pump during multiple weekly inspections, we encourage you to ensure that the pump is operating properly.

We are not proposing to require you to implement a quality improvement program (QIP) for pumps. In the Level 2 EL Generic MACT, you are required to implement a QIP if ''at least the greater of either 10 percent of the pumps in a process unit or three pumps'' are leaking. However, evaluation of compliance with current rules that include these provisions has shown that these provisions are complicated and rarely used. We request comment on whether there is need to include QIP provisions for pumps in these Uniform Standards. We also request comment on whether we should substitute the QIP provisions with a similar, but more straightforward requirement. For example, we could include a requirement that if 10 percent of the pumps in a process leak, you would have to replace a certain percentage of those pumps with dual mechanical seal pumps within a set amount of time. A provision like this would achieve similar goals to the QIP, but would be much simpler to understand and implement.

As we noted in section IV.B.1 of this preamble, we evaluated the impacts of lowering the leak definition from 2,000 ppm to 500 ppm for pumps. Based on our analysis, we concluded that for this proposed rule, 2,000 ppm is the appropriate leak definition for pumps. However, as with valves, our analyses were general and were based on assumptions that may not be applicable to all source categories that could reference these Uniform Standards. We expect that when conducting the analysis to determine whether it is appropriate to reference these Uniform Standards from each source category, we will consider the appropriate leak definitions for pumps. If the analysis shows that referencing the Uniform Standards would be appropriate with a lower leak definition for pumps, then the referencing subpart can specify the lower level and override the requirements in the Uniform Standards. We request comment and additional data supporting a different leak definition for pumps in the Uniform Standard.

Connectors in gas and vapor service and connectors in light liquid service. We note that the analysis described in section VI.B.1 of this preamble showed that the cost effectiveness of requiring instrument monitoring for connectors varies widely, depending on the number of connectors in each model. In addition, as noted previously in this section, our analysis was general and based on assumptions that may not be applicable to all source categories. Therefore, it is possible that instrument monitoring of connectors could be more cost effective on a nationwide basis for a source category in which a majority of the affected process units has a large number of connectors. As a result, we determined that the best approach was to include the provisions for instrument monitoring of connectors in the proposed Uniform Standards, but to leave the decision of whether to require instrument monitoring of connectors in gas and vapor service and instrument monitoring of connectors in light liquid service up to the rulemakings for the referencing subparts.

We expect that we will estimate the costs and emissions reduction impacts of the Uniform Standards for each potential referencing subpart. At that time, we will evaluate the necessary factors (including cost effectiveness, if appropriate) and determine whether to require instrument monitoring for connectors. By including the connector monitoring provisions in the Uniform Standards, we can ensure that the instrument monitoring provisions for connectors will be consistent with the instrument monitoring provisions for other equipment in the Uniform Standards if we determine in the future that instrument monitoring of connectors is appropriate for a particular source category.

Therefore, we are proposing that you would conduct instrument monitoring for connectors in gas and vapor service and connectors in light liquid service, as in Level 2 EL Generic MACT, only if required by your referencing subpart. We did rearrange the paragraphs and make small clarifications to the language, but aside from specifying in the Uniform Standards that connector monitoring and repair is required only if specified by your referencing subpart, there are no substantive differences between the connector requirements in the Level 2 EL Generic MACT and the connector requirements proposed in the Uniform Standards. The differences between the Level 2 EL Generic MACT and the proposed Uniform Standards are described in this section. We request comment on whether there are other requirements for connectors that we should consider.

If your referencing subpart does require connector monitoring, we are proposing two requirements to clarify that the connector requirements are analogous to the requirements for valves. First, connector monitoring data generated less than 12 months before a process unit becomes subject to this subpart would be allowed in determining monitoring frequency (as well as counting as the initial monitoring for connectors). Second, the monitoring that you are required to perform after repairing a leaking connector and within 90 days of detecting the leak is not the same monitoring that you must perform to meet the definition of ''repair.''

Finally, we are proposing to limit the types of connectors that can be classified as ''inaccessible'' connectors in 40 CFR 65.416(b). We are not proposing to include connectors that cannot be reached without elevating personnel (as in the Level 2 EL Generic MACT). These connectors would already be classified as difficult-to-monitor connectors under proposed 40 CFR 65.416(a)(2). In addition, we are not specifically including connectors that cannot be accessed at any time in a safe manner to perform monitoring. Instead, we consider these connectors to be classified as unsafe-to-monitor under proposed 40 CFR 65.416(a)(1). See section IV.B.5 of this preamble for additional detail about unsafe-to-monitor and difficult-to-monitor equipment.

Agitators in gas and vapor service and agitators in light liquid service. The requirements that we are proposing in 40 CFR 65.423 for agitators in gas and vapor service and agitators in light liquid service are mostly the same as both the Level 1 EL Generic MACT and

the Level 2 EL Generic MACT. We did reorganize the sections slightly and revise the language relative to the Level 2 EL Generic MACT to indicate more clearly the similarity between the provisions for pumps and agitators. We are also proposing to include the Level 2 EL Generic MACT requirements for weekly inspections of agitators subject to 40 CFR 65.423 with clarifications identical to those described in section IV.B.4 of this preamble for pumps in light liquid service.

Given the similarities between pumps and agitators in design, operation and current regulatory requirements, we considered lowering the leak definition for agitators from 10,000 ppm. However, we do not currently have sufficient data on agitator monitoring to conduct such an analysis. We request comment and additional data supporting either maintaining the leak definition at 10,000 ppm or lowering the leak definition.

PRD. We are proposing to require that all PRD in gas or vapor service be operated with an instrument reading of less than 500 ppm above background. No later than 5 days after the PRD begins operating in regulated material service again following a pressure release, you would be required to conduct instrument monitoring to demonstrate that the PRD is once again in compliance with the requirement to operate with an instrument reading of less than 500 ppm above background. We note that the Level 2 EL Generic MACT includes a similar standard for PRD in gas and vapor service to operate at 500 ppm above background.

In addition, your referencing subpart may specify that no releases are allowed from any PRD, as release events from PRD have the potential to emit large quantities of regulated material. In that case, it is important to identify and control any releases in a timely manner. Therefore, if your referencing subpart specifies that no releases be allowed from your PRD, we are proposing to require you to install electronic indicators on each PRD that would be able to identify and record the time and duration of each pressure release. In addition to ensuring that significant releases are addressed, these requirements will also alert operators to any operational problems with the PRD seal that could be resulting in emissions to the atmosphere. (We are also proposing that if your electronic indicator can measure the concentration of any flow through the PRD, such that it is capable of verifying that the PRD has reseated properly after any release, you would not be required to conduct additional instrument monitoring to verify that the PRD is operating below 500 ppm above background following a pressure release. You would still be required to keep a record of the concentration provided by this monitor to demonstrate that the concentration is less than 500 ppm above background.)

We request comment on the proposed requirements, including whether the PRD in liquid service should be required to meet the 500-ppm performance standard rather than conducting sensory monitoring. We also request comment on other approaches we could take to reduce leaks and manage releases from PRD.

Compressors. We are proposing that compressors either (1) be equipped with a seal system or (2) be maintained at a condition indicated by an instrument reading of less than 500 ppm above background. We did rearrange the paragraphs and make small clarifications to the language, but there are few substantive differences between the compressor requirements in the Level 2 EL Generic MACT and the compressor requirements proposed in the Uniform Standards. One of these differences is for compressors complying with 40 CFR 65.425(a). While the compressor seal is the most likely part of the compressor to leak, it is possible to have small leaks from other parts of the compressor. Therefore, we are requiring sensory monitoring for potential sources of VOC emissions other than the seal system.

As noted in section IV.B.2 of this preamble, we are clarifying that the proposed alternative to maintain compressors at an instrument reading below 500 ppm above background is considered a performance standard. We did consider specifying a time frame for repair if you monitor the compressor and get an instrument reading above 500 ppm. However, we determined that since the instrument reading above 500 ppm is a deviation from the standard and not a leak, we should not allow a set number of days for repair or allow delay of repair. Instead, the deviation for that compressor would be continued until you return the compressor to a condition indicated by an instrument reading less than 500 ppm above background. To encourage you to take action as soon as possible to return the compressor to compliance, we are proposing to require that you must provide in your semiannual periodic report the date of the instrument reading 500 ppm above background or greater and the date of the next instrument reading less than 500 ppm above background (*i.e.,* the number of days that the deviation lasted) for each compressor. We request comment on whether there are other requirements for compressors that we should consider.

Sampling connection systems. We are proposing requirements for sampling connection systems that are similar to NSPS VVa, including arranging the paragraphs of 40 CFR 65.426 for clarity. In addition, we realize that when collecting gas samples, the tubing or pipe between the valves on the sample container and in the closed-loop system will contain process gas. This trapped gas does not need to be collected or captured because it is not a purged process fluid. Therefore, consistent with NSPS VVa, we are specifying that you would not be required to collect or capture gases remaining in the tubing or piping between the closed-purge system valve(s) and sample container valves(s) after the valves are closed and the sample container is disconnected.

We are also proposing to allow you to collect and recycle the purged process fluid to a process, consistent with NSPS VVa. We are proposing to add this option in 40 CFR 65.426(a)(4) for design of the closed-purge, closed-loop or closed vent system because the Level 2 EL Generic MACT requirement to return the purged process fluid ''directly'' to a process line could be interpreted to mean that you could not route the process fluid to a process using any method other than direct piping. We intend that use of the word ''collect'' in this proposed option means the purged fluid should not be allowed to escape. The use of either containers or piping would be an acceptable means of complying with this option. Consistent with the Level 2 EL Generic MACT, we are also proposing to allow you to collect and recycle the purged process fluid to a fuel gas system that meets the requirements of proposed 40 CFR part 65, subpart M.

We are proposing to clarify through the definition of ''sampling connection system'' in proposed 40 CFR 65.295 that lines that convey samples to analyzers and analyzer bypass lines are considered part of sampling connection systems. You would be required to meet the same requirements for the purged process fluid in these lines that you are required to meet for other purged process fluids. We are also clarifying that, for the purposes of this provision, CEMS are not considered analyzers, as they are typically located on stacks and are analyzing emissions rather than process fluids.

Finally, the Level 2 EL Generic MACT includes three options for collecting, storing and transporting purged process fluids, and consistent with NSPS VVa, we are proposing to add two other options in 40 CFR 65.426(a)(4)(iv).

Specifically, we are proposing to allow you to collect, store and transport the purged process fluid to a device used to burn off-specification used oil for energy recovery in accordance with 40 CFR part 279, subpart G, because the combustion operation will result in destruction levels comparable to the other options. We are also proposing to allow you to collect, store and transport the purged process fluid to a waste management unit subject to and operated in compliance with the treatment requirements of 40 CFR 61.348(a) because waste management units meeting the treatment requirements in 40 CFR 61.348(a) and the management requirements in 40 CFR 61.343 through 61.347 must achieve emission suppression and treatment requirements similar to the requirements for group 1 streams in 40 CFR part 63, subpart G, which was already provided as an option in the Level 2 EL Generic MACT.

However, the Level 2 EL Generic MACT includes an exception to the option to collect, store and transport the purged process fluid to a waste management unit that is operated in compliance with the requirements of 40 CFR part 63, subpart G that we are not proposing, consistent with NSPS VVa. Specifically, we are not proposing to allow you to transport purged process fluid that contains regulated material to a waste management unit that has a National Pollution Discharge Elimination System (NPDES) permit instead of to a waste management unit operated in compliance with the requirements of 40 CFR part 63, subpart G, applicable to group 1 wastewater steams because NPDES permits do not require suppression from the wastewater treatment system. Therefore, the emissions from the purged process fluid would not be controlled adequately if we allowed you to send purged process fluid to a waste management unit that has a NPDES permit.

Open-ended valves and lines. Like the Level 2 EL Generic MACT, the proposed requirements for open-ended valves and lines specify that, except in certain situations, each open-ended valve or line shall be equipped with a cap, plug, blind flange or a second valve that seals the open-ended valve or line. As noted in section IV.B.1 of this preamble, inspections conducted by enforcement agencies have found that many of these closure devices are leaking due to factors such as improper installation. Therefore, we are proposing to require annual instrument monitoring of the cap, plug, blind flange or second valve to demonstrate that it seals the open-ended valve or line. An instrument reading of 500 ppm above background or greater would indicate that the open-ended valve or line is not sealed. Similar to the alternative standard for compressors, we did consider specifying a time frame for repair for an instrument reading of 500 ppm above background or greater. However, we determined that, since the instrument reading of 500 ppm above background or greater indicates a deviation from the standard for the cap, plug, blind flange or second valve to seal the open-ended valve or line rather than the presence of a leak, we determined that it would not be appropriate to provide a set number of days for repair or allow delay of repair. Instead, we expect you to take action as soon as possible to properly seal the open-ended valve or line with the cap, plug, blind flange or second valve and obtain an instrument reading less than 500 ppm above background, and we are proposing to require that you must provide in your semiannual periodic report the date of the instrument reading 500 ppm above background or greater and the date of the next instrument reading less than 500 ppm above background (*i.e.,* the number of days the deviation lasted) for each open-ended valve or line. We request comment on the appropriate requirements for open-ended valves and lines, including any additional data either supporting the proposed requirements or demonstrating that we should consider different requirements.

We are proposing to require sensory monitoring for open-ended valves and lines containing materials that would auto catalytically polymerize or would present an explosion, serious overpressure or other safety hazard if capped or equipped with a double block and bleed system. These open-ended valves and lines are exempt from the requirement to install a cap, blind flange, plug or second valve because of the risk of serious overpressure leading to catastrophic failure and, potentially, greater emissions to the atmosphere than if the line is left uncapped. However, we do believe that it is appropriate to require sensory monitoring in this case, as indications of a potential leak from the open-ended valve or line could indicate a leak in the seal of the open-ended valve.

In addition, we are proposing a few clarifications to the definition of ''open-ended valve or line.'' First, we recognize that the literal interpretation of the phrase ''one side of the valve seat in contact with process fluid and one side open to atmosphere, either directly or through open piping'' could lead you to the inaccurate conclusion that once you install a cap, plug, blind flange or second valve on the open-ended valve or line, you no longer have one side of the valve seat open to the atmosphere, so it is no longer an ''open-ended valve or line.'' However, that is not our intended interpretation. Instead, we consider an open-ended valve or line with a cap, plug, blind flange or second valve to be a controlled open-ended valve or line. Therefore, we are proposing to clarify that an open-ended valve or line with a cap, blind flange, plug or second valve on the side that would be otherwise open to the atmosphere is still considered an open-ended valve or line. Second, we are adding the words ''any length of'' to that phrase, so it reads ''or one side open to atmosphere, either directly or through any length of open piping.'' This proposed language clarifies that a valve with one side of the valve seat open to the atmosphere through a very long length of pipe is still considered an open-ended valve or line.

Equipment in closed vent systems and fuel gas systems. Current equipment leak rules are not always consistent regarding regulation of equipment in closed vent systems and fuel gas systems. We expect that closed vent systems and fuel gas systems transport gaseous streams to control devices or combustion devices, respectively, without releases to the atmosphere. Therefore, we are proposing to specify that equipment in closed vent systems and fuel gas systems operate with an instrument reading below 500 ppm above background. Similar to compressors, PRD and open-ended valves and lines, we are proposing to require annual instrument monitoring of the equipment in closed vent systems and fuel gas systems to demonstrate that it operates with an instrument reading below 500 ppm above background. An instrument reading of 500 ppm above background or greater would be a deviation.

Similar to the alternative standard for compressors, we did consider specifying a time frame for repair for an instrument reading of 500 ppm above background or greater. However, we determined that since the instrument reading of 500 ppm above background or greater indicates a deviation from the standard rather than the presence of a leak, we determined that it would not be appropriate to provide a set number of days for repair or allow delay of repair. Instead, we expect you to take action as soon as possible to return the equipment to an instrument reading less than 500 ppm above background. We are proposing to require that you must provide in your semiannual periodic report, the date of

the instrument reading 500 ppm above background or greater and the date of the next instrument reading less than 500 ppm above background (*i.e.,* the number of days that the deviation lasted) for each piece of equipment in a closed vent system or fuel gas system. We request comment on the appropriate requirements for equipment in closed vent systems and fuel gas systems, including data either supporting the proposed requirements or demonstrating that we should consider different requirements.

5. How did the EPA determine the proposed general compliance requirements for equipment leaks?

We are proposing several general clarifications and new requirements that are not specific to certain types of equipment. These clarifications and new requirements are described below.

Equipment in vacuum service. In the Level 2 EL Generic MACT, equipment in vacuum service is exempt from all of the LDAR requirements, including recordkeeping and reporting. In the Uniform Standards, we are proposing to require demonstration that equipment is in vacuum service in 40 CFR 65.416(e), including installation of a pressure gauge and alarm system that will alert an operator immediately and automatically when the pressure is such that the equipment no longer meets the definition of in vacuum service. While we continue to agree that monitoring the equipment in vacuum service for leaks is not necessary, we do find that it is appropriate for you to demonstrate continuously that your equipment is in vacuum service.

Equipment that is unsafe- or difficult-to-monitor. The provisions for equipment that is unsafe- or difficult-to-monitor are largely the same as the Level 2 EL Generic MACT. We are proposing to clarify that equipment of any type for which you are required to conduct instrument monitoring may be designated as unsafe- or difficult-to-monitor if they meet the appropriate conditions in 40 CFR 65.416(a)(1) or (2). The Level 2 EL Generic MACT limited difficult-to-monitor equipment to valves and agitators, and we found no technical feasibility reason that you should not be permitted to designate pumps and connectors as difficult-to-monitor, as well. We are also proposing to clarify that the written monitoring plans required in 40 CFR 65.416(a)(4) must address repair of any leaks you find when you conduct instrument monitoring according to the plan.

Finally, we evaluated the provisions for inaccessible connectors, and we determined that two of the provisions are more appropriately classified as factors that make the connector either difficult-to-monitor or unsafe-to-monitor. In addition, we saw no reason why these provisions should be limited to connectors rather than applicable to all equipment. Therefore, we are proposing to add ''equipment that you cannot access without the use of a motorized man-lift basket in areas where an ignition potential exists'' and ''equipment in near proximity to hazards such as electrical lines'' to the list of examples of unsafe-to-monitor equipment in proposed 40 CFR 65.416(a).

Sensory monitoring. Consistent with the Level 2 EL Generic MACT, if your equipment is subject to sensory monitoring requirements and you find evidence of a potential leak, we are proposing in 40 CFR 65.430(b) that you would be required either to use instrument monitoring to determine if there is a leak needing repair or to repair the equipment, eliminating the evidence of the potential leak. We are also proposing in 40 CFR 65.430(b)(1) to add a limit to the amount of time you would have to repair the equipment (*i.e.,* eliminate the evidence of a potential leak) to 5 days after detection, which is consistent with NSPS VVa.

Monitoring instrument calibration. Consistent with the Level 2 EL Generic MACT, we are proposing that you would calibrate the monitoring instrument with zero air and methane in air. However, we have received information that while methane in air is commonly used to calibrate flame ionization detector (FID)-based instruments, methane is not appropriate for calibrating photo ionization detector (PID)-based instruments. The other calibration gas provided in NSPS VV and NSPS VVa, n-hexane in air, is difficult to find, as 10,000 ppm n-hexane in air is close to the lower explosive limit. Instead, many users of PID-based monitoring instruments use isobutylene as the calibration gas because the response factor of isobutylene is representative of most of the gases they expect to encounter. Therefore, we are proposing to allow isobutylene in air as a calibration gas. Again, consistent with the Level 2 EL Generic MACT, we are proposing that if the instrument does not respond to methane or isobutylene, you may use another compound in air to calibrate the instrument, so the calibration procedures continue to be flexible. We request comment on whether isobutylene in air is an appropriate calibration gas and whether the use of other calibration gases is widespread enough that they should be included.

To ensure that the monitoring results are as accurate as possible, we are also proposing in 40 CFR 65.431(a)(3)(ii) to require a calibration drift assessment similar to the requirements in NSPS VVa. At a minimum, you would be required to perform a calibration drift assessment at the end of each monitoring day. Post-test calibration drift assessments constitute good practice and are a useful quality assurance/quality control (QA/QC) tool to validate the proper operation of the monitor during the monitoring period and, hence, the measurement data. We note that the proposed requirement for a calibration drift assessment is not an effort to make the method more accurate than was originally intended; it is intended as an additional quality assurance check.

As proposed, you would be required to check the instrument with the same calibration gases as before use and calculate the percent difference from the most recent calibration value. If the drift assessment shows a negative drift of more than 10 percent, then you would have to calculate the leak definition adjusted for negative drift and re-monitor all equipment monitored since the last calibration with instrument readings below the applicable leak definition and above the leak definition adjusted for negative drift. For example, if your leak definition is 500 ppm and you calculated the negative drift to be 15 percent, you would calculate the leak definition adjusted for negative drift as 425 ppm, and you would have to re-monitor equipment with instrument readings above 425 ppm and below 500 ppm to confirm that those pieces of equipment are not leaking. If the drift assessment shows a positive drift of more than 10 percent, then you would have the option to re-monitor all equipment monitored since the last calibration with instrument readings above the applicable leak definition and above the leak definition adjusted for positive drift. Using the same example, you would calculate the leak definition adjusted for negative drift as 575 ppm, and you could elect to re-monitor equipment with instrument readings above 500 ppm and below 575 ppm to show that those pieces of equipment are not actually leaking.

Delay of repair. We are proposing a limit on the amount of time you can delay repair of leaking equipment in 40 CFR 65.432(d). We agree that there are times when repair will be technically infeasible without a process unit shutdown, and we are not proposing to require immediate shutdown to accomplish those repairs. However, we are aware that some process units shut

down very infrequently, allowing equipment to continue leaking for many years. Therefore, we are proposing to specify that you may only delay repair up to the end of the next process unit shutdown or up to 5 years after the leak is detected, whichever is sooner. We believe that a limit of no more than 5 years will allow you to schedule repairs during a planned process unit shutdown while preventing repair from being delayed indefinitely. We request comment on the limit of 5 years; for comments supporting a longer amount of time, we request supporting documentation and examples demonstrating why a longer amount of time is necessary.

We are also proposing that if you have a process unit shutdown of longer than 24 hours, planned or unplanned, you would take the time during that shutdown to repair all equipment for which you delayed repair until the next process unit shutdown. We expect that you would purchase the supplies needed to repair the leaks when the leaks are first detected so that you would be prepared to make repairs during an unplanned shutdown. You would not be required to begin making repairs until the shutdown lasts 24 hours, but you would be required to extend the shutdown until all equipment for which you delayed repair until the next shutdown have been repaired. You would not be required to repair leaks detected less than 15 days before the shutdown. While we expect that you would have ordered the supplies needed for repair, they may not arrive in less than 15 days. In addition, the delay of repair requirements are intended for equipment that cannot be repaired in 15 days, so it is not reasonable to expect that you will always know in less than 15 days that a leak cannot be repaired without a process unit shutdown. We request comment on requiring repairs during any shutdown longer than 24 hours.

We are clarifying that you would continue to conduct instrument monitoring on the schedule required by 40 CFR 65.420 through 65.427 while repair of the leak is delayed. The current equipment leaks requirements do not specify clearly that monitoring may be suspended, but we are aware that some owners and operators have interpreted the current regulations to mean that monitoring is not required. However, continuing to conduct instrument monitoring while repair is delayed provides information about the magnitude of the leak during that time. If the leak grows significantly over time, you may determine that it is appropriate to reschedule the next shutdown to repair the leak sooner. You would not be required to report the results of the continued monitoring, but you would be required to keep records of those results. We are also proposing that for a pump or agitator for which you have delayed repair, you may suspend the weekly inspection until the pump or agitator is repaired.

Finally, we are proposing that unless it is technically infeasible for you to do so, when you do repair valves and connectors for which you delayed repair, you must replace leaking valves and connectors with low leak technology (*e.g.,* replacing the valve packing, flange gaskets or the entire valve or connector). While it is not cost effective to require replacement of all equipment at one time, requiring replacement for equipment that cannot be repaired within 15 days would give you time to plan the repair and purchase the necessary supplies or equipment. In addition, experience has shown that these techniques result in a longer period of time before that specific piece of equipment leaks again, so you would have fewer leaks in the process and likely would be able to take advantage of the less frequent monitoring allowed for valves and connectors. In addition, over time, you would be required to conduct fewer repairs, reducing the cost and time necessary to repair leaks. These cost reductions are expected to offset the increases in capital cost associated with the low leak technology (estimated to be about 10 to 35 percent for valves; see the presentation ''Low Leak Valve and Valve Packing Technology (Low-E Valve)'' in Docket ID No. EPA–HQ–OAR–2010–0869).

We recognize that there are situations where replacing the packing, gaskets or entire piece of equipment may not be technically feasible. In that case, you would be required to document the demonstration that such repair was technically infeasible and include the documentation in your annual periodic report. We are proposing that you would be required to evaluate this demonstration each time you delay repair for a piece of equipment. For example, suppose you previously determined that it was technically infeasible to install low leak technology to repair a valve for which you delayed repair. If that valve leaks again in the future and you have to delay repair beyond 15 days again, you would be required to demonstrate that it is still technically infeasible to install low leak technology to repair a valve; you cannot simply refer to your previous determination. We request comment on this proposed requirement, including whether there are other times that we should require installation of low leak technology and whether we should provide specific circumstances for which installation of low leak technology would not be required due to technical infeasibility (and if so, what those circumstances should be).

We note that, as we stated in the preamble to the proposed amendments to NSPS VV (71 FR 65302, November 7, 2006), sealant injection procedures such as drill and tap methods have advanced in recent years to the point that they are a viable on-line repair technique for many leaking valves. Therefore, we are again clarifying in this proposal that if sealant injection procedures such as drill and tap are a technically feasible type of repair for a specific valve, then those procedures should be attempted before you determine that it is necessary to delay repair for that valve.

6. How did the EPA determine the requirements for the alternative compliance options for equipment leaks?

Alternative for batch operations. The proposed requirements for the alternative compliance option for batch operations are essentially the same as the monitoring requirements in 40 CFR 63.1036(c) of the Level 2 EL Generic MACT. The proposed requirements include the option to elect adjusted monitoring frequencies for process units that operate infrequently, but we are also proposing to specify the minimum amount of time, or ''reasonable intervals,'' between monitoring events consistent with NSPS VVa. Section VI.B of this preamble discusses the rationale for including reasonable intervals in these Uniform Standards, and the reasonable intervals are specified in proposed 40 CFR 65.280 (the General Provisions to the Uniform Standards). We request comment on the reasonable intervals specific to the alternative compliance option for batch operations.

Alternative for routing equipment leak emissions to a closed vent system and control device or to a fuel gas system. The Level 2 EL Generic MACT includes exceptions from instrument monitoring or other standards if you route emissions from leaks of certain types of equipment directly to a fuel gas system or to a control device via a closed vent system. We considered including these provisions as a centralized alternative compliance option in the Uniform Standards. However, we believe that these options have limited applicability. For example, only certain types of equipment and seals physically can be routed directly to a closed vent system or fuel gas system. Therefore, we have

elected to provide the provisions where they are the most directly applicable (*i.e.,* with the other monitoring requirements or performance standards for that type of equipment). Specifically, we are proposing that PRD that release through a closed vent system to a control device would not be required to be operated at less than 500 ppm above background because any vapors released with an instrument reading higher than 500 ppm would be controlled by the control device. Similarly, the proposed Uniform Standards provide a compliance option consistent with the Level 2 Generic MACT for dual mechanical seal pumps, dual mechanical seal agitators and compressor seal systems routed to a fuel gas system or through a closed vent system to a control device. If you use a closed vent system and non-flare control device or a fuel gas system to meet the requirements of this subpart, we are proposing that both the closed vent system and non-flare control device or the fuel gas system, as applicable, must comply with the applicable standards of proposed 40 CFR part 65, subpart M. In addition, consistent with the Level 2 Generic MACT, we are specifying that a non-flare control device must reduce regulated material emissions reductions by 95 percent or to an outlet concentration of 20 ppmv and we are requiring a design evaluation or performance test, as specified in proposed 40 CFR part 65, subpart M for the non-flare control device. We are proposing that flares used to comply with the applicable standard meet the requirements of 40 CFR 63.11(b) of subpart A, as well as proposed 40 CFR part 65, subpart M for the closed vent system associated with the flare.

However, we are not proposing the alternative to route equipment leaks from other pumps and agitators to a fuel gas system or through a closed vent system to a control device. Based on our information, we believe the alternative is rarely, if ever, used for these types of equipment. We request comment on specific situations for which this alternative would apply, particularly from any owners and operators complying with a similar alternative under current equipment leak standards.

Alternative for enclosing a process unit and routing equipment leak emissions to a closed vent system and control device. The Level 2 EL Generic MACT includes exceptions from instrument monitoring if you enclose a process unit or portion of a process unit and vent the equipment leak emissions through a closed vent system to a control device. We considered including these provisions as alternative compliance options as part of the Uniform Standards. However, we believe that these options have limited applicability, and we expect that the types of processes an owner or operator might choose to enclose would be limited, based on factors such as the process fluid characteristics (*i.e.,* the owner or operator likely would not elect to enclose all processes at a facility). Therefore, we are not proposing any alternatives or exceptions based on enclosing process units and routing equipment leaks through a closed vent system to a control device. We request comment on this decision, including examples of specific situations in which that alternative would be most likely to apply.

Alternative for routing emissions to the process. We are not proposing specific provisions for routing emissions from equipment leaks to a process. Instead, we are clarifying through this preamble that the line routing the emissions to the process would be considered part of the process and would be required to comply with the otherwise applicable provisions.

Alternative for pressure testing. We are not proposing to include the alternative compliance option for pressure testing that is in the Level 2 EL Generic MACT. Based on the results of comparative testing and observations, we have concerns that the pressure-testing alternative may not be equivalent to the otherwise applicable LDAR requirements. Therefore, we have decided not to include that alternative in these Uniform Standards. If there is a specific source category for which the pressure-testing alternative is appropriate, we expect that the referencing subpart for that source category would include the provisions for that alternative.

Requesting an alternative means of emission limitation. The Level 2 EL Generic MACT includes specific procedures for requesting an alternative means of emission limitation not already included within that subpart. However, the provisions in the Level 2 EL Generic MACT provisions are fairly general, and there is nothing specific to requesting an alternative means of emission limitation for equipment leaks in the provisions. Therefore, after reviewing these provisions, the CAA and the General Provisions to 40 CFR part 60 and 40 CFR part 63, we have decided not to propose those provisions within 40 CFR part 65, subpart J. We are proposing to include provisions within the General Provisions to the Uniform Standards (40 CFR part 65, subpart H) for requesting an alternative means of emission limitation. See section VI.B.11 of this preamble for additional details on these provisions.

7. How did the EPA determine the requirements for using the optical gas imaging device to detect leaks?

As noted in section IV.A.5 of this preamble, we anticipate that for some source categories, specific requirements for using an optical gas imaging device to detect leaks without accompanying instrument monitoring could be an appropriate alternative to the requirements described in section IV.A.4 of this preamble. Therefore, we are proposing to allow the use of optical gas imaging as a standalone technique for detecting equipment leaks in regulated material service. However, as we also noted in section IV.A.5 of this preamble, we believe that this technique is not currently suitable for detection of leaking compounds in all industry sectors, in part, due to the limitation of the number of compounds that can be screened using this technology. Therefore, we are proposing that the provisions for use of an optical gas imaging instrument for leak detection would be allowed as an alternative only if your referencing subpart includes a direct reference to 40 CFR 65.450. We expect that a referencing subpart will include a direct reference to 40 CFR 65.450 only if it is technically feasible for the sources in that source category to follow the protocol proposed in 40 CFR part 60, appendix K. Structuring the requirements in this way ensures that the optical gas imaging techniques are applied consistently over the various source categories, but provides the referencing subpart the flexibility to define clearly when the optical gas imaging provisions may be used.

We are proposing to include a monitoring frequency of bimonthly and a leak detection level of 60 grams per hour in the Uniform Standards that would apply if the referencing subpart allows you to use the optical gas imaging alternative, but does not specify a monitoring frequency and/or leak detection level. We believe that the appropriate monitoring frequency and leak detection level for a given source category is likely to vary depending on the regulated material and other industry-specific factors. However, we currently do not have data to support setting different parameters, so we are proposing to set the levels in the Uniform Standards consistent with the AWP. Unless and until industry-specific and regulated material-specific data can be gathered using the optical gas imaging instrument, it is not reasonable to expect each referencing subpart to set

a source category-specific monitoring frequency and leak detection level. However, if data are available, the referencing subpart can include a specific monitoring frequency and/or leak detection level other than those set in the Uniform Standards.

V. Summary and Rationale for the Proposed 40 CFR Part 65 National Uniform Emission Standards for Control Devices—Subpart M

A. Summary

This section summarizes the requirements proposed under 40 CFR part 65, subpart M in this action. The proposed requirements summarized in this section are based on the EPA's review of current regulations for closed vent systems; control devices used to control process vents from reactors, distillation and other operations, as well as from emissions from storage vessels, transfer and equipment leaks; and fuel gas systems used for air emissions control. These requirements reflect our intent to implement a simplified approach to rulemaking that results in consistent requirements for these emission points across multiple source categories. Subpart M consolidates and simplifies monitoring, recordkeeping and reporting requirements from current NSPS and NESHAP, eliminates duplicative or unnecessarily burdensome requirements and examines advances in control practices and technology that could be considered for control options in future rulemakings.

In section V of this preamble, the term ''we'' refers to the EPA and the term ''you'' refers to owners and operators of sources affected by the proposed standards. Section V.B of this preamble provides our rationale for the proposed requirements in 40 CFR part 65, subpart M. Additionally, ''subpart M'' refers to proposed 40 CFR part 65, Subpart M.

1. What is the purpose of the proposed rule?

The proposed rule specifies requirements for closed vent systems collecting regulated materials from a regulated source under the referencing subpart; control devices that are used to reduce regulated material emissions from emission points affected by a subpart that references the use of subpart M, including small boilers and process heaters, oxidizers, absorbers, adsorbers, condensers, biofilters, fabric filters, sorbent injection and other control devices; and fuel gas systems used to meet the air emission control requirements of a referencing subpart. The owner or operator would use subpart M to comply with emission standards for any emission unit type (*e.g.,* process vents, transfer racks, storage tanks and equipment leaks) for which emissions are routed to a control device or fuel gas system.

2. What are the proposed general requirements for complying with this subpart?

General requirements. Facilities would be subject to some or all of the requirements of subpart M when another subpart references the use of subpart M for air emission control, or when directed by another subpart under the Uniform Standards. You would be required to meet the general provisions applicable to part 65 (*i.e.,* subpart A of 40 CFR part 65) and the general provisions applicable to the referencing subpart (*i.e.,* subpart A of 40 CFR parts 60, 61 or 63).

General requirements for halogenated vent streams. As part of the general requirements for proposed subpart M, you would be required to identify each emission stream as either a halogenated or non-halogenated vent stream for purposes of determining which requirements of subpart M apply to each vent stream.

3. What are the proposed requirements for closed vent systems?

We are proposing to require that all owners and operators using a control device to comply with a referencing subpart meet the requirements for closed vent systems. For a closed vent system that contains bypass lines that can divert the stream away from the control device to the atmosphere, you would be required to either (1) install, maintain and operate a continuous parameter monitoring system (CPMS) for flow that is capable of recording the volume of gas that bypassed the control device and is equipped with an automatic alarm system that will alert an operator immediately when flow is detected in the bypass line, or (2) to secure the bypass line valve in the non-diverting position with a car-seal or a lock-and-key type configuration. You would be required to inspect the seal or closure mechanism at least once per month to verify the valve is maintained in the non-diverting position. Use of a bypass at any time regulated materials are flowing in the closed vent system that results in a release of regulated materials to the atmosphere is considered an emissions standards deviation under the proposed rule.

The closed vent system equipment collecting regulated material from a regulated source would be subject to the applicable requirements of the equipment leak Uniform Standards of proposed 40 CFR part 65, subpart J (see section IV.A of this preamble).

4. What are the proposed monitoring and compliance requirements I must meet for each control device?

Under the proposed requirements, you would be required to conduct continuous monitoring for each boiler, process heater, oxidizer, absorber, adsorber, condenser, sorbent injection, biofilter, fabric filter or other control device used to comply with standards in the referencing subpart. The monitoring, recordkeeping and reporting requirements proposed in subpart M are applicable to all control devices. This includes control devices in series with one another (*e.g.,* an absorber and a thermal oxidizer).

For each of these control devices, you must install a CEMS capable of measuring regulated material in the exhaust stream of the control device or you may elect to install and operate a CPMS, unless disallowed by a referencing subpart. You would be required to establish operating limits for monitored parameters that indicate the control device is meeting the specified emission standard of the referencing subpart. For fabric filters, we are proposing that you equip your fabric filter with a bag leak detection system with a device able to continuously record the output signal from the sensor. Additionally, the bag leak detection system must be equipped with an alarm system that will sound when an increase in PM emissions is detected and which does not sound more than 5 percent of the operating time during a 6-month period; if the alarm sounds more than 5 percent of the operating time during a 6-month period, it is considered a deviation. The proposed rule provides guidance for calculating the alarm time and directs the corrective actions to be taken.

As part of the proposed general monitoring requirements for control devices, CEMS and CPMS must follow the requirements specified in proposed 40 CFR 65.711 and 40 CFR 65.712. For each CEMS used to comply with the referencing subpart, we are proposing that you operate and maintain each CEMS according to the requirements of your CEMS performance evaluation and monitoring plan. We are proposing that you conduct initial and periodic performance evaluations of each CEMS used to comply with the referencing subpart according to this plan. In addition, for each CPMS used to comply with the referencing subpart, we are proposing that you operate and maintain each CPMS according to the requirements of your CPMS monitoring

plan. For each bag leak detection system, you must maintain a CPMS monitoring plan, a corrective action plan and records of any bag leak detection alarm, as described in proposed 40 CFR 65.724.

All CPMS would be required to meet minimum calibration and quality control requirements, as specified in Table 4 of subpart M. For each monitored parameter, you would establish an operating limit, pursuant to the requirements of proposed 40 CFR 65.713. Table 3 of subpart M specifies the operating parameters, operating limits and data monitoring, recordkeeping and compliance frequencies for each type of control device covered by proposed subpart M. Tables 1 and 2 of subpart M specify the monitoring equipment requirements when using CEMS and CPMS. You would be required to keep monitoring system records for your CEMS or CPMS, as specified in proposed 40 CFR 65.860. Additionally, you would be required to meet the control device-specific monitoring requirements in proposed 40 CFR 65.724 through 65.800 for the specific control measure(s) being used.

In addition to monitoring, we are proposing that for each control device, you must conduct a performance test to determine compliance with the referencing subpart unless you meet the exemptions specified in proposed 40 CFR 65.702(e). You must conduct the performance test for each control device according to the requirements of proposed 40 CFR 65.820 through 65.829 (see section V.A.7 of this preamble). For fabric filters, you would be required to conduct a performance evaluation consistent with the *Fabric Filter Bag Leak Detection Guidance* (EPA–454/R–98–015, September 1997, incorporated by reference). As a burden reduction for existing regulated sources transitioning to the Uniform Standards, we are not requiring performance tests for which a previous performance test report has been submitted, if the performance test was conducted within the last 5 years and was conducted as specified in proposed subpart M. We note that some transitioning sources may be required to conduct a performance test in cases where new parameter monitoring is required (*e.g.,* carbon absorbers). We anticipate that the referencing subpart will specify, as appropriate for the individual source category, if a new performance test is required or if a prior performance test will satisfy the requirement.

Owners or operators using a fuel gas system to comply with the requirements of the referencing subpart would be required to submit a statement that the emission stream is connected to the fuel gas system in the Notification of Compliance Status Report. Fuel gas systems used to meet air emissions control would be subject to the applicable proposed equipment leak Uniform Standards of 40 CFR part 65, subpart J (see section IV.A of this preamble) as they apply to the individual equipment components comprising the fuel gas system. These requirements include specific instrument monitoring requirements for equipment in gas and vapor service and equipment in light liquid service, and specific sensory monitoring requirements for equipment in heavy liquid service and other equipment that meets certain criteria. You would also be required to meet the control device provisions in proposed 40 CFR 65.724 for small boilers and process heaters that are a part of the fuel gas system if regulated material is routed to the fuel gas system for control.

For each small boiler or process heater, thermal oxidizer, catalytic oxidizer, absorber, adsorber, condenser, biofilter, sorbent injection system or other control device used to comply with the referencing subpart, you would be required to keep the records described in section V.A.8 of this preamble.

5. What are the performance testing requirements?

The performance testing requirements for subpart M are included in proposed 40 CFR 65.820 through 65.829. Proposed 40 CFR 65.820 provides requirements for notification, development and submittal of a performance test plan, and specifies the ''performance testing facilities'' that must be provided by owners and operators required to conduct a performance test (see proposed 40 CFR 65.820(d)).

For each control device controlling regulated materials for which a performance test is required, the proposed standards specify requirements on how to test vent streams from continuous process operations, batch process operations and combined continuous and batch process operations in proposed 40 CFR 65.821. For continuous process operations, we are proposing that you conduct performance tests during ''maximum representative operating conditions for the process.'' Specifically, we are proposing that you must operate your process during the performance test in such a way that results in the most challenging condition for the control device. The most challenging condition for the control device may include, but is not limited to, the highest HAP mass loading rate to the control device, or the highest HAP mass loading rate of constituents that approach the limits of solubility for scrubbing media.

For batch process operations, performance tests must be conducted at absolute worst-case conditions or hypothetical worst-case conditions. The proposed standards define the criteria for selecting the absolute worst-case and hypothetical worst-case conditions in 40 CFR 65.822 (see section V.B.6 of this preamble). We are also proposing that you develop an emissions profile that would describe the characteristics of the vent stream at the inlet to the control device under those absolute or hypothetical worst-case conditions you selected. You would then be required to control and achieve the emission limit prescribed under the referencing subpart, and conduct your performance tests for those periods of worst-case conditions you selected (see section V.B.6 of this preamble).

For combined continuous and batch process operations, you must conduct performance tests when the batch process operations are operating at absolute worst-case conditions or hypothetical worst-case conditions, and the continuous operations are operating at the maximum representative operating conditions for the process.

Table 5 to proposed subpart M specifies the applicable test methods and procedures for each test run, based on the type of emission limit specified in the referencing subpart. As discussed in section II.E of this preamble, we anticipate that the referencing subpart will establish the emission limit that best represents the level of control needed for the source category. The referencing subpart would provide rationale for the format and units of measure for each limit, or, if applicable, rationale for the use of a surrogate in cases where methods for a specific pollutant are insufficient.

We are proposing that if you make a change to process equipment or operating conditions that would affect the operating parameter values of a control device and render the operating limits ineffective as indicators of compliance with the standard, you must conduct a performance test within 180 days of the date of startup of the change to establish new operating limits and demonstrate that you are in compliance with the applicable emission limit of the referencing subpart.

We have included additional requirements for performance testing, including sampling, duration and calculations for determining compliance

in proposed 40 CFR 65.823 through 65.829.

6. What are the additional requirements for batch process operations?

In proposed 40 CFR 65.835, we have included a method for demonstrating compliance with an aggregated percent reduction emission standard. These requirements apply when a referencing subpart allows the owner or operator to show compliance with a percent reduction by aggregating emissions over the full batch process. To demonstrate compliance, the owner or operator would use the proposed engineering evaluation methodologies to calculate uncontrolled emissions from all batch process operations for a given process that they do not want to control. The owner or operator would still determine, through performance testing, uncontrolled and controlled emissions from batch process operations that are controlled. All emissions from all batch process operations (*i.e.,* those emissions determined from the proposed engineering evaluation methodologies and those emissions determined from performance testing) would then be considered when determining compliance with the percent reduction emission limit.

In addition, we are proposing that you use these engineering evaluation methodologies if you choose to develop an emissions profile by process for determining absolute worst-case conditions of your batch process operations. You would also use these methodologies as part of your condenser design evaluation (see the specific condenser section of section V.B.3 of this preamble).

7. How can I demonstrate compliance through design evaluation?

Except for condensers, under the proposed standards, you may demonstrate compliance for a non-flare control device by conducting a design evaluation in lieu of a performance test, if allowed by the referencing subpart. The design evaluation would require documentation that the control device being used achieves the emission limit required by the referencing subpart. For condensers, we are proposing that you must conduct a design evaluation (see section V.B.3 of this preamble). The evaluation must also include documentation of the composition of the vent stream entering each control device, including flow, regulated material concentration and other site-specific information for each control device, as provided in proposed 40 CFR 65.850. If you choose to do a design evaluation, you would also submit a monitoring description with the Notification of Compliance Status. The monitoring description would contain a description of the parameters to be monitored and the associated operating limit(s), an explanation of the criteria used for selection of that parameter (or parameters) and the operating limit(s), the frequency with which monitoring will be performed, and the averaging time for each operating parameter being measured. Once the design evaluation has been conducted and operating parameters have been established, the non-flare control device must be operated and maintained such that the monitored parameters remain within the established operating limit.

8. What are the recordkeeping, notification and reporting requirements?

We are proposing that each owner or operator of the affected control device must keep the records in proposed 40 CFR 65.860. These include:

- Continuous records of the monitoring equipment operating parameters or emissions. If certain requirements are met, you have the option of maintaining a record of each measured value, or block hourly average data and the most recent three valid hours of continuous records.
- Records of the daily average value or operating block average value of each continuously monitored parameter or emissions for each operating day.
- Non-continuous records as specified in 40 CFR 65.860(b).
- Records of each operating scenario, each emission episode, and each emission profile you develop as described in proposed 40 CFR 65.860(f) for batch operations.
- Control device monitoring, calibration and maintenance records.
- Records of periods when the regulated source, control equipment or CPMS are out of control, inoperative or are not operating properly.
- For batch process operations, records of whether each batch operation was considered a standard batch, including estimated uncontrolled and controlled emissions for each nonstandard batch.
- Performance test records for each performance test performed, as described in proposed 40 CFR 65.820 through 65.829 (and discussed further in section V.A.7 of this preamble). For control devices for which a performance test is required, you would be required to keep records of the percent reduction of regulated material achieved by the control device or the concentration of regulated material at the outlet of the control device, as applicable.

You would be required to submit the reports in proposed 40 CFR 65.880, 65.882, 65.883 and 65.884; certain reports must be submitted electronically, as specified in the proposed 40 CFR part 65, subpart H (see section II.F and VI.B.7 of this preamble). As specified in proposed 40 CFR 65.880, you would be required to submit the Notification of Compliance Status by the date provided by the referencing subpart. The Notification of Compliance Status would require certifications of compliance with rule requirements, including batch calculations and design evaluation records. The report would also include the established operating limit for each monitored parameter. For halogenated vent streams, you would be required to identify any halogenated vent streams as part of the Notification of Compliance Status. The Notification of Compliance Status would also include a statement about any emissions being routed to a fuel gas system. For existing control devices that may be redirected to the Uniform Standards as current regulations are revised, you would also be required to submit a Notification of Compliance Status. However, in order to reduce burden for transitioning sources, we are providing that you would be allowed to rely on previous performance test reports as part of the submittal, as long as the performance test was conducted within the past 5 years and conducted as specified under proposed subpart M. As discussed in section V.A.4 of this preamble, some transitioning sources may be required to conduct a performance test in cases where new parameter monitoring is required.

You would be required to submit semi-annual and annual periodic reports according to the requirements in proposed 40 CFR 65.882 and 65.883. Generally, semi-annual reporting of deviations is required to submit electronically, and annual reporting of non-deviation elements is required to be submitted in hard copy, as discussed under *Types of reports* in section VI.B.7 of this preamble. We are proposing, under 40 CFR 65.884, that you submit certain reports at varying times, based on the activity being reported, including a notification of the performance test, any application to substitute a prior performance test for an initial performance test, a CEMS performance evaluation notification or CPMS monitoring plan submittal, a batch pre-compliance report and certain information, if you chose to use a control device other than those listed in this subpart.

9. When must I comply with the proposed standards?

We are not proposing to specify a compliance timeline in subpart M, so the compliance timeline specified in the referencing subpart would apply for that source category.

B. Rationale

This section provides rationale for the proposed compliance requirements for vent streams that are routed to fuel gas systems or through closed vent systems to control devices. Rationale for the associated monitoring, performance testing, reporting and recordkeeping requirements is also included.

In keeping with our intent to provide a smarter, streamlined process for rulemaking and ensure consistent standards across multiple source categories, we have structured the National Uniform Emission Standards for Control Devices to provide a common set of monitoring, testing, recordkeeping and reporting requirements that may be referenced from multiple regulations, including NSPS and NESHAP. The proposed Uniform Standards in 40 CFR part 65, subpart M are generally based on a review of the Generic MACT standards of 40 CFR part 63, subpart SS. Additionally, we reviewed other recent rules, the applicability determination index database, test reports and recent EPA decisions to identify advances in control technologies, monitoring and compliance approaches. This is in keeping with our intent that the proposed National Uniform Emission Standards for Control Devices would provide a set of supporting requirements that could be considered in future rulemakings under CAA section 111 and 112 to meet the applicable statutory requirements.

The requirements for 40 CFR part 63, subpart SS were chosen as the best starting point for these proposed standards because they were previously developed for the purpose of providing consistent control device requirements that could be referenced by multiple NESHAP subparts, and they already incorporate some improvements based on the EPA's experience with implementation of other subparts, such as the MON (71 FR 40333, issued on July 14, 2006) and the HON (59 FR 19402, issued on April 22, 1994). We have augmented the subpart SS provisions by adding requirements from other subparts to provide additional continuous monitoring options, to better accommodate batch processes and to provide requirements for additional regulated materials (*e.g.,* metals, PM) and types of control devices (e.g., fabric filters, sorbent injection) not covered by subpart SS.

We have developed the Uniform Standards for Control Devices to create a set of requirements that will ensure continuous compliance with the standards established under a referencing subpart. In developing the proposed requirements, we had the opportunity to review typical compliance methods for control devices controlling vent streams from regulations representing a variety of source categories. From this review, we considered the variation in requirements between rules and identified the most effective requirements for each control device. As such, we are proposing subpart M with more stringent requirements than may currently apply to some source categories; however, this stringency can always be overridden by the referencing subpart if deemed appropriate for the particular source category. These more stringent requirements reflect our intention to provide a consistent set of monitoring, recordkeeping and reporting requirements that reflect the most current control technologies and that are accessible and applicable for the majority of source categories complying with MACT and that would potentially reference the Uniform Standards to meet MACT. These consistent standards, if promulgated, will reduce the current overlapping and inconsistent provisions from multiple NSPS and NESHAP that may apply to a single source into a single set of requirements, thereby reducing the compliance burden for sources and government alike. Providing this common set of requirements also circumvents any undue burden on a single source category (for instance, source categories currently subject to multiple regulations). Furthermore, this approach would reduce the number of requests for alternative monitoring requirements, which are frequently made by sources required to comply with multiple NESHAP and NSPS. The proposed Uniform Standards for Control Devices also provide some additional requirements in places that we discovered, through our regulatory survey, were not adequately addressed by current regulations (*e.g.*, we have included provisions for regenerative carbon absorbers that specify how the source should handle desorbed contaminants). We note that the referencing subpart establishes the applicability of the Uniform Standards for Control Devices and the specific provisions of subpart M that may apply; therefore, a referencing subpart may structure more or less stringent requirements for a given source category as is best determined to meet MACT, GACT, AMOS or BSER. (See *Relationship to Referencing Subpart* below.)

In keeping with the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review,* we have also incorporated changes to simplify and streamline the language, improve consistency, incorporate the latest technical requirements and remove unnecessary regulatory burden to create the National Uniform Emission Standards for Control Devices. We believe that these improvements will result in a consistent, yet flexible set of standards that may be easily referenced by multiple source categories in CAA section 111 and 112 rulemakings, resulting in a more efficient regulatory process that will benefit both regulated entities and government agencies. Throughout this section, we will describe the rationale for each major proposed change from the previous rules.

Relationship to Referencing Subpart. In contrast to the Uniform Standards for Storage Vessels and Transfer Operations and the Uniform Standards for Equipment Leaks, the proposed subpart M does not establish applicability thresholds or control levels that may be relied upon by a referencing subpart. Rather, subpart M requires that the referencing subpart establish all applicability, including thresholds or tiers. We have developed subpart M without these types of thresholds because there is a greater variety of emission streams expected to be controlled under subpart M. Storage tanks and equipment leaks are generally controlled on a unit level, with a standard configuration, and the emissions mechanism by which pollutants are released to the atmosphere from these emission points is generally limited. In general, these emissions points are single points that, individually, do not represent large emission sources, and that all behave similarly. Therefore, control of emissions from these points has historically been homogenous with applicability thresholds and control levels that are easily set; storage tanks, for instance, have historically been controlled using preventative maintenance practices, while emissions from equipment leaks have been historically controlled by LDAR requirements.

Conversely, subpart M provides requirements for control devices that may control a variety of emission

streams with various configurations, flow and concentrations. It is possible for multiple process streams throughout a facility to be joined with and directed to a single control device in numerous configurations, combining emissions in one stream for control of a very large emission source. Furthermore, the number of vents to a control device may vary greatly across source categories; some source categories may reflect a standard configuration in which the process streams require multiple control devices; other source categories may reflect a standard configuration in which a single process stream requires control. Because of the many configurations that exist for individual facilities across multiple source categories, the emissions mechanism for process streams routed to control devices may vary greatly. Therefore, we have determined that the referencing subpart is the best place to determine the applicability threshold or control level for a specific source category, as the referencing subpart may consider the unique configurations, flow and concentration of regulated material within a given process stream or streams.

The Uniform Standards for Control Devices assume that the referencing subpart will establish and provide the rationale for the specific emission limits that best support the source category being regulated. The referencing subpart would address and assign applicability thresholds or control levels for any provisions of the Uniform Standards not cross-referenced by the referencing subpart. The referencing subpart could cross-reference or make exceptions, as necessary, to ensure that the proposed requirements of subpart M are appropriate to the source category. For instance, a referencing subpart with multiple applicability thresholds may only direct to a portion of subpart M for sources meeting one of those thresholds. Additionally, the referencing subpart could determine to not direct to subpart M at all for certain applicability thresholds. For example, a referencing subpart may only require CEMS for streams above a defined threshold.

Organization of Proposed Subpart M. The proposed rule is structured so that the compliance requirements for each control device are provided in separate sections. Each control device section includes the specific requirements for that control device, including monitoring, performance testing, conducting a design evaluation, and recordkeeping and reporting. Specific continuous monitoring requirements for control devices are provided in Tables 1 and 2 of subpart M. We have organized the standards this way to facilitate ease of reading and understanding, to congregate requirements for similar control devices in one place and to remove redundant text. For example, 40 CFR part 63, subpart SS includes a general section for performance testing procedures containing a specific requirement regarding the selection of sampling sites for vent streams introduced with combustion air or as a secondary fuel into certain types of boilers or process heaters. We have moved these requirements, specific only to small boilers and process heaters, to a small boiler and process heater section, which is located in proposed 40 CFR 65.724. Additionally, although subpart SS includes a separate section of requirements for halogenated scrubbers, we have consolidated these provisions with the requirements for absorbers. We reasoned that a halogenated scrubber is a specific type of absorber, and the previous requirements overlapped; combining these requirements reduces redundancy and allows for a streamlined compliance approach.

Because the proposed standards contain general monitoring and performance testing requirements that would be applicable to more than one type of control device, we have included separate sections for general monitoring requirements and performance testing requirements to reduce redundancy across rule sections. We additionally congregated the requirements for the correct operation of CEMS and CPMS, as well as requirements for establishing the operating parameters for each CPMS, into individual sections. In addition to the specific control device section that applies to you, you would comply with these proposed general monitoring requirements, located in 40 CFR 65.710 through 65.712. Likewise, you would comply with the proposed general performance testing requirements in 40 CFR 65.820 through 65.829, which include detailed provisions on the methods required for testing. We have also designated a section for general requirements for performing design evaluations. It is our intent that the proposed standards of subpart M, as organized, will have improved clarity and consistency, which will facilitate both reading and compliance as the standards are referenced in future rulemakings.

General differences between proposed 40 CFR part 65, subpart M and 40 CFR part 63, subpart SS. Although the requirements of subpart M are primarily based on 40 CFR part 63, subpart SS, we revised some of the terminology used in subpart SS to provide clarification and accommodate the broad range of source categories and control devices that could be covered by the proposed standards in the future. The National Uniform Emission Standards for Control Devices are intended to provide a common set of testing, monitoring, recordkeeping and reporting requirements that may be referenced from multiple regulations, including NSPS and NESHAP. Therefore, subparts referencing subpart M may define a range of pollutants and pollutant types (*e.g.,* HAP, criteria pollutants). To accommodate the variety of pollutants and pollutant types that may be regulated under future NSPS and NESHAP, we have used the term ''regulated material'' to mean the pollutant regulated by the referencing subpart. We have also used the term ''oxidizer'' in lieu of ''incinerator'' to refer to control devices such as thermal and catalytic oxidizers in order to differentiate these devices from other regulated incineration units.

We revised some provisions included in 40 CFR part 63, subpart SS that are redundant or unclear, including the ''route to process'' provisions. Subpart SS includes an option to route regulated material emissions from non-process operations (*i.e.,* storage tanks, transfer equipment and equipment leaks) to a process for control. The monitoring, recordkeeping and reporting language from subpart SS for this option is not included in proposed subpart M, as these requirements add unnecessary regulatory burden. The proposed Uniform Standards are consistent with the intent of subpart SS, in that owners and operators will continue to have the flexibility to route vent streams, as necessary, to control releases. However, these emission streams will not be subject to additional monitoring, recordkeeping and reporting if they are simply integrated into the process. We have assumed that vent streams that are routed to a process would be eventually released to the atmosphere through a regulated emissions point (*e.g.,* process operation, wastewater stream, equipment leak, etc.) or incorporated into a product or byproduct. Therefore, these requirements were unclear and unnecessary for the purposes of subpart M. We are soliciting comments on this change, including comment on the assumptions presented in this section. We are also requesting comments on whether some vent streams routed to the process are not released to the atmosphere through a regulated emissions point.

The proposed subpart M does not contain requirements for flares.

Proposed subparts I and J refer to 40 CFR 63.11(b) of subpart A for emissions routed to flares from storage tanks, transfer operations, and leaking equipment. It is anticipated that for process vents controlled by flares, a referencing subpart will reference either 40 CFR 63.11(b) of subpart A or include other provisions that are determined to be applicable for flares used at the source category regulated by the referencing subpart. However, we are in the process of gathering data, reviewing flare research papers and test reports, and investigating operating conditions that may impact the performance of a flare, including situations of over steaming, excess aeration, flame lift off, and high winds. Based on this information, we may in the future propose to add new flare requirements to the Uniform Standards in subpart M, which can be referenced by subparts I and J and referencing subparts.

1. How did the EPA determine the general monitoring requirements and the requirements for CEMS and CPMS?

The general monitoring requirements that we are proposing are modeled after specific requirements from 40 CFR part 63, subpart SS, which were based on monitoring and inspection requirements previously developed by the EPA for use in implementing standards for various chemical industry sources. We are supplementing these requirements by proposing continuous monitoring through the installation and operation of either a CEMS or a CPMS. CEMS have been widely used to demonstrate that air pollution control devices are being operated in a manner that ensures that emission limitations are being met, and recent regulations reflect the increasing use of CEMS as a monitoring device across multiple source categories. However, in evaluating the use of CEMS in multiple NESHAP, we determined that monitoring of individual regulated materials may not be reasonable or technically feasible for certain streams. For instance, CEMS may not be available for certain individual HAP species, or may not be economically feasible for smaller sources. In such cases, parameter monitoring provides an alternative option that ensures the control device is operating consistently and continues to achieve the required emission limits. This also provides a more cost-efficient option for some sources, without reducing compliance. Therefore, in order to create a set of standards that could be applied to a broader range of source categories, we have included requirements for both CEMS and CPMS. During the development of referencing subparts that will direct to the Uniform Standards, we will continue to assess the best monitoring option for a given source category from a technical and economic standpoint. We will provide rationale upon proposal or promulgation as to why CEMS or CPMS would be more appropriate for an individual source category, or whether additional flexibility for industry and reduced burden on smaller sources within an individual source category could be granted by allowing either a CEMS or CPMS to be used. We anticipate that in future regulations, the referencing subpart may even override the monitoring options of the proposed subpart M and require a specific monitoring technique.

We have incorporated and updated the CEMS requirements established in the MON, which were developed in consideration of a combination of monitoring requirements from the HON and Pharmaceuticals Production source categories. We have supplemented these requirements with provisions based on the CEMS-specific requirements of 40 CFR part 63, subpart A. These provisions are consolidated under proposed 40 CFR 65.711 in order to establish a set of similar requirements for CEMS in one place that may more generally apply to sources regulated under 40 CFR part 60, 61 or 63 in future rulemakings.

For CPMS, we selected monitoring equipment criteria for overall system accuracy and compatibility. These requirements, which ensure accuracy in measurements and provide confidence for testing results, were inconsistently provided in previous regulations. When these criteria are not established, there is potential that sources could elect to use very costly CPMS equipment, which is inappropriate or ineffective for measuring certain parameters and, therefore, provides inadequate data for the source category. By applying a consistent set of criteria that applies to multiple source categories, we are improving data accuracy, reducing potential costs and removing undue burden for specific source categories. We are requesting comment on whether the proposed approach for establishing CEMS calibration ranges and assessing performance will adequately ensure the accuracy of the reported average emissions that might include measurements at concentrations above the span value. We are also seeking comments on how owners and operators of CPMS are currently employing quality control and calibration methods. Additionally, we welcome information on the lifetime and degradation of CPMS equipment used to measure temperature, liquid or gas volumetric flow, pH, mass flow, pressure and sorbent injection; and whether a ''sunset period'' for existing CPMS equipment is necessary in cases where the lifetime of the monitoring components is limited.

The requirements for measurement range were selected to ensure that the CPMS could detect and record measurements beyond the normal operating range. We believe that requiring a range of at least 20 percent beyond the normal operating range is reasonable and the minimum measurement range needed to encompass most deviations. Owners and operators may desire to select equipment with even wider ranges if it is likely that measurements beyond 20 percent of the normal operating range will occur. Additionally, we are requiring a resolution of one-half the accuracy requirement or better to ensure that the accuracy of the CPMS can be calculated to at least the minimum number of significant figures for the data accuracy assessment to be meaningful. Selecting a resolution of one-half the required accuracy ensures that measurements made during validation checks can be readily compared to the accuracy requirement. We are soliciting comments on whether the proposed measurement range and accuracy requirements are reasonable and consistent with what is currently being used.

We are proposing calibration and quality control requirements for CPMS to ensure that measured parameter data is accurate to demonstrate compliance with the referencing subpart. These measures, which establish requirements for the design, operation and evaluation of CPMS, are intended to ensure the generation of good quality data both initially and on an ongoing basis and determine that the control device is meeting the required emission limit, as specified in the referencing subpart. The specifications are located in Table 4 to proposed subpart M and would apply if you were to use a temperature, liquid or gas volumetric flow, pH, mass flow, pressure or sorbent injection measurement device to determine compliance with an operating limit. These requirements also reflect the EPA's intention to improve the quality of data collected and disseminated by the agency, which will improve the quality of emission inventories and, as a result, future air quality regulations.

For temperature CPMS, we reviewed rules promulgated under parts 60, 61 and 63 that specify accuracy requirements for temperature. Although there is a wide range of accuracies specified in these rules, the accuracy

required for temperature CPMS associated with high temperature (non-cryogenic) applications, such as thermal oxidizers or boilers, generally ranges from 0.75 to 1.0 percent or from 0.5 degrees Celsius to 2.5 degrees Celsius (0.9 degrees Fahrenheit to 4.5 degrees Fahrenheit). For lower temperature (cryogenic) applications, such as wet scrubbers, the specified percent accuracies often are not as stringent; that is, accuracies are specified as a higher percentage of the measured temperature. The reason for specifying higher-percentage accuracy for lower temperature ranges is to offset the fact that the accuracy percentage applies to a lower value. Our selection of temperature accuracies of 2.8 degrees Celsius (5 degrees Fahrenheit) or 1 percent for non-cryogenic applications, and 2.8 degrees Celsius (5 degrees Fahrenheit) or 2.5 percent for cryogenic applications is consistent with the required accuracies for most standards, and we believe that the accuracies specified in the proposed performance specifications are adequate for ensuring good quality data. In addition, a review of vendor literature indicates that temperature CPMS that satisfy these accuracy requirements are readily available at reasonable costs.

Rules promulgated under parts 60, 61 and 63 that require flow rate monitoring specify flow rate accuracy in terms of percent. For liquid flow rate measurement, these rules generally require accuracies of 5 percent, and rules that require steam flow rate monitoring generally require an accuracy of 10 percent or better. We have revised these performance specifications in the proposed subpart M to require accuracies of 2 percent over the normal range of flow measured. Based on our review of vendor literature, we determined a 2-percent accuracy criterion is appropriate and available. Recognizing the differences in the relative magnitudes and the commonly used units of flow rate measurement for liquids and gases, we have specified in the proposed performance standards separate accuracy criteria for liquid and gas flow rates. For liquid flow rate CPMS, which typically are associated with wet scrubber operation, the minimum accuracy would be 1.9 liters per minute (0.5 gallons per minute) or 2 percent, whichever is greater. For gas flow rate CPMS, which often are used to monitor stack gas flow rate, the proposed performance specifications would require a minimum accuracy of 28 liters per minute (10 cubic feet/minute) or 2 percent, whichever is greater. The relative accuracy criterion of 2 percent was selected because the proposed Uniform Standards have been developed to provide the greatest level of air emissions control that may be required by a referencing subpart. As advancements in technology have improved (and are estimated to continue to improve), we have determined that future rulemakings would require more stringent accuracy requirements, and a 2-percent accuracy criterion is reasonable and achievable for the currently available flow CPMS. We note that these requirements could be revised by the referencing subpart, if a higher or lower accuracy is deemed more appropriate for a specific source category.

Although we have incorporated an accuracy criteria for liquid flow rate and gas flow rate as a percent of flow rate and in units of volumetric flow in proposed subpart M, we have concluded that it would not be reasonable to specify accuracy criteria for mass flow in units of mass flow because of the wide range of flow rates that could be monitored (*e.g.,* carbon injection rate v. rotary kiln raw material feed rate). As discussed above for liquid flow rate and gas flow rate, the 2-percent accuracy criterion is based on our review of vendor literature and is a reasonable and achievable requirement for the currently available mass flow CPMS.

Manufacturer and vendor literature indicates that pH CPMS generally have accuracies of 0.01 to 0.15 pH units. Based largely on the vendor literature, we have decided to require pH CPMS to have accuracies of 0.2 pH units or better. An accuracy of 0.2 pH units should allow most facilities that currently monitor pH to continue using their pH CPMS, provided the CPMS satisfies the other criteria specified in the proposed Uniform Standards for Control Devices.

For pressure monitoring, we reviewed the existing part 60, 61 and 63 rules that require pressure monitoring. These rules also specify a minimum accuracy. The accuracy specified generally is either 0.25 to 0.5 kilopascals (kPa) (1 to 2 inch water column (in. wc)) or 5 percent for pressure drop, and 5 to 15 percent for liquid supply pressure. A review of vendor literature indicates that most pressure transducers are accurate from 0.25 to 1.0 percent, and all but the lowest grade (Grade D) of American National Standards Institute (ANSI)-rated pressure gauges have accuracies better than 5 percent. For the proposed performance specifications for CPMS, we selected an accuracy requirement of 0.12 kPa (0.5 in. wc) or 1.0 percent, whichever is greater. We believe this level of accuracy is appropriate, considering that some control devices operate with pressure drops of less than 1.2 kPa (5 in. wc). This criterion was selected because the proposed Uniform Standards have been developed to provide the greatest level of air emissions control that may be required by a referencing subpart. The one percent criterion is consistent with vendor literature, which indicates that CPMS that are capable of achieving this accuracy are readily available.

For sorbent injection, we are specifying accuracy requirements of within 5 percent of the normal range for the sorbent injection rate, with annual performance evaluations and 3-month visual checks. These requirements are consistent with the accuracy requirements for other CPMS, including the requirements for carrier gas flow rate monitors (a similar type of monitor) in the Standards of Performance for New Sewage Sludge Incineration Units (76 FR 15404, March 21, 2011).

If your operation could be intermittent, we are requiring that you install and operate a flow indicator to identify periods of flow and no flow at the inlet or outlet of the control device. The proposed requirements are necessary to identify periods when monitored parameter or emission readings are not required or erroneous and should not be included in the daily or operating block average values. It is not necessary to monitor a control device during periods when regulated material is not routed to the control, and monitoring data during these times should not be averaged in calculating the daily or operating block average. We are proposing an annual verification check of the flow indicator to ensure that it is correctly identifying periods of no flow. We are not considering the flow indicator to be a CPMS that must meet all the provisions of proposed 40 CFR 65.712.

We are proposing to include monitoring requirements from the General Provisions of parts 60, 61 and 63 in the monitoring sections of subpart M. This places all the applicable requirements associated with monitoring (including quality checks, monitoring plan requirements, calibration, monitoring data reduction, recordkeeping and reporting) in one place and consolidated using consistent terminology. For instance, we are including provisions for a CEMS performance evaluation and monitoring plan and a CPMS monitoring plan (formerly the ''site-specific performance evaluation plan'') from the part 63 General Provisions (40 CFR 63.8) in proposed 40 CFR 65.711 and 65.712,

respectively. Subpart A of 40 CFR part 63 states that a specific subpart will indicate whether the plan must be submitted to the Administrator for approval. In the proposed rule, we are requiring that the plan be sent to the Administrator for approval for sources regulated under parts 60 and 61, as well as 40 CFR part 63. We have determined that a CEMS performance evaluation and monitoring plan or a CPMS monitoring plan, as appropriate, is necessary under subpart M to demonstrate compliance with the emission limits of a referencing subpart. However, the source must comply with the CEMS performance evaluation and monitoring plan or the CPMS monitoring plan upon submitting it to the Administrator. Changes may be necessary when the Administrator completes the review.

2. How did the EPA determine the requirements for closed vent systems?

Under the proposed standards, all closed vent systems would be required to meet the applicable provisions of proposed 40 CFR part 65, subpart J (see section IV.A of this preamble) as they apply to the individual equipment components that comprise the closed vent system. In previous rules, equipment that are in closed vent systems have been subject to annual monitoring and have not been subject to more frequent monitoring. We are proposing these requirements to ensure that a vent stream in regulated material service is properly routed to the closed vent system and delivered to the control device for reduction. The proposed rule also requires you to install and maintain a CPMS for flow through a bypass for each closed vent system bypass line that could divert a vent stream to the atmosphere. The CPMS for flow must be capable of recording the volume of the gas that bypasses the control device and be equipped with an alarm system that will alert an operator immediately and automatically when flow is detected in the bypass. These provisions are to ensure that any flow directed through a bypass is detected and identified by the operator. Alternatively, you may secure the bypass line valve in the non-diverting position with a seal mechanism. For this option, you would be required to inspect the seal or closure mechanism at least once per month to confirm that the valve is in the non-diverting position, or, for a lock-and-key type lock, maintain records that the key has been checked out. If the alarm sounds or if it is determined during the monthly inspection that a bypass has occurred, you would be required to report a deviation and to include an estimate of the resulting emissions of regulated material that bypassed the control device. The EPA's intent is that control devices are not to be bypassed; therefore, use of the bypass at any time to divert a regulated vent stream to the atmosphere would be a deviation from the emissions standards set forth by the referencing subpart.

We have not included requirements from 40 CFR part 63, subpart SS that provided monitoring exclusions for equipment such as PRD, low leg drains, high point bleeds, analyzer vents and open-ended valves or lines needed for safety purposes. This equipment could provide a means of bypassing the control device; therefore, we are proposing bypass monitoring for these devices under subpart M of the proposed standards. It is our intent that analyzer vents should be subject to the control requirements for sampling connection systems in 40 CFR part 63, subpart UU. Additionally, applying the bypass monitoring requirements to PRD, low leg drains, high point bleeds, analyzer vents and open-ended valves or lines are consistent with the District of Columbia Circuit Court's 2008 ruling in *Sierra Club* v. *EPA*, which states that emission standards must apply at all times (see section VI.B.5 of this preamble). For a discussion of the economic and cost impacts of these monitoring requirements, see section VII of this preamble.

Following the guidance of Executive Order 13563, *Improving Regulation and Regulatory Review,* we have not included requirements from 40 CFR part 63, subpart SS that we determined were redundant or an unnecessary burden on sources. For instance, although we are not changing the intent of the requirements from subpart SS, we have not included language providing specific instructions for bypass monitoring for loading arms and PRD at transfer racks; specifically, these provisions required that closed vent systems collecting regulated material from a transfer rack be operated such that regulated material vapors collected at one loading arm would not pass through another loading arm to the atmosphere. For PRD, the requirements prevented the PRD in the transfer rack's closed vent system from opening to the atmosphere during loading. These provisions are equivalently handled under the general bypass monitoring requirements of proposed 40 CFR 65.720(c) for closed vent systems, in which you would be required to prevent diversion of the stream to the atmosphere. Therefore, we are not including specific language associated with bypasses from transfer rack closed vent systems, as this additional language is redundant to the general bypass requirement. The requirement not to bypass remains.

3. How did the EPA determine the proposed compliance requirements for each control device?

For each control device, we are proposing that you meet the continuous monitoring requirements of Table 1 or Table 2 to subpart M. Table 1 to subpart M provides the requirements for facilities who comply with the referencing subpart using CEMS. We have consolidated the specific parametric monitoring requirements for each control device in Table 2 to subpart M to provide the requirements in a simplified, easily referenced format to facilitate compliance.

You must conduct a performance test for each control device according to the requirements of proposed 40 CFR 65.820 through 65.829, unless you meet the general control measures of proposed 40 CFR 65.702(e). A performance test is required because emissions measurement remains the best method to demonstrate initial compliance with regulations and determine control device performance. However, we have made exceptions for: (1) Control devices for which a CEMS is used to monitor the performance, (2) when the referencing subpart allows a design evaluation in lieu of a performance test or (3) if certain provisions have been made for a performance test extension, exemption or waiver. These exemptions allow greater flexibility for referencing subparts and are consistent with our desire to provide workable, consolidated requirements that could apply across multiple source categories.

Small boilers and process heaters. The proposed standards under subpart M include requirements that apply to small boilers and process heaters used to control emissions of regulated materials. *Small boilers and process heaters* are defined in the proposed rule as having a capacity less than 44 megawatts (MW) and a design such that the vent stream is introduced with the combustion air or as a secondary fuel. The capacity threshold and the monitoring, performance testing and recordkeeping and reporting requirements for these units were modeled after 40 CFR 63, subpart SS. We have modified these provisions for the proposed Uniform Standards to provide clarification for requirements that were found to be confusing during the implementation of subpart SS. Under subpart SS, the requirements for boilers and process heaters overlapped

with the requirements for fuel gas systems.

Fuel gas system is defined in 40 CFR part 63, subpart SS broadly as the ''* * * piping * * * that gathers gaseous streams for use as fuel gas in combustion devices. * * *'' Therefore, owners or operators that use a boiler or process heater to combust vent gas could be subject to either the boiler and process heater or the fuel gas system requirements. The testing and monitoring requirements under the control device and fuel gas system provisions of subpart SS are the same for boilers or process heaters larger than 44 MW or which have the vent gas introduced with or as the primary fuel; performance testing and monitoring are not required for vent gas routed to a fuel gas system, a boiler or process heater larger than 44 MW or a boiler or process heater in which the vent gas is introduced as or with the primary fuel. However, under the control device provisions of subpart SS, performance testing and monitoring is required in those situations in which the vent gas is introduced with combustion air or as a secondary fuel into a boiler or process heater smaller than 44 MW. Conversely, if these units (smaller than 44 MW) are part of a fuel gas system, monitoring and testing is not required under subpart SS. We propose to clarify the requirements by differentiating small boilers (less than 44 MW) with vent gas introduced to the boiler with combustion air or as a secondary fuel from larger units and those units with vent gas introduced as or with the primary fuel. Therefore, we have distinguished separate requirements for performance testing and monitoring for small boilers and process heaters under proposed 40 CFR 65.820 through 65.829, with specific parametric monitoring requirements specified in Table 2 of subpart M. Units not considered small boilers or process heaters would be required to meet the requirements of proposed 40 CFR 65.732 for fuel gas systems. The proposed fuel gas system provisions also specify that any small boilers or process heaters that are part of a fuel gas system must meet the requirements of the small boiler and process heater provisions. These changes clarify whether each unit would be subject to the requirements for boilers and process heaters or the requirements for fuel gas systems.

Additionally, we are not incorporating the requirements of 40 CFR 63.988(a)(3), which stipulate that the vent stream from the boiler or oxidizer must be introduced into the flame zone. Although we are preserving the intent of 40 CFR part 63, subpart SS, we have reasoned that this language is superfluous. We are proposing to clarify the definition of small boilers in this category as having a design such that the vent stream is introduced with the combustion air or as a secondary fuel. It is assumed that secondary fuel and combustion air are introduced into the flame zone and, therefore, the vent gas would be introduced into the flame zone.

In the proposed rule, we have not included the exemptions from conducting a performance test or design evaluation included in 40 CFR part 63, subpart SS for small boilers and process heaters which have been issued a final permit under 40 CFR part 270 and comply with the requirements of 40 CFR part 266, subpart H or which have certified compliance with the interim status requirements of 40 CFR part 266, subpart H. It is our expectation that these facilities are no longer subject to the air emissions requirements under the Resource Conservation and Recovery Act permitting rules (other than requirements that pertain during startup, shutdown and malfunction (SSM)); rather, all boilers and oxidizers previously subject to these requirements are now subject to 40 CFR part 63, subpart EEE. We have included a performance test exemption for small boilers or process heaters burning hazardous waste who have certified compliance with the requirements of 40 CFR part 63, subpart EEE by conducting comprehensive performance tests and submitting a Notification of Compliance Status per 40 CFR 63.1207(j) and 63.1210(d), and who comply with these requirements at all times, even when burning non-hazardous waste. Additionally, we have not included the subpart SS provision allowing owners or operators of small boilers and process heaters with a minimum temperature of 760 degrees Celsius and a minimum residence time of 0.5 seconds to omit the rationale for these design parameters in the design evaluation (40 CFR 63.985(b)(1)(i)(B)) documentation. This minimum temperature and residence time does not necessarily ensure a 95- or 98-percent reduction efficiency for all possible emission stream chemical compositions (see technical memorandum, *Design Criteria for Combustion,* in Docket ID No. EPA–HQ–OAR–2010–0868). Because the Uniform Standards are designed to provide requirements for a variety of source categories and emission streams, we are not proposing this exception to design evaluation rationale. Instead, we are proposing that the owner or operator of the small boiler or process heater be required to consider the auto-ignition temperature and the residence time when developing the rationale showing that their small boiler or process heater meets the applicable control efficiency and that their chosen operating parameters and ranges are appropriate. The owner or operator may determine that the appropriate temperature and residence time are 760 degrees Celsius and 0.5 seconds for their process; however, under the proposed rule, they would have to provide the rationale in their design evaluation documentation (see technical memorandum, *Design Criteria for Combustion,* in Docket ID No. EPA–HQ–OAR–2010–0868).

Oxidizers. We are proposing monitoring, recordkeeping and reporting requirements for oxidizers, based on 40 CFR part 63, subpart SS. We are proposing the requirements for thermal oxidizers and catalytic oxidizers in 40 CFR 65.726 and 65.728, respectively; these provisions are included in separate sections for ease of reading and to accommodate the additional monitoring requirements that are necessary to ensure compliance for catalytic oxidizers.

For catalytic oxidizers, we are including sampling, analysis and inspection requirements to ensure that the oxidizer is capable of meeting the required emission limits specified in the referencing subpart. We are including a monitoring method for inlet temperature monitoring, provided the difference between the inlet and outlet temperature of the catalytic bed is less than 10 degrees Celsius. A differential of 10 degrees Celsius was chosen based upon the accuracy requirements of temperature monitoring systems specified in this standard, and the typical operating temperature of a catalytic oxidizer. Allowing for measurement error on both sides of the oxidizer (inlet and outlet), 10 degrees Celsius was determined to be a range within measurement capability. The proposed method would allow you to determine a schedule for sampling and analysis of the catalyst activity, based on the degradation rate of the catalyst. If results from the catalyst sampling and analysis indicate that your catalyst will become inactive within the next 18 months, you would be required to replace the catalyst bed or take other corrective action consistent with the manufacturer's recommendations by 3 months before the catalyst is anticipated to become inactive or within half the time available between receiving the catalyst activity report and when the catalyst is expected to become inactive, whichever is less.

Additionally, you would be required to conduct an annual internal inspection of the catalyst bed. The inspection frequency would increase to semiannual or a more stringent frequency, as specified in proposed 40 CFR 65.728(a)(2)(ii), if any issues are found during the annual inspection that require corrective action. These requirements are based on our survey of the MON and the Miscellaneous Metal Parts and Products Surface Coating NESHAP, which included similar alternatives for monitoring the inlet stream temperature. The MON provided an option for monitoring the inlet stream temperature with the requirement of a 12-month check of the catalyst bed; this option was provided to accommodate emissions streams with low flow or diluted concentrations in which it would not always be possible to achieve a measurable temperature differential.

As determined under the MON, when monitoring only the inlet temperature, a catalyst-activity-level check also is needed. This is because catalyst beds can become poisoned and rendered ineffective without any apparent change in operation. The proposed sampling, analysis and inspection requirements discussed above are modeled after the Miscellaneous Metal Parts and Products Surface Coating NESHAP, which expand on the MON's requirement to conduct a 12-month check of the catalyst bed. We are providing the option to determine the schedule for sampling and analysis based on the degradation of the catalyst to provide flexibility for multiple source categories that may reference the Uniform Standards, while ensuring that catalyst beds are replaced or that other corrective actions are taken in a timely manner. A referencing subpart may determine the specific sampling and analysis schedule, in order to ensure compliance, prevent excessive downtime or avoid unreasonable costs to an individual source category.

We have included this option in subpart M only for sources in which the temperature differential between the inlet and outlet of the catalytic oxidizer during normal operating conditions is less than 10 degrees Celsius. We are not proposing this option for sources with a temperature differential of greater than 10 degrees Celsius because inlet and outlet temperature monitoring is a more accurate method of parameter monitoring and should be used, if possible, to measure the temperature differential.

As discussed for *small boilers and process heaters* in this section, we have not included the design evaluation or performance test exemptions included in 40 CFR part 63, subpart SS for oxidizers that comply with the requirements of 40 CFR part 266, subpart H, but only those oxidizers burning hazardous waste who have certified compliance with the requirements of 40 CFR part 63, subpart EEE. Additionally, as discussed for small boilers and process heaters, we have not included the subpart SS provision allowing oxidizers with a minimum temperature and residence time to omit the rationale documentation for the design evaluation.

Absorbers. In developing the proposed standards for absorbers, we have incorporated the monitoring requirements of 40 CFR part 63, subpart SS and added several monitoring options to accommodate the many absorber designs that may be used. Alternative monitoring approaches for absorbers have been the most commonly requested alternative by industry under current rules. Because of this, we have incorporated multiple monitoring schemes based upon the alternatives approved by the EPA, the different monitoring schemes in various chemical sector rules and support documents prepared by the EPA for the compliance assurance monitoring (CAM) regulation. (See *Technical Guidance Document: Compliance Assurance Monitoring,* August 1998, available at *http://www.epa.gov/ttn/emc/cam.html*.) Furthermore, because halogenated scrubbers are a type of absorber and the monitoring requirements are the same, we have merged the requirements for halogen scrubbers into the proposed standards for absorbers to reduce redundant text. We believe that integrating these additional monitoring options into the proposed standards will reduce the need for owners and operators to request the use of alternative monitoring requirements and for the EPA to review these requests, thereby improving the efficiency of the regulatory process. This is consistent with the objectives of Executive Order 13563, *Improving Regulation and Regulatory Review,* which requires that we periodically review existing regulations to examine ways to improve regulatory efficacy or reduce burden.

We are proposing the installation and operation of either a CEMS or a CPMS, following the requirements in Tables 1 or 2 of proposed subpart M. As discussed in the general monitoring requirements in section V.B.1 of this preamble, we have included provisions for both CPMS and CEMS to accommodate the variety of sources that may be controlled by a referencing subpart.

The most critical parameter for monitoring absorption systems is liquid flow to the absorber, therefore we are requiring liquid flow be monitored for all absorption systems, but have provided an option for monitoring of the liquid-to-gas ratio. Rather than calculating one minimum flow rate at maximum operating conditions that must be continuously adhered to, this alternative provision allows a facility to optimize the liquid flow for varying gas flow rates. By using a liquid-to-gas ratio, sources may save resources by reducing the liquid rate with reductions in gas flow due to periods of lower production rates.

Pressure drop is also a valuable operating parameter to monitor for absorbers. It can signal abnormal column conditions such as plugging, channeling or mal-distribution of the packing. We are proposing that you monitor the pressure drop for all absorbers as long as the normal pressure drop across the absorber is greater than 5 inches of water. If the pressure drop is typically less than 5 inches of water, it is not a sensitive monitor for absorber performance. We have also included a requirement to monitor pH for acid gas absorbers. For non-water absorbers used for VOC control, we are proposing that the chemical strength and flow rate of the chemical must be monitored. Monitoring the oxidation strength and flow rate of the chemical will ensure that enough chemical is being added to the absorber to attain at least the required amount of absorption. For particulate and metal absorbers, if the pressure drop is normally less than 5 inches of water, the owner or operator will have the choice of monitoring the inlet and outlet gas temperature; the specific gravity and outlet gas temperature; or the liquid feed pressure and outlet gas temperature. These monitoring parameters provide information on whether there has been sufficient contact between the liquid and gas.

Similar choices were provided for VOC absorbers if the normal pressure drop across the absorbers is less than 5 inches of water and the scrubbing liquid is water. The source would monitor the inlet and outlet gas temperatures, or the liquid feed pressure and outlet gas temperature.

Adsorbers. We are proposing standards for adsorbers used as control devices, based on the provisions of 40 CFR part 63, subpart SS. We have clarified language in the proposed adsorber requirements in order to develop a more inclusive set of

standards. Specifically, we have revised the former subpart SS requirements for ''carbon adsorbers'' to apply to ''adsorbers,'' and modified the applicability to pertain to adsorbers containing any type of adsorbent such as carbon, zeolite or adsorbing polymers. These proposed standards address many different adsorber configurations existing in service today, including carbon adsorbers; adsorbers that use adsorbing media other than carbon; adsorbers that use vacuum as a regeneration technique; adsorber systems that use steam or other media for regeneration; and adsorbers that are not regenerated on site. These changes allow the proposed requirements to be more broadly referenced in future CAA section 111 and 112 rulemakings and provides additional options for control for multiple source categories. Additionally, this change reduces the need for owners and operators to request the use of alternative adsorbents or monitoring methods and for the EPA to review these requests, thereby eliminating unnecessary regulatory burden to industry and improving the efficiency of the regulatory process.

Many current regulations address carbon adsorber operation, and the proposed rule has been written to address performance issues that have been identified by the EPA in implementing and enforcing these rules. Known performance issues include: The regeneration frequency of the adsorbent; the effectiveness of regeneration; the life of the adsorbent material before replacement is required; mechanical issues with the system operation including valve sequencing; and for non-regenerative systems, the expected life of the bed before replacement. The proposed rule incorporates different monitoring requirements for adsorption systems based on our review of 40 CFR part 63, subparts G, SS, GGG, MMM, FFFF, GGGGG and BBBBBB, as well as monitoring approaches that have been outlined and approved by the EPA in monitoring alternative requests.

We are proposing the use of CEMS or CPMS to ensure the adsorption system operates consistently; we have included parametric monitoring provisions in Table 2 of subpart M in order to accommodate systems where a CEMS is not used. Because there is no single parameter you can monitor to ensure that all operating aspects are functioning properly, the proposal combines several monitoring approaches, each of which addresses common adsorber system performance issues. These include: (1) Monitoring of the regeneration process, (2) establishing and adhering to a regeneration frequency, (3) daily verification of system operating parameters and (4) routine sampling of the vent stream.

The regeneration process monitoring provisions for non-vacuum systems include regeneration stream flow and adsorber temperature. These are key parameters to ensure the adsorption bed is sufficiently desorbed at the start of an adsorption cycle, and have long been known to influence adsorption performance. We have added the requirement to establish and adhere to a pre-defined interval for regeneration frequency in order to prevent overloading the bed and possibly incurring breakthrough during the adsorption cycle before regeneration is initiated. We considered alternatives to a pre-defined interval that would take into account the organic loading on the bed, but determined that regeneration on a prescribed schedule provides greater assurance that there would be sufficient adsorptive capacity at all times.

Regenerative adsorption processes are typically multiple bed systems with complicated valve and piping arrangements designed to handle the vent streams and desorption streams on a batch basis. Because the consistent operation of the valves in these systems is critical to performance, we have included requirements for daily verification of the adsorber valve sequencing and cycle time. This daily system check will ensure that the adsorber is operating with proper valve sequencing and cycle time.

While adsorption systems can achieve high levels of efficiency for removal of organic compounds from vent streams, performance degrades over time as the adsorption media deteriorates or becomes fouled. Because of this known performance deterioration, and because there are many mechanical elements in the system which can cause performance problems, we are proposing weekly measurements of the adsorber bed outlet VOC or regulated material concentration over the last 5 minutes of an adsorption cycle for each adsorber bed. These measurements are not meant to be a check against the emissions limit established by the referencing subpart; rather, it is a check to determine if the absorber performance is deteriorating and/or has deviated from typical operation. By conducting weekly checks, the owner or operator will establish knowledge of typical operating conditions, so that if performance does degrade, it will become clear based on changes in the weekly measurements. We are proposing that the owner or operator establish a maximum normal concentration to compare to the weekly measurements. If a measurement is obtained that is above the maximum normal concentration, a corrective action process must be initiated within 8 hours. We are proposing that you must develop a corrective action plan that includes investigation of the adsorbent and its efficacy, the valve sequencing system and regeneration process, and additional monitoring, as well as site-specific corrective actions appropriate to the system. This plan is not required to be submitted to the Administrator for approval, but is required to be kept as a record per the requirements of proposed 40 CFR 65.742(j)(1).

Measurements for the weekly checks on each adsorber may be taken with a portable analyzer using Method 21 of 40 CFR part 60, appendix A–7 for open ended lines, or using chromatographic analysis. Acceptable levels for end-of-cycle measurements, the maximum normal concentration will be established based on a statistical evaluation of the last 5 minutes of at least eight adsorption cycles for each adsorber. Because these measurements are taken in the last 5 minutes of the adsorption cycle, they indicate the worst-case emissions over the adsorber cycle. Therefore, they are not indicators of compliance with the emission limit, but instead are indications of non-normal operation, which trigger a corrective action. An adsorber would not be considered to be in deviation unless three consecutive weekly measurements are taken that are above the maximum normal concentration; if the requirement to initiate corrective action within 8 hours is not met; or if a weekly measurement is not performed. See section VII of this preamble for a discussion of the economic and cost impacts of these requirements.

Because the materials desorbed during the regeneration process are regulated materials and are either recovered or disposed of, we are proposing explicit requirements to treat the regulated materials extracted from a regenerative system as process wastewater or vent streams subject to control, as specified by the referencing subpart.

Very few previously published rules have addressed adsorption systems, which are not regenerated onsite. Because there is wide application of non-regenerative adsorption systems, we are including provisions for these systems in the proposed rule. For clarity, we have differentiated the proposed requirements for absorbers generated onsite and the requirements for non-regenerative adsorbers or

regenerative adsorbers that are regenerated offsite in separate sections.

As a guideline for the proposed monitoring, we used the National Emission Standards for Site Remediation (40 CFR part 63, subpart GGGGG), as well as monitoring approaches approved by the EPA in alternative requests for monitoring and in enforcement actions to address historical compliance issues with non-regenerated adsorbers. We are proposing CEMS monitoring for the adsorber exhaust. Alternatively, we are proposing requirements for dual adsorbent beds in series and daily monitoring. We have prescribed a dual bed system because the use of a single bed does not ensure continuous compliance unless the bed is replaced significantly before breakthrough. A dual bed system will allow one bed to be saturated before it is replaced and, therefore, makes efficient use of the adsorber bed without exceeding the emission limits. Facilities utilizing non-regenerative adsorbers must typically replace the adsorber bed at the end of the absorbent life and already have a second bed onsite. Therefore, we have determined that these requirements would not impose a cost increase; it would only require a second adsorber bed to be purchased earlier than it would have under previous rules. In addition, once the second adsorber was purchased, the source would need to purchase and install canisters at the same rate they would have under previous rules. In fact, the source could likely reduce costs over time because the adsorber beds can be used to a greater saturation level without risking non-compliance. Under current rules that do not require a second bed, sources must replace the beds, based on temperature readings, the vendor's bed life expectancy estimates or past history, and may replace the bed prematurely in order to avoid non-compliance. The burden of purchasing the initial additional adsorber bed, when compared to the large increase in compliance assurance, is small.

Similar to regenerative adsorbers, in order to monitor performance deterioration, we are proposing measurements of VOC or regulated materials using a portable analyzer or chromatographic analysis for non-regenerative absorbers. We are proposing that these measurements be taken daily on the outlet of the first adsorber bed in series using a sample port. Furthermore, in order to relieve some monitoring burden, we have included the option to reduce the frequency of monitoring with the portable analyzer from daily to weekly or monthly. If you choose this option, you would first be required to establish an average adsorber bed life. For periods when more than 2 months remain on the bed life, monthly monitoring can be conducted, and when more than 2 weeks remain on the bed life, weekly monitoring can be conducted. For a discussion of the economic and cost impacts of these monitoring requirements, see section VII of this preamble.

Condensers. The proposed standards include requirements for condensers used as control devices, which are based on the standards of 40 CFR part 63, subpart SS. Subpart SS requires that ''exit (product side)'' temperature be monitored; the proposed rule clarifies that the temperature of the ''condensate receiver'' be monitored. The proposed standards require a design evaluation be conducted on condensers instead of a performance test to demonstrate compliance. The equilibrium calculation for condensers using the actual measured temperature and a thorough understanding of the stream composition is an accurate method for estimating emissions in the exiting gas stream from a condenser. A performance test for condensers generally does not provide additional information that equilibrium calculations would not provide. Furthermore, requiring a design evaluation will reduce overall costs for owners and operators who are referred to the Uniform Standards for Control Devices. However, a performance test could be required by the referencing subpart if it is determined to be more appropriate for a given source category.

As part of the design evaluation, we are proposing that you use the engineering evaluation methodologies in 40 CFR 65.835(d) with the temperature of the condensate receiver to determine the outlet organic regulated material concentration. You would then be required to show the concentration meets the emission standard established in the referencing subpart, or to conduct additional calculations to demonstrate a percent reduction or aggregate percent reduction for batch process vents in a referencing subpart was being met.

In the design evaluation for condensers, we have included a provision to consider conditions under which entrainment of the condensing liquid could occur, as well as the other operating conditions traditionally included in a condenser design evaluation, such as the vent stream flow rate, relative humidity and temperature. Entrainment is an important factor in condenser performance that should be considered in a design evaluation in order to document that the condenser achieves the required emission reduction from a referencing subpart.

Biofilters. We are proposing standards for biofilters used as control devices in proposed 40 CFR 65.748. We are providing these requirements as an additional control option for the Uniform Standards for Control Devices in order to add flexibility for industry. Compliance requirements for biofilters were included in a final amendment to the MON (71 FR 40333, July 14, 2006) as a response to comment by commenters. The final amendments specified that biofilters are an option for complying with the 95-percent reduction emission limit for batch process operations. A biofilter control option was not made available for continuous process operations in the MON because of concerns that biofilters could not meet the 98-percent control efficiency standard for continuous process operations. We are proposing biofilters as a control option for both batch and continuous process operations if you can demonstrate compliance with the emission limitation or percent reduction required by the referencing subpart. We are proposing you install a CEMS capable of measuring regulated materials, or you may install a temperature CPMS for the biofilter bed.

In biofiltration, microbial activity is the primary means by which the process stream is controlled; the effectiveness of the device is maximized by maintaining preferential conditions for the growth of appropriate microbes. Temperature is a significant factor affecting the growth and maintenance of healthy microbes within the bed—temperatures that are too high or too low will result in reduced microbe colonies and reduced performance for the bed. It is also a good indicator of the health of the microbes since healthy microbes will generate heat themselves. Therefore, we are requiring bed temperature monitoring to ensure that the biofilter can achieve and maintain the emission limits specified in the referencing subpart. For a discussion of the economic and cost impacts of these requirements, see section VII of this preamble.

Given the concerns expressed in the preamble to the final MON rule regarding continuous process operations, we are also proposing requirements to monitor the moisture content of the biofilter bed and pressure drop through the biofilter bed to ensure that the biofilter can achieve the emission limit or percent reduction requirements of the referencing subpart. The moisture content of the biofilter bed

is another indicator of the health of microbes. Pressure drop through the biofilter bed is important to ensure the filter bed is not plugged.

In lieu of these additional monitoring requirements, we are also considering requiring weekly measurements of VOC or regulated material at the outlet of each biofilter bed using a portable analyzer or chromatic analyzer to monitor performance deterioration, similar to those requirements proposed for adsorbers. We are soliciting comment, including the identification or submittal of information or data, as to whether biofilter bed temperature monitoring would be enough for continuous compliance demonstration. Additionally, we are soliciting comments and supporting data or studies that assess the effectiveness of measuring additional parameters to ensure performance and compliance.

The MON does not allow a design evaluation to demonstrate compliance for biofilters; however, we have included provisions for a design evaluation if the referencing subpart allows one. A design evaluation for a biofilter may be adequate to demonstrate compliance for certain source categories; however, this will need to be considered on a source category-specific basis and justified in the referencing subpart rulemaking.

Sorbent injection and collection systems. In order to provide additional control technologies that will expand the options for future rulemakings, we are proposing requirements for sorbent injection systems that remove pollutants from exhaust gas. Sorbent injection is an emissions control technique that was developed to reduce pollutants from exhaust gas, primarily from combustion sources. The sorbent injected into the gas stream may be activated carbon, lime or any other type of material injected into a gas stream for the purposes of capturing and removing regulated materials.

Activated carbon is used in sorbent injection systems where control of mercury or dioxin and furan emissions is required. Lime or other sorbents may also be used in sorbent injection systems to remove acid gasses, such as hydrochloric acid or sulfuric acid. Sorbent injection is used in conjunction with a filtration device designed to collect the sorbent after injection.

As a basis for developing the proposed rule, we have adapted the requirements for sorbent injection systems that were included in the final rule for National Emission Standards for Hazardous Air Pollutants from the Portland Cement Manufacturing Industry (75 FR 54970, September 9, 2010). This recent NESHAP determined monitoring and performance specification requirements for sorbent injection systems and carrier gas systems that reflect the latest technical developments for these control options. In addition, facilities complying with the proposed provisions for sorbent injection would also be required to meet the requirements for fabric filters in proposed 40 CFR 65.762. The Portland Cement NESHAP requires facilities to specify and use the brand and type of sorbent used during the performance test until a subsequent performance test is conducted. We are proposing that you would be required to test if you wanted to substitute a different brand or type of sorbent. Although the Portland Cement NESHAP allows an owner or operator to substitute different brands or types of sorbent without having to do a new performance test (provided that the replacement has equivalent or improved properties compared to the sorbent used in the previous performance test), we have modified the proposed standards to require a new performance test if the sorbent is replaced with a different brand and type of sorbent than was used in the most recent performance test. As we intend the Uniform Standards for Control Devices to be referenced in both NSPS and NESHAP rulemakings across multiple source categories, this change ensures that the control device will continue to meet the emission limits or percent reduction requirements of a referencing subpart when a change of sorbent occurs. A referencing subpart may override this retest requirement if it is determined in its rulemaking to be unnecessary for the source category being regulated.

Provisions for a design evaluation for sorbent collection systems are proposed for this rule in the event that a referencing subpart allows a design evaluation to be conducted in lieu of a performance test. Because this is a relatively new control technology, there were no current rules that provided guidance for a design evaluation of a sorbent collection system. Therefore, we have developed the proposed requirements using recently published articles on activated carbon injection as a control technology. This research indicates that the parameters identified in proposed 40 CFR 65.760(d) provide the best evaluation of sorbent injection system performance.

Other control or devices. We have incorporated requirements for performance testing and the development of monitoring requirements on a case-by-case basis in order to address control devices that may be used by industry, but are not described specifically in this rule. These requirements are unchanged from the current provisions of 40 CFR part 63, subpart SS. Additionally, if other major control devices are used in specific source categories as a primary means for control, the referencing subpart can lay out such requirements needed in order to demonstrate compliance.

4. How did the EPA determine requirements for fuel gas systems?

In consideration of our experience implementing previous rules addressing fuel gas systems as control devices, we are proposing updated standards that clarify the definition of fuel gas system and ensure that these systems are achieving good combustion and control. Under 40 CFR part 63, subpart SS, owners and operators are permitted to route vent streams from storage tanks, transfer equipment and equipment leaks to a fuel gas system as a method of control (this compliance option is not specifically provided for process operations). Fuel gas systems are considered a part of the process, therefore process vent streams that are routed to a fuel gas system are not considered vent streams requiring control because they are not released to the atmosphere. The proposed rule does not specifically state that this control option is only for equipment leaks, storage tanks and transfer operations emissions. It is not necessary to allow this option for only some of the emission unit types, given that the proposed Uniform Standards may be referenced in future NESHAP and NSPS for multiple source categories and industry types, and those rulemakings can determine whether to restrict the control options for specific types of emission units.

As previously discussed for small boilers and process heaters in section V.B.3 of this preamble, small boilers or process heaters receiving vent streams subject to subpart M with a capacity less than 44 MW (in which the vent stream is introduced with combustion air or as a secondary fuel) would be subject to the requirements of proposed 40 CFR 65.724, whether they are part of a fuel gas system or not. If your fuel gas system directs the vent stream to small boilers or process heaters, you would still be required to meet the performance testing and monitoring requirements for small boilers and process heaters. As discussed in section V.B.3 of this preamble, larger boilers and process heaters in which the vent gas stream is introduced with or as the primary fuel have been recognized as units that can be confidently assumed to achieve good combustion. There is not

the same confidence in the performance of small boilers and process heaters; therefore, we are proposing that the units be tested and continuously monitored.

We expect, in most cases, the vent gas stream of fuel gas systems will be introduced as the primary fuel and/or will be routed to larger units. We want to continue to encourage the use of this otherwise waste gas. However, if small boilers and process heaters are attached to the fuel gas system, then you would be required to conduct performance testing and monitoring. We do not expect this scenario to be common. We also considered defining a fuel gas system such that the vent gas must be introduced with or as a primary fuel, but determined that this would reduce flexibility for sources.

Under the proposed standards, all fuel gas systems that are in regulated material service must perform quarterly LDAR monitoring and would be required to meet the applicable provisions of proposed 40 CFR part 65, subpart J (see section IV.A of this preamble) as they apply to the individual equipment components that comprise the fuel gas system. We are proposing these requirements to ensure that a vent stream in regulated material service is properly routed by the fuel gas system and delivered to the combustion device for destruction. We expect that most fuel gas systems meet the applicability of the LDAR requirements and are already conducting LDAR monitoring; therefore, these requirements are not expected to introduce a new or unnecessary regulatory burden for industry.

The proposed standards revise the definition of *fuel gas system* to include the requirement that the fuel in the fuel gas system be nonhalogenated. It is common for chemical sector rules to include a prohibition on combustion of halogens and a requirement for hydrogen halides or halogen reduction after combustion. However, this requirement was not explicit for vent streams routed to a fuel gas system under previous rules, and it is not our intent to allow halogenated streams to be combusted without additional control. Because fuel from fuel gas systems can be used in any number of combustion sources, hydrogen halide and halogen reduction after combustion is less likely to be feasible. Additionally, because process vent streams could be routed to the fuel gas system and not be subject to the rule, yet could still contain significant amounts of halogens, we are proposing this definition change to ensure that HAP are not created through the combustion of a regulated material.

5. How did the EPA determine the proposed requirements for fabric filters?

We have incorporated requirements for fabric filters in subpart M with the intent to simplify future rulemakings that would refer to the Uniform Standards. The proposed monitoring, recordkeeping and reporting requirements may be referenced by new or revised NSPS or NESHAP that would establish standards for PM or other regulated materials controlled by fabric filters and not previously covered by other consolidated rulemakings. As such, the consolidation of fabric filter requirements in subpart M facilitates more efficient rulemaking and ensures consistent standards for these control devices across multiple source categories. The monitoring, design evaluation and recordkeeping and reporting requirements for fabric filters were modeled after the Pesticide Active Ingredient Production NESHAP (40 CFR part 63, subpart MMM, as referenced by the MON) and the final rule for National Emission Standards for Hazardous Air Pollutants from the Portland Cement Manufacturing Industry, published on September 9, 2010 (40 CFR part 63, subpart LLL, 75 FR 54970). The proposed requirements include the installation of a bag leak detection system equipped with an alarm that will sound when an increase in relative PM emissions over a preset level is detected.

The Portland Cement Manufacturing NESHAP required that the bag leak detection system be certified by the manufacturer to be capable of detecting PM emissions at concentrations of 10 milligrams per actual cubic meter (mg/acm) or less. Because we intend the proposed Uniform Standards to be applicable for the majority of source categories complying with MACT, we considered that there may be future rulemakings that need to specify lower PM emission limits and would require a lower allowable detection limit for the bag leak detectors. Based on vendor literature, modern bag leak detection systems are capable of detecting baseline emissions as low as 1 mg/acm (see, *Fabric Filter Bag Leak Detection Guidance,* EPA–454/R–98–015, September 1997, incorporated by reference). Therefore, we are requiring that the bag leak detection system be certified at a detection level of 1 mg/acm or less. This requirement may be overridden by a referencing subpart in future rulemakings, as appropriate, based on the specific needs of the source category.

We have also added a provision previously included in the Major Source Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP (76 FR 15608, March 21, 2011), requiring that the bag leak detection system must be operated and maintained such that the alarm does not sound more than 5 percent of the operating time during a 6-month period. We are requiring records of the total alarm time and corrective actions taken following an alarm sounding for demonstration of compliance. These requirements are operation and maintenance requirements that could be adopted in future rulemakings to ensure that the fabric filter is being operated at the conditions for which the control device is meeting the emission limit specified in the referencing subpart.

Additionally, the proposed rule requires that you conduct a performance test on your fabric filter, but provisions have been included for those situations where a design evaluation is acceptable and allowed by the referencing subpart (see sections V.A.9 and V.B.8 of this preamble).

6. How did the EPA determine the performance testing requirements?

The performance testing requirements that we are proposing are modeled after specific requirements from 40 CFR part 63, subpart SS, which are based on performance testing requirements previously developed by the EPA for use in implementing standards that could apply to a variety of chemical industry sources.

We have organized the performance testing requirements to group similar topics together, and added new methods for performance testing to develop a more generic and inclusive set of control requirements that may be easily referenced in future rulemakings. In addition to using the term ''regulated material'' (see *General differences between proposed 40 CFR part 65, subpart M and 40 CFR part 63, subpart SS* at the beginning of section V.B of this preamble), we are proposing performance testing requirements that reflect this broader range of pollutants.

Although based on language from 40 CFR part 63, subpart SS, where we propose that you conduct all performance tests at maximum representative operating conditions for continuous process operations, we have defined maximum representative operating conditions to be those conditions that result in the most challenging condition for the control device. In an effort to provide more flexibility to owners and operators regarding the identification of the

proper testing conditions, the most challenging condition for the control device may include, but is not limited to, the highest HAP mass loading rate to the control device, or the highest HAP mass loading rate of constituents that approach the limits of solubility for scrubbing media. The EPA understands that there may be cases where efficiencies are dependent on other characteristics of emission streams, including the characteristics of components and the operating principles of the devices. For example, the solubility of emission stream components in scrubbing media, or emission stream component affinity in carbon adsorption systems can also define the most challenging condition for a particular control device.

For batch process operations, we are proposing consistent requirements to those in 40 CFR part 63, subparts GGG and FFFF, and are requiring that you develop an emissions profile and conduct your performance test at absolute worst-case conditions or hypothetical worst-case conditions. Although continuous operations tend to have products and operations that remain relatively constant, the control devices for batch operations may be subject to a wide variability of products and emission stream characteristics, and a performance test at ''maximum representative'' conditions for batch operations may not be representative at a later date when the products have changed. Absolute worst-case conditions are based on an emissions profile that shows periods of time when the maximum load, the regulated material loading or stream composition (including non-regulated material) is the most challenging condition for the final control device. To provide flexibility for sources, we are also proposing that you may test under hypothetical worst-case conditions as an alternative. Hypothetical worst-case conditions are simulated test conditions that, at a minimum, contain the highest hourly load of regulated material emissions that would be predicted to vent to the final control device, based on an emissions profile.

The agency's intent, when requiring the development of an emissions profile, is to determine the maximum HAP loading to a control device over time. Therefore, the proposed rule requires that the emissions to the device be evaluated by plotting HAP emissions versus time. To provide multiple options for compliance, we have allowed for the emission profile to be determined by process, by equipment or by capture and control device limitation (this would be dependent on how you choose to characterize your worst-case conditions). When sources test under worst-case conditions, this reduces, and may eliminate, in some cases, the need for any retesting at a later date when conditions change. If a source tested under normal operating conditions, then any change from these conditions would trigger a need to retest the source under the revised normal operating conditions. The concept of worst-case conditions allows sources to anticipate potential changes so that only one (initial) test is generally required, which would reduce the burden on the source. We note that the referencing subpart could require a re-test (*e.g.,* annual or every 5 years) if it is appropriate to demonstrate compliance for a given source category; this would be determined during the rulemaking process for the referencing subpart.

Building off the requirements of 40 CFR part 63, subpart SS, the MON uses a hierarchy to determine applicable requirements for combined emission streams in 40 CFR 63.2450(c)(2). For example, the MON allows you to comply with only the batch process operation requirements for combined batch and continuous process operations. However, for the proposed rule, we are not establishing a hierarchy because the referencing subpart must consider the applicable statutory requirements for the specific type of rulemaking (CAA section 111 or section 112). Instead, we are proposing that you must meet all requirements for each emission stream type in a combined emission stream (*i.e.,* both continuous and batch process operation requirements must be met). The proposed rule is written in this way to ensure compliance for each emission stream. A hierarchy may be appropriate for certain source categories; however, this will need to be considered on a source category-specific basis during the development of the referencing subpart. A referencing subpart can override specific requirements in the Uniform Standard, as appropriate.

We are proposing that if you make a change to process equipment or operating conditions that would affect the correlation between the operating parameter values of a control device and the emission reduction performance of that control device, and would render the previously established operating limits ineffective, you must conduct a performance test within 180 days of the date of startup of the change. This performance test would be necessary to establish new operating limits and demonstrate that you are in compliance with the applicable emission limit of the referencing subpart. For instance, a facility could institute changes that increase the mass flow to a thermal oxidizer, requiring a higher operating limit for temperature to maintain compliance with the emission standard of the referencing subpart. This proposed requirement is necessary to ensure that the control device remains effective for compliance with the referencing subpart.

We have consolidated the allowed test methods in Table 5 of subpart M for ease of reading. The proposed rule provides test methods based on the types of emissions limits that we anticipate would be specified in a referencing subpart. As was done in the MON (for gas streams containing formaldehyde) and in the Pharmaceuticals Production NESHAP (for gas streams containing carbon disulfide), we have provided specific test methods for determining compliance when formaldehyde or carbon disulfide makes up a significant portion of the vent stream. Consistent with our previous determinations under these rules, we have ascertained that not all methods detect these compounds accurately and these specific methods are necessary in the proposed Uniform Standards.

We also are proposing that you may use Method 320 of 40 CFR part 63, appendix A as an alternative to using Method 18 or Method 26/26A of 40 CFR part 60, appendices A–6 through A–8, to determine compliance with a specific organic regulated material compound outlet concentration or percent reduction emission limit, or a hydrogen halide emission limit specified in the referencing subpart. In response to a public comment, the Method 320 of CFR part 63, appendix A option was added to the MON at final promulgation (68 FR 63852, November 10, 2003). The EPA declared that Method 320 of CFR part 63, appendix A was an acceptable method to demonstrate compliance for any type of batch or continuous vent stream. We have augmented this provision by specifying that EPA Method 320 may only be used to demonstrate compliance with a halogen emission limit if you can show that there are no diatomic-halogen molecules present in the vent stream being tested. For vent streams with diatomic-halogens molecules, we have determined that EPA Method 18 and EPA Method 26/26A are more effective. In addition, we are not allowing EPA Method 18, ASTM D6420–99 and EPA Method 320 to test for total regulated material because these methods only work for determining the quantity of known pollutants; therefore, you could

fail to identify the ''total'' regulated material.

Because a referencing subpart may have requirements for organic HAP and metal HAP, or requirements for use of a surrogate, such as PM or fine particulate matter ($PM_{2.5}$) for metal HAP, we have incorporated provisions from the MON that tell you how to determine compliance with a PM or $PM_{2.5}$ emission limit specified in a referencing subpart. (As discussed in section II.C of this preamble, the referencing subpart would establish and provide rationale for the use of a surrogate.) As determined under the MON, Method 29 of 40 CFR part 60, appendix A–8 allows you to determine the quantity of each HAP metal at the inlet and outlet of the control device(s). Furthermore, the MON allows for a second option, since controls for PM would also control the HAP metals, to use Method 5 of 40 CFR part 60, appendix A–3 to determine the quantity of PM at the inlet and outlet of the control device(s). We are proposing Methods 201A and 202 at 40 CFR part 51, appendix M, or, if the stack contains entrained water droplets (*e.g.,* immediately after a wet scrubber), Method 5 at 40 CFR part 60, appendix A–3 and Method 202 for total $PM_{2.5}$. We have determined that EPA Methods 201 and 202 are more accurate for measurement of $PM_{2.5}$. It is our determination that the methods proposed represent the best and most recent methods for measurement of HAP, VOC, PM and $PM_{2.5}$.

7. How did the EPA determine the requirements for batch processing operations?

We are proposing language from the MON and the Pharmaceuticals Production NESHAP (40 CFR part 63, subpart GGG) to accommodate batch process operations. The MON primarily references the batch process operation provisions in the Pharmaceuticals Production NESHAP. The proposed standards are intended to be referenced from multiple regulations representing different source categories, and do not set group determinations or levels of control.

We have included provisions in proposed 40 CFR 65.826 and 40 CFR 65.827 explaining how compliance should be demonstrated for the different emission limit formats that a referencing subpart may use for batch process operations. The language accommodates percent reduction or outlet concentration limits for control devices. We have included the emission limit format from the MON that requires the owner or operator to show compliance with a percent reduction by aggregating emissions over the full batch process. These requirements would apply only when a referencing subpart requires the owner or operator to show compliance with a percent reduction using this method (see section V.A.8 of this preamble). We have included language (see equations 29 through 31 of proposed 40 CFR 65.835(a)) clarifying how to determine compliance with a percent reduction where a referencing subpart requires the owner or operator to aggregate batch emissions. The equations illustrate how you would compare the sums of the controlled and uncontrolled emissions for all batch process operations subject to control within the process to calculate the percent reduction achieved. This is a clarification of the MON language, which stated that uncontrolled and controlled emissions should be compared to demonstrate compliance, but did not provide additional details to explain how this should be done.

We are proposing engineering evaluation methodologies that are incorporated by reference from section 3 of the EPA's *Emissions Inventory Improvement Program, Volume II: Chapter 16, Methods for Estimating Air Emissions from Chemical Manufacturing Facilities,* August 2007, Final, (EPA Emissions Inventory Improvement Program (EIIP) Volume II: Chapter 16). These methods are similar to those used in the Pharmaceuticals Production NESHAP, but include some refinements, such as an iterative methodology for purging, or gas sweep of a partially filled vessel emission episode. EPA EIIP Volume II: Chapter 16 also contains additional methodologies (that were not included in the Pharmaceuticals Production NESHAP) for calculating emissions from charging to a partially filled vessel with miscible contents, and evaporation from an open top vessel or spill. We are proposing that you conduct an engineering assessment to calculate uncontrolled emissions from other emissions episodes not described in EPA EIIP Volume II: Chapter 16. We are soliciting comment on the proposed use of EPA EIIP Volume II: Chapter 16.

8. How did the EPA determine the requirements for compliance through design evaluation?

With the exception of condensers, the proposed standards under subpart M require performance testing to demonstrate compliance with the applicable standard. However, to provide flexibility, we are including requirements for a design evaluation that could apply to non-flare control devices if it is allowed by the referencing subpart. For condensers, we are proposing that you must conduct a design evaluation (see discussion for condensers in section V.B.3 of this preamble).

Subpart M is structured such that general requirements for conducting a design evaluation are included under one section (proposed 40 CFR 65.850). More specific requirements pertaining to information that must be included in the design evaluation for each type of device are included in the corresponding section for that control device. The requirements for determining the components to include in a design evaluation are based on 40 CFR part 63, subpart SS, which were previously developed by the EPA for use in implementing a generic set of control standards that could be applied for multiple source categories. To ensure that sources can demonstrate compliance with the referencing subpart, we are proposing that you must prepare both a monitoring description and design evaluation. The monitoring description provides documentation that the source is maintaining the continuous monitoring equipment such that the control device can meet the emission limits specified in the referencing subpart. For the monitoring description, you would be required to choose the parameters, the operating limit(s), the monitoring frequency and the averaging time for each operating parameter, based on site-specific information, manufacturer's specifications, engineering judgment or other significant information. Your design evaluation would include documentation demonstrating that the control device being used achieves the required emission limit of a referencing subpart, taking into account the composition of the vent stream entering the control device, flow and regulated material concentration. There were no changes made to the design evaluation provisions except for the changes to: (1) Small boilers and process heaters, (2) oxidizers regarding the minimum temperature and residence time and (3) the inclusion of a design evaluation for biofilters when allowed by the referencing subpart (see previous discussion in section V.B.3 of this preamble).

9. How did the EPA determine the required records and reports for this proposed standard?

The notification, recordkeeping and reporting requirements that we are proposing are similar to those required in 40 CFR part 63, subpart SS. However, we have streamlined the periodic

compliance reporting with title V semiannual reporting requirements, incorporated updates for clarification, left out provisions that are redundant or unnecessary and created recordkeeping and reporting requirements to address any monitoring requirements included in the Uniform Standards. Many of these details are discussed in section VI.B.6 of this preamble.

Averaging Periods. We are proposing records of the daily or operating block average (for batch operations) value of each continuously monitored parameter or emissions.

Although some regulations under 40 CFR part 60 and 40 CFR part 61 require 3-hour averaging (*e.g.,* the SOCMI Air Oxidation NSPS, 40 CFR 60 Subpart III; the SOCMI Distillation Operations NSPS, 40 CFR 60 Subpart NNN; and the SOCMI Reactor Processes NSPS, 40 CFR 60 Subpart RRR), many of the part 63 regulations require daily averages. Specifically, with the exception of the recently proposed polyvinyl chloride and copolymers (PVC) rule (40 CFR 63, subpart J for PVC Production; 76 FR 29528, May 20, 2011), which requires 3-hour averaging, daily averaging periods are used in all past part 63 NESHAP affecting the chemical and refining sectors. Therefore, the EPA has decided to allow daily averaging for all control devices, unless otherwise provided under a referencing subpart.

We also do not consider daily averaging a relaxation of the previous NSPS that currently require more frequent averaging. Specifically, the 3-hour averages in NSPS and the daily averages in part 63 should not be compared only considering the averaging time, but one should also consider the meaning of out-of-range results. Under the NSPS, an out-of-range 3-hour average does not necessarily mean the source is out of compliance. Under the 40 CFR part 60 General Provisions, compliance with emission standards is determined by a performance test (see 40 CFR 60.11(a)). Under the 40 CFR part 63 General Provisions, it is clear that deviations from monitoring parameter ranges are direct violations (see 40 CFR 63.6(e)).

Under the proposed Uniform Standards, we have adopted the significance of out-of-range results from 40 CFR part 63; therefore, an out-of-range parameter on a daily average basis is a violation. We would allow the same out-of-range parameter determinations from 40 CFR part 63 to be made in all referencing subparts, including regulations under 40 CFR part 60 and 40 CFR part 61. Therefore, although facilities from 40 CFR part 60 or 40 CFR part 61 referenced to the Uniform Standards may become subject to daily averages in lieu of 3-hour averages, they would also be considered out of compliance if the daily average is out of range, provided this change is adopted in the rulemaking for the referencing subpart.

We anticipate that the referencing subpart may ''override'' the proposed daily averaging period with a stricter requirement if it is determined that such a requirement would be necessary to maintain the emission standard for the source category covered by the referencing subpart. A good example of such a source category is the proposed PVC Production NESHAP. It was determined for proposal that, for this source category, 3-hour averages are necessary to meet MACT. We consider the development of a referencing subpart at the appropriate time to make these source-category specific decisions.

We are proposing that you must report the daily and operating block averages for each continuously monitored parameter as part of the semiannual periodic report submitted through the CEDRI (see section II.F of this preamble). The EPA relies on the submittal of performance test data and emissions and parametric monitoring data to conduct effective reviews of CAA sections 111 and 112 standards, as well as compliance determinations, emission factor development, residual risk assessments and technology reviews. These emissions averages and parameter averages could supply up-to-date information regarding the capabilities of current industry technology, identify compliance issues and supplement emissions test data for establishing emission factors, improving regulation and improving the quality of emission inventories. Collecting this data on an ongoing basis through CEDRI will greatly reduce or eliminate the burden to industry and EPA from ICR efforts.

Recordkeeping and reporting of batch operations. The recordkeeping and reporting requirements for batch operations were modeled after the MON (40 CFR part 63, subpart FFFF) and Pharmaceuticals Production NESHAP (40 CFR part 63, subpart GGG). 40 CFR Part 63, subpart SS, as promulgated, contains only provisions for combined continuous and batch operations. We have drawn the requirements from 40 CFR part 63, subparts GGG and FFFF because these NESHAP contain and clarify technical requirements for batch process operations; in particular, the MON improves upon some of the technical requirements of the Pharmaceutical Production NESHAP and reflects a set of standards that both industry and the EPA have experience in implementing. The inclusion of requirements for batch operations allows the proposed Uniform Standards to accommodate a wider range of source categories. The proposed recordkeeping and reporting requirements reflect our most current survey of batch operations under 40 CFR part 63, subparts GGG and FFFF.

The proposed subpart M includes a pre-compliance report for batch processes, as does the MON and Pharmaceuticals Production NESHAP. This report is a combination of data submittals and reports that require the EPA review and approval prior to implementation and is, therefore, due before the compliance date (6 months prior to the compliance date for existing sources and to be submitted with the application for approval of construction or reconstruction for new sources). While we have designed the requirements for batch process operations to provide flexible options for compliance for owners and operators, we must ensure compliance with the MACT, GACT and BSER standards specified in the referencing subpart. We contend that the pre-compliance report is a valuable tool for the regulatory agency responsible for making compliance determinations. The batch pre-compliance requirements include providing details on the test conditions, data, calculations and other information used to establish operating limits for all batch operations, and rationale for why each operating limit indicates the control device is meeting the specified emission limit of the referencing subpart during each specific emission episode. If you used an engineering assessment, as specified in 40 CFR 65.835(b)(2), you would also include data or other information supporting a finding that the emissions estimation equations in the proposed subpart M are inappropriate. These data would include very detailed site-specific information and complex rationale for the selection of operating limits and emissions calculations. It is important that such data are reviewed prior to compliance to provide time to revise the CEMS performance evaluation and monitoring plan or the CPMS monitoring plan and conduct any necessary onsite preparation for revised monitoring requirements, based on the EPA concerns prior to the compliance date. This will ensure that there are no periods of noncompliance resulting from selection of an unacceptable approach. In the proposed Uniform Standards, we are using the term ''batch pre-compliance report'' rather than

''pre-compliance report'' because the report is submitted for only batch processes and includes only the batch information listed in this paragraph.

There are several items required in the pre-compliance report for the two previous NESHAP that are not proposed in subpart M because they are not related to the control devices covered by this proposed rule. For example, we are not proposing requirements to determine wastewater characteristics, as required by the Pharmaceuticals Production NESHAP, because we are not proposing requirements for wastewater facilities at this time.

Several source categories, including the Miscellaneous Organic Chemical Manufacturing source category and the Pharmaceuticals Production source category, use non-dedicated, multipurpose equipment that may be configured in numerous ways to accommodate different batch processes. We anticipate that when a NSPS or NESHAP considers referencing subpart M for a batch process operation, there could be a need to anticipate alternate operating scenarios for the batch process. As such, we are proposing these requirements in subpart M in order to accommodate these alternate scenarios.

Fabric filter recordkeeping and reporting. We modeled the recordkeeping and reporting requirements for fabric filters after the Pesticide Active Ingredient Production NESHAP and the Portland Cement Manufacturing NESHAP. These rulemakings reflect previous EPA determinations for fabric filter control. We considered, but are not proposing, that pre-compliance information be submitted for these control devices. In particular, the Pesticide Active Ingredient Production NESHAP and MON require an operation and maintenance plan and corrective action plan be submitted as part of a pre-compliance report. Instead, we are proposing that each bag leak detection system must be installed, operated, calibrated and maintained in a manner consistent with the manufacturer's written specifications and recommendations, and in accordance with the guidance provided in EPA–454/R–98–015, September 1997. Therefore, we feel it is not necessary to pre-approve the fabric filter plans when these requirements are followed. A future referencing subpart may require prior approval if it is determined that it is appropriate for a given source category and considering the applicable statutory requirements for the specific rulemaking (*e.g.,* MACT, GACT and/or BSER standards), or we may choose to adopt separate requirements for a particular source category in a referencing subpart. We are proposing that the operation and maintenance plan and corrective action plan for fabric filters be submitted as part of the Notification of Compliance Status Report instead of a pre-compliance report. The manufacturer's guidance and the EPA guidance document provide adequate information for owners and operators to prepare appropriate operation and maintenance and corrective action plans. We anticipate that fabric filter operation does not vary enough to require site-specific pre-review of these documents, although a referencing subpart may always override these requirements for a given source category.

VI. Summary and Rationale for the Proposed Revision of 40 CFR Part 65 Uniform Standards General Provisions—Subpart H

This section summarizes and provides rationale for the supplemental proposal for 40 CFR part 65, subpart H. This subpart was originally proposed on January 6, 2012 (77 FR 960). This supplemental proposal generally adds new language and sections applicable to proposed subparts H, I, J and M. There are some changes to the language originally proposed, but these are relatively small changes needed to incorporate the additional Uniform Standards subparts.

In section VI of this preamble, the term ''we'' refers to the EPA and the term ''you'' refers to owners and operators affected by the proposed standards. All other entities are referred to by their respective names (*e.g.,* reviewing authorities.) Additionally, ''subpart H'' refers to proposed 40 CFR part 65, subpart H.

A. Summary

In a previous proposal of the National Uniform Emission Standards for Heat Exchangers (40 CFR part 65, subpart L), signed by the EPA Administrator on November 30, 2011 (77 FR 960, January 6, 2012), we proposed general provisions in subpart H that would apply to all sources subject to all Uniform Standards. In that proposal, we specified that 40 CFR parts 60, 61 and 63, subpart A (*i.e.,* referred to in this preamble section VI as ''the 40 CFR parts 60, 61 and 63 General Provisions'') would still apply as the General Provisions for the Uniform Standards, with relatively minor additions in subpart H. During development of proposed 40 CFR part 65, subparts I, J and M, we reviewed this approach, in part under Executive Order 13563, *Improving Regulation and Regulatory Review,* (see section II.A of this preamble for further discussion of Executive Order 13563) to ensure that this would be the best approach.

Based on this review, we have determined that certain reporting provisions in the 40 CFR parts 60, 61 and 63 General Provisions are not consistent with each other (*e.g.,* report names), and that these differences could hamper efforts to provide compliance methods for all sources under one part. Additionally, we have determined that some 40 CFR part 63 general provisions include more details (e.g., detailed instructions for requesting a performance test waiver) that are not provided for the same kind of provision in the 40 CFR parts 60 and 61 General Provisions (*e.g.,* allowing a request for a performance test waiver without detailed instructions). Applying these more detailed 40 CFR part 63 general provisions to sources covered under 40 CFR parts 60 and 61 would result in more clarity and would facilitate the compliance process for sources regulated under 40 CFR parts 60 and 61 that refer to the Uniform Standards.

As such, we have concluded that the best approach to providing general provisions for the 40 CFR part 65 Uniform Standards is to consolidate some of the part 60, 61 and 63 general provisions, and to include these consolidated general provisions in subpart H. For the current proposal, we are issuing a supplemental proposal for subpart H in order to include additional provisions applicable to all Uniform Standards, as well as provisions applicable to individual Uniform Standards in 40 CFR Part 65, Subparts I, J and M.

For this purpose, we are maintaining five sections of subpart H proposed on January 6, 2012 (77 FR 960), and adding 12 new sections. Of the five previously proposed sections, we are proposing to make changes to three sections, as follows: (1) 40 CFR 65.200 will refer to 40 CFR 65.210, which specifies which general provisions in subpart A of 40 CFR parts 60, 61 and 63 apply to all Uniform Standards; (2) 40 CFR 65.265 will include additional methods incorporated by reference for 40 CFR part 65, subparts I, J and M; (3) 40 CFR 65.295 will include additional definitions of terms used in 40 CFR part 65, subparts I, J and M. The 12 new sections address the following consolidated general provisions applicable to all Uniform Standards: (1) General requirements for complying with the standards, operation and maintenance requirements, recordkeeping and reporting; (2) how to

request a waiver for testing, recordkeeping and reporting or an alternative monitoring, recordkeeping, test method or means of emission limitation; and (3) authorities not delegated to the states.

For those 40 CFR parts 60, 61 and 63 general provisions that would apply to the Uniform Standards and that would not be consolidated into subpart H, you are referred to Table 1 of subpart H, which lists the sections or paragraphs of the 40 CFR parts 60, 61 or 63 general provisions that still apply to the Uniform Standards. In general, Table 1 lists general provisions that are associated with applicability, initial notifications and permit application requirements, and requirements that are not the typical compliance provisions that a source must meet. Examples of the types of 40 CFR part 60, 61 and 63 general provisions listed in Table 1 include: 40 CFR 60.2, 61.02 and 63.2 (definitions); 40 CFR 60.3, 61.03 and 63.3 (abbreviations); 40 CFR 60.12, 61.05, 61.19 and 63.4 (prohibited activities, circumvention and fragmentation); and 40 CFR 60.5, 61.06 and 63.5 (determination of construction or modification; preconstruction review and notification requirements). Regulated sources subject to 40 CFR parts 60, 61 or 63 would remain subject to the provisions in Table 1, as applicable.

B. Rationale

1. What is the purpose of this subpart?

40 CFR 65.200 is proposed to be changed from the previously proposed 40 CFR 65.200 to specify that you would be required to comply with the General Provisions, as specified in 40 CFR 65.210 (refers to Table 1), as well as the referencing subpart.

2. Am I subject to the requirements of this subpart?

40 CFR 65.205 is proposed to be added to subpart H to make it clear who would be required to comply with the general provisions in subpart H. Subpart H applies to owners and operators who are subject to a referencing subpart and have been expressly directed to comply with the Uniform Standards by a referencing subpart. This section is needed so that you will understand the applicability.

3. When must I comply with this subpart?

40 CFR 65.206 was added as part of efforts to make consistent the organization of the Uniform Standards. The question of when to comply is addressed in only subpart H.

4. Am I subject to the General Provisions for part 60, 61 or 63 of this part?

We are proposing to add 40 CFR 65.210 to subpart H to specify that only some 40 CFR parts 60, 61 and 63 general provisions will apply to you. As discussed in section VI.A of this preamble, we reviewed the 40 CFR parts 60, 61 and 63 General Provisions and concluded that the best approach to providing general provisions for the 40 CFR part 65 Uniform Standards is to consolidate some of the 40 CFR parts 60, 61 and 63 general provisions, and to include these consolidated general provisions in 40 CFR part 65, subparts H and M. Consolidating these provisions will allow us to streamline these general requirements for the Uniform Standards, increasing the clarity of the General Provisions and facilitating the compliance process for all parties. Consolidation will also reduce administrative burden by facilitating our process of amending the referencing subparts in the future.

To consolidate the 40 CFR parts 60, 61 and 63 general provisions, we reviewed each general provision in 40 CFR parts 60, 61 and 63. For each provision, we determined if the general provision should be: (1) Consolidated into one general provision in subpart H that applies to sources complying with any Uniform Standard (you would not comply with the original, unconsolidated part 60, 61 or 63 requirement); (2) consolidated into one general provision in 40 CFR part 65, subpart M that applies to sources complying with 40 CFR Part 65, subpart M (you would not comply with the original, unconsolidated part 60, 61 or 63 requirement); (3) referred to in Table 1 to subpart H and required, as specified in 40 CFR parts 60, 61 or 63; or (4) excluded from the Uniform Standards because the provision does not apply to the types of sources that will be regulated using the Uniform Standards (*e.g.,* opacity and visible emissions provisions).

5. What are my general requirements for complying with operation and maintenance requirements?

Under 40 CFR part 60 and 40 CFR part 61, and as specified in subpart A of both parts, compliance is demonstrated with an emission limit using the results of a performance test; however, under 40 CFR part 63, the General Provisions specify that the Administrator will determine compliance based on performance tests, monitoring data, records, operation and maintenance procedures, and conformance to the procedures. In order to remove undue burden for individual source categories and provide consistent requirements for sources complying with the Uniform Standards, we have consolidated the general operation and maintenance compliance provisions of 40 CFR part 63 in proposed 40 CFR 65.215. These proposed provisions were developed, based on 40 CFR 63.6(e), (f) and (g). The proposed provisions are different from 40 CFR 63.6(e), (f) and (g) in that they include changes in terminology and cross-references, as well as removal of SSM provisions. The consolidated provisions in 40 CFR 65, subparts H and M would apply to all sources subject to referencing subparts.

We have not included provisions for SSM in these Uniform Standards, based on a recent District of Columbia Circuit ruling. The United States Court of Appeals for the District of Columbia Circuit vacated portions of two provisions in the EPA's CAA section 112 regulations governing the emissions of HAP during periods of SSM. *Sierra Club* v. *EPA*, 551 F.3d 1019 (D.C. Cir., 2008), cert. denied, 130 S. Ct. 1735 (U.S., 2010). Specifically, the Court vacated the SSM exemptions contained in 40 CFR 63.6(f)(1) and 40 CFR 63.6(h)(1), that are part of a regulation, commonly referred to as the ''General Provisions Rule,'' that the EPA promulgated under CAA section 112. When incorporated into CAA section 112(d) regulations for specific source categories, these two provisions exempt sources from the requirement to comply with the otherwise applicable CAA section 112(d) emission standard during periods of SSM.

Consistent with *Sierra Club* v. *EPA*, the Uniform Standards, as proposed, are designed to provide for continuous compliance with the emission standards of a referencing subpart. Future rulemakings that may reference the Uniform Standards will include a determination on the need for separate standards for startup and shutdown for the specific source category. Rationale for those provisions will be supplied at the time of proposal, thus, providing an opportunity for public comment. The final rulemakings for such referencing subparts would determine whether separate standards for startup and shutdown would apply in lieu of the otherwise continuously applicable referenced Uniform Standards.

6. What are my general recordkeeping requirements?

We are proposing to add 40 CFR 65.220 to require that you maintain records for a period of 5 years, as required in 40 CFR part 63, subpart A.

These records would be required to be maintained in such a manner that they can be readily accessed and are suitable for inspection within 2-hours time. This proposed record retention policy does not specify onsite or offsite retention periods because we assume that sources primarily use electronic archival systems that can be easily accessed from on site, whether the archive exists on or off site. This will provide more flexibility for sources regulated under 40 CFR part 63 while maintaining enforceability of the rule. This would allow the use of hard copy or electronic storage technologies that enable offsite data to be quickly retrieved by the site for independent review. For sources regulated under 40 CFR part 60 and 40 CFR part 61, this proposed recordkeeping provision could represent a longer total record retention period of 5 years rather than 2 years, but would allow shorter onsite record retention. For many sources regulated under 40 CFR part 60 and 40 CFR part 61, this proposed record retention requirement represents a burden reduction compared to the title V program, which requires onsite record retention for 5 years.

7. What are my general reporting requirements?

We propose adding 40 CFR 65.225 to subpart H to consolidate and make consistent the reporting provisions in 40 CFR parts 60, 61 and 63. We considered the level of reporting that would be required for sources regulated under the Uniform Standards according to the periodic reporting requirements of the existing rules and the title V program. Many sources are subject to numerous periodic reports under various 40 CFR parts 60, 61 and 63 subparts, as well as under the title V program. Petroleum refineries, for example, are required to prepare periodic reports under multiple regulations. For example, petroleum refineries can be subject to regulations, such as subparts G, R, CC, UU and UUU of 40 CFR part 63, subparts Kb, R, VV, XX, GGG and QQQ of 40 CFR part 60 and subparts V, Y, BB and FF of 40 CFR part 61, in addition to title V reporting requirements. All of these regulations have requirements for periodic reporting, most commonly, semiannual reporting. The NESHAP for petroleum refineries, 40 CFR part 63, subpart CC, includes provisions for emission units that are subject to more than one regulation and the rule provides direction regarding which rule the source should follow to address the overlapping requirements. However, this guidance only applies when more than one rule applies to a given emission unit; the guidance does not address situations when several rules apply to the source, but there is no overlap of requirements for a given emission unit. For example, there is no guidance provided for situations, such as a source with a storage tank subject to 40 CFR part 61, subpart Y, another tank subject to 40 CFR part 60, subpart Kb and third tank subject to 40 CFR part 63, subpart CC. For this example, the source is required to know the details of the recordkeeping and reporting requirements for all three rules and submit periodic reports according to the requirements of each rule.

As discussed in section II.D of this preamble, having the Uniform Standards with different subparts referencing its use provides for a significant burden reduction due to the consolidation of requirements. Although the report content would be the same for a given emission point type, the reporting schedule is dictated by the referencing subpart; therefore, a source subject to the Uniform Standard under multiple referencing subparts applicable to different emission points could still be subject to multiple periodic reports on different reporting schedules. However, we have included in proposed subpart H, provisions modeled from the 40 CFR part 63 General Provisions, allowing adjustments to reporting schedules to arrange the reports on a consistent schedule, including 40 CFR part 70 or 40 CFR part 71 operating permit semiannual reports.

Types of reports. To consolidate and make consistent the reporting requirements under the Uniform Standards, proposed 40 CFR 65.225 groups notifications and reports into four categories: (1) Notification of Compliance Status, (2) semiannual periodic reports, (3) annual periodic reports and (4) other notifications and reports. Consolidating the reporting requirements as described in this section will make it easier for you to comply with the rule and for the EPA to enforce and review these provisions in the future.

In an effort to streamline the reporting requirements and reduce burden, we are proposing semiannual and annual periodic reports, based on whether the reporting elements are deviations or non-deviations. We considered whether it would be appropriate to eliminate periodic reports under the Uniform Standards because sources are required to document all deviations in 40 CFR part 70 or 40 CFR part 71 operating permit semiannual reports, which must also be documented in reports for the underlying rules. However, some reporting elements in the periodic reports required under existing rules are not reporting deviations. For example, periodic reports include, as applicable, reports on LDAR monitoring (such as number of equipment tested and number of leaking equipment found), new operating scenarios developed for batch operations and the associated parameter monitoring and reports on process changes. In order to address the differences between non-deviation reporting elements and to assure the appropriate level of detail for deviations, we have segregated the reporting elements into deviation and non-deviations. For non-deviation reporting elements, we are proposing that they be submitted annually in hardcopy. We have determined that annual reporting of non-deviation elements is sufficient to ensure compliance under the Uniform Standards, and anticipate that requiring these reporting elements annually, as opposed to semiannually, will create a burden reduction for industry (see section VII.D of this preamble).

Although we have maintained semiannual reporting for the deviation reporting elements in the Uniform Standards, we are proposing that they be electronically entered in the CEDRI (rather than submitted by other means). The electronic reporting system will allow owners and operators to create copies of any deviation reports they would need to submit in a 40 CFR part 70 or 40 CFR part 71 operating permit semiannual report to the permit authority. This would provide an additional burden reduction for industry, as discussed in section VII.D of this preamble.

We are proposing that the Notification of Compliance Status Reports for 40 CFR part 65, subparts I and J be submitted electronically; the Notification of Compliance Status Reports for 40 CFR part 65, subpart M would be submitted in hard copy. We are not requiring electronic submittal of the Notification of Compliance Status Report for subpart M because it contains reporting elements that contain a high level of detail and description. As discussed in section II.F of this preamble, we have determined that these reporting elements would not be easily incorporated into the electronic reporting system at this time.

The category of ''other'' notifications and reports was created to group together reports that are not part of the Notification of Compliance Status or periodic compliance reports. This group includes notifications and reports: (1) Submitted initially prior to the initial compliance demonstration; (2) that must be submitted only if you request to use alternative methods or procedures from

those specified in the proposed rule (*e.g.,* request to use alternative test method); and (3) that are needed to be submitted for certain situations (*e.g.,* notification of performance test; changes in continuous monitoring system (CMS), processes or controls; new operating scenarios for batch operations). Except for performance test and CEMS performance evaluation reports, ''other'' reports would be submitted in hard copy.

We have included provisions that would require you to report any changes in CMS, processes or controls, or new operating scenarios for batch operations that differ from what has been previously reported (either in the Notification of Compliance Status or a subsequent report) within 30 days of making the change. We must be notified of these changes because they could be germane to the determination of a deviation, such as a deviation of an operating parameter under a new operating scenario, which was employed following the last report. In this instance, the agency would need to know the parameters against which to evaluate the deviation, as established under the updated operating scenario.

Schedule. Proposed 40 CFR 65.225 also establishes a schedule for submitting the initial Notification of Compliance Status and semiannual and annual periodic reports. The Notification of Compliance Status for each regulated source would be required to be reported within 240 days after the applicable compliance date specified in the referencing subparts, or within 60 days after the completion of the initial performance test or initial compliance determination, whichever is earlier. We are requiring an annual periodic report containing non-deviation reporting elements. Reporting of deviations required by the Uniform Standards would be reported electronically with the semiannual periodic report.

Report nomenclature. Currently, the 40 CFR parts 60, 61 and 63 General Provisions refer to the same report using different nomenclature, and these differences would hamper our efforts to specify, in 40 CFR part 65, subparts I through M, requirements related to this report. For example, the initial compliance report is referred to in the 40 CFR parts 60, 61 and 63 General Provisions as a ''summary report'' (40 CFR 60.7(d)), ''compliance status information'' (40 CFR part 61, appendix A) and a ''Notification of Compliance Status'' (40 CFR 63.9(h)), respectively. In proposed 40 CFR 65.225, this initial report is renamed for all sources complying with the Uniform Standards, and is referred to as the ''Notification of Compliance Status.'' Using one name for this report for sources regulated under all three parts of title 40 will facilitate efforts to specify requirements related to this report in the proposed Uniform Standards in 40 CFR part 65, subparts I through M.

This same approach to standardizing report names has been applied to periodic compliance reports and certain other reports. The proposed Uniform Standards refer to the periodic compliance report as the ''annual periodic report'' or ''semiannual periodic report,'' which standardizes the name for the ''excess emission and continuous monitoring system performance report'' and ''summary report'' in 40 CFR part 63, the ''excess emissions and monitoring systems performance report'' and ''summary report form'' in 40 CFR part 60 and the ''compliance status information'' form in 40 CFR part 61, appendix A.

Likewise, we propose making consistent, where appropriate, the content of these similar reports in 40 CFR parts 60, 61 and 63 for the semiannual and annual periodic reports and other notifications and reports under the Uniform Standards. For example, the 40 CFR parts 60, 61 and 63 general provisions for periodic compliance reporting include reporting provisions that are similar in intent, but slightly different in content, and this discrepancy between the General Provisions complicates our efforts to specify reporting requirements in 40 CFR part 65, subparts I, J and M. The proposed ''semiannual periodic report'' and ''annual periodic report'' incorporate elements of the ''excess emission and continuous monitoring system performance report'' and ''summary report'' in 40 CFR part 63, the ''excess emissions and monitoring systems performance report'' and ''summary report form'' in 40 CFR part 60 and the ''compliance status information'' form in 40 CFR part 61, appendix A. We are also updating the contents of the semiannual and annual periodic reports by adding provisions for closed vent systems, batch operations and process changes. Refer to section V.B of this preamble for further discussion on this topic.

Other report consolidation. We are proposing to consolidate certain 40 CFR part 60, 61 and 63 general provisions that specify the technical contents of reports (*e.g.,* submittal of test plan and performance evaluation test plan), and we have determined that these provisions would best be aggregated with the monitoring, performance testing and/or reporting requirements of 40 CFR part 65, subpart M, instead of in subpart H. It will be easier for sources to locate and understand these requirements if they are included in subpart M with related testing and monitoring requirements. Combining similar requirements together would benefit both the public and private sector by simplifying compliance and enforcement. Refer to section V.B of this preamble for further discussion of this topic.

We have consolidated the reporting requirement to submit a request for alternative monitoring. The general provisions for 40 CFR parts 60, 61 and 63 all allow alternative monitoring, but 40 CFR part 60 and 40 CFR part 61 do not provide a procedure for submitting such a request. We proposed to apply the procedure specified in the 40 CFR part 63 General Provisions to all sources subject to the Uniform Standards. This proposed revision is discussed further in section VI.B.7 of this preamble. Consolidating these provisions in subpart H would provide a consistent method for requesting monitoring alternatives for all referencing subparts, adding flexibility and simplifying compliance for sources regulated under the Uniform Standards.

Where we have determined that certain reporting requirements in the 40 CFR parts 60, 61 and 63 General Provisions do not apply to the Uniform Standards, we have excluded these provisions from 40 CFR part 65, subparts H through M. For example, the 40 CFR parts 60, 61 and 63 general provisions applicable to opacity and visible emissions are not included in proposed 40 CFR 65.225 because the Uniform Standards do not address opacity and visible emissions standards. We have also not included provisions from 40 CFR part 63 related to the SSM plan and associated recordkeeping and reporting, based on the Court decision that emissions limitations under CAA section 112 must apply at all times, even during periods of SSM (see section VI.B.5 of this preamble). Although the SSM plan and recordkeeping and reporting requirements were not specifically vacated by the Court, they no longer serve the original purpose of making sure the source follows good pollution control measures during periods of SSM in return for not being in violation.

We have removed provisions that required recordkeeping and reporting for actions taken during periods when a deviation occurs. These measures, which were previously included in periodic reports existing under 40 CFR part 60 and 40 CFR part 63, required that sources document and report the corrective actions taken when a

deviation occurs, the measures adopted to correct the deviation, the nature of the repairs or adjustments to the CMS and a description of the cause of the deviation. Additionally, these provisions required more detailed reporting, such as the identification of the cause (*e.g.,* the monitoring equipment malfunction process upset, control device upset, etc.) of each period of excess emissions and parameter monitoring exceedances. The reporting elements required by these provisions are elements that were previously established as part of SSM requirements. Although we are not requiring recording or reporting of these elements as part of the semiannual periodic report, sources may wish to collect and maintain this information for EPA and corporate review in the case of an exceedance of an emission standard. Further requirements for periods of deviation will be addressed by the referencing subpart in the manner appropriate for each source category; these requirements will be established during the development of the referencing subpart.

Reporting impacts. The consolidation of reporting requirements, as discussed in this section, will create a simplified, consistent method for reporting that may be applied to multiple source categories. We anticipate that these revised requirements will improve understanding, facilitate compliance and reduce the burden associated with reporting for multiple regulations. We have estimated that reducing the reporting frequency for some reporting elements to annual; allowing semiannual periodic reports to be submitted on a consistent schedule; and converting to electronic reporting for certain reporting elements would provide a reporting burden reduction of 42 to 59 percent to typical chemical plants and refineries (see sections VI.B.6 and VII.D of this preamble for more information).

8. How do I request a waiver for recordkeeping and reporting requirements?

We are proposing that 40 CFR 65.235 be added to subpart H to provide a procedure for sources regulated under 40 CFR part 60 and 40 CFR part 61 (as well as 40 CFR part 63) to apply for and obtain approval for a recordkeeping or reporting waiver request. This proposed procedure for requesting a waiver is currently provided in the General Provisions for 40 CFR part 63, subpart A, but is not provided in the General Provisions for 40 CFR part 60 or 40 CFR part 61. 40 CFR 61.11 does provide provisions for a waiver of compliance, but does not specifically address a waiver of recordkeeping and reporting. We propose that sources regulated under 40 CFR part 61 submit the proposed application for a waiver of recordkeeping or reporting with the application requesting a waiver of compliance under 40 CFR 61.11. Applying this 40 CFR part 63, subpart A procedure to all sources referred to the Uniform Standards would add flexibility and simplify compliance and enforcement for sources regulated under the Uniform Standards.

9. How do I request alternative monitoring methods?

We propose that 40 CFR 65.240 be added to subpart H to provide a procedure for requesting alternative monitoring methods, including major, minor and intermediate changes to monitoring methods. The allowance to request alternative monitoring is currently provided in the 40 CFR parts 60, 61 and 63 General Provisions, but the 40 CFR part 60 and 40 CFR part 61 General Provisions (*i.e.,* see 40 CFR 60.13(h)(3)(i) and 61.14(g)(1)) do not provide a procedure for application and approval of such requests. Applying the 40 CFR part 63 general provisions procedure (see 40 CFR 63.8(f)(4)(ii)), with minor clarifying revisions to all sources referred to the Uniform Standards would provide a consistent method for requesting monitoring modifications and alternatives for all referencing subparts, adding flexibility and simplifying compliance for sources regulated under the Uniform Standards.

10. How do I request a waiver for performance testing requirements?

40 CFR 65.245 is proposed to be added to subpart H to provide a procedure for requesting a performance test waiver. This procedure is currently provided in the 40 CFR part 63 General Provisions, but is not provided in the 40 CFR part 60 General Provisions. The 40 CFR part 61 General Provisions (*i.e.,* 40 CFR 60.8(b)) do allow a waiver for performance tests, but do not provide a procedure for application and approval.

Applying this 40 CFR part 63 general provisions procedure to all sources referred to the Uniform Standards would update these provisions for sources regulated under 40 CFR part 60 and 40 CFR part 61 and benefit both the public and industry by simplifying compliance for and enforcement of sources regulated under the Uniform Standards.

11. How do I request to use an alternative test method?

We propose that 40 CFR 65.250 be added to subpart H to provide a procedure for requesting a different test method than specified in the Uniform Standards, including standard methods not specified, alternative test methods or changes to test methods. The allowance to request alternative test methods is provided in 40 CFR parts 60, 61 and 63, subpart A, but 40 CFR part 60 and 40 CFR part 61, subpart A do not provide a procedure for application and approval of such requests. Applying this 40 CFR part 63, subpart A procedure to all sources referred to the Uniform Standards would provide sources regulated under 40 CFR part 60 and 40 CFR part 61 with more detailed instructions, simplifying compliance and enforcement of sources regulated under the Uniform Standards.

12. What are the procedures for approval of alternative means of emission limitation?

40 CFR 65.260 is proposed to be added to subpart H to specify a procedure for requesting an alternative means of emission limitation. The 40 CFR part 61 and 40 CFR part 63 General Provisions currently include such provisions. The 40 CFR part 60 General Provisions do not include such provisions; however, such provisions are included in the underlying rules of 40 CFR part 60. We are proposing to consolidate the provisions for 40 CFR part 61 and 40 CFR part 63 into proposed subpart H for sources directed to the Uniform Standards and regulated under 40 CFR parts 60, 61 and 63. The consolidated language in proposed subpart H contains the same provisions as the other general provisions requiring the source to submit a request containing information showing that the alternative means of emission limitations achieves equivalent emission reductions to the method specified in the Uniform Standards.

13. How do you determine what regulated sources are in regulated material service?

The previously proposed 40 CFR 65.275 describes procedures for determining whether a source is ''in regulated material service,'' in the event that a referencing subpart does not provide an explanation of how to determine whether a source is ''in regulated material service.'' These previously proposed requirements are based on the procedures in 40 CFR 63.180(d), which require that you determine the percent organic HAP

content using Method 18 of 40 CFR part 60, appendix A–6. We are considering, but not proposing, applying the same concepts we used in selecting the test methods allowable for performance test methods for determining whether the source is ''in regulated materials service.'' As discussed in section V.B.6 of this preamble, we are not allowing EPA Method 18, ASTM D6420–99 and EPA Method 320 as performance test methods for total regulated material because these methods only work for determining the quantity of known pollutants; therefore, you could fail to identify the ''total'' regulated material. We are requesting comment on whether it is reasonable to consider allowing Method 320 at 40 CFR part 63, appendix A in lieu of EPA Method 18 for determining whether your regulated source is in regulated materials service when the specific organic regulated material is known, and not allowing EPA Method 18 or EPA Method 320 when there are unknown HAP present. Instead, we would specify that Method 25A at 40 CFR part 60, appendix A–7 should be used to determine if the source is ''in regulated materials service.'' This proposed 40 CFR 65.275 is identical to the previously proposed 40 CFR 65.275.

14. What authorities are not delegated to the states?

We delegate implementation and enforcement authority to a state under sections 111(c) and 112(l) of the CAA. For the Uniform Standards, the delegation of these authorities would be through the referencing subparts because the proposed Uniform Standards are a set of foundational requirements that may be used to demonstrate compliance with the emissions standards specified in the referencing subpart. However, because there are certain requirements that the EPA does not delegate to the states, and some of those requirements are located in the Uniform Standards, it is important to specify their location in the Uniform Standards. 40 CFR 65.275 is proposed to be added to subpart H to specify which authorities located in the Uniform Standards would be retained by the EPA and not delegated to a state. The proposed Uniform Standards in subpart H specify that the EPA retain authority to review and approve the following: alternative means of emission limitation; recordkeeping and reporting waivers; major changes to monitoring requirements; major changes to test methods; and using standard EPA test methods other than those listed in the Uniform Standards. This proposed list of authorities is consistent with the list of retained authorities specified 40 CFR parts 60, 61 and 63.

15. How do I determine compliance with periodic requirements?

The proposed National Uniform Emission Standards for Heat Exchangers (40 CFR part 65, subpart L), signed by the EPA Administrator on November 30, 2011 (77 FR 960, January 6, 2012), included guidance on the timing of periodic requirements, including a minimum amount of time that must pass between consecutive instances, or ''reasonable intervals.'' We provided reasonable intervals for weekly, monthly, quarterly, semiannual and annual requirements in proposed 40 CFR part 65, subpart L, and those intervals have not changed. In the process of developing the Uniform Standards, we have added periodic requirements using additional time frames. Therefore, we are proposing to add additional reasonable intervals for requirements that occur bimonthly, three times per year and biennially (*i.e.,* every 2 calendar years). We are proposing that the reasonable interval for bimonthly requirements would be 20 days, which is roughly halfway between the reasonable intervals for monthly and quarterly requirements. Requirements that must be completed ''three times per year'' are less defined in terms of a calendar period, but if the three events were evenly spaced throughout a year, they would occur about 120 days apart. We are proposing that the reasonable interval for ''three times per year'' would be 40 days, which is consistent with the reasonable intervals of about one-third of the calendar period that we proposed previously for requirements that occur quarterly or less frequently. Finally, we are proposing that for provisions that you are required to complete biennially, you would repeat those events every other calendar year. (For example, if you are required to monitor valves subject to 40 CFR part 65, subpart J biennially, and you complete the first monitoring event in January of 2014, you would be required to complete the next monitoring event on or after January 1, 2016, and on or before December 31, 2016.) This provision has the effect of requiring you to schedule each event between about 1 to 3 calendar years after the previous event. We request comment on these reasonable intervals.

16. What definitions apply to this subpart?

We are proposing definitions in subpart H for certain types of units that appear in multiple Uniform Standards, so that those terms are defined consistently. Some definitions modeled from subpart SS, UU and WW of part 63 have been revised in the proposed subpart H for clarification or applicability purposes. Refer to sections III through V of this preamble for discussions about issues related to the proposed definitions.

VII. Impacts of the Proposed Rule

The Uniform Standards provide only operational, compliance monitoring, recordkeeping and reporting requirements that would not apply to any specific source category unless and until made applicable in a subsequent rulemaking for that source category referencing the Uniform Standards; therefore, it is most appropriate to present nationwide impacts for a referencing subpart during proposal or promulgation of that subpart when the emission standards are established for a given source category and when the decision of whether to refer to the Uniform Standards (and with what modifications) is made. The referencing subpart will provide the specific applicability of the Uniform Standards and an estimate of the number of sources and emission units for the given source category. Using the estimated numbers of regulated units, the nationwide impacts can be clearly calculated and presented.

In order to provide sufficient information on the proposed Uniform Standards for comment review, we are presenting costs on a unit basis for the proposed monitoring requirements that have not been included in previous rules. Many of the requirements in the Uniform Standards are the same or are similar to previous rules and do not represent changes that will translate into a cost increase from current rules applicable to the chemical industry. Although the Uniform Standards are intended to reduce the overall burden for facilities, some of the proposed changes could cause an increase in costs. This section provides a discussion of these costs and any cost increases that could be associated with the compliance requirements of the Uniform Standards when they are applied through a referencing subpart.

A. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart I?

Generally, costs will be the same or lower for the 40 CFR part 65, subpart I standards. The proposed requirement to control emissions from degassing certain storage vessels will increase costs, as described in section III of this preamble. The proposed requirement to install monitoring devices and alarms to

alert operators of impending floating roof landing and overfill will add costs for facilities that do not already have such devices. The EPA Method 21/optical gas imaging instrument monitoring of fixed roofs will be more costly than visual inspections.

B. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart J?

There are two new provisions in the Uniform Standards for Equipment Leaks that are expected to increase costs compared to current rules. As described in section IV.B.1 of this preamble, the first of these is annual instrument monitoring for open-ended valves and lines to ensure compliance with the requirement that the cap, blind flange, plug or a second valve properly seals the open-ended valve or line. The costs for the model plants ranged from a capital cost of $810 and an annualized cost of $180 for the simple chemical manufacturing model to a capital cost of $23,000 and an annualized cost of $5,400 for the complex refinery model.

The other provision that is expected to increase costs compared to current rules is the requirement to install electronic indicators on each PRD that would be able to identify and record the time and duration of each pressure release. These costs range from a capital cost of $11,000 and an annualized capital cost of $1,600 for the simple chemical manufacturing model to a capital cost of $130,000 and an annualized capital cost of $19,000 for the complex refinery model. Additional details on the calculation of these costs are provided in the technical memorandum entitled *Analysis of Emission Reduction Techniques for Equipment Leaks,* in Docket ID No. EPA–HQ–OAR–2010–0869.

C. What are the cost increases associated with requirements proposed in 40 CFR part 65, subpart M?

We are providing a summary of the cost impacts of the proposed 40 CFR part 65, subpart M monitoring requirements in which the expected impacts will change from the typical monitoring requirements in past rules, including adsorbers, biofilters, bypasses and reporting requirements. We do not anticipate other cost impacts that would differ from those established in current regulations. We provide a summary of the costs for the proposed monitoring and reporting requirements in sections VII.C.1 through VII.C.3 of this preamble. Additional information regarding monitoring costs for closed vent system and control devices, including small boilers and process heaters, oxidizers, absorbers, adsorbers, condensers, biofilters, sorbent injection and fabric filters can be located in the technical memorandum, *Development of Monitoring Cost Estimates for the Proposed Part 65 Uniform Standards for Control Devices—Subpart M,* in Docket ID No. EPA–HQ–OAR–2010–0868.

1. What are the cost increases associated with adsorber requirements proposed in 40 CFR part 65, subpart M?

The proposed monitoring for adsorbers, both regenerative and non-regenerative, includes some requirements that are new to the typical chemical sector regulation. Table 16 of this preamble provides a list of the proposed monitoring provisions for adsorbers that have not been typically included in previous chemical sector regulations.

TABLE 16—CAPITAL AND ANNUALIZED COSTS FOR PROPOSED ADSORBER MONITORING REQUIREMENTS IN 40 CFR PART 65, SUBPART M

Control	Monitoring	Total capital costs ($)	Total annualized costs ($)
Regenerative Adsorbers	Frequency monitor	.....	5,950
	Verification monitoring	.....	5,950
	Weekly checks on outlet concentration	9,200	3,700
	Corrective action plan	.....	3,400
Non-regenerative Adsorbers	Checks on outlet concentration (costs assume an average of weekly monitoring).	9,200	3,700

As stated previously in section V.B.3 of this preamble, these monitoring requirements are important to assess whether the adsorbers are operating properly. It is difficult to estimate emissions reductions that can be attributed to these additional costs. Other than the weekly outlet concentration tests, the additional monitoring checks are designed to check for a situation that can occur, but may not for a given adsorber. If, for example, the valve sequencing of a regenerative adsorber is sluggish and the timing is not correct, the emissions reduced by the adsorber could degrade significantly. The weekly checks on the outlet concentration and associated corrective action plan for regenerative adsorbers ensure that degradation of the adsorbent, fouling or channeling is detected in a timely manner. A period of time with inadequate adsorbent would significantly reduce the emissions reductions of the adsorber. Although the degradation of the adsorbent is an anticipated event, the adsorbent life can vary with actual use; therefore, a schedule to check the outlet concentration is important to make sure that the adsorber does not operate with degraded adsorbent and can control emissions to meet the requirements of the referencing subpart.

Few past rules have included provisions for adsorbers regenerated offsite; therefore, any monitoring for non-regenerative adsorbers is additional monitoring or new for chemical sector rules. The proposed monitoring for this type of control, outlet concentration measurement, is low cost, especially considering that this is the only monitoring that is necessary for this control.

2. What are the cost increases associated with biofilter requirements proposed in 40 CFR part 65, subpart M?

Although the MON requires monitoring the temperature of the biofilter bed, we are proposing additional monitoring for moisture and pressure drop. The estimated additional costs for monitoring these parameters are included in Table 17 of this preamble.

TABLE 17—CAPITAL AND ANNUALIZED COSTS FOR PROPOSED BIOFILTER MONITORING REQUIREMENTS IN SUBPART M

Control	Monitoring	Total capital costs ($)	Total annualized costs ($)
Biofilters	Moisture content	5,400	7,100
	Pressure drop	6,400	7,400

Although the MON only allows the biofilter as a control option for batch operations, we are proposing to allow the control option for emissions from either a batch or continuous operation. To meet the additional emissions reductions usually associated with continuous operations, we have added monitoring for moisture and pressure drop to ensure good performance of the biofilter. The costs for the additional monitoring are reasonable given the added assurance of good performance achieved by including this monitoring.

3. What are the cost increases associated with bypass monitoring requirements proposed in 40 CFR part 65, subpart M?

Bypass monitoring has been a requirement of closed vent system provisions in many past regulations. However, PRD needed for safety purposes, low leg drains, high point bleeds, analyzer vents and open-ended valves or lines were previously not subject to the bypass line requirements to have a flow monitor or a car seal on each bypass line that could divert a vent stream to the atmosphere. Given the recent *Sierra Club* v. *EPA* decision vacating the 40 CFR part 63 General Provisions' exemption from emission standards during periods of SSM (see section VI.B.5 of this preamble), these equipment would be subject to this monitoring when directed to the Uniform Standards from a referencing subpart. See the discussion under section VII.B of this preamble.

D. What are the cost impacts associated with the proposed reporting requirements for the Uniform Standards?

In our survey of existing regulations for the development of the Uniform Standards, we determined that many petroleum refineries and chemical plants are subject to numerous and duplicative recordkeeping and reporting requirements under various 40 CFR parts 60, 61 and 63 subparts, as well as under the title V program. We have estimated a total recordkeeping and reporting burden for a typical refinery subject to current rules of about $106,000, with a burden of approximately $52,800 for the required reporting. For an example chemical plant, we have estimated a total recordkeeping and reporting burden of approximately $66,900 for the current rules, with a burden of about $16,000 for the current required reporting. In order to reduce burden to industry, while retaining the reporting requirements needed to monitor compliance, we are proposing annual periodic reporting for some reporting elements and we are proposing to accept semiannual reporting data elements electronically, as discussed in sections II.F and VI.B.7 of this preamble. We anticipate that the proposed reporting requirements will reduce the burden of reporting for a typical refinery by 59 percent. This would represent a burden reduction of about $31,400 for reporting burden, and a total burden reduction of 30 percent for a typical refinery. For a typical chemical plant, we anticipate that the proposed requirements will reduce the burden of reporting by 42 percent. This would represent a burden reduction of $6,780 per year for reporting, and would represent a total burden reduction of 10 percent for a typical chemical plant. However, there will be some burden for a source to initially set up their facility in the electronic reporting system. We estimated set up costs for the example refinery and chemical plant as $5,300 and $2,700, respectively. See technical memorandum, *Comparison of Reporting Burden between Hardcopy Reports Submitted under Existing Rules and Electronic Reports Submitted for Uniform Standards,* in Docket ID No. EPA–HQ–OAR–2010–0868 for additional information. These burden reductions are estimates based on two model sources; we will be refining these estimates and developing estimates associated with all electronic reporting users. These estimates will be presented in the preamble for the electronic reporting rule proposal. For a discussion of the electronic reporting, see section II.F of this preamble.

VIII. Statutory and Executive Order Reviews

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This action is not a ''significant regulatory action'' under the terms of Executive Order 12866 (58 FR 51735, October 4, 1993) and is, therefore, not subject to review under Executive Order 12866 and Executive Order 13563 (76 FR 3821, January 21, 2011).

Executive Order 13563 (76 FR 15859, March 22, 2011) directs each federal agency to ''periodically review its existing significant regulations to determine whether any such regulations should be modified, streamlined, expanded, or repealed so as to make the agency's regulatory program more effective or less burdensome in achieving the regulatory objectives.'' Through this proposal, the EPA is responding to Executive Order 13563 by presenting steps to increase the ease and efficiency of data submittal and improve data accessibility.

Specifically, the EPA is proposing that owners and operators of facilities affected by this proposal electronically submit certain specified compliance reports to the EPA. Electronic data reporting informs a number of our programs and offers several advantages over traditional paper reporting. First, electronic reporting provides the agency easy and routine access to the data needed to review and evaluate our regulations. This results in fewer future ICR, thereby saving both industry and the agency time and resources. In addition, electronic reporting of emissions data will allow the agency to develop and update emissions factors on a timelier basis. Finally, electronic reporting informs our compliance program and allows easier identification of compliance issues.

Executive Order 13563 requires the EPA to evaluate current regulatory decisions to help generate a more transparent review process. We believe that, through this proposal, electronic reporting and data collection will provide a more effective and less burdensome approach to recordkeeping

and reporting and is consistent with Executive Order 13563. The EPA prepared an additional analysis of the potential costs and benefits associated with this action. This analysis is contained in section VII of this preamble.

B. Paperwork Reduction Act

This action does not impose an information collection burden under the provisions of the Paperwork Reduction Act, 44 U.S.C. 3501, *et seq.* Burden is defined at 5 CFR 1320.3(b). The proposed Uniform Standards only provide thresholds, emissions reductions requirements, control options, testing, monitoring, recordkeeping and reporting requirements that would become applicable to a particular source category only if, and when, a future rulemaking for that source category references the Uniform Standards. The information collection burden of the Uniform Standards on a given source category cannot be determined until the Uniform Standards are referenced in a future rulemaking. Upon proposal of a rule that references the Uniform Standards, a determination of the burden estimate and an assessment for costs, economic impacts and other impacts, as appropriate, would be conducted.

C. Regulatory Flexibility Act

The Regulatory Flexibility Act generally requires an agency to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Small entities include small businesses, small organizations and small governmental jurisdictions.

For purposes of assessing the impacts of this proposed action on small entities, small entity is defined as: (1) A small business, as defined by the Small Business Administration regulations at 13 CFR 121.201; (2) a small governmental jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise that is independently owned and operated and is not dominant in its field.

After considering the economic impacts of this proposed rule on small entities, I certify that this action will not have a significant economic impact on a substantial number of small entities. This proposed rule will not directly impose any requirements on any entities, including small entities. There are no entities subject to this proposed rule unless and until the Uniform Standards are referenced in future rulemakings for particular source categories. We continue to be interested in the potential impacts of the proposed rule on small entities and welcome comments on issues related to such impacts.

D. Unfunded Mandates Reform Act

This action contains no federal mandates under the provisions of title II of the Unfunded Mandates Reform Act of 1995 (UMRA), 2 U.S.C. 1531–1538 for state, local or tribal governments or the private sector. This rule does not contain a federal mandate that may result in expenditures of $100 million or more for state, local and tribal governments, in the aggregate, or the private sector in any one year. The Uniform Standards will not apply to any source category until future rulemakings under 40 CFR part 60, 61 or 63 reference their use. Thus, this rule is not subject to the requirements of sections 202 or 205 of UMRA.

This action is also not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that might significantly or uniquely affect small governments. Upon proposal of a rule that references the Uniform Standards, consideration will be made whether that rule exceeds $100 million or more for state, local and tribal governments or presents a significant impact on small government entities.

E. Executive Order 13132: Federalism

This proposed rule does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. The Uniform Standards will not apply to any source category until a future rulemaking under 40 CFR part 60, 61 or 63 references their use; therefore, the proposed Uniform Standards do not impose substantial direct compliance costs on state or local governments. Thus, Executive Order 13132 does not apply to this proposed rule. Upon proposal of a rule that references the Uniform Standards, consideration will be made whether that rule has federalism implications. In the spirit of Executive Order 13132, and consistent with EPA policy to promote communications between the EPA and state and local governments, the EPA specifically solicits comment on this proposed rule from state and local officials.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This proposed rule does not have tribal implications, as specified in Executive Order 13175 (65 FR 67249, November 9, 2000). It will not have substantial direct effects on tribal governments, on the relationship between the federal government and Indian tribes or on the distribution of power and responsibilities between the federal government and Indian tribes, as specified in Executive Order 13175. The proposed Uniform Standards do not directly impose requirements on owners and operators of specified sources or tribal governments, but will be referred to in future rulemakings, as discussed in section II of this preamble. If any industries that are owned or operated by tribal governments may be referenced to the Uniform Standards by another subpart in the future, the effect of this proposed rule on communities of tribal governments would not be unique or disproportionate to the effect on other communities. Thus, Executive Order 13175 does not apply to this proposed rule. The EPA specifically solicits additional comment on this proposed rule from tribal officials.

G. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

The EPA interprets Executive Order 13045 (62 FR 19885, April 23, 1997) as applying only to those regulatory actions that concern health or safety risks, such that the analysis required under section 5–501 of the Executive Order has the potential to influence the regulation. This action is not subject to EO 13045 because it does not establish an environmental standard intended to mitigate health or safety risks.

H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use

The proposed rule is not a ''significant energy action'' as defined in Executive Order 13211 (66 FR 28355, May 22, 2001), because it is not likely to have a significant adverse effect on the supply, distribution or use of energy. The proposed Uniform Standards provide testing, monitoring, recordkeeping and reporting requirements only and do not specify applicability thresholds or emissions reduction performance requirements

that would have significant adverse energy impacts. The energy impacts of the proposed Uniform Standards would be determined when the standards are referenced in a future rulemaking. Therefore, we conclude that the proposed rule, when implemented, is not likely to have a significant adverse effect on the supply, distribution or use of energy.

I. National Technology Transfer and Advancement Act

Section 12(d) of the National Technology Transfer and Advancement Act of 1995 (NTTAA) Public Law 104–113, (15 U.S.C. 272 note) directs the EPA to use voluntary consensus standards (VCS) in its regulatory activities, unless to do so would be inconsistent with applicable law or otherwise impractical. VCS are technical standards (e.g., materials specifications, test methods, sampling procedures and business practices) that are developed or adopted by VCS bodies. NTTAA directs the EPA to provide Congress, through the Office of Management and Budget, explanations when the agency decides not to use available and applicable VCS. This proposed rulemaking involves technical standards. The EPA cites the following standards: Methods 1, 1A, 2, 2A, 2C, 2D, 2F, 2G, 3, 3A, 3B, 4, 5, 18, 21, 22, 23, 25A, 26, 26A, 27, 29, 201A, 202, 301 and 320 of 40 CFR part 60, appendix A. Consistent with the NTTAA, the EPA conducted searches to identify VCS in addition to these EPA methods. No applicable VCS were identified for EPA Methods 1A, 2A, 2D, 2F, 2G, 21, 22, 27, 201A or 202. The search and review results are in the docket for this rule. The search identified six VCS as acceptable alternatives to EPA test methods for the purpose of this rule. The method, ASME PTC 19.10–1981, *Flue and Exhaust Gas Analyses* (incorporated by reference-see proposed 40 CFR 65.265), is cited in this rule for its manual method for measuring the oxygen, carbon dioxide and carbon monoxide content of the exhaust gas. This part of ASME PTC 19.10–1981 is an acceptable alternative to EPA Methods 3A and 3B for the manual procedures only, and not the instrumental procedures. The VCS, ASTM D6420–99 (2010), *Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry* (incorporated by reference-see proposed 40 CFR 65.265), was designated an acceptable alternative to EPA Method 18. Likewise, the VCS, *National Institute for Occupational Safety and Health (NIOSH) Method 2010 ''Amines, Aliphatic,* is acceptable as an alternative for EPA Method 18 only for trimethylamine (CAS 121–44–8) at iron foundries.

The VCS, ASTM D6735–01, *Standard Test Method for Measurement of Gaseous Chlorides and Fluorides from Mineral Calcining Exhaust Source Impinger Method,* is acceptable as an alternative to EPA Methods 26 and 26A. The VCS, ASTM D6784–2, *Standard Test Method for Elemental, Oxidized, Particle-Bound and Total Mercury Gas Generated from Coal-Fired Stationary Sources (Ontario Hydro Method),* is acceptable as an alternative to EPA Method 29 for mercury only. The VCS, ASTM D6348–03 (2010), *Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform (FTIR) Spectroscopy,* is acceptable as an alternative to EPA Method 320, in accordance with the conditions outlined in the memorandum, *Voluntary Consensus Standard Results for National Uniform Standards for Storage Vessels and Transfer Operations (40 CFR 65 Subpart I), National Uniform Emission Standards for Equipment Leaks (40 CFR 65 Subpart J), and National Uniform Emission Standards for Control Devices (40 CFR Subpart M)* (see Docket ID. No. EPA–HQ–OAR–2010–0868).

The search for emissions measurement procedures identified 23 other VCS that were potentially applicable for the Uniform Standards in lieu of EPA reference methods. The EPA determined that these 23 standards identified for measuring emissions of the regulated pollutants or their surrogates subject to emission standards in this proposed rule were impractical due to lack of equivalency, documentation, validation data and other important technical and policy considerations. Therefore, the EPA does not intend to adopt these standards for this purpose. The reasons for the determinations for the 23 methods are in the docket for this proposed rule. For the methods required or referenced by the proposed rules, a source may apply to the EPA for permission to use alternative test methods or alternative monitoring requirements in place of any required testing methods, performance specifications or procedures, as specified in proposed 40 CFR part 65, subpart H.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

Executive Order 12898 (59 FR 7629, February 16, 1994) establishes federal executive policy on environmental justice. Its main provision directs federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies and activities on minority populations and low-income populations in the United States.

The EPA has concluded that it is not practicable to determine whether there would be disproportionately high and adverse human health or environmental effects on minority and/or low income populations from this proposed rule. The proposed Uniform Standards only provide thresholds, emissions reduction requirements and operational, testing, monitoring, recordkeeping and reporting requirements, and are not applicable until referenced by a future rulemaking for a particular source category. The impact of the proposed rule on minority and/or low-income populations would be determined during proposal in future rulemakings that reference the Uniform Standards.

List of Subjects in 40 CFR part 65

Air pollution control, Environmental protection, Incorporation by reference, Reporting and recordkeeping requirements.

Dated: February 24, 2012.

Lisa P. Jackson,

Administrator.

For the reasons stated in the preamble, title 40, chapter I, of the Code of Federal Regulations is proposed to be amended as follows:

PART 65—[AMENDED]

1. The authority citation for part 65 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

2. Replace subpart H to read as follows:

Sec.

Subpart H—National Uniform Emission Standards General Provisions

What This Subpart Covers

65.200 What is the purpose of this subpart?
65.205 Am I subject to this subpart?
65.206 When must I comply with this subpart?

General Requirements

65.210 Am I subject to the General Provisions for part 60, 61 or 63 of this part?
65.215 What are my general requirements for complying with operation and maintenance requirements?
65.220 What are my general recordkeeping requirements?

65.225 What are my general reporting requirements?
65.235 How do I request a waiver for recordkeeping and reporting requirements?
65.240 How do I request an alternative monitoring method?
65.245 How do I request a waiver for performance testing requirements?
65.250 How do I request to use an alternative test method?
65.260 What are the procedures for approval of alternative means of emission limitation?
65.265 What methods are incorporated by reference for the Uniform Standards?
65.270 How do I determine what regulated sources are in regulated material service?

Other Requirements and Information

65.275 What authorities are not delegated to the states?
65.280 How do I determine compliance with periodic requirements?
65.295 What definitions apply to the Uniform Standards?

Table to Subpart H of Part 65

Table 1 to Subpart H of Part 65—Applicable 40 CFR Parts 60, 61 and 63 General Provisions

Subpart H—National Uniform Emission Standards General Provisions

What This Subpart Covers

§ 65.200 What is the purpose of this subpart?

The purpose of this subpart is to provide general provisions for the Uniform Standards of this part. These general provisions apply to you if a subpart of part 60, 61 or 63 of this chapter references the use of this subpart. The general provisions applicable to the referencing subpart (subpart A of part 60, 61 or 63) apply to this subpart, as specified in § 65.210. Section 65.295 contains definitions of ''uniform standards'' and ''referencing subpart,'' as well as other terms used in these Uniform Standards. The General Provisions for the Consolidated Federal Air Rule (subpart A of this part) do not apply to the Uniform Standards.

§ 65.205 Am I subject to this subpart?

You are subject to this subpart if you are an owner or operator who is subject to a referencing subpart and you have been expressly directed to comply with the uniform standards by a referencing subpart.

§ 65.206 When must I comply with this subpart?

You must comply with this subpart by the date specified in the referencing subpart that directed you to comply with this subpart.

General Requirements

§ 65.210 Am I subject to the General Provisions for part 60, 61 or 63 of this part?

You must comply with the provisions of 40 CFR part 60, subpart A; 40 CFR part 61, subpart A; and 40 CFR part 63, subpart A, as applicable, that are specified in Table 1 to this subpart. Table 1 to this subpart specifies the provisions in 40 CFR part 60, subpart A; 40 CFR part 61, subpart A; and 40 CFR part 63, subpart A that continue to apply to owners or operators of regulated sources expressly referenced to the Uniform Standards. You must comply with the provisions in Table 1 to this subpart that correspond to the referencing part. All provisions of 40 CFR part 60, subpart A; 40 CFR part 61, subpart A; and 40 CFR part 63, subpart A that are not expressly referenced in Table 1 to this subpart do not apply, and the provisions of the Uniform Standards apply instead, except that provisions that were required to be met prior to implementation of the Uniform Standards still apply.

§ 65.215 What are my general requirements for complying with operation and maintenance requirements?

(a) *Operation and maintenance requirements.* You are subject to the operation and maintenance provisions specified in paragraphs (a)(1) through (3) of this section.

(1) At all times, you must operate and maintain any regulated source, including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions.

(2) The emission standards and established parameter ranges of the referencing subpart and of the Uniform Standards apply at all times, except during periods of non-operation of the regulated source (or specific portion thereof), as specified in paragraphs (a)(2)(i) and (ii) of this section. However, if a period of non-operation of one portion of a regulated source does not affect the ability of a particular emission point to comply with the specific provisions to which it is subject, then that emission point must comply with the applicable provisions of the Uniform Standards during the period of non-operation. For example, the degassing of a storage vessel would not affect the ability of a process vent to meet the requirements of subpart M of this part.

(i) For all Uniform Standards except subpart J of this part, periods of non-operation of the regulated source (or specific portion thereof) are those periods resulting in cessation of the emissions to which the Uniform Standards apply.

(ii) For subpart J of this part, periods of non-operation of the regulated source (or specific portion thereof) are those periods in which the lines are drained and depressurized, resulting in cessation of the emissions to which subpart J of this part applies.

(3) Operation and maintenance requirements are enforceable independent of emissions limitations or other requirements in relevant standards.

(b) *Compliance determination procedures.* The Administrator will follow the compliance determination procedures specified in paragraphs (b)(1) through (4) of this section.

(1) *Compliance with operating conditions.* For emission points that are required to perform continuous parameter monitoring, the Administrator will determine compliance with the required operating conditions for the monitored control devices by using operating parameter monitoring data.

(2) *Compliance with the requirement to maintain any regulated source in a manner consistent with safety and good air pollution control practices for minimizing emissions.* The Administrator will determine compliance with the requirements in paragraph (a)(1) of this section by evaluation of your use of acceptable operation and maintenance procedures. This determination will be based on information available to the Administrator that may include, but is not limited to, monitoring results, review of operation and maintenance procedures, review of operation and maintenance records, inspection of the regulated source and alternatives approved as specified in § 65.240.

(3) *Compliance with emissions standards.* Paragraphs (b)(3)(i) and (ii) of this section govern the use of data, tests and requirements to determine compliance with emissions standards.

(i) *Performance test.* The Administrator will determine compliance with emission standards of the referencing subpart and the Uniform Standards, based on the results of performance tests conducted according to the procedures specified in subpart M of this part, as applicable, unless otherwise specified in the Uniform Standards.

(ii) *Operation and maintenance requirements.* The Administrator will determine compliance with emission standards of the Uniform Standards by evaluation of your conformance with operation and maintenance requirements, including the evaluation

of monitoring data, as specified in the Uniform Standards.

(4) *Design, equipment, work practice or operational standards.* The Administrator will determine compliance with design, equipment, work practice or operational standards by the procedures specified in paragraphs (b)(4)(i) and (ii) of this section.

(i) Review of records, inspection of the regulated source and other procedures specified in the Uniform Standards.

(ii) Evaluation of your conformance with operation and maintenance requirements, as specified in paragraph (a) of this section and in the Uniform Standards.

(c) *Finding of compliance.* The Administrator will make a finding concerning a regulated source's compliance with an emission standard, design standard, work practice, operational standard or general duty requirement to maintain any regulated source in a manner consistent with safety and good air pollution control practices for minimizing emissions, as specified in paragraphs (a) and (b) of this section, upon obtaining all the compliance information required by the relevant standard (including the reports of performance test results, monitoring results and other information, if applicable), and information available to the Administrator, pursuant to paragraph (b) of this section.

§ 65.220 What are my general recordkeeping requirements?

(a) *Maintaining notifications, records and reports.* You must keep copies of notifications, reports and records required by this part for at least 5 years, except for records that reflect current operating conditions. These records and reports must be kept for 5 years after they no longer reflect current operating conditions. Examples of these records and reports include the regenerative adsorber corrective action plan required by § 65.742(e) or storage vessel capacity required by § 65.380(a).

(b) *Availability of records.* You must maintain all applicable records in such a manner that they can be readily accessed and are suitable for inspection within 2 hours after a request. Records may be maintained in hard copy or computer-readable form, including, but not limited to, on paper, computer disk, CD/DVD or magnetic tape.

§ 65.225 What are my general reporting requirements?

(a) *Required notifications and reports.* You must submit the notifications and reports specified in paragraphs (a)(1) through (4) of this section, as applicable. The notifications and reports specified in paragraphs (a)(1) through (4) of this section must meet the requirements in paragraphs (g) through (j) of this section.

(1) A Notification of Compliance Status described in paragraph (c) of this section.

(2) Semiannual periodic reports, as described in paragraph (d) of this section.

(3) Annual periodic reports, as described in paragraph (e) of this section.

(4) Other notifications and reports, as described in paragraph (f) of this section.

(b) *Responsible official.* For Notification of Compliance Status Reports, semi-annual reports, annual periodic reports, performance test reports and continuous emission monitoring system (CEMS) performance evaluation data, you must include the name, title and signature of the responsible official who is certifying the accuracy of the report and attesting to whether the source has complied with the relevant standard.

(c) *Notification of Compliance Status.* You must submit your Notification of Compliance Status, as specified in paragraphs (c)(1) and (2) of this section. The Notification of Compliance Status for subparts I and J of this part must be submitted electronically, as specified in paragraph (h) of this section and the Notification of Compliance Status for subpart M of this part must be submitted, as specified in paragraph (i) of this section.

(1) *Contents.* You must submit a Notification of Compliance Status for each regulated source subject to the Uniform Standards, containing the information specified in the applicable subparts of the Uniform Standards.

(2) *Due date.* You must submit the Notification of Compliance Status for each regulated source within 240 days after the applicable compliance date specified in the referencing subpart, or within 60 days after the completion of the initial performance test, whichever is earlier.

(d) *Semiannual periodic reports.* You must submit your periodic reports, as specified in paragraphs (d)(1) and (2) of this section. Semiannual reports must be submitted electronically as specified in paragraph (h) of this section.

(1) *Contents.* Semiannual periodic reports must include information of all deviations. A deviation includes any failure to meet a requirement or obligation under the Uniform Standards and those reporting elements specified, to be submitted in the semiannual periodic reports in the Uniform Standards.

(2) *Due date.* Semiannual periodic reports must be submitted semiannually, no later than 60 calendar days after the end of each 6-month period. The first report must be submitted, as specified in either paragraph (d)(2)(i) or (ii) of this section, as applicable.

(i) The first report must be submitted no later than the last day of the month that includes the date 8 months after the date the source became subject to this part or 6 months after the date since the last part 60, 61 or 63 periodic report was submitted for the applicable requirement, whichever is earlier.

(ii) For sources complying with the Uniform Standards at initial startup, the first report must cover the 6 months after the Notification of Compliance Status is due. The first report must be submitted no later than the last day of the month that includes the date 8 months after the Notification of Compliance Status is due.

(e) *Annual periodic report.* You must submit your annual periodic reports, as specified in paragraphs (e)(1), (2) and (i) of this section.

(1) *Contents.* Annual periodic reports must include all information specified for annual periodic reports in the Uniform Standards.

(2) *Due date.* Annual periodic reports must be submitted annually, no later than 60 calendar days after the end of each 12-month period. The first report must be submitted, as specified in either paragraph (e)(2)(i) or (ii) of this section, as applicable.

(i) The first report must be submitted no later than the last day of the month that includes the date 14 months after the date the source became subject to this part or 12 months after the date since the last part 60, 61 or 63 periodic report was submitted for the applicable requirement, whichever is earlier.

(ii) For sources complying with the Uniform Standards at initial startup, the first report must cover the 12 months after the Notification of Compliance Status is due. The first report must be submitted no later than the last day of the month that includes the date 14 months after the Notification of Compliance Status is due.

(f) *Other notifications and reports.* You must submit the reports specified in paragraphs (f)(1) through (3), and (i) of this section, as applicable.

(1) *Other reports required in this subpart.* You must submit the reports specified in paragraphs (f)(1)(i) through (iv) of this section.

(i) Any request for a waiver for recordkeeping or reporting requirements, as specified in § 65.235.

(ii) Any request for an alternative or change in monitoring or an alternative recordkeeping method, as specified in § 65.240.

(iii) Any request for a waiver for a performance testing requirement, as specified in § 65.245.

(iv) Any request to use a different method than one specified in the Uniform Standards, as specified in § 65.250.

(2) *Other reports required in subpart I of this part.* You must submit the reports specified in paragraphs (f)(2)(i) through (ii) of this section.

(i) Notification of inspection (§ 65.388(a)).

(ii) Requests for alternate devices (§ 65.388(b)).

(3) *Other reports required in subpart M of this part.* You must submit the reports specified in paragraphs (f)(3)(i) through (xi) of this section.

(i) Notification of performance test (§ 65.884(a)).

(ii) Performance test reports (§ 65.884(b)) submitted, as specified in paragraph (k) of this section.

(iii) Notification of CEMS performance evaluation (§ 65.884(c)).

(iv) CEMS performance evaluation and monitoring plan (§ 65.884(c)).

(v) CEMS performance evaluations (§ 65.884(d)) submitted, as specified in paragraph (k) of this section.

(vi) Continuous parameter monitoring system (CPMS) monitoring plan (§ 65.884(e)).

(vii) Application to substitute a prior performance test (§ 65.884(f)).

(viii) A batch precompliance report (§ 65.884(g)).

(ix) Request for approval of an alternative monitoring parameter or use of a control device other than those listed in subpart M of this part (§ 65.884(h)).

(x) Changes in continuous monitoring system, processes or controls (§ 65.884(i)).

(xi) New operating scenarios for batch operations (§ 65.884(j)).

(g) *General report content.* All notifications and reports submitted, pursuant to the Uniform Standards, including reports that combine information from the Uniform Standards and a referencing subpart, must include the information specified in paragraphs (g)(1) through (8) of this section.

(1) Company name, address and telephone number (fax number may also be provided).

(2) The name, address and telephone number of the person to whom inquiries should be addressed, if different than the owner or operator.

(3) The address (physical location) of the reporting facility.

(4) Identification of each regulated source covered in the submission.

(5) Identification of which referencing subpart is applicable to each regulated source.

(6) Identification of which Uniform Standards are applicable to that regulated source.

(7) Summaries and groupings of the information specified in paragraphs (g)(4) through (6) of this section are permitted.

(8) The date of the report.

(h) *Electronic report submittals.* You must electronically submit all semiannual periodic reports and the 40 CFR part 65, subpart I and 40 CFR part 65, subpart J portions of the Notification of Compliance Status to the Administrator using the Compliance and Emissions Data Reporting Interface (CEDRI) on or before the applicable due date.

(i) *Non-CEDRI submitted reports.* You must submit notifications and reports not required to be submitted electronically according to the procedures in paragraphs (i)(1) through (4) of this section.

(1) Notifications and reports not required to be submitted electronically under this part must be sent to the Administrator at the appropriate EPA Regional Office, and to the delegated State authority; except if you request permission to use an alternative means of emission limitation, as provided for in § 65.260, you must submit the request to the Director of the Office of Air Quality Planning and Standards (C404–04), U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711. The EPA Regional Office may waive the requirement to receive a copy of any notification or report at its discretion.

(2) If any State requires a notice that contains all the information required in a notification or report listed in this part, you may send the appropriate EPA Regional Office a copy of the notification or report that you sent to the state to satisfy the requirements of this part for that notification or report.

(3) Wherever this subpart specifies ''postmark'' dates, submittals may be sent by methods other than the U.S. Mail (for example, by email, fax or courier) upon mutual agreement with the Administrator. Submittals must be sent on or before the specified date.

(4) If acceptable to both the Administrator and you, notifications and reports may be submitted on electronic media.

(j) *Adjustment to timing of submittals.* Adjustment to timing of submittals may be made according to the provisions specified in paragraphs (j)(1) through (4) of this section.

(1) *Alignment with title V submission.* You may submit semiannual periodic reports required by this part, on the same schedule as the title V periodic report for the facility. If you use this option, you need not obtain prior approval, but must assure no reporting gaps from the last semiannual periodic report for the relevant standards. You must clearly identify the change in reporting schedule in the first report after the change is made, filed under paragraph (d) of this section. The requirements of paragraph (g) of this section are not waived when implementing this change.

(2) *Request for adjustment.* You may arrange, by mutual agreement (which may be a standing agreement) with the Administrator, a common schedule on which reports required by this part must be submitted throughout the year, as long as the reporting period is not extended. If you wish to request a change in a time period or due date for a particular requirement, you must request the adjustment as soon as practical before the subject activity is required to take place. You must include in the request the information you consider to be useful to convince the Administrator that an adjustment is warranted. A request for a change to the semiannual or annual periodic reporting schedules need only be made once for every schedule change and not once for every semiannual or annual report submitted. Until an adjustment of a due date has been approved by the Administrator, you remain subject to the requirements of the Uniform Standards. For periodic reports submitted for each relevant standard, the allowance for a consolidated schedule applies beginning 1 year after the regulated source's compliance date for that standard.

(3) *Approval of request for adjustment.* If, in the Administrator's judgment, your request for an adjustment to a particular due date is warranted, the Administrator will approve the adjustment. The Administrator will notify you of approval or disapproval of the request for an adjustment within 15 calendar days of receiving sufficient information to evaluate the request.

(4) *Notification of delay.* If the Administrator is unable to meet a specified deadline, you will be notified of any significant delay and informed of the amended schedule.

(k) *Electronic submittal of performance test and CEMS performance evaluation data.* You must

submit performance test and CEMS performance evaluation data using EPA's Electronic Reporting Tool (ERT) according to the procedures in paragraphs (k)(1) through (4) of this section.

(1) Within 60 days after the date of completing each performance test required by Uniform Standards, you must submit performance test data electronically to EPA's Central Data Exchange (CDX) by using the ERT (see *http://www.epa.gov/ttn/chief/ert/index.html*). Only data collected using test methods compatible with ERT are subject to this requirement, to be submitted electronically to EPA's CDX. If a non-supported test method is used, you must submit the performance test report within 60 days, as specified in paragraph (i) of this section.

(2) If you claim that some of the information being submitted for performance tests is confidential business information (CBI), you must omit such CBI data from the electronic submissions and submit a complete ERT file, including information claimed to be CBI, on a compact disk or other commonly used electronic storage media (including, but not limited to, flash drives) to EPA by the due date specified in paragraph (j)(1) of this section. The electronic media must be clearly marked as CBI, with the company name, facility location, contact name and phone number, and mailed to U.S. EPA/OAQPS/CORE CBI Office, Attention: WebFIRE Administrator, MD C404–02, 4930 Old Page Rd., Durham, NC 27703.

(3) Within 60 days after the date of completing each CEMS performance evaluation test required by § 65.711(c), you must submit the relative accuracy test audit data electronically into EPA's CDX by using the ERT, as described in paragraph (k)(1) of this section.

(4) The Administrator or the delegated authority may request a report in any form suitable for the specific information, (e.g., by commonly used electronic media, such as spreadsheet, on CD or hard copy). The Administrator retains the right to require submittal of reports in paper format.

§ 65.235 How do I request a waiver for recordkeeping and reporting requirements?

You may request a waiver from recordkeeping or reporting according to the procedures in paragraphs (a) and (b) of this section. The Administrator will process the waiver according to the procedures in paragraphs (c) through (e) of this section. You remain subject to the reporting and recordkeeping requirements of the Uniform Standards until a waiver has been granted by the Administrator.

(a) *Waiver application.* You may apply for a waiver from recordkeeping or reporting requirements if your regulated source is achieving the relevant standard(s), or your source is operating under an extension of compliance under § 63.6(i) of this chapter, or a waiver of compliance under § 61.11 of this chapter, or you have requested an extension or waiver of compliance and the Administrator is still considering that request.

(b) *Extension of compliance request.* If an application for a waiver of recordkeeping or reporting is made, the application must accompany the request for an extension of compliance under § 63.6(i) of this chapter or the request for a waiver of compliance under § 61.10(b) of this chapter, any required compliance progress report or compliance status report required in the source's title V permit application, or a permit modification application or a periodic report required under this part, whichever is applicable. The application must include whatever information you consider useful to convince the Administrator that a waiver of recordkeeping or reporting is warranted.

(c) *Approval or denial of waiver.* The Administrator will approve or deny a request for a waiver of recordkeeping or reporting requirements when performing one of the following actions:

(1) Approves or denies an extension of compliance under § 63.6(i) of this chapter or a waiver of compliance under § 61.10(b) of this chapter.

(2) Makes a determination of compliance following the submission of a required semiannual periodic report.

(3) Makes a determination of suitable progress toward compliance following the submission of a compliance progress report, whichever is applicable.

(d) *Waiver conditions.* A waiver of any recordkeeping or reporting requirement granted under this section may be conditioned on other recordkeeping or reporting requirements deemed necessary by the Administrator.

(e) *Waiver cancellation.* Approval of any waiver granted under this section does not abrogate the Administrator's authority under the Clean Air Act or in any way prohibit the Administrator from later canceling the waiver. The cancellation will be made only after notice is given to you.

§ 65.240 How do I request an alternative monitoring method?

You may submit a request for approval to use alternatives (major, intermediate or minor changes to monitoring methods) to the monitoring provisions of the Uniform Standards, as specified in paragraphs (a) through (d) of this section.

(a) *Contents.* An application for alternative monitoring must contain the information specified in paragraphs (a)(1) through (3) of this section.

(1) Information justifying your request for an alternative monitoring method, such as the technical or economic infeasibility, or the impracticality of the regulated source using the required method.

(2) A description of the proposed alternative monitoring system that addresses the four elements contained in the definition of monitoring in § 65.295.

(3) A CEMS performance evaluation and monitoring plan, as specified in § 65.711(c) or a CPMS monitoring plan, as specified in § 65.712(c), as applicable.

(b) *Request due date.* You must submit the application for an alternative monitoring method, as specified in paragraphs (b)(1) through (3) of this section.

(1) You may submit the application at any time, provided that it is submitted with enough time prior to the compliance date specified in the referencing subpart to ensure a timely review by the Administrator in order to conduct the alternative monitoring method after the compliance date.

(2) If the alternative monitoring procedure will serve as the performance test method that is to be used to demonstrate compliance with a referencing subpart, the application must be submitted at least 60 days before the performance test is scheduled to begin and must meet the requirements for an alternative test method under § 65.250.

(3) For a request to make a minor change to monitoring, you must submit your request with your CEMS performance evaluation and monitoring plan required in § 65.711(c) or your CPMS monitoring plan required in § 65.712(c), as applicable. Approval of the plan will constitute approval of the minor change.

(c) *Approval or denial of request to use alternative monitoring.* The Administrator will notify you of approval or intention to deny approval of the request to use an alternative monitoring method within 30 calendar days after receipt of the original request and within 30 calendar days after receipt of any supplementary information that is submitted. Before disapproving any request to use an alternative method, the Administrator will notify the applicant of the Administrator's intention to disapprove

the request together with the information specified in paragraphs (c)(1) and (2) of this section.

(1) Notice of the information, and findings on which the intended disapproval is based.

(2) Notice of opportunity for you to present additional information to the Administrator before final action on the request. At the time the Administrator notifies you of the intention to disapprove the request, the Administrator will specify how much time you will have after being notified of the intended disapproval to submit the additional information.

(d) *Use of an alternative monitoring method.* Procedures applicable to sources that have requested an alternative monitoring method are specified in paragraphs (d)(1) through (3) of this section.

(1) You are subject to the monitoring requirements of the Uniform Standards, unless permission to use an alternative monitoring method has been granted by the Administrator. Once an alternative is approved, you must use the alternative for the emission points or regulated sources cited in the approval, and must meet the monitoring requirements of the Uniform Standards for all other emission points or regulated sources.

(2) If the Administrator approves the use of an alternative monitoring method for a regulated source, you must continue to use the alternative monitoring or method unless you receive approval from the Administrator to use another method.

(3) If the Administrator finds reasonable grounds to dispute the results obtained by an alternative monitoring method, requirement or procedure, the Administrator may require the use of a method, requirement or procedure specified in the Uniform Standards. If the results of the specified and alternative methods, requirements or procedures do not agree, the results obtained by the method, requirement or procedure specified in the Uniform Standards will prevail.

§ 65.245 How do I request a waiver for performance testing requirements?

You may request a waiver from the requirements to conduct a performance test by following the procedures specified in paragraphs (a) through (e) of this section. Unless and until a waiver of a performance testing requirement has been granted by the Administrator under this paragraph, you remain subject to the performance testing requirements in §§ 65.820 through 65.829.

(a) *Conditions of request.* You may apply for a waiver from the performance testing requirements specified if one or more of the conditions in paragraph (a)(1) through (3) apply.

(1) You are meeting the Uniform Standards on a continuous basis.

(2) You are operating under an extension of compliance, as specified in § 63.6(i) of this chapter.

(3) You have requested an extension of compliance, as specified in § 61.11 and the Administrator is still considering that request.

(b) *Contents of request.* The request must include information justifying your request for a waiver, such as the technical or economic infeasibility, or the impracticality of the regulated source performing the required test.

(c) *Timing of request.* The waiver application must be submitted, as specified in paragraph (c)(1) or (2) of this section.

(1) If you request an extension of compliance under § 63.6(i) of this chapter, the application for a waiver of an initial performance test must accompany the information required for the request for an extension of compliance, and must be submitted on the schedule in § 63.6(i) of this chapter.

(2) If you have not requested an extension of compliance or if you have requested an extension of compliance and the Administrator is still considering that request, the application for a waiver of a performance test must be submitted at least 60 days before performance testing would be required. The application may accompany a Notification of Compliance Status Report or semiannual periodic report, as specified in § 65.225(c) or (d).

(d) *Approval of request to waive performance test.* The Administrator will approve or deny a request for a waiver of a performance test made under paragraph (a) of this section by completing any one of the actions specified in paragraphs (d)(1) through (4) of this section.

(1) Approves or denies an extension of compliance under § 63.6(i)(8) or under § 63.11.

(2) Approves or disapproves a performance test plan under § 65.820(c).

(3) Makes a determination of compliance following the submission of a required compliance status report or periodic report.

(4) Makes a determination of suitable progress towards compliance following the submission of a compliance progress report.

(e) *Waiver cancellation.* Approval of any waiver granted under this section does not abrogate the Administrator's authority under the Clean Air Act or in any way prohibit the Administrator from later canceling the waiver. The cancellation will be made only after notice is given to you.

§ 65.250 How do I request to use an alternative test method?

You may submit a request for approval to use an alternative test method (i.e., major, intermediate or minor change to a test method, or an EPA test method other than one in the Uniform Standards), as described in paragraphs (a) through (d) of this section.

(a) *Contents of request.* Except as specified in paragraph (a)(3) of this section, you must include the information specified in paragraphs (a)(1) and (2) of this section in the request for approval to use an alternative test method.

(1) A justification for using the proposed alternative method instead of using the method specified in the Uniform Standards.

(2) Results of applying Method 301 at 40 CFR part 63, appendix A of this part to validate the alternative test method. This may include the use of only specific procedures of EPA Method 301, if use of such procedures are sufficient to validate the alternative test method.

(3) For minor changes to a test method and for EPA test methods other than those specified in the Uniform Standards, Method 301 at 40 CFR part 63, appendix A of this part is not required to validate the test method.

(b) *Timing of request.* You must submit the request to use an alternative test method at least 60 days before the performance test is scheduled to begin. However, you may submit the request well in advance of the date 60 days before the performance test is scheduled to begin to ensure a timely review by the Administrator in order for you to meet the performance test date specified in the referencing subpart. This request may be submitted as part of the performance test plan required by § 65.820.

(c) *Review of alternative test methods.* The Administrator will determine whether your validation of the proposed alternative test method is adequate and issue an approval or disapproval. If the request for approval of an alternative test method is submitted with the performance test plan, approval of the performance test plan will indicate approval of the alternative test method. The procedure for test plan approval is specified in § 65.820.

(d) *Use of alternative test method.* You must follow the provisions of paragraphs (d)(1) through (4) regarding the use of alternative test methods.

(1) If you have not received notification of approval/disapproval within 45 days after submission of the request to use an alternative method and the request satisfies the requirements in paragraphs (a) and (b) of this section, you may conduct the performance test using the alternative method.

(2) If you use an alternative test method for a regulated source during a required performance test, you must continue to use the alternative test method for subsequent performance tests at that regulated source until you receive approval from the Administrator to use another test method, as allowed under this section.

(3) If the Administrator finds reasonable grounds to dispute the results obtained by an alternative test method for the purposes of demonstrating compliance with a relevant standard, the Administrator may require the use of a test method specified in the Uniform Standards.

(4) Neither the validation and approval process nor the failure to validate an alternative test method abrogates your responsibility to comply with the requirements of the Uniform Standards.

§ 65.260 What are the procedures for approval of alternative means of emission limitation?

(a) *General procedures.* You may request a determination of equivalence for an alternative means of emission limitation to the requirements of design, equipment, work practice or operational standards of the Uniform Standards. If, in the judgment of the Administrator, an alternative means of emission limitation will achieve a reduction in regulated material emissions at least equivalent to the reduction in emissions from that source achieved under any design, equipment, work practice or operational standards (but not performance standards) in the Uniform Standards, the Administrator will publish in the **Federal Register**, a notice permitting the use of the alternative means for purposes of compliance with that requirement. Such notice will restrict the permission to the stationary source(s) or category(ies) of sources from which the alternative emission standard will achieve equivalent emission reductions.

(1) The notice may provide permission on the condition that the alternative means of emission limitation must include requirements to assure the proper operation and maintenance of equipment and practices that would be required for compliance with the alternative emission standard, including appropriate quality assurance and quality control requirements that are deemed necessary.

(2) Any such notice will be published only after public notice and an opportunity for a hearing.

(3) A manufacturer of control devices or monitoring equipment may request an alternative means of emission limitation approval for their product.

(b) *Contents of submittal.* You must include the information specified in paragraphs (b)(1) through (4) of this section in your request for alternative means of emission limitation, as applicable.

(1) In order to obtain approval, any person seeking permission to use an alternative means of emission limitation under this section must collect, verify and submit to the Administrator information showing that the alternative means achieves equivalent emission reductions. If you seek permission to use an alternative means of emission limitation and you have not previously performed testing, you must also submit the proposed performance test plan required in § 65.820(b). If you seek permission to use an alternative means of emission limitation, based on previously performed testing, you must submit the results of that testing, a description of the procedures followed in testing or monitoring and a description of pertinent conditions during testing or monitoring.

(2) If you request an alternative means of emission limitation, you must submit a description of the proposed testing, monitoring, recordkeeping and reporting that you will use and the proposed basis for demonstrating compliance.

(3) Any testing or monitoring conducted to request permission to use an alternative emission standard must be appropriately quality assured and quality controlled, as specified in § 65.820(b), as applicable.

(4) If you request the use of an alternate device for a fitting on a floating roof, as described in § 65.315(e), you must submit an application, including emissions test results and an analysis demonstrating that the alternate device has an emission factor that is less than or equal to the emission factor for the device specified in § 65.315(a). The test results must include all documentation required by the applicable test methods and documentation of monitoring during the performance test of any operating parameters on which you establish limits. The tests must be conducted using full-size or scale-model storage vessels that accurately collect and measure all regulated material emissions using a given control technique, and that accurately simulate wind and account for other emission variables, such as temperature and barometric pressure, or an engineering analysis that the Administrator determines is an accurate method of determining equivalence.

(c) *Compliance.* If the Administrator makes a determination that a means of emission limitation is a permissible alternative to the requirements of design, equipment, work practice or operational standards of the Uniform Standards, you must either comply with the alternative or comply with the requirements of the Uniform Standards, as applicable.

§ 65.265 What methods are incorporated by reference for the Uniform Standards?

The materials listed in this section are incorporated by reference in the corresponding sections of the Uniform Standards. These incorporations by reference were approved by the Director of the **Federal Register** in accordance with 5 U.S.C. 552(a) and 1 CFR part 51. These materials are incorporated as they exist on the date of the approval, and notice of any change in these materials will be published in the **Federal Register**. The materials are available for purchase at the corresponding addresses noted in this section, and all are available for inspection at the National Archives and Records Administration (NARA), at the Air and Radiation Docket and Information Center, U.S. EPA, EPA West Building, Room 3334, 1301 Constitution Ave. NW., Washington, DC, and at the EPA Library, 109 T.W. Alexander Drive, Room C261, U.S. EPA, Research Triangle Park, North Carolina. For information on the availability of this material at NARA, call (202) 741–6030, or go to: *http://www.archives.gov/federal_register/code_of_federal_regulations/ibr_locations.html.*

(a) The following materials are available for purchase from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22161, (703) 605–6000 or (800) 553–6847; or for purchase from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402, (202) 512–1800.

(1) Office of Air Quality Planning and Standards (OAQPS), Fabric Filter Bag Leak Detection Guidance, EPA–454/R–98–015, September 1997 (EPA–454/R–98–015).

(2) Emissions Inventory Improvement Program, Volume II: Chapter 16, Methods for Estimating Air Emissions from Chemical Manufacturing Facilities, August 2007, Final, (EPA EIIP Volume II: Chapter 16) *http://www.epa.gov/*

ttnchie1/eiip/techreport/volume02/index.html.

(3) Test Method for Vapor Pressure of Reactive Organic Compounds in Heavy Crude Oil Using Gas Chromatography, *http://yosemite.epa.gov/R9/R9Testmethod.nsf*.

(b) The following materials are available for purchase from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, Pennsylvania 19428–2959, (610) 832–9585, *http://www.astm.org*.

(1) ASTM D6420–99(2010), Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry.

(2) ASTM D1946–90(2006), Standard Practice for Analysis of Reformed Gas by Gas Chromatography.

(3) ASTM D4809–09a, Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method).

(4) ASTM D2879–95(2011), Standard Test Method for Hydrocarbon Types in Low Olefinic Gasoline by Mass Spectrometry.

(c) The following materials are available for purchase from ASME, Information Central Orders/Inquiries, P.O. Box 2300, Fairfield, New Jersey 07007–2300, (800) 843–2763, *http://www.asme.org*.

(2) ASME B31.3–2010, Process Piping.

(d) The following materials are available for purchase from the National Technical Information Service (NTIS), Alexandria, Virginia 22312, (800) 553–6847, *http://www.ntis.gov*.

(1) Flammability Characteristics of Combustible Gases and Vapors, Zabetakis, M.G., U.S. Bureau of Mines, Bulletin 627, 1965.

(2) [Reserved].

(e) The following materials are available for purchase from the American Petroleum Institute (API), 1220 L Street NW., Washington, DC 20005–4070, (202) 682–8000, *http://www.api.org*.

(1) Evaporative Loss From External Floating Roof Tanks, API MPMS Chapter 19.2, September 1, 2003.

(2) [Reserved].

§ 65.270 How do I determine what regulated sources are in regulated material service?

If you are subject to a uniform standard that includes requirements for regulated sources ''in regulated material service,'' you must determine if regulated sources or equipment are in regulated material service using either paragraph (a) or (b) of this section, as applicable.

(a) If the referencing subpart includes a procedure or definition of ''in regulated material service,'' you must use the procedure or definition of ''in regulated material service'' in the referencing subpart.

(b) If the referencing subpart does not include a procedure or definition of ''in regulated material service,'' you must use the procedures specified in paragraphs (b)(1) through (3) of this section.

(1) Regulated sources or equipment that can reasonably be expected to be in regulated material service are presumed to be in regulated material service unless you demonstrate that the regulated sources or equipment are not in regulated material service.

(2) Except as provided in paragraph (b)(1) and (3) of this section, you must use Method 18 of 40 CFR part 60, appendix A–6 and either of the methods specified in paragraphs (b)(2)(i) or (ii) of this section to demonstrate that regulated sources or equipment are not in regulated material service.

(i) Determine the weight percent regulated material content of the process fluid that is contained in or contacts the regulated source as the arithmetic sum of the weight percent concentration of each compound defined as regulated material. Demonstrate that the regulated material concentration is less than 5 weight percent on an annual average basis.

(ii) Demonstrate that the non-regulated material content exceeds 95 percent by weight on an annual average basis.

(3) You may use good engineering judgment rather than the procedures in paragraph (b)(1) or (2) of this section to determine if regulated sources or equipment are not in regulated material service. However, when you and the Administrator do not agree on whether the regulated sources or equipment are in regulated material service, you must use the procedures in paragraph (b)(2) of this section to resolve the disagreement.

§ 65.275 What authorities are not delegated to the states?

In delegating implementation and enforcement authority to a state under sections 111(c) and 112(l) of the Clean Air Act, the following authorities are retained by the Administrator and not transferred to a state:

(a) In § 65.235, request for recordkeeping and reporting waiver.

(b) In § 65.240, major changes to monitoring methods.

(c) In § 65.250, major changes to test methods or a different EPA method than one specified in the Uniform Standards.

(d) In 65.260, alternative means of emissions limitation.

§ 65.280 How do I determine compliance with periodic requirements?

Except as specified in paragraph (c) of this section, if you are subject to a requirement in the Uniform Standards to complete a particular task on a periodic basis, you must comply, as described in paragraphs (a) and (b) of this section.

(a) *Periods of time.* All terms in the Uniform Standards that define a period of time for completion of required tasks (*e.g.,* daily, weekly, monthly, quarterly, annually), refer to the standard calendar periods.

(b) *Reasonable intervals.* You may comply with such periodic requirements by completing the required task any time within the standard calendar period, provided there is a reasonable interval between completion of two instances of the same task. Reasonable intervals are described in paragraphs (b)(1) through (8) of this section.

(1) Tasks that you are required to complete weekly must be separated by at least 3 calendar days.

(2) Tasks that you are required to complete monthly must be separated by at least 14 calendar days.

(3) Tasks that you are required to complete bimonthly (*i.e.,* every 2 calendar months) must be separated by at least 20 calendar days.

(4) Tasks that you are required to complete quarterly must be separated by at least 30 calendar days.

(5) Tasks that you are required to complete three times per year must be separated by at least 40 calendar days.

(6) Tasks that you are required to complete semiannually (*i.e.,* once every 2 quarters or twice per year) must be separated by at least 60 calendar days.

(7) Tasks that you are required to complete annually must be separated by at least 120 calendar days.

(8) Tasks that you are required to complete biennially (*i.e.,* once every 2 calendar years) must be completed every other calendar year.

(c) *Exceptions.* (1) Paragraphs (a) and (b) of this section do not apply to reports that you are required to submit under the General Provisions applicable to the referencing subpart (*e.g.,* subpart A parts 60, 61 or 63).

(2) If the paragraph in the Uniform Standards that imposes a periodic requirement specifies a different schedule for complying with that requirement, you must follow that

schedule instead of the requirements in paragraphs (a) and (b) of this section.

(3) Time periods may be changed by mutual agreement between you and the Administrator, as specified in § 65.225(j). For example, a period could begin on the compliance date or another date, rather than on the first day of the standard calendar period. For each time period that is changed by agreement, the revised period applies until it is changed. A new request is not necessary for each recurring period.

(4) Nothing in paragraphs (a) and (b) of this section shall be construed as prohibiting you from conducting a periodic task at a more frequent interval than required.

§ 65.295 What definitions apply to the Uniform Standards?

All terms used in the Uniform Standards have the meaning given them in the Clean Air Act, the referencing subpart and in this section. The definition in the referencing subpart takes precedence.

Alternative test method means any method of sampling and analyzing for an air pollutant other than a test method specified in the Uniform Standards. An alternative test method can include other EPA test methods that are not specified by the Uniform Standards; methods other than EPA test methods; or changes to test methods (*i.e.,* minor, intermediate or major changes to test methods). For methods other than EPA standard test methods and changes other than minor changes to test methods, you must demonstrate to the Administrator's satisfaction using Method 301 at 40 CFR part 63, appendix A, that an alternative test method produces results adequate for use in place of a test method specified in the Uniform Standards.

Atmospheric storage vessel means any storage vessel that is not a pressure vessel.

Automatic bleeder vent (or vacuum breaker vent) means a device used to equalize the pressure of the vapor space across the deck as the floating roof is either being landed on or floated off of its legs or other support devices. Typically, the device consists of a well in the deck with a cover. A guided leg is attached to the underside of the cover which comes in contact with the floor when the storage vessel is being emptied, just prior to the point that the floating roof lands on its supports. When in contact with the bottom of the storage vessel, the guided leg mechanically lifts the cover off the well. Alternatively, the device may be activated by increased pressure (or vacuum) in the vapor space below the landed floated roof that is created by changes in the liquid level while the floating roof is landed.

Barge means any vessel that transports regulated material liquids in bulk on inland waterways or at sea.

Batch emission episode means a discrete venting episode that may be associated with a single unit operation. A unit operation may have more than one batch emission episode. For example, a displacement of vapor resulting from the charging of a vessel with regulated material will result in a discrete emission episode that will last through the duration of the charge and will have an average flow rate equal to the rate of the charge. If the vessel is then heated, there will also be another discrete emission episode resulting from the expulsion of expanded vapor. Both emission episodes may occur in the same vessel or unit operation. There are possibly other emission episodes that may occur from the vessel or other process equipment, depending on process operations.

Batch operation means a noncontinuous operation involving intermittent or discontinuous feed into process vessels and, in general, involves the emptying of the process vessels after the operation ceases and prior to beginning a new operation. Addition of raw material and withdrawal of product do not occur simultaneously in a batch operation.

Boiler means any enclosed combustion device that extracts useful energy in the form of steam and is not an incinerator or a process heater.

Bottoms receiver means a tank that collects bottoms from continuous distillation before the stream is sent for storage or for further downstream processing. A rundown tank is an example of a bottoms receiver.

Breakthrough means the time when the level of regulated material detected is at the highest concentration allowed to be discharged from an adsorber system, as determined by the referencing subpart.

By compound means by individual stream components, not carbon equivalents.

Cargo tank means a liquid-carrying tank permanently attached and forming an integral part of a motor vehicle or truck trailer. This term also refers to the entire cargo tank motor vehicle or trailer. Vacuum trucks used exclusively for maintenance or spill response are not considered cargo tanks.

Car-seal means a seal that is placed on a device that is used to change the position of a valve (*e.g.,* from opened to closed) in such a way that the position of the valve cannot be changed without breaking the seal.

Catalytic oxidizer means a thermal oxidizer where the gas stream, after passing through the enclosed combustion chamber, also passes through a catalyst bed. The catalyst has the effect of increasing the oxidation reaction rate, enabling conversion at lower reaction temperatures than in thermal oxidizers.

Closed-loop system means an enclosed system that returns process fluid to the process and is not vented directly to the atmosphere.

Closed-purge system means a system or combination of systems and portable containers to capture purged liquids. Containers for purged liquids must be covered or closed when not being filled or emptied.

Closed vent system means a system that is not open to the atmosphere and is composed of piping, ductwork, connections and, if necessary, flow inducing devices that transport gas or vapor from an emission point to a control device.

Combustion device means an individual unit of equipment, such as an incinerator, process heater or boiler, used for the combustion of organic emissions.

Connector means flanged, screwed or other joined fittings used to connect pipelines, a pipeline and a process vessel, or a pipeline and a piece of equipment, or that close an opening in a pipe that could be connected to another pipe. A common *connector* is a flange. Joined fittings welded completely around the circumference of the interface are not considered *connectors*.

Container means a portable unit in which a regulated material is stored, transported, treated or otherwise handled. Examples of containers include, but are not limited to, drums, dumpsters, roll-off boxes and portable cargo containers known as ''portable tanks'' or ''totes.'' Transport vehicles and barges are not containers.

Continuous emission monitoring system (CEMS) means the total equipment that may be required to meet the data acquisition and availability requirements of this subpart, used to sample, condition (if applicable), analyze and provide a record of emissions.

Continuous operation means any operation that is not a batch operation.

Continuous parameter monitoring system (CPMS) means the total equipment that may be required to meet the data acquisition and availability requirements of the Uniform Standards, used to sample, condition (if

applicable), analyze and provide a record of process or control system parameters.

Continuous record means documentation, either in hard copy or computer readable form, of data values measured at least once every 15 minutes and recorded at the frequency specified in § 65.860(a).

Control device means, with the exceptions noted below, a combustion device, recovery device, recapture device or any combination of these devices used to comply with this subpart or a referencing subpart. Process condensers or fuel gas systems are not considered to be control devices.

Control system means the combination of the closed vent system and the control devices used to collect and control vapors or gases from a regulated source.

Corrective action analysis and/or Corrective action plan means a description of all reasonable interim and long-term measures, if any, that are available, and an explanation of why the selected corrective action is the best alternative, including, but not limited to, any consideration of cost effectiveness.

Day means a calendar day.

Deck cover means a device that covers an opening in a floating roof deck. Some deck covers move horizontally relative to the deck (*i.e.,* a sliding cover).

Double block and bleed system means two block valves connected in series with a bleed valve or line that can vent the line between the two block valves.

Ductwork means a conveyance system such as those commonly used for heating and ventilation systems. It is often made of sheet metal and often has sections connected by screws or crimping. Hard-piping is not ductwork.

Empty or *emptying* means the partial or complete removal of stored liquid from a storage vessel. Storage vessels that contain liquid only as wall or bottom clingage, or in pools due to bottom irregularities, are considered completely empty.

Equipment means each pump, compressor, agitator, pressure relief device (PRD), sampling connection system, open-ended valve or line, valve, connector and instrumentation system that contains or contacts regulated material; and any control devices or systems used to comply with subpart J of this part. Equipment does not include process equipment, monitoring equipment, vapor collection equipment or testing equipment.

External floating roof or *EFR* means a floating roof located in a storage vessel without a fixed roof.

Fill or *filling* means the introduction of liquid into a storage vessel or container, but not necessarily to capacity.

First attempt at repair means to take action for the purpose of stopping or reducing leakage of regulated material to the atmosphere. A *first attempt at repair* includes monitoring, as specified in § 65.431(a) and (b) to verify that the leak is repaired, unless you determine by other means that the leak is not repaired.

Fittings means any cover or other device to close an opening through a fixed roof or through the deck of a floating roof for automatic bleeder vents (vacuum breaker vents), rim space vents, leg sleeves, deck drains, access hatches, gauge float wells, sample wells, columns, guidepoles, ladders, conservation vents, PRD or any other opening on the fixed roof or floating roof deck.

Fixed roof storage vessel means a vessel with roof that is mounted (*i.e.,* permanently affixed) on a storage vessel and that does not move with fluctuations in stored liquid level. All horizontal tanks are classified as fixed roof storage vessels.

Flexible enclosure device means a seal made of an elastomeric fabric (or other material) which completely encloses a slotted guidepole or ladder and eliminates the vapor emission pathway from inside the storage vessel through the guidepole slots or ladder slots to the outside air.

Flexible fabric sleeve seal means a seal made of an elastomeric fabric (or other material) which covers an opening in a floating roof deck, and which allows the penetration of a fixed roof support column. The seal is attached to the rim of the deck opening and extends to the outer surface of the column. The seal is draped (but does not contact the stored liquid) to allow the horizontal movement of the deck relative to the column.

Floating roof means a roof that floats on the surface of the liquid in a storage vessel. A floating roof substantially covers the stored liquid surface (but is not necessarily in contact with the entire surface), and is comprised of a deck, a rim seal and miscellaneous deck fittings.

Flow indicator means a device that indicates whether gas flow is or whether the valve position would allow gas flow to be present in a line.

Fuel gas means gases that are combusted to derive useful work or heat.

Fuel gas system means the offsite and onsite piping and flow and pressure control system that gathers gaseous streams generated by onsite operations, may blend them with other sources of gas and transports the gaseous streams for use as fuel gas in combustion devices or in-process combustion equipment, such as furnaces and gas turbines, either singly or in combination. Piping that routes emissions to boilers or process heaters as the primary fuel or introduced with the primary fuel are considered fuel gas systems.

Halogenated vent stream or *halogenated stream* means a stream determined to have a mass rate of halogen atoms of 0.45 kilograms per hour or greater, determined by the procedures presented in § 65.702(c).

Hard-piping means pipe or tubing that is manufactured and properly installed using good engineering judgment and standards, such as ASME B31.3–2010, Process Piping (incorporated by reference, see § 65.265).

In gas and vapor service means that a piece of equipment in regulated material service contains a gas or vapor at operating conditions.

In heavy liquid service means that a piece of equipment in regulated material service is not in gas and vapor service or in light liquid service.

In light liquid service means that a piece of equipment in regulated material service contains a liquid that meets the following conditions: (1) The vapor pressure of one or more of the organic compounds is greater than 0.3 kilopascals at 20 degrees Celsius; (2) The total concentration of the pure organic compounds constituents having a vapor pressure greater than 0.3 kilopascals at 20 degrees Celsius is equal to or greater than 20 percent by weight of the total process stream; (3) The fluid is a liquid at operating conditions. (Note to definition of ''in light liquid service'': Vapor pressures may be determined by standard reference texts or ASTM D–2879(2011), Standard Test Method for Hydrocarbon Types in Low Olefinic Gasoline by Mass Spectrometry (incorporated by reference, see § 65.265).

In liquid service means that a piece of equipment in regulated material service is not in gas and vapor service.

In regulated material service means, unless specified otherwise in the referencing subpart, a regulated source or portion of a regulated source (*e.g.,* a piece of equipment) that either contains or contacts a fluid (liquid or gas) that is at least 5 percent by weight of regulated material (as defined in the referencing subpart), as determined according to the provisions of § 65.270. The provisions of § 65.270 also specify how to determine that a regulated source or portion of a

regulated source is not *in regulated material service.*

In vacuum service means that equipment, a closed vent system, fuel gas system or storage vessel is operating at an internal pressure that is at least 0.7 pounds per square inch gauge (psig) below ambient pressure.

Initial fill means the first introduction of liquid into a storage vessel that is either newly constructed or has not contained any regulated material for a year or longer.

Initial startup means, for new sources, the first time the source begins production. For additions or changes not defined as a new source by the referencing subpart, *initial startup* means the first time additional or changed equipment is put into operation. *Initial startup* does not include operation solely for testing of equipment. Initial startup does not include subsequent startup of process units following malfunction or process unit shutdowns. Except for equipment leaks, *initial startup* also does not include subsequent startups (of process units following changes in product for flexible operation units or following recharging of equipment in batch operations).

In-situ sampling systems means non-extractive samplers or in-line samplers.

Instrumentation system means a group of equipment used to condition and convey a sample of the process fluid to analyzers and instruments for the purpose of determining process operating conditions (*e.g.,* composition, pressure, flow, etc.). Valves and connectors are the predominant type of equipment used in *instrumentation systems;* however, other types of equipment may also be included in these systems. Only valves nominally 0.5 inches and smaller, and connectors nominally 0.75 inches and smaller in diameter are considered instrumentation systems. Valves greater than nominally 0.5 inches and connectors greater than nominally 0.75 inches associated with *instrumentation systems* are not considered part of *instrumentation systems* and must be monitored individually.

Intermediate change to monitoring means a modification to federally required monitoring involving ''proven technology'' (generally accepted by the scientific community as equivalent or better) that is applied on a site-specific basis and that may have the potential to decrease the stringency of the associated emission limitation or standard. Though site-specific, an intermediate change may set a national precedent for a source category and may ultimately result in a revision to the federally required monitoring. Examples of intermediate changes to monitoring include, but are not limited to:

(1) Use of a CEMS in lieu of a parameter monitoring approach;

(2) Decreased frequency for non-continuous parameter monitoring or physical inspections;

(3) Changes to quality control requirements for parameter monitoring; and

(4) Use of an electronic data reduction system in lieu of manual data reduction.

Intermediate change to test method means a within-method modification to a federally enforceable test method involving ''proven technology'' (generally accepted by the scientific community as equivalent or better) that is applied on a site-specific basis and that may have the potential to decrease the stringency of the associated emission limitation or standard. Though site-specific, an intermediate change may set a national precedent for a source category and may ultimately result in a revision to the federally enforceable test method. In order to be approved, an intermediate change must be validated according to EPA Method 301 (40 CFR part 63, appendix A) to demonstrate that it provides equal or improved accuracy and precision. Examples of intermediate changes to a test method include, but are not limited to:

(1) Modifications to a test method's sampling procedure, including substitution of sampling equipment that has been demonstrated for a particular sample matrix and use of a different impinger absorbing solution;

(2) Changes in sample recovery procedures and analytical techniques, such as changes to sample holding times and use of a different analytical finish with proven capability for the analyte of interest; and

(3) ''Combining'' a federally required method with another proven method for application to processes emitting multiple pollutants.

Internal floating roof or *IFR* means a floating roof located in a storage vessel with a fixed roof. An EFR located in a storage vessel to which a fixed roof has been added is considered to be an *internal floating roof.*

Internal guidepole sleeve means a cylindrical device that fits on the inside of a slotted guidepole and blocks the vapor emission pathway from the interior of the guidepole through the guidepole slots to the outside air.

Liquid-mounted seal means a resilient or liquid-filled rim seal designed to contact the stored liquid.

Liquids dripping means any visible leakage from the seal including dripping, spraying, misting, clouding and ice formation. Indications of *liquids dripping* include puddling or new stains that are indicative of an existing evaporated drip.

Major change to monitoring means a modification to federally required monitoring that uses ''unproven technology or procedures'' (not generally accepted by the scientific community) or is an entirely new method (sometimes necessary when the required monitoring is unsuitable). A major change to monitoring may be site-specific or may apply to one or more source categories and will almost always set a national precedent. Examples of major changes to monitoring include, but are not limited to:

(1) Use of a new monitoring approach developed to apply to a control technology not contemplated in the applicable regulation;

(2) Use of a predictive emission monitoring system (PEMS) in place of a required CEMS;

(3) Use of alternative calibration procedures that do not involve calibration gases or test cells;

(4) Use of an analytical technology that differs from that specified by a performance specification;

(5) Decreased monitoring frequency for a CEMS, continuous opacity monitoring system, PEMS or CPMS;

(6) Decreased monitoring frequency for a leak detection and repair program; and

(7) Use of alternative averaging times for reporting purposes.

Major change to test method means a modification to a federally enforceable test method that uses ''unproven technology or procedures'' (not generally accepted by the scientific community) or is an entirely new method (sometimes necessary when the required test method is unsuitable). A major change to a test method may be site-specific or may apply to one or more sources or source categories, and will almost always set a national precedent. In order to be approved, a major change must be validated according to EPA Method 301 (40 CFR part 63, appendix A). Examples of major changes to a test method include, but are not limited to:

(1) Use of an unproven analytical finish;

(2) Use of a method developed to fill a test method gap;

(3) Use of a new test method developed to apply to a control technology not contemplated in the applicable regulation; and

(4) Combining two or more sampling/analytical methods (at least one

unproven) into one for application to processes emitting multiple pollutants.

Maximum representative operating conditions means process operating conditions that result in the most challenging condition for the control device. The most challenging condition for the control device may include, but is not limited to, the highest hazardous air pollutant (HAP) mass loading rate to the control device or the highest HAP mass loading rate of constituents that approach the limits of solubility for scrubbing media.

Maximum true vapor pressure or *MTVP* means the equilibrium partial pressure exerted by the total regulated material in the stored or transferred liquid at the temperature equal to the highest calendar-month average of the liquid storage or transfer temperature for liquids stored or transferred above or below the ambient temperature or at the local maximum monthly average temperature, as reported by the National Weather Service, for liquids stored or transferred at the ambient temperature, as determined using methods specified in § 65.306.

Mechanical shoe seal or *metallic shoe seal* means a rim seal consisting of a band of metal (or other suitable material) as the sliding contact with the wall of the storage vessel, and a fabric seal to close the annular space between the band and the rim of the floating roof deck. The band is typically formed as a series of sheets (shoes) that are overlapped or joined together to form a ring. The sheets are held vertically against the wall of the storage vessel by springs, weighted levers or other mechanisms and are connected to the floating roof by braces or other means. The lower end of the band extends into the stored liquid.

Minor change to monitoring means:

(1) A modification to federally required monitoring that:

(i) Does not decrease the stringency of the compliance and enforcement measures for the relevant standard;

(ii) Has no national significance (*e.g.,* does not affect implementation of the applicable regulation for other regulated sources, does not set a national precedent and individually does not result in a revision to the monitoring requirements); and

(iii) Is site-specific, made to reflect or accommodate the operational characteristics, physical constraints or safety concerns of a regulated source.

(2) Examples of minor changes to monitoring include, but are not limited to:

(i) Modifications to a sampling procedure, such as use of an improved sample conditioning system to reduce maintenance requirements;

(ii) Increased monitoring frequency; and

(iii) Modification of the environmental shelter to moderate temperature fluctuation and, thus, protect the analytical instrumentation.

Minor change to test method means:

(1) A modification to a federally enforceable test method that:

(i) Does not decrease the stringency of the emission limitation or standard;

(ii) Has no national significance (*e.g.,* does not affect implementation of the applicable regulation for other regulated sources, does not set a national precedent and individually does not result in a revision to the test method); and

(iii) Is site-specific, made to reflect or accommodate the operational characteristics, physical constraints or safety concerns of a regulated source.

(2) Examples of minor changes to a test method include, but are not limited to:

(i) Field adjustments in a test method's sampling procedure, such as a modified sampling traverse, or location to avoid interference from an obstruction in the stack, increasing the sampling time or volume, use of additional impingers for a high moisture situation, accepting particulate emission results for a test run that was conducted with a lower-than-specified temperature, substitution of a material in the sampling train that has been demonstrated to be more inert for the sample matrix; and

(ii) Changes in recovery and analytical techniques, such as a change in quality control/quality assurance requirements needed to adjust for analysis of a certain sample matrix.

Monitoring means the collection and use of measurement data or other information to control the operation of a process or pollution control device or to verify a work practice standard relative to assuring compliance with applicable requirements. Monitoring is composed of four elements:

(1) Indicator(s) of performance—the parameter or parameters you measure or observe for demonstrating proper operation of the pollution control measures or compliance with the applicable emissions limitation or standard. Indicators of performance may include direct or predicted emissions measurements (including opacity), operational parametric values that correspond to process or control device (and capture system) efficiencies or emissions rates and recorded findings of inspection of work practice activities, materials tracking or design characteristics. Indicators may be expressed as a single maximum or minimum value, a function of process variables (for example, within a range of pressure drops), a particular operational or work practice status (for example, a damper position, completion of a waste recovery task, materials tracking) or an interdependency between two or among more than two variables.

(2) Measurement techniques—the means by which you gather and record information of or about the indicators of performance. The components of the measurement technique include the detector type, location and installation specifications, inspection procedures, and quality assurance and quality control measures. Examples of measurement techniques include CEMS, continuous opacity monitoring systems, CPMS, and manual inspections that include making records of process conditions or work practices.

(3) Monitoring frequency—the number of times you obtain and record monitoring data over a specified time interval. Examples of monitoring frequencies include at least four points equally paced for each hour for continuous emissions or parametric monitoring systems, at least every 10 seconds for continuous opacity monitoring systems and at least once per operating day (or week, month, etc.) for work practice or design inspections.

(4) Averaging time—the period over which you average and use data to verify proper operation of the pollution control approach or compliance with the emissions limitation or standard. Examples of averaging time include a 3-hour average in units of the emissions limitation, a 30-day rolling average emissions value, a daily average of a control device operational parametric range and an instantaneous alarm.

Non-repairable means that it is technically infeasible to repair a piece of equipment from which a leak has been detected without a process unit shutdown.

Nonstandard batch means a batch process that is operated outside of the range of operating conditions that are documented in an existing operating scenario, but is still a reasonably anticipated event. For example, a nonstandard batch occurs when additional processing or processing at different operating conditions must be conducted to produce a product that is normally produced under the conditions described by the standard batch. A nonstandard batch may be necessary, as a result of a malfunction, but it is not itself a malfunction.

Open-ended valve or line means any valve, except relief valves, having one

side of the valve seat in contact with process fluid and one side open to atmosphere, either directly or through any length of open piping. An *open-ended valve or line* with a cap, blind flange, plug or second valve on the side that would be otherwise open to the atmosphere is still considered an *open-ended valve or line.*

Operating block means a period of time that is equal to the time from the beginning to end of batch process operations within a process.

Optical gas imaging instrument means an instrument capable of producing an image that makes visible emissions that otherwise may be invisible to the naked eye.

Owner or operator means any person who owns, leases, operates, controls or supervises a regulated source or a stationary source of which a regulated source is a part.

Performance test means the collection of data resulting from the execution of a test method (usually three emission test runs) used to demonstrate compliance with a relevant emission limit, as specified in the performance test section of 40 CFR part 65, subpart M or in the referencing subpart.

Pole float means a float located inside a guidepole that floats on the surface of the stored liquid. The rim of the float has a wiper or seal that extends to the inner surface of the pole.

Pole sleeve means a device that extends from either the cover or the rim of an opening in a floating roof deck to the outer surface of a pole that passes through the opening. The sleeve extends into the stored liquid.

Pole wiper means a seal that extends from either the cover or the rim of an opening in a floating roof deck to the outer surface of a pole that passes through the opening.

Polymerizing monomer means a compound that may form polymer buildup in pump mechanical seals resulting in rapid mechanical seal failure.

Pressure release means the emission of materials resulting from the system pressure being greater than the set pressure of the PRD. This release may be one release or a series of releases over a short time period.

Pressure relief device (PRD) means a safety device used to prevent operating pressures from exceeding the maximum allowable working pressure of the process component. Examples of *pressure relief devices* are a spring-loaded pressure relief valve and a rupture disk. Except for devices used to comply with the vapor balancing requirements in § 65.320(c), devices that are actuated either by a pressure of less than or equal to 2.5 psig or by a vacuum are not *pressure relief devices.*

Pressure vessel means a storage vessel that is used to store liquids or gases and is designed not to vent to the atmosphere as a result of compression of the vapor headspace in the pressure vessel during filling of the pressure vessel to its design capacity.

Primary fuel means the fuel that provides the principal heat input to a combustion device. To be considered primary, the fuel must be able to sustain operation without the addition of other fuels.

Process condenser means a condenser whose primary purpose is to recover material as an integral part of a regulated batch process. All condensers recovering condensate from a regulated batch process at or above the boiling point or all condensers in line prior to a vacuum source, are considered process condensers. Typically, a primary condenser or condensers in series, are considered to be integral to the batch regulated process if they are capable of and normally used for the purpose of recovering chemicals for fuel value (*i.e.,* net positive heating value), use, reuse or for sale for fuel value, use or reuse. This definition does not apply to a condenser that is used to remove materials that would hinder performance of a downstream recovery device as follows:

(1) To remove water vapor that would cause icing in a downstream condenser.

(2) To remove water vapor that would negatively affect the adsorption capacity of carbon in a downstream carbon adsorber.

(3) To remove high molecular weight organic compounds or other organic compounds that would be difficult to remove during regeneration of a downstream carbon adsorber.

Process heater means an enclosed combustion device that transfers heat liberated by burning fuel directly to process streams or to heat transfer liquids other than water. A process heater may, as a secondary function, heat water in unfired heat recovery sections.

Process tank means a tank or other vessel that is used within a process to collect material discharged from a feedstock storage vessel or component within the process before the material is transferred to other components within the process or a product storage vessel. Examples of process tanks include surge control vessels, bottoms receivers and weigh tanks. In addition, all vessels in which a unit operation is conducted, including, but not limited to reaction, mixing and separation are process tanks.

Process unit means, unless specified otherwise in the applicable referencing subpart, the components assembled to produce an intended intermediate or final product. A *process unit* can operate independently if supplied with sufficient feed or raw materials and sufficient storage facilities for the product. All components located within the fence line of the plant site are included in the *process unit.* Components located offsite are not included within any *process unit.*

Process unit shutdown means a work practice or operational procedure that stops production from a process unit, or part of a process unit during which it is technically feasible to clear process material from a process unit, or part of a process unit, consistent with safety constraints and during which, repairs can be affected. The following are not considered process unit shutdowns:

(1) An unscheduled work practice or operations procedure that stops production from a process unit, or part of a process unit, for less than 24 hours.

(2) An unscheduled work practice or operations procedure that would stop production from a process unit, or part of a process unit, for a shorter period of time than would be required to clear the process unit, or part of the process unit of materials and start up the unit, and would result in greater emissions than delay of repair of leaking components, until the next scheduled process unit shutdown.

(3) The use of spare equipment and technically feasible bypassing of equipment without stopping production.

Referencing subpart means the subpart that directs you to comply with one or more applicable Uniform Standards (subparts I through M of this part). A *referencing subpart* for one Uniform Standard may also be a *referencing subpart* for another Uniform Standard.

Regulated material means chemicals or groups of chemicals (such as volatile organic compounds or HAP) that are regulated by the referencing subpart.

Regulated source means the stationary source, the group of stationary sources or the portion of a stationary source that is regulated by a relevant standard or other requirement established, pursuant to a referencing subpart.

Repair means that:

(1) If indications of a potential leak or liquids dripping are observed during sensory monitoring or a visual inspection, then the equipment, seal, fitting or other emissions source is adjusted, or otherwise altered, to eliminate the indications of a potential leak or liquids dripping.

(2) If a leak is detected by instrument monitoring, then the equipment, seal, fitting or other emissions source is adjusted or otherwise altered to eliminate a leak, as defined in the applicable sections of subparts I through M of this part and the emissions source is monitored, as specified in § 65.431(a) and (b) to verify that emissions are below the applicable instrument reading that defines a leak.

(3) If a leak is detected by a sensor or by failure of one or more design or inspection criteria, then the equipment, seal, fitting or other emissions source is adjusted, or otherwise altered, to return the emissions source to conditions such that the sensor no longer indicates a leak or that the emissions source is meeting the design or inspection criteria, as applicable.

(4) If a leak is detected by optical gas imaging, then the equipment, seal, fitting or other emissions source is adjusted, or otherwise altered, to eliminate the leak and the emissions source is monitored, as specified in § 65.450(b)(2) to verify that the leak can no longer be imaged by the optical gas imaging instrument.

(5) Repair does not mean repairs to CEMS or CPMS.

Rim seal means a device attached to the rim of a floating roof deck that spans the annular space between the deck and the wall of the storage vessel. When a floating roof has only one such device, it is a primary seal; when there are two seals (one mounted above the other), the lower seal is the primary seal and the upper seal is the secondary seal.

Run means one of a series of emission or other measurements needed to determine emissions for a representative operating period or cycle, as specified in 40 CFR part 65, subpart M or in the referencing subpart. Unless otherwise specified, a run may be either intermittent or continuous within the limits of good engineering practice.

Run down tank means a tank in which the product from a still, agitator or other processing equipment is received, and from which, the product is pumped to a storage vessel.

Rupture disk means a PRD that consists of a diaphragm held between flanges. The diaphragm splits when the pressure on the process side exceeds the design set pressure.

Sampling connection system means an assembly of piping and equipment within a process unit used during periods of representative operation to take samples of the process fluid. Lines that convey samples to analyzers and analyzer bypass lines are part of sampling connection systems. A device or apparatus used to take non-routine grab samples is not considered a *sampling connection system.*

Secondary fuel means a fuel fired through a burner other than the primary fuel burner that provides supplementary heat, in addition to the heat provided by the primary fuel.

Sensor means a device that measures a physical quantity or the change in a physical quantity, such as temperature, pressure, flow rate, pH or liquid level.

Sensory monitoring means visual, audible, olfactory or any other detection method used to determine a potential leak to the atmosphere.

Set pressure means the pressure at which a properly operating PRD begins to open to relieve atypical process system operating pressure.

Slotted guidepole means a guidepole or gaugepole that has slots or holes through the wall of the pole. The slots or holes allow the stored liquid to flow into the pole at liquid levels above the lowest operating level.

Small boiler or process heater means a boiler or process heater that has a design capacity less than 44 megawatts, and in which the vent stream is introduced with the combustion air or as a secondary fuel.

Startup means the setting into operation of a process unit, a piece of equipment or a control device that is subject to the Uniform Standards.

Storage capacity means the internal volume of a storage vessel from the floor to the top of the shell. For example, for a flat-bottomed storage vessel, the storage capacity is determined by multiplying the internal cross-sectional area of the storage vessel by the height of the shell. The calculation must be modified, as necessary, to account for floors that are not flat (*e.g.,* slope-bottomed, cone-up or cone-down).

Storage vessel means a stationary unit that is constructed of non-earthen materials (such as wood, concrete, steel, fiberglass or plastic), which provides structural support and is designed to hold an accumulation of liquids or other materials. The following are not considered storage vessels:

(1) Vessels permanently attached to motor vehicle, such as trucks, railcars, barges or ships;

(2) Vessels storing liquid that contains regulated material only as an impurity;

(3) Wastewater tanks; and

(4) Process tanks.

Submerged loading means the filling of a transport vehicle through a submerged fill pipe whose discharge is no more than 6 inches from the bottom of the tank. Bottom loading of transport vehicles is included in this definition.

Supplemental combustion air means the air that is added to a vent stream after the vent stream leaves the unit operation. Air that is part of the vent stream as a result of the nature of the unit operation is not considered supplemental combustion air. Air required to operate combustion device burner(s) is not considered supplemental combustion air. Air required to ensure the proper operation of catalytic oxidizers, to include the intermittent addition of air upstream of the catalyst bed to maintain a minimum threshold flow rate through the catalyst bed or to avoid excessive temperatures in the catalyst bed, is not considered to be supplemental combustion air.

Surge control vessel means feed drums, recycle drums and intermediate vessels as part of any continuous operation. *Surge control vessels* are used within a process unit when in-process storage, mixing or management of flow rates or volumes is needed to introduce material into continuous operations.

Tank car means an unpowered type of rolling stock (or vehicle) with a permanently attached vessel that is designed to carry liquid freight by rail.

Thermal oxidizer means a combustion device with an enclosed combustion chamber (*i.e.,* an enclosed fire box) that is used for destroying organic compounds. Auxiliary fuel may be used to heat waste gas to combustion temperatures.

Transfer operations means the loading into a transport vehicle or container of organic liquids from a transfer rack.

Transfer rack means a single system used to load organic liquids into transport vehicles or containers. It includes all loading and unloading arms, pumps, meters, shutoff valves, relief valves and other piping and equipment necessary for the transfer operation. Transfer equipment and operations that are physically separate (*i.e.,* do not share common piping, valves and other equipment) are considered to be separate transfer racks.

Transport vehicle means a cargo tank or tank car.

Uniform Standard(s) mean(s) any one or all of subparts I, J, K, L and M of this part.

Unslotted guidepole or *solid guidepole* means a guidepole or gaugepole that does not have slots or holes through the wall of the pole at or above the level of the floating roof when it is at its lowest operating level.

Vapor-mounted seal means a rim seal designed not to be in contact with the stored liquid. Vapor-mounted seals may include, but are not limited to, resilient seals and flexible wiper seals.

Wastewater stream means the wastewater generated by a particular process unit, tank or treatment process.

Wastewater tank means a stationary structure that is designed to contain an accumulation of wastewater or any liquid or solid material containing volatile organics that is removed from a wastewater stream and is constructed of non-earthen materials (*e.g.,* wood, concrete, steel, plastic) that provides structural support.

You means an owner or operator of a regulated source under the Uniform Standards.

TABLE 1 TO SUBPART H OF PART 65—APPLICABLE 40 CFR PARTS 60, 61 AND 63 GENERAL PROVISIONS

Part of 40 CFR	General provisions from 40 CFR parts 60, 61 and 63 that continue to apply to owners and operators of regulated sources subject to the uniform standards of this part
A. 40 CFR part 60, subpart A provisions for referencing subparts from part 60	§ 60.1
	§§ 60.2, 60.3, 60.4 [1]
	§ 60.5
	§ 60.6
	§ 60.7(a)(1) and (a)(3)
	§ 60.8(a)
	§§ 60.9, 60.10, 60.12
	§ 60.14
	§ 60.15
	§ 60.16
	§ 60.17
B. 40 CFR part 61, subpart A provisions for referencing subparts from part 61	§§ 61.01 through 61.03, 61.04,[1] 61.05 through 61.09
	§ 61.10(b)
	§ 61.11
	§ 61.13(a)
	§§ 61.15 through 61.19
C. 40 CFR part 63, subpart A provisions for referencing subparts from part 63	§ 63.1 [2]
	§§ 63.2, 63.3, 63.4
	§ 63.5
	§ 63.6(a) through (d), (i) and (j)
	§ 63.7(a) [3]
	§ 63.9(b), (c), (d), (h)(5)
	§ 63.10(b)(2)(xiv), (d)(4)
	§ 63.11(a), (c), (d), (e)
	§§ 63.12, 63.13, 63.15

[1] Except that the requirements associated with where to submit reports does not apply; electronic submittal is required, as specified in § 65.225.

[2] Except for § 63.1(a)(10) through (12).

[3] Except that a waiver of performance testing is specified in § 65.245, and the conditions of § 63.7(c)(3)(ii)(B) do not apply to this paragraph.

3. Add subpart I to read as follows:

Subpart I—National Uniform Emission Standards for Storage Vessels and Transfer Operations

Sec.

What This Subpart Covers

65.300 What is the purpose of this subpart?
65.301 Am I subject to this subpart?
65.302 What parts of my plant does this subpart cover?
65.303 What parts of the General Provisions apply to me?

General Requirements

65.305 What requirements in this subpart apply to me?
65.306 How must I determine the MTVP of stored material?

Standards and Compliance Requirements for Storage Vessels

65.310 What requirements must I meet for an atmospheric storage vessel equipped with a fixed roof?
65.315 What requirements must I meet for an atmospheric storage vessel with a floating roof?
65.320 What requirements must I meet for a fixed roof atmospheric storage vessel if I use vapor balance?
65.325 What requirements must I meet for a fixed roof atmospheric storage vessel if I route emissions through a closed vent system to a control device?
65.330 What requirements must I meet for a fixed roof atmospheric storage vessel if I route emissions to a fuel gas system?
65.340 What requirements must I meet for a pressure vessel?

Standards and Compliance Requirements for Transfer Operations

65.360 What requirements must I meet for control of transport vehicles and transfer operations to load transport vehicles?
65.370 What requirements must I meet for control of transfer operations to load containers?

Recordkeeping and Reporting

65.380 What records must I keep?
65.382 What information must I submit in my Notification of Compliance Status?
65.384 What information must I submit in my semiannual periodic report?
65.386 What information must I submit in my annual periodic report?
65.388 What other reports must I submit and when?

Other Requirements and Information

65.390 What definitions apply to this subpart?

List of Tables in Subpart I of Part 65

Table 1 to Subpart I of Part 65—Standards and Compliance Requirements for Storage Vessels and Transfer Operations
Table 2 to Subpart I of Part 65—Inspection and Monitoring Requirements and Schedule for Storage Vessels Equipped With an IFR
Table 3 to Subpart I of Part 65—Inspection and Monitoring Requirements and Schedule for Storage Vessels Equipped With an EFR

What This Subpart Covers

§ 65.300 What is the purpose of this subpart?

This subpart specifies requirements to meet the emission standards of a referencing subpart for storage vessels and transfer operations.

§ 65.301 Am I subject to this subpart?

You are subject to this subpart if you are an owner or operator who is subject to a referencing subpart and you have been expressly directed to comply with the Uniform Standards of this subpart by a referencing subpart.

§ 65.302 What parts of my plant does this subpart cover?

This subpart applies to storage vessels and transfer operations that contain or contact regulated material and are subject to a referencing subpart.

§ 65.303 What parts of the General Provisions apply to me?

The General Provisions of 40 CFR parts 60, 61 and 63 apply to this subpart, as specified in subpart H of this part.

General Requirements

§ 65.305 What requirements in this subpart apply to me?

The provisions of this subpart apply to storage vessels and transfer operations that contain or contact regulated material, as specified in paragraphs (a) through (e) of this section.

(a) For each atmospheric storage vessel that meets the requirements in item 1 of Table 1 to this subpart, you must comply with § 65.310. Alternatively, you may elect to comply with either paragraph (a)(1) or (a)(2) of this section.

(1) Comply with § 65.310 if you install an internal floating roof, vapor balance or connect the storage vessel to a closed vent system and control device, but you are not required to comply with § 65.315, § 65.320 or § 65.325.

(2) Comply with any of the options in paragraphs (b)(1) through (4) of this section.

(b) For each atmospheric storage vessel that meets the size and maximum true vapor pressure (MTVP) thresholds in item 2 or item 3 of Table 1 to this subpart, you must comply with either paragraph (b)(1), (2), (3) or (4) of this section.

(1) Use an external floating roof or a fixed roof with an internal floating roof, in accordance with § 65.315. This option may be used only if the MTVP of the stored liquid is less than 76.6 kilopascals (kPa).

(2) Vapor balance in accordance with § 65.320.

(3) Maintain a fixed roof and route emissions through a closed vent system to a control device, in accordance with § 65.325.

(4) Route emissions to a fuel gas system in accordance with § 65.330. This option may not be used when the displaced vapors from the storage vessel include halogenated compounds.

(c) For each pressure vessel, you must comply with § 65.340.

(d) For transfer operations that involve loading of transport vehicles, you must comply with § 65.360.

(e) For transfer operations that involve loading of containers, you must comply with § 65.370.

§ 65.306 How must I determine the MTVP of stored material?

(a) Determine the MTVP at the times specified in paragraphs (b) through (d) of this section and keep records, as specified in paragraph (e) of this section. For a single-component stock, use any one of the methods specified in paragraphs (a)(1), (2), (3) or (5) of this section. For a mixture of compounds (such as petroleum liquids), use any one of the methods specified in paragraphs (a)(2) through (5) of this section.

(1) As obtained from standard reference texts.

(2) In accordance with methods described in chapter 19.2 of the API Manual of Petroleum Measurement Standards, ''Evaporative Loss from Floating Roof Tanks'' (incorporated by reference, see § 65.265). If you need the total vapor pressure of a petroleum liquid mixture (e.g., crude oil or gasoline), you must test for Reid vapor pressure and distillation slope, as applicable, to determine the constants A and B for the vapor pressure equation. If only part of a mixture is regulated material, you must test to determine the composition of the stored liquid. Testing is not required if you determine, based on engineering judgment, that the mixture contains less than 1-percent regulated material by weight.

(3) As determined by the ''American Society for Testing and Materials Method D2879–83'' (incorporated by reference, see § 65.265).

(4) As determined using ''Test Method for Vapor Pressure of Reactive Organic Compounds in Heavy Crude Oil Using Gas Chromatography'' (incorporated by reference, see § 65.265).

(5) Any other method approved by the Administrator in accordance with § 65.250.

(b) Determine the MTVP for each storage vessel that contains a regulated material either prior to the required submittal date of your Notification of Compliance Status or prior to the initial fill with regulated material, whichever is later.

(c) Determine the MTVP each time the storage vessel is filled with a different type of material.

(d) Determine the MTVP at least annually if the storage vessel stores a mixture and it was determined to be subject to § 65.305(a) the last time the MTVP was determined.

(e) Keep records of each MTVP determination, as specified in § 65.380(b)(2).

Standards and Compliance Requirements for Storage Vessels

§ 65.310 What requirements must I meet for an atmospheric storage vessel equipped with a fixed roof?

You must equip the storage vessel with a fixed roof and operate in accordance with paragraphs (a) through (d) of this section.

(a) *Closure requirements.* Each opening in the fixed roof must be equipped with a cover or other type of closure device.

(b) *Operating requirements.* (1) Except as specified in paragraph (b)(2) of this section, the fixed roof must be installed with each closure device secured in the closed position when the storage vessel contains regulated material.

(2) You may open closure devices or remove the fixed roof under the conditions specified in paragraphs (b)(2)(i) and (ii) of this section.

(i) A closure device may be opened or the roof may be removed when needed to provide access for manual operations such as maintenance, inspection, sampling and cleaning.

(ii) Opening of a spring-loaded conservation vent or similar type of device that vents to the atmosphere (or allows air to enter the storage vessel) is allowed to maintain the tank internal operating pressure within tank design specifications when loading operations or diurnal ambient temperature fluctuations cause the pressure inside the storage vessel to migrate beyond the operating pressure range for the storage vessel.

(c) *Monitoring requirements.* (1) Except as specified in paragraph (c)(2)

or (3) of this section, monitor each potential source of vapor leakage from the fixed roof and its closure devices for leaks in accordance with either paragraph (c)(1)(i) or (ii) of this section. Conduct monitoring while the storage vessel contains regulated material.

(i) Monitor using Method 21 of 40 CFR part 60, appendix A–7, in accordance with § 65.431(a) and (b). A leak is detected if you obtain an instrument reading greater than 500 parts per million by volume. Conduct monitoring within 90 days after the initial fill and at least annually.

(ii) Monitor in accordance with the protocol for optical gas imaging, as specified in 40 CFR part 60, appendix K. You may use this monitoring option only if at least one compound in the emissions can be detected by the optical gas imaging instrument. A leak is detected if you observe an image of emissions when using the optical gas imaging instrument. Conduct monitoring within 90 days after the initial fill and at least semiannually.

(2) If you determine parts of the roof are unsafe to monitor using Method 21 of part 60, appendix A–7, because operating personnel would be exposed to an imminent or potential danger as a consequence of complying with such monitoring, then the inspection requirements specified in paragraph (c)(1)(i) of this section do not apply and you must comply with the requirements specified in paragraphs (c)(2)(i) through (iii) of this section.

(i) You must prepare and maintain at the plant site written documentation that identifies all parts of the fixed roof and any closure devices that are unsafe to monitor and explains why such parts are unsafe to monitor.

(ii) You must develop and implement a written plan and schedule to conduct inspections during times when it is safe to do so. The required inspections must be performed as frequently as practicable, but do not need to be performed more than annually. Keep a copy of the written plan and schedule at the plant site, as specified in § 65.380(c)(4).

(iii) As an alternative to paragraphs (c)(2)(i) and (ii) of this section, you may monitor the parts of the roof identified in paragraph (c)(2)(i) of this section by using optical gas imaging, as specified in paragraph (c)(1)(ii) of this section, if the criteria in paragraph (c)(1)(ii) of this section and 40 CFR part 60, appendix K, are met.

(3) No monitoring is required during a calendar year when either of the conditions in paragraph (c)(3)(i) or (ii) of this section are met.

(i) The storage vessel stores no regulated material at any time during the calendar year.

(ii) The storage vessel is emptied less than 120 days since the last inspection and no regulated material is stored in the storage vessel for the remainder of the year.

(4) Keep records of the date of each inspection, as specified in § 65.380(c)(1), and keep records of each leak, as specified in § 65.380(c)(2). Provide notification of each inspection, as specified in § 65.388(a)(1).

(d) *Repair requirements.* When a leak is identified during monitoring required under paragraph (c) of this section, you must either complete repairs or completely empty the storage vessel within 45 days. If a repair cannot be completed or the vessel cannot be completely emptied within 45 days, you may use up to two extensions of up to 30 additional days each. Keep records documenting each decision to use an extension, as specified in § 65.380(c)(3). Not repairing or emptying the storage vessel within the time frame specified in this paragraph (d) is a deviation and must be reported in your semiannual periodic report, as specified in § 65.384(a).

§ 65.315 What requirements must I meet for an atmospheric storage vessel with a floating roof?

You must comply with the requirements in paragraphs (a) through (g) of this section.

(a) *Design requirements.* (1) *Fixed roof in combination with internal floating roof.* An internal floating roof (IFR) must be equipped with one of the seal configurations listed in paragraph (a)(1)(i), (ii) or (iii) of this section.

(i) A liquid-mounted seal.

(ii) A mechanical shoe seal.

(iii) Two seals mounted one above the other. The lower seal may be vapor-mounted.

(2) *External floating roof.* An external floating roof (EFR) must be equipped with one of the seal configurations listed in paragraph (a)(2)(i) or (ii) of this section.

(i) A liquid-mounted seal and a secondary seal.

(ii) A mechanical shoe seal and a secondary seal. The upper end of the shoe(s) must extend a minimum of 24 inches above the stored liquid surface.

(3) *Deck fittings.* Openings through the deck of the floating roof must be equipped, as described in paragraphs (a)(3)(i) through (x) of this section.

(i) Each opening, except those for automatic bleeder vents (vacuum breaker vents) and rim space vents, must have its lower edge below the surface of the stored liquid.

(ii) Each opening, except those for automatic bleeder vents (vacuum breaker vents), rim space vents, leg sleeves and deck drains, must be equipped with a deck cover. The deck cover must be equipped with a gasket between the cover and the deck.

(iii) Each automatic bleeder vent (vacuum breaker vent) and rim space vent must be equipped with a gasketed lid, pallet, flapper or other closure device.

(iv) Each opening for a fixed roof support column may be equipped with a flexible fabric sleeve seal instead of a deck cover.

(v) Each opening in an internal floating roof for a sample well may be equipped with a slit fabric seal or similar device that covers at least 90 percent of the opening instead of a deck cover.

(vi) Each opening for a deck drain that empties into the stored liquid must be equipped with a slit fabric seal or similar device that covers at least 90 percent of the opening.

(vii) Each cover on access hatches and gauge float wells must be designed to be bolted or fastened when closed.

(viii) Each opening for an unslotted guidepole must be equipped with a pole wiper, and each unslotted guidepole must be equipped with either a gasketed or welded cap on the top of the guidepole.

(ix) Each opening for a slotted guidepole must be equipped with one of the control device configurations specified in paragraph (a)(3)(ix)(A), (B), (C) or (D) of this section.

(A) A pole wiper and a pole float. The wiper or seal of the pole float must be at or above the height of the pole wiper.

(B) A pole wiper and a pole sleeve.

(C) A flexible enclosure device and either a gasketed or welded cap on the top of the guidepole.

(D) An internal guidepole sleeve, a pole wiper and either a gasketed or welded cap on the top of the guidepole.

(x) Each opening for a ladder that has at least one slotted leg must be equipped with one of the control device configurations specified in paragraph (a)(3)(x)(A), (B) or (C) of this section.

(A) A pole float in the slotted leg and pole wipers for both legs. The wiper or seal of the pole float must be at or above the height of the pole wiper.

(B) A ladder sleeve and pole wipers for both legs of the ladder.

(C) A flexible enclosure device and either a gasketed or welded cap on the top of the slotted leg.

(b) *Operational requirements.* (1) The floating roof must be floating on the liquid surface at all times, except that it may be supported by the leg supports or

other support devices (*e.g.,* hangers from the fixed roof) under the circumstances specified in paragraphs (b)(1)(i) through (vi) of this section. Any other floating roof landing event is a deviation and must be recorded, as specified in § 65.380(d)(1), and reported in your semiannual periodic report, as specified in § 65.384(b).

(i) During the initial fill.

(ii) When necessary for maintenance or inspection, including refill, provided you also comply with either paragraph (b)(1)(ii)(A) or (B) of this section.

(A) If the storage vessel does not need to be completely empty in order to perform the maintenance or inspection, then refill must begin no later than 24 hours after the roof is landed. Refill must be performed in accordance with paragraph (b)(2) of this section.

(B) If the storage vessel must be completely empty in order to perform the maintenance or inspection, then actions to completely empty the storage vessel must begin no later than 24 hours after the roof is landed. Refill may occur at any time after the storage vessel is completely empty.

(iii) When necessary to support a change in service to an incompatible liquid, including refill. Actions to completely empty the storage vessel must begin no later than 24 hours after the roof is landed. Refill may occur at any time after the storage vessel is completely empty.

(iv) When necessary to take the storage vessel out of service. Actions to completely empty the storage vessel must begin no later than 24 hours after the roof is landed.

(v) When the vapors are routed through a closed vent system to a non-flare control device that reduces regulated material emissions by at least 90 percent by weight from the time the floating roof is landed until the floating roof is within 10 percent by volume of being refloated. You must comply with the requirements in subpart M of this part for the closed vent system and the applicable non-flare control device(s). To demonstrate initial compliance with the 90-percent reduction requirement, you must conduct either a design evaluation, as specified in § 65.850, or a performance test, as specified in §§ 65.820 through 65.829.

(vi) When non-halogenated vapors are routed through a closed vent system to a flare that reduces regulated material emissions from the time the floating roof is landed until the floating roof is within 10 percent by volume of being refloated. You must comply with the requirements in subpart M of this part for the closed vent system and the requirements of § 63.11(b) of this chapter for the flare.

(2) Once you start filling or refilling a storage vessel that has a landed floating roof, you may not suspend filling or refilling until the roof is floating (except when the quantity of liquid produced in one batch is insufficient to float the roof, and the output from additional batches will be added before any material is withdrawn from the storage vessel), and you may not withdraw liquid from the storage vessel while simultaneously filling or refilling.

(3) Each cover over an opening in the floating roof, except for automatic bleeder vents (vacuum breaker vents) and rim space vents, must be closed at all times, except when the cover must be open for access.

(4) Each automatic bleeder vent (vacuum breaker vent) and rim space vent must be closed at all times, except when required to be open to relieve excess pressure or vacuum, in accordance with the manufacturer's design, and during periods when the floating roof is allowed to be supported by its legs or other support devices.

(5) Each guidepole cap and slotted ladder leg cap must be closed at all times except when gauging the liquid level or taking liquid samples.

(c) *Inspection requirements.* Inspect internal floating roofs in accordance with Table 2 to this subpart, and inspect external floating roofs in accordance with Table 3 to this subpart. You must also comply with paragraphs (c)(1) through (6) of this section, as specified in Table 2 to this subpart, or Table 3 to this subpart, as applicable. If a floating roof fails an inspection, comply with the repair requirements specified in paragraph (d) of this section. Keep records of the inspections, as specified in § 65.380(d)(2), and report inspection failures in your annual periodic report, as specified in § 65.386(a).

(1) Visually inspect for any of the conditions specified in paragraphs (c)(1)(i) through (iv) of this section at the frequency specified in Table 2 to this subpart or Table 3 to this subpart, as applicable. Observing any of these conditions constitutes an inspection failure. These inspections may be performed entirely from the top side of the floating roof, as long as there is visual access to all deck fittings and the top rim seal specified in paragraph (a) of this section.

(i) Stored liquid on the floating roof.

(ii) Holes or tears in the primary or secondary seal (if one is present).

(iii) Floating roof deck, deck fittings or rim seals that are not functioning as designed (as specified in paragraph (a) of this section).

(iv) Failure to comply with the operational requirements of paragraph (b) of this section.

(2) If you comply with Option 1 or Option 3 in Table 2 to this subpart or Option 1 in Table 3 to this subpart, inspect each deck fitting in accordance with paragraph (c)(2)(i) of this section. If you comply with Option 2 in Table 2 to this subpart or Option 3 in Table 3 to this subpart, monitor each deck fitting in accordance with paragraph (c)(2)(iii) of this section. If you comply with Option 2 in Table 3 to this subpart, monitor each deck fitting in accordance with paragraph (c)(2)(ii) of this section.

(i) Measure the gap between each deck fitting gasket or wiper (required by paragraph (a) of this section) and any surface that it is intended to seal. The inspector must attempt to slide a ⅛ inch diameter probe between the gasket or wiper and the surface against which it is intended to seal. Each location where the probe passes freely (without forcing or binding) between the two surfaces constitutes a gap and an inspection failure.

(ii) Use Method 21 of 40 CFR part 60, appendix A–7, in accordance with § 65.431(a) and (b) to monitor all sources of potential vapor leakage around each fitting. Conduct monitoring only when the roof is floating on the stored liquid. An instrument reading greater than 500 ppmv constitutes an inspection failure. This option may be used only for an EFR.

(iii) Monitor the deck fittings using an optical gas imaging instrument in accordance with the protocol for optical gas imaging, as specified in 40 CFR part 60, appendix K. You may use this monitoring option only if at least one compound in the emissions can be detected by the optical gas imaging instrument. Conduct monitoring only when the roof is floating on the stored liquid. Any imaged emissions constitutes an inspection failure.

(3) If you comply with Option 1 in Table 3 to this subpart, conduct seal gap inspections for an EFR by determining the presence and size of gaps between the rim seals and the wall of the storage vessel in accordance with the procedures specified in paragraph (c)(3)(i) through (iv) of this section. Any exceedance of the gap requirements specified in paragraphs (c)(3)(ii) and (iii) of this section constitutes inspection failure.

(i) Rim seals must be measured for gaps at one or more levels while the EFR is floating, as specified in paragraphs (c)(3)(i)(A) through (F) of this section.

(A) The inspector must hold a ⅛ inch diameter probe vertically against the inside of the storage vessel wall, just above the rim seal, and attempt to slide the probe down between the seal and the vessel wall. Each location where the probe passes freely (without forcing or binding against the seal) between the seal and the vessel wall constitutes a gap.

(B) Determine the length of each gap by inserting the probe into the gap (vertically) and sliding the probe along the vessel wall in each direction as far as it will travel freely without binding between the seal and the vessel wall. The circumferential length along which the probe can move freely is the gap length.

(C) Determine the maximum width of each gap by inserting probes of various diameters between the seal and the vessel wall. The smallest probe diameter should be ⅛ inch, and larger probes should have diameters in increments of ⅛ inch. The diameter of the largest probe that can be inserted freely anywhere along the length of the gap is the maximum gap width.

(D) Determine the average width of each gap by averaging the minimum gap width (⅛ inch) and the maximum gap width.

(E) The area of a gap is the product of the gap length and average gap width.

(F) Determine the ratio of accumulated area of rim seal gaps to storage vessel diameter by adding the area of each gap, and dividing the sum by the nominal diameter of the storage vessel. Determine this ratio separately for primary and secondary rim seals.

(ii) The ratio of seal gap area to vessel diameter for the primary seal must not exceed 10 square inches per foot of vessel diameter, and the maximum gap width must not exceed 1.5 inches.

(iii) The ratio of seal gap area to vessel diameter for the secondary seal must not exceed 1 square inch per foot, and the maximum gap width must not exceed 0.5 inches, except when you must pull back or remove the secondary seal to inspect the primary seal.

(iv) If you determine that it is unsafe to perform an EFR inspection as specified in paragraph (c)(3)(i) of this section, comply with the requirements of paragraph (c)(3)(iv)(A) or (B) of this section.

(A) Perform the inspection no later than 30 days after the determination that the floating roof is unsafe.

(B) Completely empty the storage vessel no later than 45 days after determining the floating roof is unsafe. If the vessel cannot be completely emptied within 45 days, you may utilize up to two extensions of up to 30 additional days each. Keep records documenting each decision to use an extension, as specified in § 65.380(d)(3).

(4) If you comply with Option 3 in Table 3 to this subpart, monitor the circumference of the floating roof when the roof is floating on stored liquid using an optical gas imaging instrument in accordance with the procedures specified in the protocol for optical gas imaging in 40 CFR part 60, appendix K. This monitoring option may be used only if at least one compound emitted from the storage vessel can be detected by the optical gas imaging instrument. Any imaged emissions constitutes an inspection failure.

(5) If you comply with Option 2 in Table 3 to this subpart, monitor the interface between the rim seal and the tank shell and any gaps in the secondary seal using Method 21 of 40 CFR part 60, appendix A–7, in accordance with § 65.431(a) and (b). Conduct monitoring when the roof is floating on stored liquid. An instrument reading greater than 500 ppmv constitutes an inspection failure.

(6) If you comply with Option 2 in Table 2 to this subpart, monitor the circumference of the IFR using an optical gas imaging instrument in accordance with the protocol for optical gas imaging, as specified in 40 CFR part 60, appendix K. You may use this monitoring option only if at least one compound in the emissions can be detected by the optical gas imaging instrument. Conduct monitoring when the roof is floating on stored liquid. Any imaged emissions constitutes an inspection failure.

(d) *Repair requirements.* Any condition causing an inspection failure under paragraph (c) of this section that is observed during an inspection required by paragraph (c) of this section or that you observe while conducting other activities on the storage vessel (*e.g.,* maintenance or sampling) must be repaired, as specified in paragraph (d)(1) or (2) of this section.

(1) If the inspection is performed while the storage vessel is completely empty, you must complete repairs before refilling the storage vessel with regulated material.

(2) If the inspection is performed while the storage vessel is not completely empty, you must complete repairs or completely empty the storage vessel within 45 days. If a repair cannot be completed or the vessel cannot be completely emptied within 45 days, you may use up to two extensions of up to 30 additional days each. Keep records documenting each decision to use an extension, as specified in § 65.380(d)(3). Not repairing or emptying the storage vessel within the time frame specified in this paragraph (d) is a deviation and must be reported in your semiannual periodic report, as specified in § 65.384(a).

(e) *Alternative means of emission limitation.* (1) An alternate device may be substituted for a device specified in paragraph (a) of this section if the alternate device has an emission factor less than or equal to the emission factor for the device specified in paragraph (a) of this section. Requests for the use of alternate devices must be submitted, as specified in § 65.388(b).

(2) Tests to determine emission factors for an alternate device must accurately simulate representative conditions under which the device and storage vessel will operate, such as wind speed, ambient and liquid temperatures, pressure or vacuum, and filling and withdrawal rates, but without creating an unsafe condition. You must include a copy of the proposed testing protocol in your request.

(f) *Floating roof landing monitoring requirements.* (1) Each storage vessel must be equipped with a system that provides a visual or audible signal when the floating roof (IFR or EFR) is about to be landed on its legs or other support devices (*e.g.,* hangers from the fixed roof).

(2) Each time a floating roof is landed, even if the alarm did not activate, estimate the amount of regulated material emitted to the atmosphere during the time the floating roof is landed. Keep records of this emissions estimate, as specified in § 65.380(d)(1). Report the estimated emissions in your annual periodic report, as specified in § 65.386(b).

(g) *Overfill monitoring requirements.* (1) Each storage vessel must be equipped with monitoring equipment that provides a visual or audible signal when the storage vessel is about to be overfilled.

(2) Each time the storage vessel is overfilled, estimate the amount of regulated material spilled and the amount emitted to the atmosphere. Keep records of this emissions estimate, as specified in § 65.380(i). Report the estimated emissions in your annual periodic report, as specified in § 65.386(c).

§ 65.320 What requirements must I meet for a fixed roof atmospheric storage vessel if I use vapor balance?

If you elect to use vapor balancing to control emissions from a fixed roof storage vessel, you must comply with the requirements in paragraphs (a) through (d) of this section.

(a) *Fixed roof requirements.* Operate and maintain the fixed roof, as specified in § 65.310(a) and (b), except that § 65.310(b)(2)(ii) does not apply for the purposes of this section; monitor the fixed roof, as specified in § 65.310(c); and repair leaks, as specified in § 65.310(d). Keep records of monitoring and repair, as specified in § 65.380(e)(1), and report deviations in your semiannual periodic report, as specified in §§ 65.310(d) and 65.384(a).

(b) *Vapor balance requirements.* (1) *Design requirements.* (i) The vapor balancing system must be designed and operated to route vapors displaced from loading of the storage vessel to the transport vehicle or barge from which the storage vessel is filled.

(ii) All vapor connections and lines on the storage vessel must be equipped with closures that seal upon disconnect.

(2) *Testing requirements.* (i) Transport vehicles must have a current certification in accordance with the U.S. Department of Transportation (DOT) pressure test requirements of 49 CFR part 180 for cargo tanks and 49 CFR 173.31 for tank cars. Keep records of these certifications, as specified in § 65.380(e)(2).

(ii) Barges must have been pressure tested for vapor tightness within the 365-day period prior to being used in a vapor balancing system to comply with the control requirements in this section. Pressure testing must be conducted in accordance with paragraphs (b)(2)(ii)(A) through (F) of this section, and you must maintain copies of documentation showing the required testing was conducted, as specified in § 65.380(e)(3). You must either conduct the test at your facility or obtain documentation of the test from the barge owner or operator.

(A) Each barge must be pressurized with dry air or inert gas to no more than the pressure of the lowest-pressure relief valve setting.

(B) Once the pressure is obtained, the dry air or inert gas source must be shut off.

(C) At the end of ½ hour, the pressure in the barge and piping must be measured. The change in pressure must be calculated using Equation 1 of this section.

$$P = P_i - P_f \qquad \text{(Eq. 1)}$$

Where:

P = Change in pressure, inches of water.

P_i = Pressure in barge when air/gas source is shut off, inches of water.

P_f = Pressure in barge at the end of ½ hour after air/gas is shut off, inches of water.

(D) The change in pressure, P, must be compared to the pressure drop calculated using Equation 2 of this section.

$$PM = 0.861 \times P_i \times (L/V) \qquad \text{(Eq. 2)}$$

Where:

PM = Maximum allowable pressure change, inches of water.

P_i = Pressure in barge when air/gas source is shut off, pounds per square inch absolute (psia).

L = Maximum permitted loading rate of the barge, barrels per hour

V = Total volume of barge, barrels.

(E) If P is less than or equal to PM, the vessel is vapor tight.

(F) If P is greater than PM, the vessel is not vapor tight and the source of the leak must be identified and repaired before retesting.

(3) Monitoring requirements. For pieces of equipment in the vapor balancing system, comply with § 65.325(b) and (d), except as specified in paragraphs (b)(3)(i) through (iii) of this section. Keep records, as specified in § 65.380(e)(5).

(i) When § 65.325(b) refers to a ''closed vent system,'' it means a ''vapor balancing system'' for the purposes of this section.

(ii) When subpart M of this part, which is referenced from § 65.325(b), refers to ''bypass lines that divert a vent stream away from a control device and to the atmosphere,'' it means ''bypass lines that divert displaced storage vessel emissions to the atmosphere and away from the transport vehicle or barge from which the storage vessel is being filled'' for the purposes of this section.

(iii) As an alternative to the otherwise applicable monitoring requirements specified in subpart J of this part, you may elect to comply with the alternative monitoring frequencies in § 65.440 for equipment in a vapor balancing system that convey emissions from a storage vessel for the purposes of this subpart.

(c) *Operating requirements.* (1) Liquid must be unloaded only when the transport vehicle's vapor collection equipment or barge's vapor collection equipment is connected to the storage vessel's vapor balancing system.

(2) Each pressure relief device on the storage vessel or on the transport vehicle or barge must remain closed while the storage vessel is being filled.

(3) Pressure relief devices on storage vessels must be set to no less than 2.5 pounds per square inch gauge (psig) at all times to prevent breathing losses, unless you provide rationale in the Notification of Compliance Status specified in § 65.382(c) explaining why a lower value is sufficient to prevent breathing losses at all times or control breathing losses by another method. Keep records of the vent settings, as specified in § 65.380(e)(4).

(d) *Overfill monitoring requirements.* Comply with the monitoring and alarm requirements and related recordkeeping and reporting requirements specified in § 65.315(g).

§ 65.325 What requirements must I meet for a fixed roof atmospheric storage vessel if I route emissions through a closed vent system to a control device?

If you elect to control emissions from a fixed roof atmospheric storage vessel by routing emissions through a closed vent system to a control device, you must comply with the requirements in paragraphs (a) through (e) of this section.

(a) *Fixed roof requirements.* Except as specified in paragraph (e) of this section, operate and maintain the fixed roof, as specified in § 65.310(a) and (b), except that § 65.310(b)(2)(ii) does not apply for the purposes of this section; monitor the fixed roof, as specified in § 65.310(c); and repair leaks, as specified in § 65.310(d). Keep records of monitoring and repair, as specified in § 65.380(f)(1), and report deviations in your semiannual periodic report, as specified in §§ 65.310(d) and 65.384(a).

(b) *Closed vent system requirements.* Except as specified in paragraph (e) of this section, for the closed vent system, comply with the requirements specified in § 65.720(b) through (d) and paragraphs (b)(1) through (3) of this section.

(1) Equipment in the closed vent system is in regulated material service when it conveys emissions from the storage vessel. For such equipment, comply with § 65.410(a) or (c) and applicable sections referenced therein, except that § 65.410(a)(2)(ii) does not apply for the purposes of this subpart. When § 65.410(c) refers to ''your referencing subpart,'' it means ''the subpart that references subpart I.'' You must conduct the monitoring while the equipment is in regulated material service.

(2) Comply with § 65.430 for each potential source of emissions in the closed vent system that is not defined as

a piece of equipment. Keep identification records, as specified in § 65.380(f)(5).

(3) Keep records, as specified in § 65.380(f)(2).

(c) *Control device requirements.* Comply with the requirements specified in paragraphs (c)(1) through (4) of this section, as applicable. Keep records, as specified in § 65.380(f)(3).

(1) A non-flare control device must meet the requirements for the applicable control device in subpart M of this part; and reduce organic regulated material emissions by at least 95 percent by weight or to an outlet concentration of regulated material less than 20 ppmv. If the regulated material is a subset of organic compounds (*e.g.,* hazardous air pollutants (HAP)), you may demonstrate compliance by reducing emissions to an outlet concentration less than 20 ppmv as total organic compounds (TOC). You must reduce the hydrogen halide and halogen emissions from combusted halogenated vent streams, as defined in § 65.295, by at least 99 percent by weight or to an outlet concentration less than 20 ppmv. The halogenated vent stream determination must be based on the emission rate at the maximum expected fill rate of the storage vessel.

(2) A flare must meet the requirements of § 63.11(b) of this chapter. You must not use a flare to control halogenated vent streams, as defined in § 65.295.

(3) To demonstrate initial compliance with the emission limit(s) specified in paragraph (c)(1) of this section, you must conduct either a design evaluation, as specified in § 65.850, or a performance test, as specified in §§ 65.820 through 65.829.

(4) During periods of planned routine maintenance of a control device, operate the storage vessel in accordance with paragraphs (c)(4)(i) and (ii) of this section. Keep records, as specified in § 65.380(f)(4).

(i) Do not add material to the storage vessel during periods of planned routine maintenance.

(ii) Limit periods of planned routine maintenance for each control device to no more than 360 hours per year (hr/yr).

(d) *Overfill monitoring requirements.* Comply with the monitoring and alarm requirements and related recordkeeping and reporting requirements specified in § 65.315(g).

(e) *Alternative requirements.* Paragraphs (a) and (b) of this section do not apply if the fixed roof and closed vent system are maintained in vacuum service, provided you comply with § 65.410(b)(1) through (3) for fittings on the fixed roof and equipment in the closed vent system and you keep records, as specified in § 65.380(f)(2).

§ 65.330 What requirements must I meet for a fixed roof atmospheric storage vessel if I route emissions to a fuel gas system?

If you elect to control emissions from a fixed roof storage vessel by routing emissions to a fuel gas system, you must comply with paragraphs (a) through (d) of this section.

(a) *Fixed roof requirements.* Except as specified in paragraph (d) of this section, operate and maintain the fixed roof, as specified in § 65.310(a) and (b), except that § 65.310(b)(2)(ii) does not apply for the purposes of this section; monitor the fixed roof, as specified in § 65.310(c); and repair leaks, as specified in § 65.310(d). Keep records of monitoring and repair, as specified in § 65.380(g)(1), and report deviations in your semiannual periodic report, as specified in §§ 65.310(d) and 65.384(a).

(b) *Fuel gas system requirements.* Except as specified in paragraph (d) of this section, comply with the requirements specified in paragraphs (b)(1) through (3) of this section.

(1) Comply with the requirements for fuel gas systems as specified in § 65.732(a), (c), and (d).

(2) Comply with the requirements for equipment leaks, as specified in subpart J of this part and paragraphs (b)(2)(i) and (ii) of this section.

(i) Equipment in the fuel gas system is in regulated material service when it conveys emissions from the storage vessel. For such equipment, comply with § 65.410(a) or (c) and applicable sections referenced therein, except that § 65.410(a)(2)(ii) does not apply for the purposes of this subpart. When § 65.410(c) refers to ''your referencing subpart,'' it means ''the subpart that references subpart I.'' You must conduct the monitoring while the equipment is in regulated material service.

(ii) Comply with § 65.430 for each potential source of emissions from the fuel gas system that is not defined as a piece of equipment (*e.g.,* an access hatch). Keep identification records, as specified in § 65.380(g)(3).

(3) Keep records of the fuel gas system, as specified in § 65.380(g)(2).

(c) *Overfill monitoring requirements.* Comply with the monitoring and alarm requirements and related recordkeeping and reporting requirements specified in § 65.315(g).

(d) *Alternative requirements.* Paragraphs (a) and (b) of this section do not apply if the fixed roof and fuel gas system are maintained in vacuum service, provided you comply with § 65.410(b)(1) through (3) for fittings on the fixed roof and equipment in the fuel gas system and you keep records, as specified in § 65.380(g)(2).

§ 65.340 What requirements must I meet for a pressure vessel?

If you have a pressure vessel that contains any regulated material, you must operate and maintain the pressure vessel, as specified in paragraphs (a) through (d) of this section.

(a) The pressure vessel must be designed to operate with no detectable emissions at all times.

(b) All openings in the pressure vessel must be equipped with closure devices.

(c) Conduct initial and annual performance tests by monitoring in accordance with either paragraph (c)(1) or (2) of this section to demonstrate compliance with paragraph (a) of this section.

(1) Monitor each point on the pressure vessel through which regulated material could potentially be emitted using Method 21 of 40 CFR part 60, appendix A–7, in accordance with the procedures specified in § 65.431(a) and (b) and paragraphs (c)(1)(i) through (iii) of this section.

(i) When § 65.431(a)(5) refers to ''monitoring when the equipment in regulated material service or in use with any other detectable material,'' it means ''monitoring when the pressure vessel contains a regulated material with a concentration representative of the range of concentrations for the materials expected to be stored in the pressure vessel'' for the purposes of this section.

(ii) Section 65.431(a)(6) does not apply for the purposes of this section.

(iii) Each instrument reading greater than 500 ppmv is a deviation. Comply with paragraphs (c)(1)(iii)(A) through (C) of this section each time you obtain an instrument reading greater than 500 ppmv.

(A) Estimate the flow rate and total regulated material emissions from the defect. Assume the pressure vessel has been emitting for half of the time since the last performance test, unless other information supports a different assumption.

(B) Keep records of the performance test and emission estimates, as specified in § 65.380(h)(1).

(C) Submit information in your semiannual periodic report, as specified in § 65.384(c).

(2) Monitor each point on the pressure vessel through which regulated material potentially could be emitted using an optical gas imaging instrument, as specified in paragraphs (c)(2)(i) and (ii) of this section.

(i) Operate and maintain the optical gas imaging instrument in accordance with the protocol for optical gas imaging

in 40 CFR part 60, appendix K. The optical gas imaging instrument must be able to detect at least one compound emitted from the storage vessel.

(ii) Each image of emissions is a deviation. Comply with paragraphs (c)(2)(ii)(A) and (B) of this section each time you detect an image when using an optical gas imaging instrument.

(A) Estimate emissions, as specified in paragraph (c)(1)(iii)(A) of this section.

(B) Keep records and report information, as specified in paragraphs (c)(1)(iii)(B) and (C) of this section.

(d) Whenever material regulated by a referencing subpart is in the pressure vessel, operate the pressure vessel as a closed system that does not vent to the atmosphere except at those times when purging of inerts or noncondensables from the pressure vessel is required and the purge stream is routed through a closed vent system to a control device in accordance with paragraphs (d)(1) through (3) of this section, as applicable. Keep records, as specified in § 65.380(h)(2), and report deviations in your semiannual periodic report, as specified in § 65.384(c).

(1) For the closed vent system, comply with § 65.325(b).

(2) For a non-flare control device, comply with requirements for the applicable control device in subpart M of this part, and comply with paragraphs (d)(2)(i) and (ii) of this section.

(i) A non-flare control device must reduce organic regulated material emissions by at least 98 percent by weight or to an outlet concentration of total regulated material less than 20 ppmv. If the regulated material is a subset of organic compounds (*e.g.,* HAP), you may demonstrate compliance by reducing emissions to an outlet concentration less than 20 ppmv as TOC. You must reduce the hydrogen halide and halogen emissions from combusted halogenated vent streams, as defined in § 65.295, by at least 99 percent by weight or to an outlet concentration less than 20 ppmv. The halogenated vent stream determination must be based on the emission rate at the maximum expected fill rate of the pressure vessel.

(ii) To demonstrate initial compliance with the emission limit(s) specified in paragraph (d)(2)(i) of this section, you must conduct either a design evaluation, as specified in § 65.850, or a performance test, as specified in §§ 65.820 through 65.829.

(3) For a flare, comply with the requirements of § 63.11(b) of this chapter. You must not use a flare to control halogenated vent streams, as defined in § 65.295.

Standards and Compliance Requirements for Transfer Operations

§ 65.360 What requirements must I meet for control of transport vehicles and transfer operations to load transport vehicles?

For each transfer rack that is used to load transport vehicles with regulated material, you must comply with paragraphs (a) and (b) of this section. You must also comply with paragraph (c) of this section for transport vehicles that are loaded with regulated material.

(a) *Transfer method.* Transfer regulated liquids to transport vehicles using submerged loading or bottom loading.

(b) *Displaced emissions control.* For each loading arm that transfers regulated material at a facility that transfers through all transfer racks a total of more than 35 million gallons per year (gal/yr) of liquids with a weighted average MTVP equal to or greater than 4 psia, comply with either paragraph (b)(1), (2) or (3) of this section.

(1) Route displaced emissions from the transport vehicle through a closed vent system to a control device and comply with paragraphs (b)(1)(i) through (iii) of this section. Keep records, as specified in § 65.380(j)(2).

(i) For the closed vent system, comply with the requirements specified in § 65.720(b) through (d) and paragraphs (b)(1)(i)(A) through (C) of this section.

(A) Determine if a piece of equipment in the closed vent system is in regulated material service, based on the MTVP of each transferred material that generates vapor that contacts the equipment. If any such vapor meets the definition of ''in regulated material service,'' comply with § 65.410(a) or (c) and applicable sections referenced therein, except that § 65.410(a)(2)(ii) does not apply for the purposes of this subpart. When § 65.410(c) refers to ''your referencing subpart'' it means ''the subpart that references subpart I.'' If equipment in the closed vent system contacts regulated material from transfers, but is not in regulated material service, comply with requirements in § 65.430, unless you are required to comply with § 65.429 for other emissions conveyed by the closed vent system.

(B) If equipment in the closed vent system is determined to be in regulated material service, conduct monitoring and inspections when the closed vent system is conveying vapor that causes the equipment in the closed vent system to be in regulated material service (*e.g.,* when transferring material that generates vapor that meets the threshold for ''in regulated material service''). If equipment in the closed vent system contacts regulated material, but is not in regulated material service, conduct inspections when regulated material vapors are flowing through the closed vent system (*e.g.,* when filling any transport vehicle that generates vapor that contains regulated material). No monitoring or inspection is required during monitoring periods when the closed vent system conveys no regulated material.

(C) Comply with § 65.430 for each potential source of vapor leakage in the closed vent system that is not defined as a piece of equipment. Keep identification records, as specified in § 65.380(j)(3).

(ii) For a non-flare control device, comply with the applicable requirements in subpart M of this part, and comply with paragraphs (b)(1)(ii)(A) and (B) of this section.

(A) A non-flare control device must reduce organic regulated material emissions by at least 95 percent by weight or to an outlet concentration of total organic regulated material less than 20 ppmv. If the regulated material is a subset of organic compounds (*e.g.,* HAP), you may demonstrate compliance by reducing emissions to an outlet concentration less than 20 ppmv as TOC. You must reduce the hydrogen halide and halogen emissions from combusted halogenated vent streams, as defined in § 65.295, by at least 99 percent by weight or to an outlet concentration less than 20 ppmv. The halogenated vent stream determination must be based on the emission rate at the maximum expected fill rate of the pressure vessel.

(B) To demonstrate initial compliance with the emission limit specified in paragraph (b)(1)(ii)(A) of this section, you must conduct either a design evaluation, as specified in § 65.850, or a performance test, as specified in §§ 65.820 through 65.829.

(iii) For flares, comply with the requirements of § 63.11(b) of this chapter. You must not use a flare to control halogenated vent streams, as defined in § 65.295.

(2) Route displaced emissions from the transport vehicle to a fuel gas system and comply with the requirements specified in paragraphs (b)(2)(i) through (iii) of this section.

(i) Comply with the requirements for fuel gas systems, as specified in § 65.732(a), (c) and (d).

(ii) For equipment in the fuel gas system, comply with the requirements for equipment leaks, as specified in subpart J of this part, and paragraphs (b)(2)(ii)(A) through (C) of this section.

(A) Determine if a piece of equipment in the fuel gas system is in regulated

material service, based on the MTVP of each transferred material that generates vapor that contacts the equipment. If any such vapor meets the definition of ''in regulated material service,'' comply with § 65.410(a) or (c) and applicable sections referenced therein, except that § 65.410(a)(2)(ii) does not apply for the purposes of this subpart. When § 65.410(c) refers to ''your referencing subpart,'' it means ''the subpart that references subpart I.'' If equipment in the fuel gas system contacts regulated material from transfers, but is not in regulated material service, comply with requirements specified in § 65.430, unless you are required to comply with § 65.427 for other emissions conveyed by the fuel gas system (*e.g.,* process vent emissions).

(B) For equipment in the fuel gas system that is determined to be in regulated material service, conduct monitoring and inspections, while transferring any material that generates vapor that causes the equipment in the fuel gas system to be in regulated material service. Alternatively, you may conduct monitoring and inspections when the fuel gas system is conveying vapors from other emission points that cause the equipment to be in regulated material service. If equipment in the fuel gas system contacts regulated material, but is not in regulated material service, conduct inspections when regulated material vapors are flowing through the fuel gas system (*e.g.,* when filling any transport vehicle with liquid that contains regulated material).

(C) Comply with § 65.430 for each potential source of emissions in the fuel gas system that is not defined as a piece of equipment. Keep identification records, as specified in § 65.380(j)(3).

(iii) Keep records, as specified in § 65.380(j)(7).

(3) Design and operate a vapor balancing system, as specified in paragraphs (b)(3)(i) through (v) of this section. This option may not be used if the applicable storage vessel is controlled using a floating roof. Keep records, as specified in § 65.380(j)(5).

(i) The vapor balancing system must be designed to route vapors displaced from the loading of regulated liquids into transport vehicles back to the storage vessel from which the liquid being loaded originated or to another storage vessel connected to a common header.

(ii) The vapor balancing system must be designed to prevent any regulated material vapors collected at one transfer rack from passing to another transfer rack.

(iii) All vapor connections and lines in the vapor collection equipment and vapor balancing system must be equipped with closures that seal upon disconnect.

(iv) Each pressure relief device on the transport vehicle and storage vessel must remain closed while the transport vehicle is being filled with regulated material.

(v) For pieces of equipment in the vapor balancing system, comply with paragraph (b)(1)(i) of this section, except that when paragraph (b)(1)(i) of this section refers to a ''closed vent system,'' it means a ''vapor balancing system'' for the purposes of this section.

(c) Transport vehicles. (1) Except when loading transport vehicles that meet the requirements in paragraph (c)(2) of this section, you must ensure that regulated material liquids are loaded only into transport vehicles that have a current certification in accordance with the DOT pressure test requirements in 49 CFR part 180 for cargo tanks or 49 CFR 173.31 for tank cars. Keep records of these certifications, as specified in § 65.380(j)(6).

(2) Each transport vehicle that is loaded with regulated material that has a MTVP greater than 4 psia at a transfer rack that is subject to this section must pass an annual vapor tightness test conducted using Method 27 of 40 CFR part 60, appendix A–8. Either you or the owner of the transport vehicle may conduct the test. Conduct the test using a time period (t) for the pressure and vacuum tests of 5 minutes. The initial pressure (P_i) for the pressure test must be 460 millimeters (mm) of water, gauge. The initial vacuum (V_i) for the vacuum test must be 150 mm of water, gauge. The maximum allowable pressure and vacuum changes (Δp, Δv) for transport vehicles is 25 mm of water, or less, in 5 minutes. Keep records of each test, as specified in § 65.380(j)(1).

(3) You must act to assure that your vapor balancing system, closed vent system or fuel gas system is connected to the transport vehicle's vapor collection equipment during each loading of a transport vehicle at the regulated source. Examples of actions to accomplish this include training drivers in the hookup procedures and posting visible reminder signs at the transfer racks that load regulated material.

§ 65.370 What requirements must I meet for control of transfer operations to load containers?

For each transfer rack that is used to load containers, you must comply with paragraphs (a) through (c) of this section, as applicable.

(a) Except as specified in paragraph (c) of this section, you must transfer regulated material into containers using either submerged fill or a fitted opening in the top of the container through which the regulated material is filled, with subsequent purging of the transfer line before removing it from the container opening.

(b) Whenever a container that is subject to this paragraph contains a regulated material, you must install all covers and closure devices for the container, and secure and maintain each closure device in the closed position, except when access to the container is necessary, such as for adding or removing material, sampling or cleaning. If the container is 55 gallons (gal) or larger, the transferred liquid has a MTVP greater than 4 psia, and the container is used for onsite storage, comply with either paragraph (b)(1) or (2) of this section.

(1) Demonstrate initially and at least annually that the container is vapor tight by testing in accordance with Method 27 of 40 CFR part 60, appendix A–8. Conduct the test using a time period (t) for the pressure and vacuum tests of 5 minutes. The initial pressure (P_i) for the pressure test must be 460 mm of water, gauge. The initial vacuum (V_i) for the vacuum test must be 150 mm of water, gauge. The maximum allowable pressure and vacuum changes (Δp, Δv) for all tested containers is 76 mm of water, or less, in 5 minutes. Keep records of each test, as specified in § 65.380(j)(1).

(2) Monitor annually each potential leak interface on the container using Method 21 of 40 CFR part 60, appendix A–7, in accordance with § 65.431(a) and (b), and paragraphs (b)(2)(i) through (iv) of this section.

(i) Section 65.431(a)(6) does not apply for the purposes of this section.

(ii) When § 65.431(a) and (b) refers to ''equipment,'' it means ''each potential leak interface on the container'' for the purposes of this section.

(iii) A leak is identified when you obtain an instrument reading greater than 500 ppmv.

(iv) For each leak, either repair the leak or empty the container within 15 days after detecting the leak.

(c) As an alternative to complying with paragraph (a) of this section, you may elect to control displaced vapors generated when filling the container in accordance with paragraph (c)(1), (2) or (3) of this section, as applicable.

(1) Design and operate a vapor balancing system to route vapors displaced from the loading of regulated material into containers directly (*e.g.,* no intervening tank or containment area, such as a room) to the storage vessel from which the liquid being loaded

originated or to another storage vessel connected to a common header. For equipment in the vapor balancing system, comply with § 65.360(b)(3), except when § 65.360(b)(1)(i), which is referenced from § 65.360(b)(3), refers to a ''transport vehicle,'' it means a ''container'' for the purposes of this section. Keep records, as specified in § 65.380(j)(5).

(2) Vent displaced emissions directly through a closed vent system to a control device in accordance with paragraph (c)(2)(i) through (iii) of this section.

(i) Comply with § 65.360(b)(1)(i) for the closed vent system, except that when § 65.360(b)(1)(i) refers to a ''transport vehicle,'' it means a ''container'' for the purposes of this section.

(ii) Comply with § 65.360(b)(1)(ii) or (iii) for the applicable control device.

(iii) Keep records, as specified in § 65.380(j)(2).

(3) When filling, locate the containers in an enclosure that is exhausted through a closed vent system to a control device, as specified in paragraphs (c)(3)(i) and (ii) of this section.

(i) Design and operate the enclosure in accordance with the criteria for a permanent total enclosure, as specified in ''Procedure T—Criteria for and Verification of a Permanent or Temporary Total Enclosure'' under 40 CFR 52.741, appendix B. The enclosure may have permanent or temporary openings to allow worker access; passage of containers through the enclosure by conveyor or other mechanical means; entry of permanent mechanical or electrical devices; or to direct airflow into the enclosure. Perform the verification procedure for the enclosure, as specified in Section 5.0 to ''Procedure T—Criteria for and Verification of a Permanent or Temporary Total Enclosure'' initially when the enclosure is first installed and, thereafter, annually. Keep records of these verifications, as specified in § 65.380(j)(4).

(ii) Comply with § 65.360(b)(1)(i) for the closed vent system and comply with § 65.360(b)(1)(ii) or (iii) for the applicable control device.

Recordkeeping and Reporting

§ 65.380 What records must I keep?

(a) *Vessel dimensions and storage capacity.* For each storage vessel that is subject to the referencing subpart, keep a record of the dimensions of the storage vessel and an analysis of the storage capacity of the storage vessel.

(b) *Liquid stored and MTVP.* (1) Keep a list of all the types of liquids stored.

(2) Keep a record of each MTVP determination and the supporting information used in the determination.

(c) *Monitoring and repair records for fixed roofs complying with § 65.310, § 65.320, § 65.325 or § 65.330.* (1) Record the date of each monitoring required by § 65.310(c).

(2) For each leak detected during monitoring required by § 65.310(c), record the location of the leak, a description of the leak, the date of detection, a description of actions taken to repair the defect and the date repair was completed. When using Method 21 of 40 CFR part 60, appendix A–7, keep a record of the instrument reading. When using optical gas imaging, keep a record of the video image.

(3) If you elect to use an extension in accordance with § 65.310(d), keep records, as specified in paragraphs (c)(3)(i) through (iii) of this section.

(i) Records for a first extension must include a description of the defect, documentation that alternative storage capacity was unavailable in the 45-day period after the inspection and a schedule of actions that you took in an effort to either repair or completely empty the storage vessel during the extension period.

(ii) For a second extension, if needed, you must maintain records documenting that alternative storage capacity was unavailable during the first extension period and a schedule of the actions you took to ensure that the control device was repaired or the vessel was completely emptied by the end of the second extension period.

(iii) Record the date on which the storage vessel was completely emptied, if applicable.

(4) If applicable, maintain a copy of the written plan required by § 65.310(c)(2)(ii) for parts of fixed roofs that are unsafe to monitor.

(d) *Records for floating roofs complying with § 65.315. (1) Floating roof landings.* For each floating roof landing, keep the records specified in paragraphs (d)(1)(i) through (iv) of this section, as required by § 65.315(f)(2).

(i) The date when a floating roof is set on its legs or other support devices.

(ii) The date when the roof was refloated.

(iii) Whether the process of refloating was continuous (*i.e.,* once started, filling or refilling was not suspended until the roof was refloated, except for filling from batch production, as specified in § 65.315(b)(2)).

(iv) Estimated emissions from the landing event.

(2) *Inspection results.* Keep records of floating roof inspection results, as specified in paragraphs (d)(2)(i) and (ii) of this section, as required by § 65.315(c).

(i) If the floating roof passes inspection, keep a record that includes the information specified in paragraphs (d)(2)(i)(A) and (B) of this section. If the floating roof fails inspection, keep a record that includes the information specified in paragraphs (d)(2)(i)(A) through (E) of this section.

(A) Identification of the storage vessel that was inspected.

(B) The date of the inspection.

(C) A description of all inspection failures.

(D) A description of all repairs and the dates they were made.

(E) The date the storage vessel was completely emptied, if applicable.

(ii) Keep records of the data specified in paragraphs (d)(2)(ii)(A) through (C) of this section, as applicable for EFR inspections and monitoring.

(A) EFR seal gap measurements, including the raw data obtained and any calculations performed, as required by § 65.315(c)(3).

(B) Instrument readings when monitoring is conducted using Method 21 of 40 CFR part 60, appendix A–7.

(C) A record of the video image when monitoring is conducted using optical gas imaging.

(3) *Documentation of inspection and repair extensions.* If you elect to use an extension in accordance with § 65.315(c)(3)(iv)(B) or (d)(2), keep records, as specified in paragraphs (d)(3)(i) through (iii) of this section.

(i) Records for a first extension must include an explanation of why it was unsafe to perform the inspection, documentation that alternative storage capacity was unavailable during the 45-day period after determining the floating roof is unsafe to inspect and a schedule of actions that you took in an effort to completely empty the storage vessel during the extension period.

(ii) For a second extension, if needed, you must maintain records documenting that alternative storage capacity was unavailable during the first extension period and a schedule of actions that you took to ensure that the vessel was completely emptied by the end of the second extension period.

(iii) Record the date on which the storage vessel was completely emptied, if applicable.

(e) *Records for fixed roof storage vessels that vapor balance to comply with § 65.320.* (1) Keep records of fixed roof monitoring and repair, as specified in paragraph (c) of this section.

(2) For transport vehicles, keep records of DOT certification(s) required by § 65.320(b)(2)(i).

(3) For barges, keep records of vapor tightness pressure test documentation

required by § 65.320(b)(2)(ii). The documentation must include the information in paragraphs (e)(3)(i) through (ix) of this section.

(i) Test title: Barge Pressure Test.

(ii) Barge owner and address.

(iii) Barge identification number.

(iv) Testing location.

(v) Test date.

(vi) Tester name and signature.

(vii) Witnessing inspector, if any: Name, signature and affiliation.

(viii) Initial and final test pressures and the time at the beginning and end of the test.

(ix) Test results: Actual pressure change in 30 minutes, mm of water.

(4) Keep records of the pressure relief vent setting that prevents breathing losses from the storage vessel required by § 65.320(c)(3).

(5) For equipment in the vapor balancing system, keep records, as required by subpart J of this part.

(f) *Records for fixed roof storage vessels vented to a control device complying with § 65.325.* (1) Keep records of fixed roof monitoring and repair, as specified in paragraph (c) of this section.

(2) For the closed vent system, keep records, as specified in subpart J of this part and subpart M of this part.

(3) For a non-flare control device, keep the applicable records specified in subpart M of this part. For flares, keep records of all visual emissions observed, periods when a pilot flame is out, and any periods that the pilot flames are not monitored.

(4) Record the day and time at which planned routine maintenance periods begin and end, and the type of maintenance performed on the control device. If you need more than 240 hr/yr, keep a record that explains why additional time up to 360 hr/yr was needed and describes how you minimized the amount of additional time needed.

(5) Keep a record identifying each potential source of vapor leakage in the closed vent system that is not defined as a piece of equipment, as required by § 65.325(b)(2).

(g) *Records for fixed roof storage vessels vented to a fuel gas system complying with § 65.330.* (1) Keep records of fixed roof monitoring and repair, as specified in paragraph (c) of this section.

(2) For the fuel gas system, keep records, as specified in subpart J of this part and subpart M of this part.

(3) Keep a record identifying each potential source of vapor leakage in the fuel gas system that is not defined as a piece of equipment, as required by § 65.330(b)(2).

(h) *Records for pressure vessels complying with § 65.340.* (1) For each performance test required by § 65.340(c), keep records of the information in paragraphs (h)(1)(i) through (iii).

(i) The date of the test.

(ii) The instrument reading (and background level, if you adjust for background, as described in § 65.431(a)(7)), if you test using Method 21 of 40 CFR part 60, appendix A–7.

(iii) The video image, if you test using optical gas imaging.

(2) Keep records of the information in paragraphs (h)(2)(i) through (iv) of this section when the performance test required by § 65.340(c) detects a defect.

(i) Date each defect was detected.

(ii) Date of the next performance test that shows either the instrument reading is less than 500 ppmv when using Method 21 of 40 CFR part 60, appendix A–7, or no image is detected when using an optical gas imaging instrument.

(iii) Start and end dates of each period after the date in paragraph (h)(2)(i) of this section when the pressure vessel was completely empty.

(iv) Estimated emissions from each defect.

(3) When complying with § 65.340(d), keep records for the closed vent system, as specified in subpart J of this part and subpart M of this part, and for a non-flare control device, keep the applicable records specified in subpart M of this part. For flares, keep records of all visual emissions observed, periods when a pilot flame is out, and any periods that the pilot flames are not monitored.

(i) *Records of overfilling.* For each storage vessel that is subject to § 65.305(b), keep records of each date when the storage vessel is overfilled and estimates of the amount of regulated material spilled and emitted to the atmosphere, as required by § 65.315(g), § 65.320(d), § 65.325(d), or § 65.330(c).

(j) *Records for transfer operations.* (1) Keep records of the information listed in paragraphs (j)(1)(i) through (ix) of this section for each transport vehicle and container for which testing using Method 27 of 40 CFR part 60, appendix A–8 is required by § 65.360(c)(2) or § 65.370(b)(1). You must update the documentation file for each subject transport vehicle and container at least once per year to reflect current test results, as determined by Method 27 of 40 CFR part 60, appendix A–8.

(i) Test title: Transport Vehicle or Container Pressure Test—EPA Reference Method 27.

(ii) Transport vehicle or container owner and address.

(iii) Transport vehicle or container identification number.

(iv) Testing location.

(v) Date of test.

(vi) Tester name and signature.

(vii) Witnessing inspector, if any: Name, signature and affiliation.

(viii) Initial and final test pressures, initial and final test vacuums and the time at the beginning and end of the test.

(ix) Test results: Actual pressure and vacuum changes in 5 minutes, mm of water (average for 2 runs, as required by Method 27 of 40 CFR part 60, appendix A–8).

(2) If you use a closed vent system and control device, as specified in § 65.360(b)(1) or § 65.370(c)(2)(ii), keep records for the closed vent system, as specified in subpart J of this part and subpart M of this part, and for a non-flare control device, keep the applicable records specified in subpart M of this part. For flares, keep records of all visual emissions observed, periods when a pilot flame is out, and any periods that the pilot flames are not monitored.

(3) Keep a record identifying each potential source of vapor leakage in the closed vent system or fuel gas system that is not defined as a piece of equipment, as required by § 65.360(b)(1)(i)(C) or (2)(ii)(C).

(4) For containers filled inside an enclosure, as specified in § 65.370(c)(3)(i), keep records of the most recent set of calculations and measurements performed to verify that the enclosure meets the criteria of a permanent total enclosure, as specified in ''Procedure T—Criteria for and Verification of a Permanent or Temporary Total Enclosure'' under 40 CFR 52.741, appendix B.

(5) If you use a vapor balancing system, as specified in § 65.360(b)(3) or § 65.370(c)(1), keep records of the date of each sensory inspection or instrument monitoring, the number of potential leaks to the atmosphere that you identified and the records required by subpart J of this part for monitoring conducted in accordance with § 65.430(b)(2) and the requirements referenced therein.

(6) For transport vehicles, keep records of DOT certification(s) required by § 65.360(c)(1).

(7) If you route emissions from transport vehicles to a fuel gas system, as specified in § 65.360(b)(2), keep records as specified in subpart M of this part.

(k) *Continuous Parameter Monitoring System (CPMS) Records for closed vent systems in vacuum service.* Keep records of the inspections, checks and

performance evaluations required by subpart J of this part for your CPMS.

§ 65.382 What information must I submit in my Notification of Compliance Status?

You must include the information listed in paragraphs (a) through (c) of this section, as applicable, in the Notification of Compliance Status that you submit according to the procedures in § 65.225.

(a) The identification of each storage vessel in the regulated source under the referencing subpart, its storage capacity and the liquid stored in the storage vessel.

(b) The identification of each transfer rack in the regulated source under the referencing subpart.

(c) If applicable, you must include rationale, pursuant to § 65.320(c)(3), explaining why pressure lower than 2.5 psig is sufficient to prevent breathing losses from pressure relief devices on storage vessels.

§ 65.384 What information must I submit in my semiannual periodic report?

Submit the information specified in paragraphs (a) through (f) of this section, as applicable, in semiannual periodic reports that you submit, as specified in § 65.225.

(a) If you do not empty or repair leaks before the end of the second extension period, as required by § 65.310(d) or § 65.315(d)(2), report the date when the storage vessel was emptied or repaired.

(b) Report the storage vessel identification and the start and end dates of each floating roof landing that does not meet the criteria specified in § 65.315(b)(1).

(c) If you obtain an instrument reading greater than 500 ppmv or an image of a leak when monitoring a pressure vessel in accordance with § 65.340(c)(1) or (2), submit a copy of the records specified in § 65.380(h)(2).

(d) If you use a closed vent system and non-flare control device, as specified in § 65.325, § 65.360(b)(1) or § 65.370(c)(2), submit information in semiannual reports, as specified in subparts J and M of this part. For flares, report any instances when visual emissions occur longer than 5 minutes during any 2 consecutive hours, a pilot flame is out, or the pilot flames are not monitored.

(e) If you use a vapor balancing system, as specified in § 65.320, § 65.360(b)(3) or § 65.370(c)(1), submit information in semiannual reports, as specified in subparts J and M of this part.

(f) If you use a fuel gas system, as specified in § 65.330 or § 65.360(b)(2), submit information in semiannual reports, as specified in subparts J and M of this part.

§ 65.386 What information must I submit in my annual periodic report?

You must report the information specified in paragraphs (a) through (c) of this section, as applicable, in annual periodic reports that you submit, as specified in § 65.225.

(a) *Inspection results.* You must submit a copy of the inspection record (required by § 65.380(c)(2), (d)(3) and (g)(1)) when an inspection failure or leak is detected.

(b) *Estimated emissions from floating roof landings.* Submit a copy of the estimated emissions record when a floating roof is landed, as specified in § 65.380(d)(1).

(c) *Estimated emissions from overfilling.* Submit a copy of the estimated emissions record when a storage vessel is overfilled, as specified in § 65.380(i).

§ 65.388 What other reports must I submit and when?

(a) *Notification of inspection.* (1) Except as specified in paragraphs (a)(2) and (3) of this section, you must notify the Administrator at least 30 days prior to a storage vessel inspection required by § 65.310(c) or § 65.315(c). This notification may be included in your next annual periodic report if the annual periodic report will be submitted so that it is received by the Administrator at least 30 days prior to the inspection.

(2) Except as specified in paragraph (a)(3) of this section, if an inspection is unplanned and you could not have known about the inspection 30 days in advance, then you must notify the Administrator at least 7 days before the inspection. Notification must be made by telephone immediately, followed by written documentation demonstrating why the inspection was unplanned. Alternatively, the notification, including the written documentation, may be made in writing and sent so that it is received by the Administrator at least 7 days before the inspection.

(3) A delegated state or local agency may waive the requirement for notification of storage vessel inspections.

(b) *Requests for alternate devices.* If you request the use of an alternate device, as described in § 65.315(e), you must submit an application in accordance with § 65.260.

Other Requirements and Information

§ 65.390 What definitions apply to this subpart?

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart H of this part, unless otherwise specified in the referencing subpart.

List of Tables to Subpart I of Part 65

TABLE 1 TO SUBPART I OF PART 65—STANDARDS AND COMPLIANCE REQUIREMENTS FOR STORAGE VESSELS AND TRANSFER OPERATIONS

[As required in §§ 65.310, 65.315, 65.320, 65.325, 65.330, 65.360 and 65.370, you must comply with each applicable control requirement for storage vessels and transfer operations specified in the following table.]

For a(n) . . .	You must . . .
1. Atmospheric storage vessel that stores any regulated material and does not meet criteria specified in item 2 or item 3 to this table.	a. Comply with § 65.310 and the requirements referenced therein; or b. Comply with the requirements in item 2 to this table.
2. Atmospheric storage vessel ≥20,000 gal and <40,000 gal that stores material with a MTVP ≥1.9 psia.	a. Comply with § 65.315 and the requirements referenced therein, provided the MTVP of the stored liquid is less than 76.6 kPa; or b. Comply with § 65.320 and the requirements referenced therein; or c. Comply with § 65.325 and the requirements referenced therein; or d. Comply with § 65.330 and the requirements referenced therein.
3. Atmospheric storage vessel ≥40,000 gal that stores material with a MTVP ≥0.75 psia.	a. Comply with item 2 to this table.

TABLE 1 TO SUBPART I OF PART 65—STANDARDS AND COMPLIANCE REQUIREMENTS FOR STORAGE VESSELS AND TRANSFER OPERATIONS—Continued

[As required in §§ 65.310, 65.315, 65.320, 65.325, 65.330, 65.360 and 65.370, you must comply with each applicable control requirement for storage vessels and transfer operations specified in the following table.]

For a(n) . . .	You must . . .
4. Pressure vessels	a. Comply with § 65.340 and the requirements referenced therein.
5. Transfer operations that involve loading of transport vehicles	a. Comply with § 65.360 and the requirements referenced therein.
6. Transfer operations that involve loading of containers	a. Comply with § 65.370 and the requirements referenced therein.

TABLE 2 TO SUBPART I OF PART 65—INSPECTION AND MONITORING REQUIREMENTS AND SCHEDULE FOR STORAGE VESSELS EQUIPPED WITH AN IFR

[As required in § 65.315(c), you must inspect and monitor IFR, as specified in the following table.]

For each IFR, comply with . . .	You must . . .	At the following times . . .	Except . . .
1. Option 1; or	a. From within the storage vessel, inspect the floating roof deck, deck fittings and rim seal(s) in accordance with § 65.315(c)(1) and (2)(i); and	i. Before the initial fill of the storage vessel, and.	Not applicable.
		ii. Each time the storage vessel is completely emptied and degassed, or before the date 10 years after the previous inspection from within the storage vessel, whichever occurs first.	(1) If the storage vessel is out of service on the date 10 years after the previous inspection, the inspection may be delayed, provided it is conducted prior to filling the storage vessel with regulated material.
	b. From openings in the fixed roof or from within the storage vessel, visually inspect the floating roof deck, deck fittings and rim seal in accordance with § 65.315(c)(1).	i. At least annually	(1) Identification of holes or tears in the rim seal is required only for the seal that is visible from the top of the storage vessel. (2) This inspection is not required in a calendar year when you conduct an inspection in accordance with item 1.a of this table.
2. Option 2; or	a. From within the storage vessel, inspect the floating roof deck, deck fittings and rim seal(s) in accordance with § 65.315(c)(1); and	i. Before the initial fill of the storage vessel; and.	See item 2.b.i.(1) of this table.
		ii. Each time the storage vessel is completely emptied and degassed, or before the date 10 years after the previous inspection from within the storage vessel, whichever occurs first.	(1) If the storage vessel is out of service on the date 10 years after the previous inspection, the inspection may be delayed provided it is conducted prior to filling the storage vessel with regulated material.
	b. From openings in the fixed roof, monitor each deck fitting in accordance with § 65.315(c)(2)(iii); and	i. Within 90 days after initial fill; and	(1) This option may be used only if the criteria for optical gas imaging in § 65.315(c)(2)(iii) and 40 CFR part 60, appendix K are met.
		ii. At least annually	Not applicable.
	c. From openings in the fixed roof, monitor the circumference of the IFR in accordance with § 65.315(c)(6).	i. Within 90 days after initial fill; and	See item 2.b.i.(1) of this table.
		ii. At least annually	Not applicable.
3. Option 3	a. As an alternative to Option 1 in this table, for an IFR with two rim seals, inspect the roof deck, deck fittings, and rim seals from within the storage vessel in accordance with § 65.315(c)(1) and (2)(i).	i. Before the initial fill; and	Not applicable.
		ii. Each time the storage vessel is completely emptied and degassed, or before the date 5 years after the previous inspection from within the storage vessel, whichever occurs first.	(1) If the storage vessel is out of service on the date 5 years after the previous inspection, the inspection may be delayed provided it is conducted prior to filling the storage vessel with regulated material.

TABLE 3 TO SUBPART I OF PART 65—INSPECTION AND MONITORING REQUIREMENTS AND SCHEDULE FOR STORAGE VESSELS EQUIPPED WITH AN EFR

[As required in § 65.315(c), you must inspect and monitor EFR, as specified in the following table.]

For each EFR, comply with . . .	You must . . .	At the following times . . .	Except . . .
1. Option 1; or	a. Inspect the primary rim seal, as specified in § 65.315(c)(3), and	i. Within 90 days after the initial fill of the storage vessel, and	Not applicable.
		ii. Before the date 5 years after the previous primary seal gap inspection.	Not applicable.
	b. Inspect the secondary rim seal, as specified in § 65.315(c)(3), and	i. Within 90 days after the initial fill of the storage vessel, and	Not applicable.
		ii. At least annually.	Not applicable.
	c. Visually inspect the floating roof deck, deck fittings and secondary seal, as specified in § 65.315(c)(1); and	i. At least annually.	(1) Identification of holes or tears in the rim seal is required only for the seal that is visible from the top of the storage vessel.
	d. Inspect the deck fittings, as specified in § 65.315(c)(2)(i).	i. At least annually.	Not applicable.
2. Option 2	a. Monitor the circumference of the EFR in accordance with § 65.315(c)(5); and	i. Within 90 days after initial fill; and	Not applicable.
		ii. At least annually.	Not applicable.
	b. Monitor each deck fitting in accordance with § 65.315(c)(2)(ii); and	i. Within 90 days after initial fill; and	Not applicable.
		ii. At least annually.	Not applicable.
	c. Visually inspect the floating roof deck, deck fittings and secondary seal in accordance with § 65.315(c)(1).	i. At least annually.	(1) Identification of holes or tears in the rim seal is required only for the seal that is visible from the top of the storage vessel.
3. Option 3	a. Monitor the circumference of the EFR in accordance with § 65.315(c)(4); and	i. Within 90 days after initial fill; and	(1) This option may be used only if the criteria for optical gas imaging in § 65.315(c)(4) and 40 CFR part 60, appendix K are met.
		ii. At least annually.	Not applicable.
	b. Monitor each deck fitting in accordance with § 65.315(c)(2)(iii); and	i. Within 90 days after initial fill; and	(1) This option may be used only if the criteria for optical gas imaging in § 65.315(c)(2)(iii) and 40 CFR part 60, appendix K are met.
		ii. At least annually.	Not applicable.
	c. Visually inspect the floating roof deck, deck fittings and secondary seal in accordance with § 65.315(c)(1).	i. At least annually.	(1) Identification of holes or tears in the rim seal is required only for the seal that is visible from the top of the storage vessel.

4. Add subpart J to read as follows:

Sec.

Subpart J—National Uniform Emission Standards for Equipment Leaks

What This Subpart Covers

65.400 What is the purpose of this subpart?
65.401 Am I subject to this subpart?
65.402 What parts of my plant does this subpart cover?
65.403 What parts of the General Provisions apply to me?

Emission Limits and Other Standards—General

65.410 What are my compliance options?
65.413 What are the standards and compliance requirements for closed vent systems, control devices and fuel gas systems used to comply with this subpart?
65.415 How must I identify equipment?
65.416 How must I designate special equipment?

Equipment Leak Standards

65.420 What are the standards and compliance requirements for valves in gas and vapor service and valves in light liquid service?
65.421 What are the standards and compliance requirements for pumps in light liquid service?
65.422 What are the standards and compliance requirements for connectors in gas and vapor service and connectors in light liquid service?
65.423 What are the standards and compliance requirements for agitators in gas and vapor service and agitators in light liquid service?
65.424 What are the standards and compliance requirements for pressure relief devices?
65.425 What are the standards and compliance requirements for compressors?
65.426 What are the standards and compliance requirements for sampling connection systems?
65.427 What are the standards and compliance requirements for open-ended valves and lines?
65.428 What are the standards and compliance requirements for other equipment that contacts or contains regulated material?
65.429 What are the standards and compliance requirements for equipment in closed vent systems and fuel gas systems?

Equipment Leak Monitoring and Repair

65.430 What are my sensory monitoring requirements?
65.431 What instrument monitoring methods must I use to detect leaks?
65.432 What are my leak identification and repair requirements?

Alternative Equipment Leak Standards

65.440 What is the alternative means of emission limitation for equipment in batch operations?

Optical Gas Imaging Standards for Detecting Equipment Leaks

65.450 What are the standards and compliance requirements for using an optical gas imaging instrument to detect leaks?

Notifications, Reports and Records

65.470 What notifications and reports must I submit?

65.475 What are my recordkeeping requirements?

Other Requirements and Information

65.490 What definitions apply to this subpart?

List of Tables in Subpart J of Part 65

Table 1 to Subpart J of Part 65—Instrument Readings That Define a Leak for Equipment Complying With § 65.430(b)(2)

Table 2 to Subpart J of Part 65—Monitoring Frequency for Equipment in Batch Operations Complying With § 65.440

Subpart J—National Uniform Emission Standards for Equipment Leaks

What This Subpart Covers

§ 65.400 What is the purpose of this subpart?

This subpart specifies requirements to meet the emission standards of a referencing subpart for equipment leaks.

§ 65.401 Am I subject to this subpart?

You are subject to this subpart if you are an owner or operator who is subject to a referencing subpart and you have been expressly directed to comply with this subpart by a referencing subpart.

§ 65.402 What parts of my plant does this subpart cover?

This subpart applies to equipment in process units, closed vent systems and fuel gas systems that contains or contacts regulated material and is subject to a referencing subpart. This subpart applies to valves, pumps, connectors, agitators, pressure relief devices, compressors, sampling connection systems, open-ended valves and lines, instrumentation systems and any other equipment, as defined in the referencing subpart. This subpart also applies to closed-purge and closed-loop systems used to meet the requirements of this subpart.

§ 65.403 What parts of the General Provisions apply to me?

The General Provisions of 40 CFR parts 60, 61 and 63 apply to this subpart, as specified in subpart H of this part.

Emission Limits and Other Standards—General

§ 65.410 What are my compliance options?

(a) Except as specified in paragraphs (b) and (c) of this section, for each regulated source that is subject to control requirements for equipment leaks in a referencing subpart, you must comply with paragraphs (a)(1) through (3) of this section.

(1) Identify subject equipment in accordance with §§ 65.415 and 65.416.

(2) Comply with the requirements in paragraph (a)(2)(i) of this section or, as applicable, comply with the alternative specified in paragraph (a)(2)(ii) of this section.

(i) As applicable, comply with the equipment-specific standards in §§ 65.420 through 65.429 and the related requirements in §§ 65.430 through 65.432.

(ii) As an alternative to paragraph (a)(2)(i) of this section, if you have equipment in a batch operation, you may elect to comply with the alternative monitoring frequency requirements in § 65.440.

(3) Comply with the applicable notification, reporting and recordkeeping requirements in §§ 65.470 and 65.475.

(b) You are not required to comply with the requirements of §§ 65.420 through 65.440 for equipment in vacuum service, provided that you comply with paragraphs (b)(1) through (3) of this section.

(1) Identify the equipment, as specified in § 65.415(f).

(2) Continuously demonstrate that the equipment remains in vacuum service, as described in § 65.416(e).

(3) Comply with the applicable recordkeeping requirements in § 65.475(b)(6).

(c) If your referencing subpart specifies that you may comply with the optical gas imaging requirements in § 65.450 as an alternative to complying with paragraph (a) of this section, you must comply with paragraphs (c)(1) through (3) of this section if you elect to comply with the optical gas imaging alternative.

(1) Identify subject equipment in accordance with § 65.415.

(2) Comply with § 65.450 for leak detection and repair.

(3) Comply with the applicable notification, reporting and recordkeeping requirements in §§ 65.470 and 65.475(e).

§ 65.413 What are the standards and compliance requirements for closed vent systems, control devices and fuel gas systems used to comply with this subpart?

A closed vent system and non-flare control device or a fuel gas system used to meet applicable requirements in §§ 65.420 through 65.427 must meet the applicable requirements of subpart M of this part. A flare used to meet applicable requirements in §§ 65.420 through 65.427 must meet the applicable requirements in § 63.11(b) of this chapter. You must not use a flare to control halogenated vent streams, as defined in § 65.295. The non-flare control device must also meet the requirements of paragraphs (a) and (b) of this section.

(a) A non-flare control device must reduce regulated material emissions by at least 95 percent by weight or to an outlet concentration less than 20 ppmv.

(b) To demonstrate initial compliance with the emission limit specified in paragraph (a) of this section, you must conduct either a design evaluation or a performance test in accordance with subpart M of this part.

§ 65.415 How must I identify equipment?

You must identify equipment subject to this subpart, as described in paragraphs (a) through (g) of this section. Identification of the equipment does not require physical tagging of the equipment. For example, the equipment may be identified on a plant site plan, in log entries, by designation of process unit boundaries, by some form of weatherproof identification or by other appropriate methods.

(a) *Connectors.* Except for inaccessible, ceramic or ceramic-lined connectors meeting the provision of § 65.422(d)(3) and connectors in instrumentation systems identified, pursuant to paragraph (d) of this section, identify the connectors subject to the requirements of this subpart. You need not individually identify each connector if you identify all connectors in a designated area or length of pipe subject to the provisions of this subpart as a group and you indicate the number of connectors subject. The identification of connectors must be complete no later than either the compliance date, as specified in your referencing subpart, or before completion of the initial round of monitoring required by § 65.422(a)(2), whichever is later.

(b) *Pressure relief devices.* Identify the pressure relief devices in gas or vapor service that vent to the atmosphere under the provisions of § 65.424(a) and the pressure relief devices in gas or vapor service routed through a closed

vent system to a control device under the provisions of § 65.424(d).

(c) *Instrumentation systems.* Identify instrumentation systems subject to the provisions of § 65.430(a). You do not need to identify individual valves, pumps, connectors or other pieces of equipment within an instrumentation system.

(d) *Equipment in heavy liquid service.* Identify the equipment in heavy liquid service, under the provisions of § 65.430(c).

(e) *Equipment in service less than 300 hours per calendar year.* Identify, either by list, location (area or group) or other method, equipment in regulated material service less than 300 hours per calendar year within a process unit subject to the provisions of this subpart.

(f) *Equipment in vacuum service.* Identify, either by list, location (area or group) or other method, equipment in vacuum service within a process unit subject to the provisions of this subpart.

(g) *Other equipment.* Identify any other equipment subject to any of the provisions in § 65.410.

§ 65.416 How do I designate special equipment?

(a) *Equipment that is unsafe- or difficult-to-monitor. (1) Designation and criteria for unsafe-to-monitor.* You may designate the equipment listed in paragraphs (a)(1)(i) though (iv) of this section as unsafe-to-monitor if you determine that monitoring personnel would be exposed to an immediate danger as a consequence of complying with the monitoring requirements of this subpart. Examples of unsafe-to-monitor equipment include, but are not limited to, equipment under extreme pressure or heat, equipment that you cannot access without the use of a motorized man-lift basket in areas where an ignition potential exists or equipment in near proximity to hazards such as electrical lines.

(i) Valves complying with § 65.420 or § 65.440.

(ii) Pumps complying with § 65.421 or § 65.440.

(iii) Connectors complying with § 65.422 or § 65.440.

(iv) Agitators complying with § 65.423 or § 65.440.

(2) *Designation and criteria for difficult-to-monitor.* You may designate the equipment listed in (a)(2)(i) though (iv) as difficult-to-monitor if you determine that the equipment cannot be monitored without elevating the monitoring personnel more than 7 feet above a support surface or it is not accessible in a safe manner when it is in regulated material service.

(i) Valves complying with § 65.420 or § 65.440. In a new source, the number of valves you designate as difficult-to-monitor must be less than 3 percent of the total number of valves in that new source, unless all of the difficult-to-monitor valves in that source are low leak technology, as described in § 65.432(e)(3).

(ii) Pumps complying with § 65.421 or § 65.440.

(iii) Connectors complying with § 65.422 or § 65.440.

(iv) Agitators complying with § 65.423 or § 65.440.

(3) *Identification of unsafe- or difficult-to-monitor equipment.* You must record the identity of equipment designated as unsafe-to-monitor according to the provisions of paragraph (a)(1) of this section and record the identity of equipment designated as difficult-to-monitor according to the provisions of paragraph (a)(2) of this section. For both types of equipment, you must also record the planned schedule for monitoring this equipment and an explanation why the equipment is unsafe- or difficult-to-monitor, as specified in § 65.475(b)(2)(ii).

(4) *Written plan requirements.* For equipment designated as unsafe-to-monitor or difficult-to-monitor, you must have a written plan that meets the requirements of paragraph (a)(4)(i) or (ii) of this section, as applicable. You must keep the plan onsite as long as the equipment is designated unsafe-to-monitor or difficult-to-monitor.

(i) For equipment designated as unsafe-to-monitor according to the provisions of paragraph (a)(1) of this section, you must have a written plan that requires monitoring of the equipment as frequently as practical during safe-to-monitor times, but not more frequently than the periodic monitoring schedule otherwise applicable, and repair of the equipment according to the procedures in § 65.432 if a leak is detected. If applicable, your written plan must also address how you will address any indications of liquids dripping observed during a weekly visual inspection.

(ii) For equipment designated as difficult-to-monitor according to the provisions of paragraph (a)(2) of this section, you must have a written plan that requires monitoring of the equipment at least once per calendar year and repair of the equipment according to the procedures in § 65.432 if a leak is detected. If applicable, your written plan must also address how you will address any indications of liquids dripping observed during a weekly visual inspection.

(b) *Inaccessible connectors.* You may designate a connector as an inaccessible connector if it meets any of the provisions specified in paragraphs (b)(1) through (3) of this section, as applicable.

(1) The connector is buried.

(2) The connector is insulated in a manner that prevents access to the connector by a monitor probe.

(3) The connector is obstructed by equipment or piping that prevents access to the connector by a monitor probe.

(c) *Compressors operating with an instrument reading of less than 500 parts per million (ppm) above background.* Identify the compressors that you elect to designate as operating with instrument reading of less than 500 parts per million (ppm) above background under the provisions of § 65.425(b).

(d) *Pressure relief devices (PRD) in regulated material service that vent to atmosphere.* If your referencing subpart specifies that releases to the atmosphere from a pressure relief device (PRD) is not allowed, identify all PRD in regulated material service, the process components served by the PRD and whether the PRD vent to atmosphere or through a closed vent system to a control device. This identification may be used to meet the requirements of § 65.415(b).

(e) *Equipment in vacuum service.* For equipment in vacuum service that contains or contacts regulated material, you must demonstrate that the equipment is operated and maintained in vacuum service, as described in paragraphs (e)(1) through (3) of this section.

(1) *In vacuum service alarm.* You must install a continuous parameter monitoring system (CPMS) to measure pressure and an alarm system that will alert an operator immediately and automatically when the pressure is such that the equipment no longer meets the definition of in vacuum service. The alarm must be located such that the alert is detected and recognized easily by an operator. For the CPMS, you must check for obstructions (e.g., pressure tap pluggage) at least once each process operating day. You must conduct a performance evaluation annually, a check of all mechanical connections for leakage monthly and a visual inspection of all components for integrity, oxidation and galvanic corrosion every 3 months.

(2) *In vacuum service alarm procedures.* If the alarm is triggered for equipment operating in vacuum service, as specified in paragraph (e)(1) of this section, you must immediately initiate procedures to get the equipment back into vacuum service, or you may chose to comply with the requirements of § 65.410(a)(2).

(3) In vacuum service alarm records. You must maintain records, as specified in § 65.475(b)(6).

Equipment Leak Standards

§ 65.420 What are the standards and compliance requirements for valves in gas and vapor service and valves in light liquid service?

Except as provided in paragraph (d) of this section, you must comply with the requirements specified in paragraphs (a) through (c) of this section for valves in gas and vapor service and valves in light liquid service.

(a) *Instrument monitoring and leak detection.* You must conduct instrument monitoring, as specified in § 65.431 and paragraphs (a)(1) through (3) of this section.

(1) *Instrument reading that defines a leak.* The instrument reading that defines a leak is 500 ppm or greater.

(2) *Monitoring frequency.* Except as specified in paragraph (a)(2)(vi) of this section, you must monitor valves for leaks monthly for the first 2 months after initial startup. After the first 2 months following initial startup, you must monitor valves for leaks at the frequency specified in paragraphs (a)(2)(i) through (v) of this section. You must also keep a record of the start date and end date of each monitoring period under this section for each process unit, as specified in § 65.475(c)(1)(i).

(i) At process units with at least 2-percent leaking valves, calculated according to paragraph (b) of this section, you must monitor each valve according to either paragraph (a)(2)(i)(A) or (B) of this section.

(A) Monitor each valve monthly.

(B) If the summed number of valves found to be leaking (*i.e.,* ''V_L'' in Equation 2 in paragraph (b)(1)(ii) of this section) over the last two monitoring periods is three or less, you may elect to monitor each valve quarterly.

(ii) At process units with less than 2-percent leaking valves, calculated as specified in paragraph (b) of this section, you must monitor each valve quarterly, except as provided in paragraphs (a)(2)(iii) through (v) of this section.

(iii) At process units with less than 1-percent leaking valves, you may elect to monitor each valve semiannually.

(iv) At process units with less than 0.5-percent leaking valves, you may elect to monitor each valve annually.

(v) At process units with less than 0.25 percent leaking valves, you may elect to monitor each valve biennially.

(vi) Monitoring data generated before the regulated source became subject to the referencing subpart and meeting the criteria of either § 65.431(a)(1) through (5), or § 65.431(a)(6), may be used to qualify initially for less frequent monitoring under paragraphs (a)(2)(ii) through (v) of this section.

(3) *Valve subgrouping.* For a process unit or a group of process units to which this subpart applies, you may choose to subdivide the valves in the applicable process unit or group of process units and apply the provisions of paragraph (b)(2) of this section to each subgroup. If you elect to subdivide the valves in the applicable process unit or group of process units, then the provisions of paragraphs (a)(3)(i) through (vii) of this section apply.

(i) The overall performance of total valves in the applicable process unit or group of process units to be subdivided must be less than 2-percent leaking valves, as detected according to paragraphs (a)(1) and (2) of this section and, as calculated according to paragraphs (b)(1)(ii) and (b)(2) of this section.

(ii) The initial assignment or subsequent reassignment of valves to subgroups shall be governed by the provisions of paragraphs (a)(3)(ii)(A) through (C) of this section.

(A) You must determine which valves are assigned to each subgroup. Valves with less than 1 year of monitoring data or valves not monitored within the last 12 months must be placed initially into the most frequently monitored subgroup until at least 1 year of monitoring data have been obtained.

(B) Any valve or group of valves can be reassigned from a less frequently monitored subgroup to a more frequently monitored subgroup provided that you monitored the valves to be reassigned during the most recent monitoring period for the less frequently monitored subgroup. The monitoring results must be included with that less frequently monitored subgroup's associated percent leaking valves calculation for that monitoring event.

(C) Any valve or group of valves can be reassigned from a more frequently monitored subgroup to a less frequently monitored subgroup provided that the valves to be reassigned have not leaked for the period of the less frequently monitored subgroup (*e.g.,* for the last 12 months, if the valve or group of valves is to be reassigned to a subgroup being monitored annually). Non-repairable valves may not be reassigned to a less frequently monitored subgroup.

(iii) Every 6 months, you must determine if the overall performance of total valves in the applicable process unit or group of process units is less than 2-percent leaking valves and so indicate the performance in the next periodic report. You must calculate the overall performance of total valves in the applicable process unit or group of process units as a weighted average of the percent leaking valves of each subgroup according to Equation 1 of this section:

$$\%V_{LO} = \frac{\sum_{i=1}^{n} \left(\%V_{Li} \times V_i\right)}{\sum_{i=1}^{n} V_i} \qquad \text{(Eq. 1)}$$

Where:

$\%V_{LO}$ = Overall performance of total valves in the applicable process unit or group of process units.

$\%V_{Li}$ = Percent leaking valves in subgroup i, most recent value calculated according to the procedures in paragraphs (b)(1)(ii) and (b)(2) of this section.

V_i = Number of valves in subgroup i.

n = Number of subgroups.

(iv) If the overall performance of total valves in the applicable process unit or group of process units, determined according to paragraph (a)(3)(iii) of this section, is 2-percent leaking valves or greater, you may no longer subgroup and must revert to the program required in paragraphs (a)(1) and (2) of this section for that applicable process unit or group of process units. You can again elect to comply with the valve subgrouping procedures of paragraph (a)(3) of this section if future overall performance of total valves in the process unit or group of process units is again less than 2 percent.

(v) You must maintain the records specified in § 65.475(c)(1)(ii).

(vi) To determine the monitoring frequency for each subgroup, use the

calculation procedures of paragraph (b)(2) of this section.

(vii) Except for the overall performance calculations required by paragraphs (a)(3)(i) and (iii) of this section, each subgroup must be treated as if it were a process unit for the purposes of applying the provisions of this section.

(b) *Percent leaking valves calculation.* You must calculate the percent leaking valves in accordance with paragraphs (b)(1) through (3) of this section.

(1) *Calculation basis and procedures.* (i) You must decide no later than the compliance date specified in the referencing subpart or upon revision of an operating permit whether to calculate percent leaking valves on a process unit or group of process units basis. Once you have decided, all subsequent percentage calculations must be made on the same basis, and this also must be the basis used for comparison with the subgrouping criteria specified in paragraph (a)(3)(i) of this section.

(ii) Calculate the percent leaking valves for each monitoring period for each process unit or valve subgroup, as provided in paragraph (a)(3) of this section, using Equation 2 of this section:

$$\%V_L = (V_L / V_T) \times 100 \qquad \text{(Eq. 2)}$$

Where:

$\%V_L$ = Percent leaking valves.

V_L = Number of valves found leaking, as determined through periodic monitoring, as required in paragraph (a) of this section, including those valves found leaking, pursuant to paragraphs (c)(2)(iii)(A) and (B) of this section and excluding non-repairable valves, as provided in paragraph (b)(3) of this section.

V_T = The total number of valves monitored.

(2) *Calculation for monitoring frequency.* When determining the next monitoring frequency for each process unit or valve subgroup currently subject to monthly, quarterly or semiannual monitoring frequencies, the percent leaking valves shall be the arithmetic average of the percent leaking valves from the last two monitoring periods. When determining the next monitoring frequency for each process unit or valve subgroup currently subject to annual or biennial monitoring frequencies, the percent leaking valves shall be the arithmetic average of the percent leaking valves from the last three monitoring periods.

(3) *Non-repairable valves.* You must include non-repairable valves in the calculation of percent leaking valves, as specified in paragraphs (b)(3)(i) and (ii) of this section.

(i) You must include a non-repairable valve in the calculation of percent leaking valves the first time the valve is identified as leaking and non-repairable.

(ii) You may exclude a number of non-repairable valves (identified and included in the percent leaking valves calculation in a previous period, as required in paragraph (b)(3)(i)) up to a maximum of 1 percent of the total number of valves in regulated material service at a process unit. If the number of non-repairable valves exceeds 1 percent of the total number of valves in regulated material service at a process unit, you must include the number of non-repairable valves exceeding 1 percent of the total number of valves in regulated material service in the calculation of percent leaking valves.

(c) *Leak repair.* (1) If a leak is determined, pursuant to paragraph (a) of this section, then you must repair the leak using the procedures in § 65.432, as applicable.

(2) After a leak has been repaired, you must monitor the valve at least once within the first 3 months after its repair. The monitoring required by this paragraph is in addition to the monitoring required to satisfy the definitions of repair and first attempt at repair.

(i) You must conduct monitoring, as specified in § 65.431(a) and determine whether the valve has resumed leaking, as specified in § 65.431(b).

(ii) If the timing of the monitoring required by paragraph (a) of this section coincides with the timing of the monitoring specified in this paragraph, you may use the monitoring required by paragraph (a) of this section to satisfy the requirements of this paragraph. Alternatively, you may perform other monitoring to satisfy the requirements of this paragraph, regardless of whether the timing of the monitoring period for periodic monitoring coincides with the time specified in this paragraph.

(iii) If a leak is detected by monitoring that is conducted, pursuant to paragraph (c)(2) of this section, you must follow the provisions of paragraphs (c)(2)(iii)(A) and (B) of this section to determine whether that valve must be counted as a leaking valve for purposes of paragraph (b)(1)(ii) of this section.

(A) If you elected to use periodic monitoring required by paragraph (a) of this section to satisfy the requirements of paragraph (c)(2) of this section, then you must count the valve as a leaking valve.

(B) If you elected to use other monitoring, prior to the periodic monitoring required by paragraph (a) of this section, to satisfy the requirements of paragraph (c)(2) of this section, then you must count the valve as a leaking valve unless it is repaired and shown by periodic monitoring not to be leaking.

(d) *Special provisions for valves.* (1) *Fewer than 250 valves.* Any valve located at a plant site with fewer than 250 valves in regulated material service is exempt from the requirements for monthly monitoring specified in paragraph (a)(2)(i) of this section. Instead, you must monitor each valve in regulated material service for leaks quarterly or comply with paragraph (a)(2)(iii), (iv) or (v) of this section, except as provided in paragraphs (d)(1) and (2) of this section.

(2) *No stem or packing gland.* Any valve that is designed with a valve mechanism that is not connected to a device that penetrates the valve housing (*e.g.,* a check valve) is exempt from the requirements of paragraphs (a) through (c) of this section. You must instead conduct sensory monitoring according to § 65.430.

(3) *Unsafe-to-monitor valves.* Any valve that you designate, in accordance with § 65.416(a)(1), as an unsafe-to-monitor valve is exempt from paragraphs (a) through (c) of this section. You must monitor and repair the valve according to the written plan specified in § 65.416(a)(4)(i).

(4) *Difficult-to-monitor valves.* Any valve that you designate, in accordance with § 65.416(a)(2) as a difficult-to-monitor valve is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor and repair the valve according to the written plan specified in § 65.416(a)(4)(ii).

§ 65.421 What are the standards and compliance requirements for pumps in light liquid service?

Except as specified in paragraph (d) of this section, you must comply with the requirements specified in paragraphs (a) through (c) of this section for pumps in light liquid service.

(a) *Instrument monitoring and leak detection.* You must conduct instrument

monitoring, as specified in § 65.431 and paragraphs (a)(1) and (2) of this section.

(1) *Instrument reading that defines a leak.* The instrument reading that defines a leak is specified in paragraphs (a)(1)(i) and (ii) of this section.

(i) 5,000 ppm or greater for pumps handling polymerizing monomers.

(ii) 2,000 ppm or greater for all other pumps.

(2) *Monitoring frequency.* You must monitor the pumps monthly to detect leaks. For a pump that begins operation after the initial startup date for the process unit, monitor within 30 days after the end of the pump startup period, unless the pump is replacing a leaking pump or if the pump meets any of the specifications in paragraph (d) of this section.

(b) *Leak repair.* If a leak is detected, pursuant to paragraph (a) of this section, then you must repair the leak using the procedures in § 65.432, as applicable.

(c) *Visual inspection.* (1) You must check each pump by visual inspection each calendar week for indications of liquids dripping from the pump seal.

(2) If there are indications of liquids dripping from the pump seal at the time of the weekly inspection, you must follow the procedure specified in either paragraph (c)(2)(i) or (ii) (if applicable) of this section prior to the next required inspection, except as specified in paragraph (c)(2)(iii) of this section.

(i) Before the next weekly inspection, you must repair the pump seal, as defined in § 65.295 for indications of liquids dripping.

(ii) You must monitor the pump, as specified in § 65.431(a).

(A) If the instrument reading indicates a leak, as specified in § 65.431(b) and paragraph (a)(1) of this section, a leak is detected, and you must repair it using the procedures in § 65.432.

(B) If the instrument reading does not indicate a leak, as specified in § 65.431(b) and paragraph (a)(1) of this section, then a leak is not detected and no repair is required.

(iii) If you observed liquids dripping during the last weekly inspection and the characteristics of the liquids dripping have not changed since that last weekly inspection (*e.g.,* frequency of drips, different color, different odor), then you are not required to comply with paragraph (c)(2)(i) or (ii) of this section prior to the next weekly inspection.

(3) You must document each inspection, as specified in § 65.475(c)(2)(i). If you comply with paragraph (c)(2)(iii) of this section, the record must include a description of the characteristics of the liquids dripping.

(d) *Special provisions for pumps.*

(1) *Dual mechanical seal pumps.* Each pump equipped with a dual mechanical seal system that includes a barrier fluid system is exempt from the requirements of paragraph (a) of this section, provided you meet the requirements specified in paragraphs (d)(1)(i) through (viii) of this section.

(i) Each dual mechanical seal system meets the requirements specified in paragraph (d)(1)(i)(A), (B) or (C) of this section.

(A) The seal system is operated with the barrier fluid at a pressure that is at all times greater than the pump stuffing box pressure.

(B) The seal system is equipped with a barrier fluid degassing reservoir that is connected by a closed vent system to a control device or is routed to a fuel gas system. The closed vent system and control device or the fuel gas system must meet § 65.413.

(C) The seal system is equipped with a closed-loop system that purges the barrier fluid into a process stream.

(ii) The barrier fluid is not in light liquid service.

(iii) Each barrier fluid system is equipped with a sensor that will detect failure of the seal system, the barrier fluid system or both.

(iv) Unless the pump is located within the boundary of an unmanned plant site, each sensor described in paragraph (d)(1)(iii) of this section is observed daily or is equipped with an alarm.

(v) Each pump is checked by visual inspection each calendar week for indications of liquids dripping from the pump seal. You must document each inspection, as specified in § 65.475(c)(2)(ii). If there are indications of liquids dripping from the pump seal at the time of the weekly inspection, you must follow the procedure specified in paragraph (d)(1)(v)(A) or (B) of this section prior to the next required inspection.

(A) Before the next weekly inspection, you must repair the pump seal, as defined in § 65.295 for indications of liquids dripping.

(B) You must monitor the pump, as specified in § 65.431(a) and determine if there is a leak of regulated material in the barrier fluid, as specified in § 65.431(b). If an instrument reading of 2,000 ppm or greater is measured, a leak is detected.

(vi) You must determine, based on design considerations and operating experience, criteria applicable to the presence and frequency of drips and to the sensor that indicate failure of the seal system, the barrier fluid system or both. You must keep records of the design criteria, as specified in § 65.475(c)(2)(iii).

(vii) If indications of liquids dripping from the pump seal exceed the criteria established in paragraph (d)(1)(vi) of this section, or if, based on the criteria established in paragraph (d)(1)(vi) of this section, the sensor indicates failure of the seal system, the barrier fluid system or both, a leak is detected.

(viii) When you detect a leak, pursuant to paragraph (d)(1)(v)(B) or (d)(1)(vii) of this section, you must repair it, as specified in § 65.432.

(2) *No external shaft.* Any pump that is designed with no externally actuated shaft penetrating the pump housing is exempt from the requirements of paragraph (a) of this section.

(3) *Unmanned plant site.* Any pump that is located within the boundary of an unmanned plant site is exempt from the weekly visual inspection requirement of paragraphs (c) and (d)(1)(v) of this section, and the daily requirements of paragraph (d)(1)(iv) of this section, provided that each pump is visually inspected as often as practical and at least monthly.

(4) *Unsafe-to-monitor pumps.* Any pump that you designate, in accordance with § 65.416(a)(1), as an unsafe-to-monitor pump, is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor, inspect and repair the pump according to the written plan specified in § 65.416(a)(4)(i).

(5) *Difficult-to-monitor pumps.* Any pump that you designate, in accordance with § 65.416(a)(2), as a difficult-to-monitor pump is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor, inspect and repair the pump according to the written plan specified in § 65.416(a)(4)(ii).

§ 65.422 What are the standards and compliance requirements for connectors in gas and vapor service and connectors in light liquid service?

If required by your referencing subpart, you must comply with the requirements specified in paragraphs (a) through (c) of this section for connectors in gas and vapor service and connectors in light liquid service except as provided in paragraph (d) of this section.

(a) *Instrument monitoring and leak detection.* You must conduct instrument monitoring, as specified in § 65.431 and paragraphs (a)(1) and (2) of this section.

(1) *Instrument reading that defines a leak.* The instrument reading that defines a leak is 500 ppm or greater.

(2) *Initial monitoring.* You must monitor all connectors in the process unit initially for leaks by the later of either 12 months after the compliance

date specified in a referencing subpart or 12 months after initial startup. If all connectors in the process unit have been monitored for leaks, meeting the criteria of either § 65.431(a)(1) through (5) or § 65.431(a)(6) prior to the compliance date specified in the referencing subpart, no initial monitoring is required, provided either no process changes have been made since the monitoring or you can show that the results of the monitoring, with or without adjustments, reliably demonstrate compliance despite process changes. If required to monitor because of a process change, you are required to monitor only those connectors involved in the process change.

(3) *Monitoring frequency.* After the initial monitoring (or monitoring conducted before the regulated source became subject to the referencing subpart) required in paragraph (a)(2) of this section, you must monitor connectors for leaks at the frequency specified in paragraphs (a)(3)(i) through (iii) of this section, depending on the result of the percent-leaking-connectors calculation specified in paragraph (b) of this section. You must also keep a record of the start date and end date of each monitoring period under this section for each process unit, as specified in § 65.475(c)(3)(i).

(i) If the percent leaking connectors in the process unit was greater than or equal to 0.5 percent, then you must monitor annually.

(ii) If the percent leaking connectors in the process unit was greater than or equal to 0.25 percent, but less than 0.5 percent, then monitor within 4 years. You are not required to monitor all connectors at the same time in the 4-year period, but you must separate monitoring of an individual connector by at least 2 years.

(iii) If the percent leaking connectors in the process unit was less than 0.25 percent, then monitor, as provided in paragraph (a)(3)(iii)(A) of this section and either paragraph (a)(3)(iii)(B) or (C) of this section, as appropriate.

(A) You must monitor at least 50 percent of the connectors within 4 years of the start of the monitoring period.

(B) If the percent-leaking-connectors calculated from the monitoring results in paragraph (a)(3)(iii)(A) of this section is greater than or equal to 0.35 percent of the monitored connectors, you must monitor all connectors that have not yet been monitored during that monitoring period as soon as practical, but within the next 6 months. At the conclusion of monitoring, a new monitoring period shall be started, pursuant to paragraph (a)(3) of this section, based on the percent leaking connectors of the total monitored connectors.

(C) If the percent leaking connectors calculated from the monitoring results in paragraph (a)(3)(iii)(A) of this section is less than 0.35 percent of the monitored connectors, you must monitor all connectors that have not yet been monitored within 8 years of the start of the monitoring period.

(b) *Percent leaking connectors calculation.* You must calculate the percent leaking connectors using Equation 3 of this section:

$$\%C_L = \left(C_L / C_T\right) \times 100 \qquad \text{(Eq. 3)}$$

Where:

$\%C_L$ = Percent leaking connectors.

C_L = Number of connectors found leaking during the monitoring period, as determined through periodic monitoring required in paragraph (a)(2) or (3) of this section.

C_T = Total number of connectors monitored.

(c) *Leak repair.* (1) If a leak is determined, pursuant to paragraph (a) of this section, then you must repair the leak using the procedures in § 65.432, as applicable.

(2) After a leak has been repaired, you must monitor the connector, as specified in § 65.431(a), once within the first 90 days after its repair to confirm that it is not leaking. The monitoring required by this paragraph is in addition to the monitoring required to satisfy the definitions of repair and first attempt at repair.

(d) *Special provisions for connectors.* (1) *Unsafe-to-monitor connectors.* Any connector that you designate, in accordance with § 65.416(a)(1), as an unsafe-to-monitor connector is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor and repair the connector according to the written plan specified in § 65.416(a)(4)(i).

(2) *Difficult-to-monitor connectors.* Any connector that you designate, in accordance with § 65.416(a)(2), as a difficult-to-monitor connector is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor, inspect and repair the connector according to the written plan specified in § 65.416(a)(4)(ii).

(3) *Inaccessible, ceramic or ceramic-lined connectors.* (i) Any connector that meets the provisions of paragraph (d)(3)(i)(A) or (B) of this section is exempt from the requirements of paragraphs (a) through (c) of this section and from the reporting and recordkeeping requirements of §§ 65.470 and 65.475.

(A) Any connector you designate, in accordance with § 65.416(b), as an inaccessible connector.

(B) Any connector that is ceramic or ceramic-lined (*e.g.,* porcelain, glass or glass-lined).

(ii) If you observe indications of a potential leak from any connector identified in paragraph (d)(2)(i) of this section by visual, audible, olfactory or other means, you must eliminate the visual, audible, olfactory or other indications of a potential leak to the atmosphere as soon as practical, but no later than the end of the next process unit shutdown or 5 years after detection, whichever is sooner.

§ 65.423 What are the standards and compliance requirements for agitators in gas and vapor service and agitators in light liquid service?

Except as provided in paragraph (d) of this section, you must comply with the requirements specified in paragraphs (a) through (c) of this section for agitators in gas and vapor service and agitators in light liquid service.

(a) *Instrument monitoring and leak detection.* You must conduct instrument monitoring, as specified in § 65.431 and paragraphs (a)(1) and (2) of this section.

(1) *Instrument reading that defines a leak.* The instrument reading that defines a leak is 10,000 ppm or greater.

(2) *Monitoring frequency.* You must monitor each agitator seal monthly to detect leaks.

(b) *Leak repair.* If a leak is detected, then you must repair the leak using the procedures in § 65.432, as applicable.

(c) *Visual inspection.* You must check each agitator seal by visual inspection each calendar week for indications of liquids dripping from the agitator seal. You must document each inspection, as specified in § 65.475(c)(4)(i). If there are indications of liquids dripping from the agitator seal at the time of the weekly inspection, you must follow the procedures specified in paragraph (c)(1) or (2) of this section prior to the next required inspection.

(1) Before the next weekly inspection, you must repair the agitator seal, as defined in § 65.295 for indications of liquids dripping.

(2) You must monitor the agitator seal, as specified in § 65.431(a). If an instrument reading of 10,000 ppm or greater is measured, as specified in § 65.431(b), a leak is detected, and you must repair it according to paragraph (b) of this section.

(d) *Special provisions for agitators.* (1) *Dual mechanical seal agitators.* Each agitator equipped with a dual mechanical seal system that includes a barrier fluid system is exempt from the requirements of paragraph (a) of this section, provided you meet the requirements specified in paragraphs (d)(1)(i) through (vi) of this section.

(i) Each dual mechanical seal system meets the requirements specified in paragraph (d)(1)(i)(A), (B) or (C) of this section.

(A) The seal system is operated with the barrier fluid at a pressure that is, at all times greater than the agitator stuffing box pressure.

(B) The seal system is equipped with a barrier fluid degassing reservoir that is connected by a closed vent system to a control device or is routed to a fuel gas system. The closed vent system and control device or the fuel gas system must meet § 65.413.

(C) The seal system is equipped with a closed-loop system that purges the barrier fluid into a process stream.

(ii) The barrier fluid is not in light liquid service.

(iii) Each barrier fluid system is equipped with a sensor that will detect failure of the seal system, the barrier fluid system or both.

(iv) Unless the agitator seal is located within the boundary of an unmanned plant site, each sensor described in paragraph (d)(1)(iii) of this section is observed daily or is equipped with an alarm.

(v) Each agitator seal is checked by visual inspection each calendar week for indications of liquids dripping from the agitator seal. You must document each inspection, as specified in § 65.475(c)(4)(ii). If there are indications of liquids dripping from the agitator seal at the time of the weekly inspection, you must follow the procedure specified in paragraph (d)(1)(v)(A) or (B) of this section prior to the next required inspection.

(A) Before the next weekly inspection, you must repair the agitator seal, as defined in § 65.295 for indications of liquids dripping.

(B) You must monitor the agitator seal, as specified in § 65.431(a) and determine if there is a leak of regulated material in the barrier fluid, as specified in § 65.431(b). If an instrument reading of 10,000 ppm or greater is measured, a leak is detected.

(vi) You must determine, based on design considerations and operating experience, criteria applicable to the presence and frequency of drips and to the sensor that indicate failure of the seal system, the barrier fluid system or both. You must keep records of the design criteria, as specified in § 65.475(c)(4)(iii).

(vii) If indications of liquids dripping from the agitator seal exceed the criteria established in paragraph (d)(1)(vi) of this section, or if, based on the criteria established in paragraph (d)(1)(vi) of this section, the sensor indicates failure of the seal system, the barrier fluid system or both, a leak is detected.

(viii) When you detect a leak, pursuant to paragraph (d)(1)(v)(B) or (d)(1)(vii) of this section, you must repair it, as specified in § 65.432.

(2) *No external shaft.* Any agitator that is designed with no externally actuated shaft penetrating the agitator housing is exempt from paragraph (a) of this section.

(3) *Unmanned plant site.* Any agitator that is located within the boundary of an unmanned plant site is exempt from the weekly visual inspection requirement of paragraphs (c) and (d)(1)(v) of this section, and the daily requirements of paragraph (d)(1)(iv) of this section, provided that each agitator is visually inspected as often as practical and at least monthly.

(4) *Equipment obstructions.* Any agitator seal that is obstructed by equipment or piping that prevents access to the agitator by a monitor probe is exempt from the monitoring requirements of paragraph (a) of this section. You must instead conduct sensory monitoring, as described in § 65.430.

(5) *Unsafe-to-monitor agitator seals.* Any agitator seal that you designate, in accordance with § 65.416(a)(1), as an unsafe-to-monitor agitator seal is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor, inspect and repair the agitator seal according to the written plan specified in § 65.416(a)(4)(i).

(6) *Difficult-to-monitor agitator seals.* Any agitator seal that you designate, in accordance with § 65.416(a)(2), as a difficult-to-monitor agitator seal is exempt from the requirements of paragraphs (a) through (c) of this section. You must monitor, inspect and repair the agitator seal according to the written plan specified in § 65.416(a)(4)(ii).

§ 65.424 What are the standards and compliance requirements for pressure relief devices?

Except as specified in paragraph (d), you must comply with the requirements specified in paragraphs (a) and (b) of this section for PRD in gas and vapor service. If your referencing subpart specifies that releases to the atmosphere from PRD in regulated material service are not allowed, you must comply with the requirements specified in paragraph (c) or (d) of this section for all PRD in regulated material service.

(a) Operating requirements. Operate each PRD in gas or vapor service with an instrument reading of less than 500 ppm above background.

(b) Release requirements. If a PRD in gas or vapor service vents or releases to atmosphere, you must comply with either paragraph (b)(1) or (2) of this section following the release.

(1) If the PRD does not consist of or include a rupture disk, conduct instrument monitoring, as specified in § 65.431 no later than 5 calendar days after the PRD returns to regulated material service following a pressure release to verify that the PRD is operating with an instrument reading of less than 500 ppm. An instrument reading of 500 ppm or greater is a deviation.

(2) If the PRD consists of or includes a rupture disk, install a replacement disk as soon as practicable after a pressure release, but no later than 5 calendar days after the pressure release. You must also conduct instrument monitoring, as specified in § 65.431 no later than 5 calendar days after the PRD returns to regulated material service following a pressure release to verify that the PRD is operating with an instrument reading of less than 500 ppm. An instrument reading of 500 ppm or greater is a deviation.

(c) *Pressure release management.* If your referencing subpart specifies that releases to the atmosphere from PRD in regulated material service are not allowed, you must comply with the requirements specified in paragraphs (c)(1) and (2) of this section for all PRD in regulated material service, and any release from a PRD in regulated material service is a deviation.

(1) You must equip each PRD in regulated material service with a device(s) that is capable of identifying and recording the time and duration of each pressure release and of notifying operators that a pressure release has occurred. If this instrument is capable of measuring the concentration of leaks through the PRD, then you may use this instrument to meet the requirements of paragraph (b) of this section.

(2) If any PRD in regulated material service vents or releases to atmosphere, you must calculate the quantity of regulated material released during each pressure relief event. Calculations may be based on data from the PRD monitoring alone or in combination with process parameter monitoring data and process knowledge.

(d) *PRD routed to a control device.* If all releases and potential leaks from your PRD are routed through a closed vent system to a control device, you are not required to comply with paragraphs (a), (b) or (c) (if applicable) of this section. Both the closed vent system and control device must meet § 65.413.

§ 65.425 What are the standards and compliance requirements for compressors?

You must comply with either the requirements specified in paragraph (a) or (b) of this section for compressors in regulated material service.

(a) *Seal system standard.* Each compressor must be equipped with a seal system that includes a barrier fluid system and that prevents leakage of process fluid to the atmosphere. You must comply with paragraphs (a)(1) through (4) of this section.

(1) *Compressor seal system.* Each compressor seal system must meet the applicable requirements specified in paragraph (a)(1)(i), (ii) or (iii) of this section.

(i) The seal system is operated with the barrier fluid at a pressure that is at all times greater than the compressor stuffing box pressure.

(ii) The seal system is equipped with a barrier fluid degassing reservoir that is connected by a closed vent system to a control device or is routed to a fuel gas system. The closed vent system and control device or the fuel gas system must meet § 65.413.

(iii) The seal system is equipped with a closed-loop system that purges the barrier fluid directly into a process stream.

(2) *Barrier fluid system.* The barrier fluid must not be in light liquid service. Each barrier fluid system must be equipped with a sensor that will detect failure of the seal system, barrier fluid system or both. Each sensor must be observed daily or must be equipped with an alarm unless the compressor is located within the boundary of an unmanned plant site.

(3) *Failure criterion and leak detection.* (i) You must determine, based on design considerations and operating experience, a criterion that indicates failure of the seal system, the barrier fluid system or both. If the sensor indicates failure of the seal system, the barrier fluid system or both, based on the criterion, a leak is detected, and you must repair it, pursuant to § 65.432, as applicable.

(ii) You must keep records of the design criteria, as specified in § 65.475(c)(6)(i).

(4) You must comply with § 65.430 for all potential points of vapor leakage on the compressor other than the seal system.

(b) *Alternative compressor standard.* (1) You must designate that the compressor operates with an instrument reading of less than 500 ppm above background at all times. Any instrument reading of 500 ppm above background or greater is a deviation.

(2) You must conduct instrument monitoring of all potential points of vapor leakage initially upon designation, annually and at other times requested by the Administrator to demonstrate that the compressor operates with an instrument reading of less than 500 ppm above background.

(3) You must keep records of the compliance tests, as specified in § 65.475(c)(6)(ii).

§ 65.426 What are the standards and compliance requirements for sampling connection systems?

Except as provided in paragraph (b) of this section, you must comply with the requirements specified in paragraph (a) of this section for sampling connection systems in regulated material service. For the purposes of the definition of ''sampling connection system'' in § 65.295, a continuous emission monitoring system is not an analyzer vent.

(a) *Equipment design and operation.* Each sampling connection system must be equipped with a closed-purge, closed-loop or closed vent system. Each closed-purge, closed-loop or closed vent system must meet the applicable requirements specified in paragraphs (a)(1) through (4) of this section, as applicable.

(1) Gases displaced during filling of a sample container are not required to be collected or captured.

(2) Containers that are part of a closed-purge system must be covered or closed when not being filled or emptied.

(3) Gases remaining in the tubing or piping between the closed-purge system valve(s) and sample container valves(s) after the valves are closed and a sample container is disconnected are not required to be collected or captured.

(4) Each closed-purge, closed-loop or closed vent system must be designed and operated to meet requirements in either paragraph (a)(4)(i), (ii), (iii) or (iv) of this section.

(i) Return the purged process fluid directly to the process line.

(ii) Collect and recycle the purged process fluid to a process or to a fuel gas system that meets the requirements of subpart M of this part.

(iii) Capture and transport all the purged process fluid to a control device that meets § 65.413.

(iv) Collect, store and transport the purged process fluid to a system or facility identified in paragraph (a)(4)(iv)(A), (B), (C), (D) or (E) of this section.

(A) A waste management unit, as defined in 40 CFR 63.111, if the waste management unit is subject to and operated in compliance with the provisions of 40 CFR part 63, subpart G, applicable to group 1 wastewater streams.

(B) A treatment, storage or disposal facility subject to regulation under 40 CFR parts 262, 264, 265 or 266.

(C) A facility permitted, licensed or registered by a state to manage municipal or industrial solid waste, if the process fluids are not hazardous waste, as defined in 40 CFR part 261.

(D) A waste management unit subject to and operated in compliance with the treatment requirements of § 61.348(a), provided all waste management units that collect, store or transport the purged process fluid to the treatment unit are subject to and operated in compliance with the management requirements of §§ 61.343 through 61.347.

(E) A device used to burn-off specification used oil for energy recovery in accordance with 40 CFR part 279, subpart G, provided the purged process fluid is not hazardous waste, as defined in 40 CFR part 261.

(b) *In-situ sampling systems.* In-situ sampling systems and sampling systems without purges are exempt from the requirements of paragraph (a) of this section.

§ 65.427 What are the standards and compliance requirements for open-ended valves and lines?

Except as provided in paragraph (c) of this section, you must comply with the requirements specified in paragraphs (a) and (b) of this section for all open-ended valves and lines in regulated material service.

(a) *Equipment and operational requirements.* Equip open-ended valves and lines with a cap, blind flange, plug or second valve so that the open-ended valve or line operates with an instrument reading of less than 500 ppm above background. The cap, blind flange, plug or second valve must seal the open-ended valve or line at all times, except during operations requiring process fluid flow through the

open-ended valve or line, during maintenance or during operations that require venting the line between block valves in a double block and bleed system. If the open-ended valve or line is equipped with a second valve, close the valve on the process fluid end before closing the second valve.

(b) *Instrument monitoring.* You must conduct instrument monitoring, as specified in § 65.431 on the cap, blind flange, plug or second valve installed, pursuant to paragraph (a) of this section initially upon installation, annually and at other times requested by the Administrator to demonstrate that the open-ended valve or line operates with an instrument reading of less than 500 ppm above background. Any instrument reading of 500 ppm above background or greater is a deviation.

(c) *Special provisions for open-ended valves and lines.* (1) *Emergency shutdown exemption.* Open-ended valves and lines in an emergency shutdown system that are designed to open automatically in the event of a process upset are exempt from the requirements of paragraphs (a) and (b) of this section. If your referencing subpart specifies that releases are not allowed from open-ended valves and lines in an emergency shutdown system that are designed to open automatically in the event of a process upset, than any release from such an open-ended valve or line is a deviation.

(2) *Polymerizing materials exemption.* Open-ended valves and lines containing materials that would autocatalytically polymerize or would present an explosion, serious overpressure or other safety hazard if capped or equipped with a double block and bleed system, as specified in paragraph (a) of this section are exempt from the requirements of paragraphs (a) and (b) of this section. You must instead conduct sensory monitoring, as described in § 65.430.

§ 65.428 What are the standards and compliance requirements for other equipment that contacts or contains regulated material?

You must conduct sensory monitoring, as described in § 65.430 for the equipment specified in paragraphs (a) through (i) of this section.

(a) All equipment at a plant site with less than 1,500 total pieces of equipment.

(b) Any equipment that contains or contacts regulated material, but is not in regulated material service.

(c) Equipment in regulated material service less than 300 hours per calendar year.

(d) Valves, pumps, connectors and agitators in heavy liquid service.

(e) Connectors in gas and vapor service and connectors in light liquid service not required by your referencing subpart to comply with the provisions of § 65.422.

(f) Instrumentation systems.

(g) Pressure relief devices in liquid service.

(h) Any equipment for which sensory monitoring is required specifically by a provision in §§ 65.420 through 65.427.

(i) Other equipment, as required by your referencing subpart.

§ 65.429 What are the standards and compliance requirements for equipment in closed vent systems and fuel gas systems?

You must meet the requirements of this section for equipment in any closed vent system or fuel gas system required to comply with subpart M of this part. You are not required to comply with §§ 65.420 through 65.428 for equipment complying with this section.

(a) You must conduct instrument monitoring, as specified in § 65.431 of all potential points of vapor leakage on any equipment in a closed vent system or fuel gas system initially upon installation, annually and at other times requested by the Administrator to demonstrate that the equipment operates with an instrument reading of less than 500 ppm above background. Any instrument reading of 500 ppm above background or greater is a deviation.

(b) You must keep records of the compliance tests, as specified in § 65.475(c)(9).

Equipment Leak Monitoring and Repair

§ 65.430 What are my sensory monitoring requirements?

(a) You must conduct sensory monitoring, as defined in § 65.295 for equipment identified in § 65.428. You must also comply with paragraph (b) through (d) of this section, as applicable.

(b) If indications of a potential leak to the atmosphere are found by sensory monitoring methods, you must comply with either paragraph (b)(1) or (2) of this section.

(1) Within 5 calendar days of detection, you must comply with either paragraph (b)(1)(i) or (ii) of this section.

(i) Repair the equipment, as defined in § 65.295 for indications of a potential leak to the atmosphere detected during sensory monitoring.

(ii) Determine that no bubbles are observed at potential leak sites during a leak check, using a soap solution.

(2) Conduct instrument monitoring, as described in § 65.431 within 5 calendar days of detection and repair the equipment in accordance with § 65.432 if the instrument reading is equal to or greater than the applicable level in Table 1 to this subpart.

(c) Except as provided in paragraph (c)(4) of this section, you must comply with the requirements of either paragraph (c)(1) or (2) of this section for equipment in heavy liquid service. Paragraph (c)(3) of this section describes how to determine or demonstrate that a piece of equipment is in heavy liquid service.

(1) Retain information, data and analyses used to determine that a piece of equipment is in heavy liquid service.

(2) When requested by the Administrator, demonstrate that the piece of equipment or process is in heavy liquid service.

(3) A determination or demonstration that a piece of equipment or process is in heavy liquid service shall include an analysis or demonstration that the process fluids do not meet the definition of ''in light liquid service.'' Examples of information that could document this include, but are not limited to, records of chemicals purchased for the process, analyses of process stream composition, engineering calculations or process knowledge.

(4) You are not required to comply with paragraphs (c)(1) through (3) of this section if all the equipment of a certain type (*e.g.,* valves) in your process unit is subject to sensory monitoring, as required by paragraphs (a) and (b) of this section.

(d) You must comply with the recordkeeping requirements of § 65.475(b)(5) for equipment in regulated material service less than 300 hours per calendar year.

§ 65.431 What instrument monitoring methods must I use to detect leaks?

(a) *Instrument monitoring methods.* Instrument monitoring, as required under this subpart, shall comply with the requirements specified in paragraphs (a)(1) through (7) of this section.

(1) *Monitoring method.* Monitor, as specified in Method 21 of 40 CFR part 60, appendix A–7, except as otherwise provided in this section. Traverse the instrument probe around all potential leak interfaces as close to the interface as possible, as described in Method 21 of 40 CFR part 60, appendix A–7.

(2) *Monitoring instrument performance criteria.* (i) Except as provided in paragraph (a)(2)(ii) of this section, the volatile organic compounds (VOC) monitoring instrument must meet the performance criteria of Method 21 of 40 CFR part 60, appendix A–7, except

the instrument response factor criteria in section 8.1.1.2 of Method 21 must be for the representative composition of the process fluid, not each individual hydrocarbon compound in the stream. For process streams that contain nitrogen, air, water or other inerts that are not hydrocarbons, the representative stream response factor must be determined on an inert-free basis. The response factor may be determined at any concentration for which monitoring for leaks will be conducted.

(ii) If there is no instrument commercially available that will meet the performance criteria specified in paragraph (a)(2)(i) of this section, the instrument readings may be adjusted by multiplying by the representative response factor of the process fluid, calculated on an inert-free basis, as described in paragraph (a)(2)(i) of this section.

(3) *Monitoring instrument calibration procedure.* (i) Calibrate the VOC monitoring instrument before use on each day of its use by the procedures specified in Method 21 of 40 CFR part 60, appendix A–7.

(ii) Perform a calibration drift assessment, at a minimum, at the end of each monitoring day, as specified in paragraphs (a)(3)(ii)(A) through (D) of this section.

(A) Check the instrument using the same calibration gas(es) that were used to calibrate the instrument before use. Follow the procedures specified in Method 21 of 40 CFR part 60, appendix A–7, section 10.1, except do not adjust the meter readout to correspond to the calibration gas value.

(B) Record the instrument reading for each scale used, as specified in paragraph (b) of this section. Divide these readings by the initial calibration values for each scale and multiply by 100 to express the calibration drift as a percentage.

(C) If any calibration drift assessment shows a negative drift of more than 10 percent from the initial calibration value, then you must re-monitor all equipment monitored since the last calibration with instrument readings below the applicable leak definition and above the applicable leak definition adjusted for negative drift. Determine the leak definition adjusted for negative drift according to Equation 4 of this section:

$$L_{ND} = L \times \frac{(100 - ND)}{100} \qquad \text{(Eq. 4)}$$

Where:

L_{ND} = Applicable leak definition adjusted for negative drift, ppm.
L = Applicable leak definition, ppm.
ND = Magnitude of negative drift calculated, as described in paragraph (a)(3)(ii)(B) of this section, percent.

(D) If any calibration drift assessment shows a positive drift of more than 10 percent from the initial calibration value, then, at your discretion, you may re-monitor all equipment monitored since the last calibration with instrument readings above the applicable leak definition and below the applicable leak definition adjusted for positive drift. Determine the leak definition adjusted for positive drift according to Equation 5 of this section:

$$L_{PD} = L \times \frac{(100 + PD)}{100} \qquad \text{(Eq. 5)}$$

Where:

L_{PD} = Applicable leak definition adjusted for positive drift, ppm.
L = Applicable leak definition, ppm.
PD = Magnitude of positive drift calculated, as described in paragraph (a)(3)(ii)(B) of this section, percent.

(4) *Monitoring instrument calibration gas.* Calibration gases shall be zero air (less than 10 ppm of hydrocarbon in air); and the gases specified in paragraph (a)(4)(i) of this section, except as provided in paragraph (a)(4)(ii) of this section.

(i) Mixtures of methane in air at a concentration no more than 2,000 ppm greater than the leak definition concentration of the equipment monitored. If the monitoring instrument's design allows for multiple calibration scales, then calibrate the lower scale with a calibration gas that is no higher than 2,000 ppm above the concentration specified as a leak and calibrate the highest scale with a calibration gas that is approximately equal to 10,000 ppm. If only one scale on an instrument will be used during monitoring, you need not calibrate the scales that will not be used during that day's monitoring.

(ii) A calibration gas other than methane in air may be used if the instrument does not respond to methane or if the instrument does not meet the performance criteria specified in paragraph (a)(2)(i) of this section. In such cases, the calibration gas may be a mixture of one or more of the compounds to be measured in air.

(5) *Monitoring performance.* Perform monitoring when the equipment is in regulated material service or is in use with any other material that is detectable by an instrument operated in accordance with Method 21 of 40 CFR part 60, appendix A–7, and paragraphs (a)(1) through (4) of this section.

(6) *Monitoring data.* Monitoring data obtained prior to the regulated source becoming subject to the referencing subpart that do not meet the criteria specified in paragraphs (a)(1) through (5) of this section may still be used to qualify initially for less frequent monitoring under the provisions in § 65.420(a)(2) or (3) for valves or § 65.422(a)(3) for connectors, provided the departures from the criteria or from the specified monitoring frequency of § 65.420(a)(2) or (3) or § 65.422(a)(3) are minor and do not significantly affect the quality of the data. Examples of minor departures are monitoring at a slightly different frequency (such as every 6 weeks instead of monthly or quarterly), following the performance criteria of section 8.1.1.2 of Method 21 of 40 CFR part 60, appendix A–7, instead of paragraph (a)(2) of this section, or monitoring using a different leak definition if the data would indicate the presence or absence of a leak at the concentration specified in this subpart. Failure to use a calibrated instrument is not considered a minor departure.

(7) *Instrument monitoring using local ambient concentration (background) adjustments.* You may elect to adjust the instrument readings for the local ambient concentration (''background''). If you elect to adjust instrument readings for background, you must determine the local ambient

concentration using the procedures in section 8.3.2 of Method 21 of 40 CFR part 60, appendix A–7.

(b) *Using instrument readings.* (1) If you elect not to adjust instrument readings for background, as described in paragraph (a)(7) of this section, you must comply with paragraphs (b)(1)(i) and (ii) of this section.

(i) Monitor the equipment according to the procedures specified in paragraphs (a)(1) through (5) of this section.

(ii) Compare all instrument readings directly to the applicable leak definition or performance level for the monitored equipment to determine whether there is a leak or to determine compliance with § 65.424(a) (pressure relief devices), § 65.425(b) (alternative compressor standard) or § 65.427(b) (open-ended lines and valves).

(2) If you elect to adjust instrument readings for background, as described in paragraph (a)(7) of this section, you must comply with paragraphs (b)(2)(i) through (iv) of this section.

(i) Monitor the equipment according to the procedures specified in paragraphs (a)(1) through (5) of this section.

(ii) Determine the background level, as described in paragraph (a)(7) of this section.

(iii) Compute the arithmetic difference between the maximum concentration indicated by the instrument and the background level determined.

(iv) Compare this arithmetic difference to the applicable leak definition or performance level for the monitored equipment to determine whether there is a leak or to determine compliance with § 65.424(a) (pressure relief devices), § 65.425(b) (alternative compressor standard) or § 65.427(b) (open-ended lines and valves).

§ 65.432 What are my leak identification and repair requirements?

(a) *Leaking equipment identification and records.*

(1) When each leak is detected, pursuant to §§ 65.420 through 65.428, § 65.440 or § 65.450, attach a weatherproof and readily visible identification to the leaking equipment.

(2) When each leak is detected, record and keep the information specified in § 65.475(b)(8)(i).

(b) *Leak repair schedule.* (1) Except as provided in paragraph (b)(4) of this section, you must make a first attempt at repair, as defined in § 65.295, no later than 5 calendar days after the leak is detected. First attempt at repair for pumps includes, but is not limited to, tightening the packing gland nuts and/or ensuring that the seal flush is operating at design pressure and temperature. First attempt at repair for valves includes, but is not limited to, tightening the bonnet bolts, and/or replacing the bonnet bolts, and/or tightening the packing gland nuts, and/or injecting lubricant into the lubricated packing. Unless you determine, by other means, that the first attempt at repair was not successful, you must conduct instrument monitoring following the first attempt at repair, but no later than 5 calendar days after the leak is detected to determine whether the first attempt at repair was successful.

(2) Except as provided in paragraphs (b)(4), (d) and (e) of this section, if the first attempt at repair required by paragraph (b)(1) of this section was not successful, you must repair each leak detected as soon as practical, but not later than 15 calendar days after it is detected. If required by the applicable definition of ''repair'' in § 65.295, you must conduct monitoring following the repair, but no later than 15 calendar days after the leak is detected to determine whether the repair was successful.

(3) You must keep records, as specified in § 65.475(b)(8)(ii) through (iv).

(4) You may designate equipment as unsafe-to-repair, if you determine that repair personnel would be exposed to an immediate danger as a consequence of complying with the repair requirements of this subpart. You are not required to comply with paragraphs (b)(1) and (2) for equipment that you have designated unsafe-to-repair, but you must keep records, as specified in § 65.475(b)(8)(v). You must also comply with paragraph (d) of this section.

(c) *Leak identification removal.*

(1) *Valves in gas and vapor service.* The leak identification on a valve may be removed after it has been monitored, as specified in § 65.420(c)(2) and no leak has been detected during that monitoring.

(2) *Connectors in gas and vapor service.* The leak identification on a connector may be removed after it has been monitored, as specified in § 65.422(c)(2) and no leak has been detected during that monitoring.

(3) *Other equipment.* Except as specified in paragraphs (c)(1) and (2) of this section, you may remove the identification that you placed, pursuant to § 65.432(a)(1), on equipment determined to have a leak after it is repaired.

(d) *Delay of repair.* Delay of repair is allowed for any of the conditions specified in paragraphs (d)(1) through (5) of this section. If you delay repair, you must comply with paragraph (e) of this section. You must also maintain records, as specified in § 65.475(b)(8)(vi) and (vii).

(1) Delay of repair of equipment for which leaks have been detected is allowed if repair within 15 days after a leak is detected is technically infeasible without a process unit shutdown, provided you comply with paragraphs (d)(1)(i) through (iii) of this section.

(i) You must repair this equipment as soon as practical, but no later than the end of the next process unit shutdown or 5 years after detection, whichever is sooner. For the purposes of this section, a process unit shutdown is any shutdown that lasts more than 24 hours, regardless of whether it was planned or unplanned.

(ii) Except as specified in paragraph (d)(1)(iii) of this section, you must repair all equipment for which you have delayed repair during the process unit shutdown.

(iii) If you detect a leak less than 15 days before the process unit shutdown, you are not required to repair that leak during the process unit shutdown.

(2) Delay of repair of equipment for which leaks have been detected is allowed if the equipment is designated as unsafe to repair according to paragraph (b)(4) of this section. You must repair this equipment as soon as practical, but no later than the end of the next process unit shutdown or 5 years after detection, whichever is sooner.

(3) Delay of repair of equipment for which leaks have been detected is allowed for equipment that you isolate from the process such that it does not contact or contain regulated material.

(4) Delay of repair for valves, connectors and agitators is also allowed if you meet the provisions of paragraphs (d)(4)(i) and (ii) of this section.

(i) You document the planned repair date and demonstrate that emissions of purged material resulting from immediate repair would be greater than the fugitive emissions likely to result from delay of repair.

(ii) When you do repair the equipment, the purged material is collected and destroyed, collected and routed to a fuel gas system or routed through a closed vent system to a control device. The fuel gas system or the closed vent system and the control device must meet § 65.413.

(5) Delay of repair for pumps is also allowed if you meet the provisions of paragraphs (d)(5)(i) and (ii) of this section.

(i) Repair will consist of any of the design changes specified in paragraph (d)(5)(i)(A), (B), (C) or (D) of this section.

(A) Replacing the existing seal design with a new system that you have determined will provide better performance. You must document the demonstration that the new system will provide better performance than the existing seal.

(B) Installing a dual mechanical seal system that meets the requirements of § 65.421(d)(1).

(C) Installing a pump that meets the requirements of § 65.421(d)(2).

(D) Installing a system that routes emissions through a closed vent system to a control device or to a fuel gas system. The closed vent system and control device or the fuel gas system must meet § 65.413.

(ii) You complete repair as soon as practical, but not later than 6 months after the leak was detected.

(e) *Requirements following the determination that delay of repair is necessary.* (1) You must continue to monitor equipment for which you have delayed repair according to the provisions of paragraph (d)(1), (2), (4) or (5) of this section. You must monitor the equipment on the schedule required by §§ 65.420 through 65.427, § 65.440 or § 65.450, as applicable. You must maintain records of this monitoring, as specified in § 65.475(b)(8)(viii).

(2) If you delay repair for a pump or agitator according to the provisions of paragraph (d)(1), (2), (3), (4) or (5) of this section, you may suspend the weekly visual inspection required by § 65.421(c) for pumps or § 65.423(c) for agitators.

(3) Unless it is technically infeasible to do so, when you repair a valve or connector for which you have delayed repair according to the provisions of paragraph (d)(1), (2), (3) or (4) of this section, you must replace the leaking equipment with low leak technology, as described in paragraphs (e)(3)(i) through (iv) of this section. You must develop a written plan that addresses the demonstration of whether a device or repair technique qualifies as low leak technology, criteria for selecting the low leak technology to be used for a repair and installation procedures for the selected technology.

(i) Low leak technology for valves includes, but is not limited to, the options in paragraphs (e)(3)(i)(A) through (D) of this section.

(A) Repacking the valve or replacing the existing valve packing with low emissions packing.

(B) Replacing the leaking valve with a valve designed to accommodate low emissions packing.

(C) Replacing the existing valve with a bellow seal valve.

(D) Other repair or replacement that has been tested rigorously and did not leak above 500 ppm during the entirety of the test.

(ii) Low leak technology for connectors includes, but is not limited to, the options in paragraphs (e)(3)(ii)(A) through (C) of this section.

(A) Replacing the flange gasket.

(B) Replacing the entire connector.

(C) Other repair or replacement that has been tested rigorously and did not leak above 500 ppm during the entirety of the test.

(iii) If you cannot replace the leaking equipment with low leak technology, then you would be required to explain why that replacement is technically infeasible in your annual periodic report, pursuant to § 65.470(c)(3).

(iv) If that equipment leaks again in the future and you delay the repair beyond 15 days, you must conduct a new analysis of the technical feasibility of using low leak technology.

Alternative Equipment Leak Standards

§ 65.440 What is the alternative means of emission limitation for equipment in batch operations?

For equipment in a batch operation that operates in regulated material service during the calendar year, you may comply with the equipment monitoring requirements specified in paragraphs (a) through (c) of this section as an alternative to complying with the requirements of §§ 65.420 through 65.427.

(a) You must comply with the requirements of §§ 65.420 through 65.427, as modified by paragraph (b) of this section.

(b) Monitor the equipment to detect leaks by the method specified in § 65.431 and as specified in paragraphs (b)(1) through (3) of this section.

(1) Each time the process components and transport piping are reconfigured for the production of a different product, monitor the equipment in the reconfigured process unit for leaks within 30 days of startup of the process. Do not include this initial monitoring of reconfigured equipment in determining percent leaking equipment in the process unit.

(2) You may elect to monitor pumps, valves and agitators at the frequencies specified in Table 2 to this subpart. Determine the operating time as the proportion of the year the batch operation that is subject to the provisions of this subpart is operating.

(3) The monitoring frequencies specified in paragraph (b)(2) of this section are not requirements for monitoring at specific intervals and can be adjusted to accommodate process operations. You may monitor anytime during the specified monitoring period (*e.g.,* month, quarter, year), provided the monitoring is conducted at a reasonable interval after completion of the last monitoring campaign. Reasonable intervals are defined in § 65.280.

(c) You must keep the records for equipment in batch operations, as specified in § 65.475(d).

Optical Gas Imaging Standards for Detecting Equipment Leaks

§ 65.450 What are the standards and compliance requirements for using an optical gas imaging instrument to detect leaks?

(a) *Introduction.* This section contains requirements for the use of an optical gas imaging instrument used to identify leaking equipment.

(b) *Applicability.* You may only use an optical gas imaging instrument to screen for leaking equipment if the requirements in paragraphs (b)(1) through (3) of this paragraph are met.

(1) Your referencing subpart must directly reference this section and specify that the use of an optical gas imaging instrument is allowed to screen for leaking equipment.

(2) The optical gas imaging instrument must be able to meet all of the criteria and requirements specified in 40 CFR part 60, appendix K for optical gas imaging instruments, and you must conduct monitoring, as specified in 40 CFR part 60, appendix K.

(3) You may only use the optical gas imaging instrument as an alternative to provisions that would otherwise require you to conduct monitoring, as described in §§ 65.430 and 65.431. You must continue to comply with all other requirements in §§ 65.420 through 65.427 (*e.g.,* weekly inspections of pumps, pursuant to § 65.421(c); for PRD, installation of a device that is capable of identifying and recording the time and duration of each pressure release, pursuant to § 65.424(c), if applicable; sampling connection system requirements in § 65.426).

(c) *Compliance requirements.* You must meet the requirements of paragraphs (c)(1) through (7) of this section.

(1) Pursuant to § 65.415, you must identify the equipment and process units for which the optical gas imaging instrument will be used to identify leaks.

(2) Unless your referencing subpart specifies otherwise, the leak detection level for all equipment is 60 grams per hour.

(3) Unless your referencing subpart specifies otherwise, you must monitor all equipment identified in paragraph (c)(1) of this section bimonthly.

(4) For equipment identified in paragraph (c)(1) of this section, you may not use the provisions for less frequent monitoring, based on the percent of equipment leaking in §§ 65.420(a)(2) and 65.422(a)(3).

(5) When following the leak survey procedure in 40 CFR part 60, appendix K, a leak is detected if you see any emissions using the optical gas imaging instrument. The leaking equipment must be identified for repair, as required in § 65.432(a).

(6) You must repair the leaking equipment as required in § 65.432(b) through (e).

(7) Monitoring to confirm repair of leaking equipment must be conducted using the procedures referenced in paragraph (b)(2) of this section.

(d) *Recordkeeping.* You must comply with the requirements in § 65.475(e).

Notifications, Reports and Records

§ 65.470 What notifications and reports must I submit?

(a) *Notification of Compliance Status.* You must include the information listed in paragraphs (a)(1) through (4) of this section, as applicable, in the Notification of Compliance Status that you submit according to the procedures in § 65.225.

(1) The notification must provide the information listed in paragraphs (a)(1)(i) through (iii) of this section for each regulated source subject to the requirements of this subpart.

(i) Process unit, closed vent system or fuel gas system identification.

(ii) Number of each equipment type (*e.g.,* valves, pumps).

(iii) Method of compliance with the standard (*e.g.,* ''monthly leak detection and repair,'' ''equipped with dual mechanical seals,'' ''in vacuum service'').

(2) For valves subject to § 65.420 and connectors subject to § 65.422, provide the historical monitoring data you are using to qualify for less frequent monitoring in lieu of having to do initial monitoring, if applicable.

(3) If you are required to comply with § 65.424(c), provide the information in paragraphs (a)(3)(i) and (ii) of this section.

(i) Description of the monitoring system to be implemented, including the PRD and process parameters to be monitored.

(ii) A description of the alarms or other methods by which operators will be notified of a release.

(4) For closed vent systems, non-flare control devices and fuel gas systems, pursuant to § 65.413, provide the applicable information specified in § 65.880.

(b) Semiannual periodic report. You must report the information specified in paragraphs (b)(1) through (5) of this section, as applicable, in the semiannual periodic report that you submit, as specified in § 65.225.

(1) For compressors, pursuant to § 65.425(b), that are to be operated with an instrument reading of less than 500 ppm, report the date of any instrument reading 500 ppm or greater and the date of the next instrument reading of less than 500 ppm.

(2) For PRD in gas or vapor service, pursuant to § 65.424(b), any instrument reading of 500 ppm or greater, more than 5 days after the PRD returns to service after a release.

(3) For open-ended valves and lines, pursuant to § 65.427(b), report the date of any instrument reading 500 ppm or greater and the date of the next instrument reading of less than 500 ppm.

(4) If your referencing subpart specifies that releases are not allowed from PRD in regulated material service to the atmosphere, report each release, including duration of the release and estimate of quantity of substances released.

(5) For open-ended lines in an emergency shutdown system that are designed to open automatically in the event of a process upset (and are not required to install a cap/plug), report each release if your referencing subpart states that releases from these types of open-ended lines are not allowed.

(6) For equipment in closed vent systems and fuel gas systems, pursuant to § 65.429, report the date of any instrument reading 500 ppm or greater and the date of the next instrument reading of less than 500 ppm.

(7) For closed vent systems, non-flare control devices and fuel gas systems, pursuant to § 65.413, provide the applicable information specified in § 65.882. For flares, report any instances when visual emissions occur longer than 5 minutes during any 2 consecutive hours, a pilot flame is out, or the pilot flames are not monitored.

(c) *Annual periodic report.* You must report the information specified in paragraphs (c)(1) through (8) of this section, as applicable, in the annual periodic report that you submit, as specified in § 65.225.

(1) Provide a summary table that includes the information specified in paragraphs (c)(1)(i) through (iv) of this section for each process unit.

(i) For the equipment specified in paragraphs (c)(1)(i)(A) through (E) of this section, report the number of each type of equipment for which leaks were detected.

(A) Valves, pursuant to § 65.420(a).

(B) Pumps, pursuant to § 65.421(a), (d)(1)(v)(B) and (d)(1)(vii).

(C) Connectors, pursuant to § 65.422(a).

(D) Agitators, pursuant to § 65.423(a), (d)(1)(v)(B) and (d)(1)(vii).

(E) Compressors, pursuant to § 65.425(a).

(ii) Report the total number of valves and connectors monitored and the percent leaking, pursuant to §§ 65.420(b) (valves) and 65.422(b) (connectors).

(iii) For each type of equipment specified in paragraphs (c)(1)(i)(A) through (E) of this section, report the number of leaks that were not repaired, as required by § 65.432.

(iv) Identify the number of valves that are determined by § 65.420(b)(3) to be non-repairable.

(2) Where you delay any repair, pursuant to § 65.432(d), report that delay of repair has occurred and explain why delay of repair is necessary.

(3) If you delayed repair for a valve or connector and you demonstrated that it is technically infeasible to repair the equipment using low leak technology, pursuant to § 65.432(e)(3), include documentation of that demonstration.

(4) For PRD subject to § 65.424(b), report confirmation that you conducted all monitoring to show compliance conducted within the reporting period.

(5) For compressors, pursuant to § 65.425(b), that are to be operated with an instrument reading of less than 500 ppm, report confirmation that you conducted all monitoring to show compliance conducted within the reporting period.

(6) For open-ended lines and valves, pursuant to § 65.427(b), report confirmation that you conducted all monitoring to show compliance conducted within the reporting period.

(7) For equipment in closed vent systems and fuel gas systems, pursuant to § 65.429, report confirmation that you conducted all monitoring to show compliance conducted within the reporting period.

(8) Report the information listed in § 65.470(a)(1) through (3) for the Notification of Compliance Status for regulated sources with later compliance dates. Report any revisions to items reported in an earlier Notification of Compliance Status if the method of compliance has changed since the last report.

§ 65.475 What are my recordkeeping requirements?

(a) *Recordkeeping system.* You may develop and use one recordkeeping system to comply with the

recordkeeping requirements for all of your sources that are subject to the provisions of this subpart. The recordkeeping system must identify the type of program being implemented (e.g., quarterly monitoring, dual mechanical seals) for each type of equipment. The records required by this subpart are specified in paragraphs (b) through (f) of this section.

(b) *General equipment records.* (1) As specified in § 65.415, you must keep equipment identification records if the equipment is not physically tagged and you elect to identify the equipment subject to this subpart through written documentation such as a log or other designation.

(2) If you designate equipment as either unsafe- or difficult-to-monitor, you must keep the records specified in paragraph (b)(2)(i) through (iii) of this section onsite as long as the equipment is designated as either unsafe- or difficult-to-monitor.

(i) You must maintain the identity of unsafe- and difficult-to-monitor equipment, as specified in § 65.416(a).

(ii) You must keep records of the planned schedule for monitoring unsafe- or difficult-to-monitor equipment and an explanation why the equipment is unsafe- or difficult-to-monitor, as specified in § 65.416(a)(3).

(iii) You must keep a written plan for monitoring unsafe- or difficult-to-monitor equipment, as required by § 65.416(a)(4). Your plan must include procedures for repairing any leaks found when monitoring is conducted.

(3) You must maintain the identity of compressors operating with an instrument reading of less than 500 ppm, as specified in § 65.416(c).

(4) You must keep records associated with the determination that equipment is in heavy liquid service, as specified in § 65.430(c), if applicable.

(5) You must keep records associated with the determination that equipment is in regulated material service less than 300 hours per calendar year, as specified in § 65.430(d), if applicable.

(6) For equipment in vacuum service, you must keep records of any pressure alarms triggered, including the date and time the alarm was triggered, as well as the duration the equipment was not in vacuum service.

(7) You must maintain records of the information specified in paragraphs (b)(7)(i) through (vi) of this section for monitoring instrument calibrations conducted according to sections 8.1.2 and 10 of Method 21 of 40 CFR part 60, appendix A–7, and § 65.431(a)(3) and (4).

(i) Date of calibration and initials of operator performing the calibration.

(ii) Calibration gas cylinder identification, certification date and certified concentration.

(iii) Instrument scale(s) used.

(iv) A description of any corrective action taken if the meter readout could not be adjusted to correspond to the calibration gas value in accordance with section 10.1 of Method 21 of 40 CFR part 60, appendix A–7.

(v) Results of each calibration drift assessment required by § 65.431(a)(3)(ii) (*i.e.,* instrument reading for calibration at end of the monitoring day and the calculated percent difference from the initial calibration value).

(vi) If you make your own calibration gas, a description of the procedure used.

(8) You must keep the records specified in paragraphs (b)(8)(i) through (viii) of this section for leaking equipment detected according to § 65.431 and repaired according to § 65.432. You must keep the information for connectors complying with the 8-year monitoring period allowed under § 65.422(a)(3)(iii) for 5 years beyond the date of its last use.

(i) The date the leak was detected and the maximum instrument reading measured by Method 21 of 40 CFR part 60, appendix A–7, including the background concentration if you elect to adjust instrument readings for background, as described in § 65.431(a)(7).

(ii) The date of first attempt to repair the leak.

(iii) The date of successful repair of the leak.

(iv) Maximum instrument reading measured by Method 21 of 40 CFR part 60, appendix A–7, at the time the leak is successfully repaired or determined to be non-repairable.

(v) A record of the identity and an explanation, as specified in § 65.432(b)(4) for any equipment designated as unsafe-to-repair.

(vi) ''Repair delayed,'' the reason for the delay if a leak is not repaired within 15 calendar days after discovery of the leak and, where appropriate, why the repair was technically infeasible without a process unit shutdown, pursuant to § 65.432(d)(1), or the calculation showing that emissions of purged material resulting from immediate repair would be greater than the fugitive emissions likely to result from delay of repair, pursuant to § 65.432(d)(4)(i). As an alternative to listing the reason for delay of repair for each leak, you may elect to develop written guidelines that identify the conditions that justify a delay of repair. If you elect to develop written guidelines, you may document the reason for delay of repair for each leak in your records by citing the relevant sections of the written guidelines. You must maintain the written guidelines at the plant site.

(vii) Dates of process unit shutdowns that occur while the equipment is unrepaired.

(viii) Instrument readings measured by Method 21 of 40 CFR part 60, appendix A–7, while repair is delayed.

(9) You must keep the applicable records specified in § 65.860 for closed vent systems, control devices and fuel gas systems used to comply with this subpart.

(c) *Specific equipment records.* You must keep the records specified in paragraphs (c)(1) through (9) of this section as applicable to the compliance options with which you are complying.

(1) For valves, you must maintain the records specified in paragraphs (c)(1)(i) through (iii) of this section.

(i) The start and end dates of each monitoring period for each process unit, as specified in § 65.420(a)(2).

(ii) If you decided to subgroup valves, pursuant to § 65.420(a)(3), the valve subgrouping records specified in paragraphs (c)(1)(ii)(A) through (D) of this section.

(A) Which valves are assigned to each subgroup.

(B) Monitoring results and calculations made for each subgroup for each monitoring period.

(C) Which valves are reassigned, the last monitoring result prior to reassignment and when they were reassigned.

(D) The results of the semiannual overall performance calculation required in § 65.420(a)(3)(iii).

(iii) The inputs and results for the calculation to determine percent leaking valves in § 65.420(b)(1).

(2) For pumps, you must maintain the records specified in paragraphs (c)(2)(i) through (iii) of this section.

(i) Pursuant to § 65.421(c), documentation that pump visual inspections occurred, the date of each inspection and the results of each inspection, including a description of the characteristics of the liquids dripping, if observed.

(ii) Pursuant to § 65.421(d)(1)(v), documentation that dual mechanical seal pump visual inspections occurred, the date of each inspection and the results of each inspection.

(iii) Pursuant to § 65.421(d)(1)(vi), documentation of the criteria that indicate failure of the seal system, the barrier fluid system or both. Record the design criteria selected, explanations of how those criteria were selected and any changes to the criteria and the reason for the changes.

(3) For connectors, you must maintain the records specified in paragraphs (c)(3)(i) and (ii) of this section.

(i) The start date and end date of each monitoring period for each process unit, pursuant to § 65.422(a)(3).

(ii) The inputs and results for the calculation to determine percent leaking connectors in § 65.422(b).

(4) For agitators, you must maintain the records specified in paragraphs (c)(4)(i) through (iii) of this section.

(i) Pursuant to § 65.423(c), documentation that agitator seal visual inspections occurred, the date of each inspection and the results of each inspection.

(ii) Pursuant to § 65.423(d)(1)(v), documentation that dual mechanical seal agitator visual inspections occurred, the date of each inspection and the results of each inspection.

(iii) Pursuant to § 65.423(d)(1)(vi), documentation of the criteria that indicate failure of the seal system, the barrier fluid system or both. Record the design criteria selected, explanations of how those criteria were selected, and any changes to the criteria and the reason for the changes. This record must be available for review by an inspector.

(5) For pressure relief devices, you must maintain records of the information specified in paragraphs (c)(5)(i) through (iii) of this section.

(i) Pursuant to § 65.424(b), the dates of pressure releases and the dates and results of monitoring following a pressure release, including the background level measured and the maximum instrument reading measured during the monitoring (or the concentration measured by the monitor required by § 65.424(c), if applicable).

(ii) Pursuant to § 65.424(b)(2), the date the rupture disk was replaced.

(iii) Pursuant to § 65.424(c)(2), the quantity of regulated material released during each pressure relief event.

(6) For compressors, you must maintain the records specified in paragraphs (c)(6)(i) and (ii) of this section.

(i) Pursuant to § 65.425(a)(3), documentation of the criteria that indicate failure of the seal system, the barrier fluid system or both. Record the design criteria selected, explanations of how those criteria were selected, and any changes to the criteria and the reason for the changes.

(ii) Pursuant to § 65.425(b), for compressors operating under the alternative compressor standard, records of the dates and results of each compliance test, including the background level measured and the maximum instrument reading measured during each compliance test.

(7) For sampling connection systems complying with § 65.426, you must maintain the records specified in paragraphs (c)(7)(i) and (ii) of this section.

(i) Records of the date of each purge.

(ii) An estimate of the amount of material purged.

(8) Pursuant to § 65.427(b), for open-ended valves and lines, records of the dates and results of each compliance test, including the background level measured and the maximum instrument reading measured during each compliance test.

(9) Pursuant to § 65.413, for equipment in closed vent systems and fuel gas systems, records of the dates and results of each compliance test, including the background level measured and the maximum instrument reading measured during each compliance test.

(d) *Records for the alternative compliance option for equipment in batch operations.* For equipment in each batch operation complying with § 65.440, you must maintain the records specified in paragraphs (b) and (c) of this section, as applicable, as well as paragraphs (d)(1) through (3) of this section.

(1) Prepare a list of equipment added to the batch operation since the last monitoring period required in § 65.440.

(2) Record and keep, pursuant to the referencing subpart and this subpart, the date and results of the monitoring required in § 65.440 for equipment added to a batch operation since the last monitoring period. If no leaking equipment is found during this monitoring, you must record that the inspection was performed, but records of the actual monitoring results are not required.

(3) Maintain records demonstrating the proportion of the time during the calendar year the equipment is in use in a batch operation that is subject to the provisions of this subpart. Examples of suitable documentation are records of time in use for individual pieces of equipment or average time in use for the process unit. These records are not required if you do not adjust monitoring frequency by the time in use, as provided in § 65.440(b)(2) and (3).

(4) Document that the equipment was in service at the time you conducted instrument monitoring, pursuant to § 65.440.

(e) *Records for optical gas imaging.* Pursuant to § 65.450, you must keep the records described in paragraphs (e)(1) through (5) of this section:

(1) The equipment and process units for which you choose to use the optical gas imaging instrument.

(2) All records required by 40 CFR part 60, appendix K.

(3) A video record to document the leak survey results. The video record must include a time and date stamp for each monitoring event.

(4) Identification of the equipment screened and the time and date of the screening.

(5) Documentation of repairs attempted and repairs delayed, as specified in paragraph (b)(8)(ii) through (viii) of this section. If you confirm repair of a leak using the optical gas imaging instrument, then instead of the maximum instrument reading measured by Method 21 of 40 CFR part 60, appendix A–7 required by paragraph (b)(8)(iv) of this section, you must keep a video record following repair to confirm the equipment is repaired. You must keep the information for connectors complying with the 8-year monitoring period allowed under § 65.422(a)(3)(iii) for 5 years beyond the date of its last use.

(f) *Flare records.* If you use a flare as specified in § 65.413, you must keep records of all visual emissions observed, periods when a pilot flame is out, and any periods that the pilot flames are not monitored.

Other Requirements and Information

§ 65.490 What definitions apply to this subpart?

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart H of this part, unless otherwise specified in the referencing subpart.

List of Tables in Subpart J of Part 65

TABLE 1 TO SUBPART J OF PART 65—INSTRUMENT READINGS THAT DEFINE A LEAK FOR EQUIPMENT COMPLYING WITH § 65.430(B)(2)

If you comply with § 65.430(b)(2) for . . .	The instrument reading that defines a leak is . . .
1. Valves	i. 500 ppm.

TABLE 1 TO SUBPART J OF PART 65—INSTRUMENT READINGS THAT DEFINE A LEAK FOR EQUIPMENT COMPLYING WITH § 65.430(B)(2)—Continued

If you comply with § 65.430(b)(2) for . . .	The instrument reading that defines a leak is . . .
2. Pumps	i. 5,000 ppm for pumps handling polymerizing monomers and 2,000 ppm for all other pumps.
3. Connectors	i. 500 ppm.
4. Agitators	i. 10,000 ppm.
5. Instrumentation systems	i. 10,000 ppm.
6. PRD	i. 500 ppm.
7. Compressors	i. 500 ppm.
8. Open ended valves or lines	i. 500 ppm.

TABLE 2 TO SUBPART J OF PART 65—MONITORING FREQUENCY FOR EQUIPMENT IN BATCH OPERATIONS COMPLYING WITH § 65.440

If the equipment in a batch operation is in use . . .	And you would be required to monitor the equipment in a process operating the entire year . . .	You must monitor the equipment in the batch operation . . .
1. 0 to less than 25 percent of the hours during the year	a. Monthly	i. Quarterly.
	b. Quarterly	i. Annually.
	c. Semiannually	i. Annually.
2. 25 to less than 50 percent of the hours during the year	a. Monthly	i. Quarterly.
	b. Quarterly	i. Semiannually.
	c. Semiannually	i. Annually.
3. 50 to less than 75 percent of the hours during the year	a. Monthly	i. Bimonthly.
	b. Quarterly	i. Three times per year.
	c. Semiannually	i. Semiannually.
4. 75 to 100 percent of the hours during the year	a. Monthly	i. Monthly.
	b. Quarterly	i. Quarterly.
	c. Semiannually	i. Semiannually.

5. Add subpart M to read as follows:

Sec.

Subpart M—National Uniform Emission Standards for Control Devices

General

65.700 What is the purpose of this subpart?
65.701 Am I subject to this subpart?
65.702 What are my general requirements for complying with this subpart?
65.703 What parts of my plant does this subpart cover?
65.704 What parts of the General Provisions apply to me?
65.705 What definitions apply to this subpart?

Control Devices

65.710 What general monitoring requirements must I meet for control devices?
65.711 What are the requirements for continuous emission monitoring systems (CEMS)?
65.712 What are the requirements for continuous parameter monitoring systems (CPMS)?
65.713 How do I establish my operating limits?
65.720 What requirements must I meet for closed vent systems?
65.724 What requirements must I meet for small boilers and process heaters?
65.726 What monitoring requirements must I meet for thermal oxidizers?
65.728 What monitoring requirements must I meet for catalytic oxidizers?
65.732 What monitoring requirements must I meet for fuel gas systems?
65.740 What monitoring requirements must I meet for absorbers?
65.742 What monitoring requirements must I meet for adsorbers regenerated onsite?
65.744 What monitoring requirements must I meet for non-regenerative adsorbers?
65.746 What requirements must I meet for condensers?
65.748 What requirements must I meet for biofilters?
65.760 What requirements must I meet for sorbent injection and collection systems?
65.762 What requirements must I meet for fabric filters?
65.800 What requirements must I meet for other control devices?

Performance Testing

65.820 What are the performance testing requirements?
65.821 At what process conditions must I conduct performance testing?
65.822 At what process conditions must I conduct performance testing for batch process operations?
65.823 How do I sample from vent streams?
65.824 What is the performance test duration?
65.825 What performance test methods do I use?
65.826 How do I calculate emissions in parts per million by volume concentration?
65.827 How do I demonstrate compliance with a percent reduction requirement?
65.828 How do I determine percent reduction?
65.829 How do I demonstrate compliance with a hydrogen halide and halogen emission limit specified in a referencing subpart?
65.830 When can an engineering assessment be used and what does it include?

Batch Emission Calculations

65.835 What emissions calculations must I use for batch process operations for purposes of compliance with an aggregated percent reduction?

Design Evaluation

65.850 How do I demonstrate compliance through design evaluation?

Recordkeeping

65.855 How do I calculate monitoring data averages?
65.860 What records must I keep?

Reporting

65.880 What information do I submit as part of my Notification of Compliance Status?
65.882 What information must I submit in my semiannual periodic report?

65.884 What other reports must I submit and when?

List of Tables in Subpart M of Part 65

Table 1 to Subpart M of Part 65—CEMS Monitoring
Table 2 to Subpart M of Part 65—Monitoring Equipment as an Alternative to CEMS Monitoring
Table 3 to Subpart M of Part 65—Operating Parameters, Operating Limits and Data Monitoring, Recordkeeping and Compliance Frequencies

Table 5 to Subpart M of Part 65—Methods and Procedures for Conducting Performance Tests for Vent Streams

Subpart M—National Uniform Emission Standards for Control Devices

General

§ 65.700 What is the purpose of this subpart?

This subpart specifies requirements to meet the emission standards of a referencing subpart for closed vent systems, control devices and routing of air emissions to a fuel gas system.

§ 65.701 Am I subject to this subpart?

You are subject to this subpart if you are an owner or operator who is subject to a referencing subpart and you have been expressly directed to comply with this subpart by a referencing subpart.

§ 65.702 What are my general requirements for complying with this subpart?

(a) You must comply with the following:

(1) The applicable provisions of subpart H of this part.

(2) The General Provisions that are applicable to the referencing subpart (*i.e.,* subpart A of parts 60, 61 or 63 of this chapter), as specified in subpart H and the referencing subpart.

(3) The section(s) of this subpart corresponding to the control measure(s) being used.

(4) § 65.720 for closed vent systems.

(5) All applicable requirements referenced in the provisions listed in paragraphs (a)(1) through (4) of this section.

(b) *Operation of closed vent systems, control devices or fuel gas systems.* You must operate closed vent systems, control devices or fuel gas systems used to comply with the referencing subpart, at all times when emissions are vented to or collected by these systems or devices.

(c) *Halogenated vent streams.* Unless required to do so by paragraph (d) of this section, you may determine whether each vent stream is halogenated by establishing the mass emission rate and the vent stream concentration (parts per million by volume (ppmv), by compound) of halogen atoms, based on one or more of the procedures specified in paragraphs (c)(1) through (5) of this section.

(1) Process knowledge that no halogen, hydrogen halides or organic halides are present in the process.

(2) Applicable engineering assessment, as discussed in § 65.830.

(3) Concentration of compounds containing halogen and hydrogen halides measured by Method 26 or 26A at 40 CFR part 60, appendix A–8, and organic halides measured by Method 18 of 40 CFR part 60, appendix A–6.

(4) Concentration of compounds containing hydrogen halides may be measured by Method 320 at 40 CFR part 63, appendix A.

(5) Any other method or data that has been validated according to the applicable procedures in Method 301 at 40 CFR part 63, appendix A.

(d) *Halogenated vent stream control requirements.* If you control a vent stream using a boiler, process heater, oxidizer or fuel gas system, you must determine whether the vent stream is halogenated, pursuant to paragraph (c) of this section. If you determine the vent stream is halogenated, you must convey the gas stream exiting the boiler, process heater or oxidizer to a halogen reduction device, such as an absorber meeting the requirements of § 65.740, or other device meeting the requirements of § 65.800, before it is discharged to the atmosphere. You may use a halogen reduction device to reduce the vent stream halogen atom mass emission rate to less than 0.45 kilogram per hour and, thus, make the vent stream nonhalogenated.

(e) *Performance test requirements.* You must conduct a performance test according to the procedures in §§ 65.820 through 65.829. However, you are not required to conduct a performance test if any of the control measures specified in paragraphs (e)(1) through (5) of this section are used.

(1) A control device for which the referencing subpart allows a design evaluation as an alternative to the performance test.

(2) You use a continuous emission monitoring system (CEMS) meeting the requirements in § 65.711 to monitor the performance of the control device that would otherwise require performance testing.

(3) Control measures for which you have received an approved performance test waiver, according to § 65.245 of this chapter.

(4) If a prior performance test was conducted using the same procedures specified in § 65.724(b) for boilers and process heaters, § 65.726(b) for thermal oxidizers, § 65.728(b) for catalytic oxidizers, § 65.740(b) for absorbers, § 65.742(f) for adsorbers regenerated on site, § 65.744(b) for non-regenerative adsorbers, § 65.746(b) for condensers, § 65.748(b) for biofilters, § 65.760(b) for sorbent injection, § 65.762(b) for fabric filters and § 65.800(b) for other control devices, as applicable, and, either no process changes have been made since the test or you can demonstrate that the results of the performance test, with or without adjustments, reliably demonstrate compliance despite process changes, you may only use a prior performance test that is less than 5 years old in lieu of a performance test. You must request permission to substitute a prior performance test by application to the Administrator that includes the information specified in § 65.884(f). You must be able to establish appropriate operating limits using the information collected during the prior performance test. If a performance test is waived, you are still subject to any subsequent or periodic performance test requirements.

(5) If you use a condenser and comply with § 65.746.

(f) *Process changes.* If you make a change to process equipment or operating conditions that is expected to affect the operating parameter values of a control device and render the operating limits ineffective as indicators of compliance with the standard, you must conduct a performance test, as specified in paragraph (e) of this section, within 180 days of the date of start-up of the change to establish new operating limits and demonstrate that the changed emission point is in compliance with the applicable emission limit of the referencing subpart. Whenever you make a change, you must report the change, as specified in § 65.884(i).

(g) *Monitoring data averages.* You must calculate monitoring data averages, as specified in § 65.855.

(h) *Recordkeeping.* You must keep up-to-date, readily accessible records of applicable records, as specified in § 65.860.

(i) *Reports.* You must submit reports, as specified in §§ 65.880 through 65.884.

§ 65.703 What parts of my plant does this subpart cover?

This subpart applies to control devices that receive regulated material and that are used to comply with a referencing subpart. This subpart also applies to closed vent systems that route

regulated material to control devices and fuel gas systems that receive regulated material.

§ 65.704 What parts of the General Provisions apply to me?

The General Provisions of 40 CFR parts 60, 61 and 63 apply to this subpart, as specified in subpart H of this part.

§ 65.705 What definitions apply to this subpart?

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart H of this part, unless otherwise specified in the referencing subpart.

Control Devices

§ 65.710 What general monitoring requirements must I meet for control devices?

(a) You must meet the general monitoring requirements of this section for all control devices used to comply with the referencing subpart.

(b) If you choose to use a CEMS to meet the requirements as specified in Table 1 to this subpart, you must comply with the provisions specified in § 65.711. If you choose to use a continuous parameter monitoring system (CPMS) to meet the requirements, as specified in Table 2 to this subpart, you must comply with the provisions specified in § 65.712.

(c) You are not required to operate CEMS or CPMS during periods of no flow, or no flow of regulated material to the control device; however, if flow could be intermittent, you must install a flow indicator to identify periods of flow/no flow at the inlet or outlet of the control device. You must keep records of periods of flow/no flow, or no flow of regulated material to the control device, as specified in § 65.860(i). Flow indicators used only to identify periods of flow and no flow are not subject to the requirements of § 65.712. However, you must perform a flow meter verification check annually. You must perform the annual verification check for at least two points, one at the instrument's zero and the other at the instrument's span.

(d) All monitoring equipment must be capable of providing a continuous record.

(e) A deviation means any of the cases listed in paragraphs (e)(1) through (5) of this section. Monitoring data are not required to be collected during periods of non-operation of the process unit or portion thereof (resulting in cessation of the emissions to which monitoring applies).

(1) Periods of excess emissions, which are those periods when the daily or block average value from a CEMS, reduced to the units of the emissions standards, as specified in § 65.711(j), exceeds an emission limit specified in the referencing subpart.

(2) Operating parameter exceedances, which are those periods when the daily or block average value of one or more monitored operating parameters is outside the operating limit established under this rule.

(3) Any discharges to the atmosphere through a bypass line.

(4) Any period when you route regulated materials to a monitored emission point that you do not collect data using your CEMS, CPMS or other required non-continuous monitoring, as applicable. This does not include periods of normally scheduled quality assurance activities in your CEMS performance evaluation and monitoring plan or CPMS monitoring plan that require the instrument to be offline (*e.g.,* during calibration checks).

(5) Any period when you route regulated emissions to a monitored emission point when the continuous monitoring system (CMS) is not operating properly or is out of control, as specified in § 65.711(i) or § 65.712(d).

§ 65.711 What are the requirements for continuous emission monitoring systems (CEMS)?

(a) *General.* You must comply with the requirements of this section for each CEMS unless the Administrator specifies or approves a change (minor, intermediate or major) in methodology or an alternative for the specified monitoring requirements and procedures, as provided in § 65.240.

(b) *Operation of CEMS.* You must install, maintain and operate each CEMS, as specified in paragraphs (b)(1) through (11) of this section.

(1) Install each CEMS according to the procedures contained in the applicable performance specification(s) listed in paragraph (h) of this section. Locate the sampling probe or other interface at a measurement location relative to each regulated process unit such that you obtain representative measurements of emissions from the regulated source (*e.g.,* on or downstream of the last control device).

(2) When you combine the regulated emissions from two or more regulated emission units before release to the atmosphere, you may install an applicable CEMS for each emissions unit or for the combined emissions stream, provided the monitoring is sufficient to demonstrate compliance with the emission limit for each emissions unit.

(3) If the relevant emission limit is a mass emission standard and the regulated emissions from a regulated emissions unit are released to the atmosphere through more than one emission point, you must install an applicable CEMS at each emission point.

(4) You must ensure the readout (that portion of the CEMS that provides a visual display or record), or other indication of emissions, from any CEMS required for compliance with an emission standard is readily accessible onsite for operational control or inspection by the operator of the source.

(5) You must conduct a CEMS performance evaluation, pursuant to the schedule specified in the referencing subpart, and periodically, as specified in your CEMS performance evaluation and monitoring plan described in paragraph (c) of this section.

(6) All CEMS must complete a minimum of one cycle of operation (sampling, analyzing and data recording) for each successive 15-minute period.

(7) Except for maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero and span adjustments, you must operate all CEMS and collect data continuously when you route regulated emissions to the monitored emission point.

(8) Upon submittal of the CEMS performance evaluation and monitoring plan to the Administrator for approval, you must operate and maintain each CEMS according to the CEMS performance evaluation and monitoring plan specified in paragraph (c) of this section.

(9) You must modify the CEMS performance evaluation and monitoring plan to incorporate the Administrator's comments and resubmit the plan for approval to the Administrator within 30 days of receiving the Administrator's comments. Upon re-submittal to the Administrator for approval, you must operate and maintain each CEMS in conformance with the revised CEMS performance evaluation and monitoring plan.

(10) For each CEMS, you must comply with the procedures for out-of-control periods described in paragraph (i) of this section.

(11) You must reduce data from each CEMS, as specified in paragraph (j) of this section.

(c) *Quality control program.* You must develop and implement a CEMS quality control program documented in a CEMS performance evaluation and monitoring

plan. You must include in the CEMS performance evaluation and monitoring plan the information specified in paragraphs (c)(1) through (3) of this section.

(1) Routine quality control and assurance procedures that address the requirements of paragraph (d) of this section.

(2) CEMS evaluation procedures that meet the requirements of paragraph (e) of this section.

(3) Additional information, as listed in paragraph (f) of this section.

(d) *CEMS performance evaluation and monitoring plan contents—routine quality control and assurance procedures.* In the CEMS performance evaluation and monitoring plan, you must include a description of the procedures listed in paragraphs (d)(1) through (6) of this section and a schedule for conducting these procedures. The routine procedures must provide an assessment of CEMS performance and must be consistent with and incorporate applicable provisions of the procedures specified in paragraph (g) of this section.

(1) Initial and subsequent calibration of the CEMS and acceptance criteria.

(2) Determination and adjustment of the calibration drift of the CEMS.

(3) Preventive maintenance of the CEMS, including spare parts inventory.

(4) Data recording, calculations and reporting;

(5) Accuracy audit procedures, including sampling and analysis methods.

(6) Program of corrective action for a CEMS that is not operating properly or is out-of-control.

(e) *CEMS performance evaluation and monitoring plan contents—CEMS evaluation.* In the CEMS performance evaluation and monitoring plan, you must include the information listed in paragraphs (e)(1) through (6) of this section.

(1) A description of the applicable CEMS evaluation procedure specified in paragraph (h) of this section and the site-specific details and procedures necessary to describe the applicable procedure for your specific operation.

(2) The evaluation program objectives.

(3) Acceptance criteria.

(4) An evaluation program summary.

(5) Data quality objectives. (The pre-evaluation expectations of precision, accuracy and completeness of data.)

(6) Conditions that would trigger a CEMS evaluation, which must include, at a minimum, a newly installed CEMS; an existing CEMS that is newly used to demonstrate compliance with a referencing subpart and has not previously had a CEMS evaluation; a process change that is expected to affect the performance of the CEMS; and the Administrator's request for a performance evaluation under section 114 of the Clean Air Act. A CEMS that is newly used to demonstrate compliance with a referencing subpart that has previously had a CEMS evaluation, as specified in this paragraph (e) of this section, and has followed routine quality assurance procedures, as specified in paragraph (d) of this section, since the previous CEMS evaluation, does not trigger an additional CEMS evaluation unless a change is also made that is expected to affect the performance of the CEMS.

(f) *CEMS performance evaluation and monitoring plan contents—additional information.* In the CEMS performance evaluation and monitoring plan, you must include information that provides background about the source and monitoring equipment, as specified in paragraphs (f)(1) through (4) of this section.

(1) Identification of the pollutant being monitored by the CEMS and the expected concentrations, including worst case concentrations at normal operation and during possible process upsets.

(2) Description of the monitoring equipment, including the information specified in paragraphs (f)(2)(i) through (vii) of this section.

(i) Manufacturer and model number for all monitoring equipment components.

(ii) Performance specifications, as provided by the manufacturer and any differences expected for your installation and operation.

(iii) Location of the CMS sampling probe or other interface and a justification of how the location meets the requirements of paragraph (b)(1) of this section.

(iv) Placement of the CEMS readout, or other indication of emissions, indicating how the location meets the requirements of paragraph (b)(2) of this section.

(v) Span of the analyzer.

(vi) Justification of the selection for the specific monitoring equipment with respect to the pollutant and pollutant concentrations expected.

(vii) Identification of the cycle time for the CEMS, indicating that it meets the requirement of (b)(3) of this section.

(3) Description of the data collection and reduction systems, including the information specified in paragraphs (f)(3)(i) through (iv) of this section.

(i) A copy of the data acquisition system algorithm used to reduce the measured data into the reportable form of the standard and calculate the applicable averages.

(ii) Identification of whether the algorithm excludes data collected during CEMS breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments.

(iii) If the data acquisition algorithm does not exclude data collected during CEMS breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments, then include a description of your procedure for excluding this data when the averages calculated, as specified in § 65.855, are determined.

(iv) If the measured data are converted to the reportable form of the standard and/or averages calculated manually, documentation of the calculation procedure.

(4) Identification of the applicable EPA performance specification(s) for the CEMS.

(g) *CEMS procedures.* You must operate each CEMS in accordance with each of the applicable procedures in paragraphs (g)(1) through (4) of this section and the CEMS performance evaluation and monitoring plan in paragraph (c) of this section.

(1) Except as provided in paragraphs (g)(2) through (4) of this section, you must comply with procedure 1 at 40 CFR part 60, appendix F. If you operate a CEMS, based on Fourier transform infrared spectroscopy, you must replace the Relative Accuracy Test Audit requirements of procedure 1 with the validation requirements and criteria of sections 11.1.1 and 12.0 of Performance Specification 15 of part 60, appendix B.

(2) If you operate a particulate matter CEMS, you must comply with procedure 2 at 40 CFR part 60, appendix F, instead of procedure 1 at 40 CFR part 60, appendix F.

(3) If you operate a mercury CEMS, you must comply with procedure 5 at 40 CFR part 60, appendix F, instead of procedure 1 at 40 CFR part 60, appendix F.

(4) If you operate a CEMS, meeting Performance Specification 9 or 15 requirements, you must determine the target analyte(s) for calibration using either process knowledge of the vent stream or the presurvey screening procedures in section 16 of Method 18 at 40 CFR part 60, appendix A–6 on the control device outlet stream.

(h) *Certification.* As specified in the CEMS performance evaluation and monitoring plan in paragraph (c) of this section, you must perform a CEMS evaluation and certify your CEMS in accordance with the performance specifications listed in paragraphs (h)(1) through (9) of this section, as specified in paragraphs (h)(10) and (11) of this section, and in accordance with your CEMS performance evaluation and monitoring plan specified in paragraph (c) of this section. Paragraph (h)(12) of this section provides for situations when the performance specifications listed in paragraphs (h)(1) through (9) of this section are not applicable. The performance specifications listed in paragraphs (h)(1) through (11) of this section are found in appendix B of part 60.

(1) For particulate matter, Performance Specification 11.

(2) For hydrogen halides, Performance Specification 15.

(3) For mercury, Performance Specification 12A or 12B.

(4) For sulfur dioxide, Performance Specification 2.

(5) For total hydrocarbons, Performance Specification 8A.

(6) For speciated organic compounds using a gas chromatograph, Performance Specification 9.

(7) For speciated organic compounds using Fourier transform infrared spectroscopy, Performance Specification 15.

(8) For oxygen or carbon dioxide, Performance Specification 3.

(9) For carbon monoxide, Performance Specification 4, if your emission limit is above 200 ppmv, or Performance Specification 4A if your emission limit is equal to or less than 200 ppmv.

(10) If you operate a CEMS meeting Performance Specification 9 or 15, you must determine the target analyte(s) for calibration using either process knowledge of the vent stream or the pre-survey screening procedures in section 16 of Method 18 at 40 CFR part 60, appendix A–6 on the control device outlet stream.

(11) You may only use Performance Specification 15 to measure hydrogen halides if you are not required to include halogens in your measurement or you can demonstrate that there are no halogens in the vent stream.

(12) If you wish to use a CEMS with no applicable Performance Specification, you must submit a request for approval to use an alternate monitoring method according to § 65.240. Your alternative monitoring method request must include the procedures for a CEMS evaluation and other information typically contained in a Performance Specification. This information must also be included in the CEMS performance evaluation and monitoring plan specified on paragraph (d) of this section.

(i) *Out-of-control periods.* For each CEMS, you must comply with the out-of-control procedures described in paragraph (i) of this section when the CEMS is out-of-control, as defined in paragraph (i)(1).

(1) If the conditions in paragraph (i)(1)(i) or (ii) of this section occur, the CEMS is out-of-control.

(i) If the zero (low-level), mid-level (if applicable) or high-level calibration drift exceeds two times the applicable calibration drift specification in the applicable performance specification.

(ii) A CEMS is out of control if the CEMS fails a performance test audit (*e.g.*, cylinder gas audit), relative accuracy test audit or linearity test audit.

(2) When the CEMS is out of control, you must take the necessary corrective action and repeat all necessary tests that indicate the system is out of control. You must take corrective action and conduct retesting until the performance requirements are below the applicable limits. The beginning of the out-of-control period is the hour you conduct a performance check (*e.g.*, calibration drift) that indicates an exceedance of the performance requirements established in this section. The end of the out-of-control period is the hour following the completion of corrective action and successful demonstration that the system is within the allowable limits. You must not use data recorded during periods the CEMS is out of control in data averages and calculations, used to report emissions or operating levels, as specified in § 65.855(b).

(j) *CEMS data reduction.* You must reduce data from a CEMS, as specified in paragraphs (j)(1) through (4) of this section.

(1) Convert all CEMS emission data into units of the emission limit of the referencing subpart for reporting purposes using the conversion procedures specified in that subpart. After conversion into units of the emission limit, you may round the data to the same number of significant digits as used in that emission limit.

(2) If a referencing subpart specifies an emission standard in a specific percent oxygen, you must correct the concentrations, as measured by the CEMS in accordance with § 65.826(b).

(3) Calculate averages, as specified in § 65.855.

(4) Record the CEMS data, as specified in § 65.860.

(k) The CEMS performance evaluation and monitoring plan must be submitted for approval to the Administrator 60 days before the CEMS evaluation is to be conducted.

(l) If you are not proposing any alternative monitoring methods and are intending to demonstrate compliance using the monitoring method(s) specified in this section, you do not have to wait for approval of your CEMS performance evaluation and monitoring plan before conducting the CEMS evaluation or before following the other procedures of the CEMS performance evaluation and monitoring plan.

(m) If you are proposing an alternative monitoring method, follow the procedures in § 65.240.

§ 65.712 What are the requirements for continuous parameter monitoring systems (CPMS)?

(a) *General.* You must comply with the requirements of this section for each CPMS unless the Administrator specifies or approves a change (minor, intermediate or major) in methodology or an alternative for the specified monitoring requirements and procedures, as provided in § 65.240.

(b) *Operation of CPMS.* You must install, maintain and operate each CPMS, as specified in paragraphs (b)(1) through (11) of this section.

(1) Install and locate each CPMS sampling probe or other interface at a measurement location relative to each regulated process unit or control device being monitored such that you obtain representative measurements of the operating parameter from the regulated source or control device (*e.g.,* on or downstream of the last control device).

(2) You must ensure the readout (that portion of the CPMS that provides a visual display or record), or other indication of the monitored operating parameter from any CPMS required for compliance is readily accessible onsite for operational control or inspection by the operator of the source.

(3) All CPMS must complete a minimum of one cycle of operation (sampling, analyzing and data recording) for each successive 15-minute period.

(4) Except for maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero and span adjustments, you must operate all CPMS and collect data continuously when you route regulated emissions to the monitored emission point.

(5) Upon submittal of the CPMS monitoring plan to the Administrator for approval, you must operate and maintain each CPMS according to the

CPMS monitoring plan specified in paragraph (c) of this section.

(6) You must modify the CPMS monitoring plan to incorporate the Administrator's comments and resubmit the plan for approval to the Administrator within 30 days of receiving the Administrator's comments. Upon re-submittal to the Administrator for approval, you must operate and maintain each CPMS in conformance with the revised CPMS monitoring plan.

(7) For each CPMS, you must comply with the out-of-control procedures described in paragraphs (d) of this section.

(8) You must reduce data from a CPMS, as specified in paragraphs (e) of this section.

(9) All monitoring equipment must meet the minimum accuracy, calibration and quality control requirements specified in Table 4 to this subpart.

(10) Your CPMS must be capable of measuring the appropriate parameter over a range that extends from a value that is at least 20 percent less than the lowest value that you expect your CPMS to measure, to a value that is at least 20 percent greater than the highest value that you expect your CPMS to measure. The data recording system associated with each CPMS must have a resolution that is equal to or better than one-half of the required system accuracy.

(11) All CPMS must be installed, operational and calibrated, as specified in paragraph (b) of this section, within 24 hours before conducting the performance test or, if a performance test is not required, prior to the compliance date. Subsequent calibrations must be conducted, as specified in the CPMS monitoring plan, as specified in paragraph (c) of this section.

(c) *Quality control program.* You must develop and implement a CPMS quality control program documented in a CPMS monitoring plan. The CPMS monitoring plan must contain the information listed in paragraphs (c)(1) through (5) of this section.

(1) The information specified in § 65.225(g).

(2) Identification of the parameter to be monitored by the CPMS and the expected parameter range, including worst case and normal operation.

(3) Description of the monitoring equipment, including the information specified in (c)(3)(i) through (viii) of this section.

(i) Manufacturer and model number for all monitoring equipment components.

(ii) Performance specifications, as provided by the manufacturer, and any differences expected for your installation and operation.

(iii) The location of the CMS sampling probe or other interface and a justification of how the location meets the requirements of paragraph (b)(1) of this section.

(iv) Placement of the CPMS readout, or other indication of parameter values, indicating how the location meets the requirements of paragraph (b)(2) of this section.

(v) Span of the analyzer.

(vi) Identify the parameter detected by the parametric signal analyzer and the algorithm used to convert these values into the operating parameter monitored to demonstrate compliance, if the parameter detected is different from the operating parameter monitored.

(vii) Justification for the selection of the specific monitoring equipment with respect to the parameter and expected parameter values.

(viii) Identify the cycle time for the CPMS.

(4) Description of the data collection and reduction systems, including the information specified in paragraphs (c)(4)(i) through (iv) of this section.

(i) A copy of the data acquisition system algorithm used to reduce the measured data into the reportable form of the standard and calculate the applicable averages.

(ii) Identification of whether the algorithm excludes data collected during CPMS breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments.

(iii) If the data acquisition algorithm does not exclude data collected during CEMS breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments, then include a description of your procedure for excluding this data when the averages calculated, as specified in § 65.855 are determined.

(iv) If the measured data are converted to the reportable form of the standard and/or averages calculated manually, documentation of the calculation procedure.

(5) Routine quality control and assurance procedures, including descriptions of the procedures listed in paragraphs (c)(5)(i) through (vi) of this section and a schedule for conducting these procedures. The routine procedures must provide an assessment of CPMS performance.

(i) Initial and subsequent calibration of the CPMS and acceptance criteria.

(ii) Determination and adjustment of the calibration drift of the CPMS.

(iii) Daily checks for indications that the system is responding. If the CPMS system includes an internal system check, you may use the results to verify the system is responding, as long as you check the internal system results daily for proper operation and the results are recorded.

(iv) Preventive maintenance of the CPMS, including spare parts inventory.

(v) Data recording, calculations and reporting.

(vi) Program of corrective action for a CPMS that is not operating properly.

(d) *Out-of-control periods.* For each CPMS, you must comply with the out-of-control procedures described in paragraphs (d)(1) and (2) of this section.

(1) A CPMS is out-of-control if the zero (low-level), mid-level (if applicable) or high-level calibration drift exceeds two times the accuracy requirement of Table 4 of this subpart.

(2) When the CPMS is out of control, you must take the necessary corrective action and repeat all necessary tests that indicate the system is out of control. You must take corrective action and conduct retesting until the performance requirements are below the applicable limits. The beginning of the out-of-control period is the hour you conduct a performance check (*e.g.,* calibration drift) that indicates an exceedance of the performance requirements established in this section. The end of the out-of-control period is the hour following the completion of corrective action and successful demonstration that the system is within the allowable limits. You must not use data recorded during periods the CPMS is out of control in data averages and calculations, used to report emissions or operating levels, as specified in § 65.855(b).

(e) *CPMS data reduction.* You must reduce data from a CPMS, as specified in paragraphs (e)(1) through (4) of this section.

(1) You may round the data to the same number of significant digits, as used in that emission limit.

(2) Periods of non-operation of the process unit (or portion thereof), resulting in cessation of the emissions to which the monitoring applies must not be included in daily averages.

(3) Calculate averages, as specified in § 65.855.

(4) The data from a CPMS must be recorded, as specified in § 65.860.

(f) *Monitoring plan submittal date.* The CPMS monitoring plan must be submitted for approval to the

Administrator 60 days before the initial CPMS evaluation is to be conducted.

(g) *Implementing the monitoring plan.* If you are not proposing any alternative monitoring methods and are intending to demonstrate compliance using the monitoring method(s) specified in this section, you do not have to wait for approval of your CPMS monitoring plan before conducting the performance test or before following the procedures of the CPMS monitoring plan.

(h) *Alternative monitoring method.* If you are proposing an alternative monitoring method, follow the procedures in § 65.240.

§ 65.713 How do I establish my operating limits?

You must establish operating limits for operating parameters required to be monitored by this subpart by following the requirements in this section or you may request approval of monitoring alternatives, as specified in § 65.884(h).

(a) You must establish the operating limit for each operating parameter for each control device, based on the operating parameter values recorded during the performance test, and may be supplemented by engineering assessments and/or manufacturer's recommendations. Performance testing is not required to be conducted over the entire range of allowed operating parameter values.

(b) The established operating limit must represent the conditions for which the control device is meeting the specified emission limit of the referencing subpart.

(c) You must establish your operating limit as an operating parameter range, minimum operating parameter level or maximum operating parameter level, as specified in Table 3 to this subpart, as applicable. Where this subpart does not specify which format to use for your operating limit (*e.g.,* operating range, or minimum/maximum operating levels), you must determine which format best establishes proper operation of the control device such that the control device is meeting the specified emission limit of the referencing subpart.

(d) The operating limit may be based on ranges or limits previously established under a referencing subpart. If a performance test is not required for a control device and, except as specified in § 65.748(b) for biofilters, the operating limit may be based on engineering assessments and/or manufacturer's recommendations included in the required design evaluation.

(e) For batch processes, you may establish operating limits for individual emission episodes, including each distinct episode of vent stream emissions, if applicable. If you elect to establish separate operating limits for different emission episodes within a batch process, then you must comply with the provisions in paragraphs (e)(1) and (2) of this section.

(1) Maintain a daily schedule or log of operating scenarios for batch processes according to § 65.860(f)(1).

(2) Provide rationale for each operating limit for each emission episode in a batch pre-compliance report, as specified in § 65.884(g). You must also report the rationale according to § 65.884(j).

§ 65.720 What requirements must I meet for closed vent systems?

(a) *General.* If you operate a closed vent system that collects regulated material from a regulated source, you must meet the applicable requirements of this section. You must also meet the applicable requirements of subpart J of this part.

(b) *Collection of emissions.* Each closed vent system must be designed and operated to collect the regulated material vapors from the emission point, and to route the collected vapors to a control device with no release to the atmosphere through bypass lines.

(c) *Bypass lines.* Use of the bypass at any time to divert a regulated vent stream is an emissions standards deviation for all pollutants regulated by the referencing subpart. The use of the bypass during a performance test invalidates the performance test. You must comply with the provisions of either paragraphs (c)(1) or (2) of this section for each closed vent system that contains bypass lines that could divert a vent stream to the atmosphere.

(1) *Bypass line flow indicator.* Install, maintain and operate a CPMS for flow, as specified in paragraphs (c)(1)(i) and (ii) of this section.

(i) Install a CPMS for flow at the entrance to any bypass line. The CPMS must record the volume of the gas stream that bypassed the control device.

(ii) Equip the CPMS for flow with an alarm system that will alert an operator immediately and automatically when flow is detected in the bypass line. Locate the alarm such that an operator can easily detect and recognize the alert.

(2) *Bypass line valve configuration.* Secure the bypass line valve in the non-diverting position with a car-seal or a lock-and-key type configuration. You must visually inspect the seal or closure mechanism at least once every month to verify that the valve is maintained in the non-diverting position, and the vent stream is not diverted through the bypass line.

(d) *Bypass records.* For each closed vent system that contains bypass lines that could divert a vent stream away from the control device and to the atmosphere, or cause air intrusion into the control device, you must keep a record of the information specified in either paragraph (d)(1) or (2) of this section, as applicable.

(1) You must maintain records of any alarms triggered because flow was detected in the bypass line, including the date and time the alarm was triggered and the duration of the flow in the bypass line. You must also maintain records of all periods when the vent stream is diverted from the control device or air intrudes into the control device. You must include an estimate of the volume of gas, the concentration of regulated material in the gas and the resulting emissions of regulated material that bypassed the control device.

(2) Where a seal mechanism is used to comply with paragraph (c)(2) of this section, hourly records of flow are not required. In such cases, you must record the date that you complete the monthly visual inspection of the seals or closure mechanisms. You must also record the occurrence of all periods when the seal or closure mechanism is broken, the bypass line valve position has changed or the key for a lock-and-key type lock has been checked out. You must include an estimate of the volume of gas, the concentration of regulated material in the gas and the resulting emissions of regulated material that bypassed the control device.

§ 65.724 What requirements must I meet for small boilers and process heaters?

(a) *Small boiler or process heater monitoring.* You must install the monitoring equipment and meet the requirements specified for small boilers and process heaters in either Table 1 or Table 2 to this subpart, even if the small boiler or process heater is part of a fuel gas system.

(b) *Small boiler or process heater performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, and paragraphs (b)(1) and (2) of this section, even if the small boiler or process heater is part of a fuel gas system, unless one of the provisions in paragraph (c) of this section is met.

(1) When demonstrating compliance with a percent reduction emission limit in a referencing subpart, you must determine the weight-percent reduction of organic regulated material or total organic compounds (minus methane and ethane) across the device by comparing the total organic compounds (minus methane and ethane) or organic regulated material in all combusted vent

streams and primary and secondary fuels with the total organic compounds (minus methane and ethane) or organic regulated material exiting the combustion device, respectively.

(2) When determining the weight-percent reduction, you must locate the sampling sites for the measurement of total organic regulated material or total organic compound (minus methane and ethane) concentrations, as applicable, at the inlet of the small boiler or process heater such that all vent streams and primary and secondary fuels introduced into the boiler or process heater are included.

(c) *Small boiler or process heater performance test exemptions.* You are not required to conduct a performance test if any of the general control measures specified in § 65.702(e) are used. You are also not required to conduct a performance test if your small boiler or process heater burns hazardous waste and has certified compliance with the requirements of part 63, subpart EEE of this chapter by conducting comprehensive performance tests; you have submitted to the Administrator a notification of compliance under §§ 63.1207(j) and 63.1210(d) documenting compliance with the requirements of part 63, subpart EEE of this chapter; and you comply with these requirements at all times, even when you burn non-hazardous waste.

(d) *Boiler or process heater design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850. The design evaluation must demonstrate that the small boiler or process heater meets the applicable emission limit; consider the auto ignition temperature of the regulated material and the vent stream flow rate; establish the design minimum and average flame zone temperatures and combustion zone residence time; and describe the method and location where the vent stream is introduced into the flame zone.

(e) *Boiler or process heater performance test records.* If you have chosen to monitor operating parameters in Table 2 to this subpart, you must record the operating parameters, as specified in paragraphs (e)(1) and (2) of this section, as applicable, measured during each performance test conducted, pursuant to §§ 65.820 through 65.829.

(1) Record the fire box temperature measured during the performance test at least every 15 minutes and average the temperature over each run of the performance test.

(2) Record a location description of the vent stream junction into the boiler or process heater.

(f) *Boiler or process heater monitoring records.* You must keep the records specified in paragraphs (f)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

§ 65.726 What monitoring requirements must I meet for thermal oxidizers?

(a) *Thermal oxidizer monitoring.* You must install the monitoring equipment and meet the requirements specified for thermal oxidizers in either Table 1 or 2 to this subpart.

(b) *Thermal oxidizer performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless any of the general control measures specified in § 65.702(e) are used. You are also not required to conduct a performance test if your thermal oxidizer burns hazardous waste and has certified compliance with the requirements of part 63, subpart EEE of this chapter by conducting comprehensive performance tests; you have submitted to the Administrator a notification of compliance under §§ 63.1207(j) and 63.1210(d) documenting compliance with the requirements of part 63, subpart EEE of this chapter; and you comply with these requirements at all times, even when you burn non-hazardous waste.

(c) *Thermal oxidizer design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the oxidizer meets the applicable emission limit, the design evaluation must consider the auto-ignition temperature of the regulated material and the vent stream flow rate and establish the design minimum and average temperature in the combustion zone and the combustion zone residence time.

(d) *Thermal oxidizer performance test records.* If you have chosen to monitor operating parameters in Table 2 to this subpart, you must record the fire box temperature measured during each performance test conducted, pursuant to §§ 65.820 through 65.829. Record the fire box temperature at least every 15 minutes and average the temperature over each run of the performance test.

(e) *Thermal oxidizer monitoring records.* You must keep the records specified in paragraphs (e)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

§ 65.728 What monitoring requirements must I meet for catalytic oxidizers?

(a) *Catalytic oxidizer monitoring.* You must install the monitoring equipment and meet the requirements specified for catalytic oxidizers in either Table 1 or 2 to this subpart. For catalytic oxidizers for which you have selected to monitor temperature at the inlet of the catalyst bed, as specified in Table 2 to this subpart, you must conduct catalyst checks according to paragraphs (a)(1) and (2) of this section.

(1) You must conduct sampling and analysis of the catalyst and meet the requirements of paragraphs (a)(1)(i) through (iv) of this section.

(i) You must determine a schedule for conducting sampling and analysis of the catalyst, based upon the expected degradation rate of the catalyst, and following the manufacturer's or catalyst supplier's recommended procedures for sampling and analysis.

(ii) The catalyst sampling and analysis schedule must be included in the performance test plan specified in § 65.820(b) and approved by the Administrator.

(iii) If results from the catalyst sampling and analysis indicate that your catalyst will become inactive in 18 months or less, you must replace the catalyst bed or take other corrective action consistent with the manufacturer's recommendations within 3 months before the catalyst is anticipated to become inactive or within half the time available between receiving the catalyst activity report and when the catalyst is expected to become inactive, whichever is less. Additionally, you must determine if a more frequent catalyst replacement schedule is necessary.

(iv) If you replace the catalyst bed with a catalyst different from the

catalyst used during the performance test, you must conduct a new performance test according to paragraph (b) of this section.

(2) You must conduct annual internal inspections of the catalyst bed to check for fouling, plugging, mechanical breakdown, channeling, abrasion and settling, and follow the procedures specified in paragraph (a)(2)(i) through (iii) of this section.

(i) If indications of fouling, plugging, mechanical breakdown, channeling, abrasion or settling are found during the internal inspection of the catalyst, you must replace the catalyst bed or take other corrective action consistent with the manufacturer's recommendations.

(ii) If you find any of these issues during the annual inspection, then you must increase your inspection frequency to semi-annual. You must increase the inspection frequency from semi-annual to quarterly, and quarterly to monthly, if you find any issues requiring corrective action during the semi-annual or quarterly inspection. You may return the inspection frequency to the next less stringent frequency level when no issues are found during an inspection.

(iii) If you replace the catalyst bed with a catalyst different from the catalyst used during the performance test, you must conduct a new performance test according to paragraph (b) of this section.

(b) *Catalytic oxidizer performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless any of the general control measures specified in § 65.702(e) are used. You are also not required to conduct a performance test if your catalytic oxidizer burns hazardous waste and has certified compliance with the requirements of part 63, subpart EEE of this chapter by conducting comprehensive performance tests; you have submitted to the Administrator a notification of compliance under §§ 63.1207(j) and 63.1210(d) documenting compliance with the requirements of part 63, subpart EEE of this chapter; and you comply with these requirements at all times, even when you burn non-hazardous waste.

(c) *Catalytic oxidizer design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the oxidizer meets the applicable emission limit, the design evaluation must consider the vent stream flow rate and you must establish the design minimum and average temperatures across the catalyst bed inlet and outlet.

(d) *Catalytic oxidizer performance test records.* If you have chosen to monitor operating parameters in Table 2 to this subpart, you must record the upstream and downstream temperatures and the temperature difference across the catalyst bed measured during each performance test conducted, pursuant to §§ 65.820 through 65.829. Record the upstream and downstream temperatures and the temperature difference across the catalyst bed at least every 15 minutes and average each temperature and temperature differential over each run of the performance test.

(e) *Catalytic oxidizer monitoring records.* You must keep the records specified in paragraphs (e)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

(f) *Catalytic oxidizer other records.* For catalytic oxidizers for which you have selected the monitoring specified in Table 2 to this subpart, you must also maintain records of the results of the catalyst sampling and inspections required by paragraphs (a)(1) and (2) of this section, including any subsequent corrective actions taken.

§ 65.732 What monitoring requirements must I meet for fuel gas systems?

(a) You must submit a statement that the emission stream is connected to the fuel gas system in the Notification of Compliance Status Report, as required, pursuant to § 65.880(b).

(b) You must meet the requirements of subpart J of this part for all components of a fuel gas system.

(c) If you have small boilers or process heaters that are part of a fuel gas system, you must also comply with the provisions of § 65.724 for the small boilers or process heaters.

(d) You must not route halogenated vent streams to a fuel gas system unless the requirements of § 65.702(d) are met.

§ 65.740 What monitoring requirements must I meet for absorbers?

(a) *Absorber monitoring.* You must install the monitoring equipment and meet the requirements specified for absorbers in either Table 1 or 2 to this subpart.

(b) *Absorber performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless any of the general control measures specified in § 65.702(e) are used.

(c) *Absorber design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the absorber meets the applicable emission limit, address the characteristics specified in paragraphs (c)(1) and (2) of this section, as applicable.

(1) For an absorber, the design evaluation must consider the vent stream composition, constituent concentrations, liquid-to-gas ratio, absorber liquid flow rate and concentration, temperature, pressure drop and the reaction kinetics or absorption characteristics of the constituents with the scrubbing liquid. The design evaluation must establish the design exhaust vent stream organic compound concentration level.

(2) For tray and packed column absorbers, the design evaluation must consider the characteristics specified in paragraph (c)(1) of this section, in addition to type and total number of theoretical and actual trays, type and total surface area of packing for the entire column and type and total surface area for individual packed sections if the column contains more than one packed section.

(d) *Absorber performance test records.* If you have chosen to monitor operating parameters in Table 2 to this subpart, you must keep readily accessible records of the data specified in paragraphs (d)(1) and (2) of this section, as applicable, measured during each performance test conducted, pursuant to §§ 65.820 through 65.829.

(1) The absorber influent liquid flow rate or liquid-to-gas ratio measured during the performance test. Record the influent liquid flow rate or liquid-to-gas ratio at least every 15 minutes and average the flow rate or liquid-to-gas ratio over each run of the performance test.

(2) If applicable, the pressure drop through the absorber, the pH of the absorber liquid effluent, exit gas temperature, inlet gas temperature, specific gravity, liquid feed pressure, oxidation chemical flow rate and/or the oxidation chemical strength of the absorber liquid influent measured during the performance test. Record the pressure drop through the absorber, the pH of the absorber liquid effluent, exit gas temperature, inlet gas temperature, specific gravity, liquid feed pressure, oxidation chemical flow rate and/or the

oxidation chemical strength of the absorber liquid influent at least every 15 minutes and average each operating parameter over each run of the performance test.

(e) *Absorber monitoring records.* You must keep the records specified in paragraphs (e)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in paragraph § 65.860(a).

§ 65.742 What monitoring requirements must I meet for adsorbers regenerated onsite?

(a) *General.* If you use regenerative adsorption systems that you regenerate onsite, you must treat the regulated materials extracted from the adsorption system as process wastewater or process vents subject to control levels required by the referencing subpart.

(b) *Regenerative adsorber monitoring.* You must install the monitoring equipment and conduct the monitoring, as specified in either Table 1 or Table 2 to this subpart for regenerative adsorption systems that you regenerate onsite. For regenerative adsorbers, except those monitored with CEMS, you must also conduct the checks specified in paragraphs (c) and (d) of this section, include in your monitoring plan required in § 65.712(c) your plans for complying with paragraph (d) of this section and develop a corrective action plan, as specified in paragraph (e) of this section.

(c) *Regenerative adsorber valve and cycle verification.* For regenerative adsorbers, except those monitored with CEMS, you must perform a verification of the adsorber during each day of operation. The verification must be through visual observation or through an automated alarm or shutdown system that monitors and records system operational parameters. The verification must confirm that the adsorber is operating with proper valve sequencing and cycle time.

(d) *Regenerative adsorber weekly measurements.* For regenerative adsorbers, except those monitored with CEMS, you must conduct weekly measurements of each adsorber bed outlet volatile organic compounds or regulated materials concentration over the last 5 minutes of an adsorption cycle using the methods and procedures in paragraph (d)(1) of this section. If the measured concentration is greater than the maximum normal concentration established in paragraph (d)(2) of this section, you must take corrective action, as specified in the corrective action plan required in paragraph (e) of this section.

(1) You must measure the concentration using the method that you used to establish the maximum normal concentration, and the method must be one of the methods specified in paragraphs (d)(1)(i) through (iii) of this section. You must use Method 1 or 1A at 40 CFR part 60, appendix A–1 to select the sampling location, which should be at the centrally located 10-percent area of the stack or sample port cross-section.

(i) Use chromatographic analysis by using Method 18 at 40 CFR part 60, appendix A. Calibrate the instrument following the procedures described in EPA Method 18 using a calibration gas or gas mixture containing the compounds present in the adsorber vent gas that can be measured by the method.

(ii) Use a portable analyzer, in accordance with Method 21 at 40 CFR part 60, appendix A–7, for open-ended lines. Where EPA Method 21 uses the term ''leak definition,'' you must substitute the term ''maximum normal concentration.'' Calibrate the instrument following the procedures described in EPA Method 21 using one of the calibration gases specified in paragraphs (d)(1)(ii)(A) through (D) of this section.

(A) A calibration gas or gas mixture representative of the normal compound(s) present in the adsorber vent gas.

(B) Propane.

(C) Methane.

(D) Isobutylene.

(iii) Use a flame ionization analyzer by using Method 25A at 40 CFR part 60, appendix A–7. Calibrate the instrument following the procedures described in EPA Method 25A using propane.

(2) You must establish a maximum normal concentration for each adsorber bed vent gas, as specified in paragraphs (d)(2)(i) through (iv) of this section.

(i) For each adsorber bed, measure the outlet volatile organic compound or regulated material concentration weekly, as specified in paragraph (d) of this section, during the last 5 minutes of the adsorption cycle for at least 8 weeks. These measurements must be taken within a 90-day time period.

(ii) Calculate the average outlet concentration for each adsorber bed as the average of the outlet concentrations measured, as required in paragraph (d)(2)(i) of this section.

(iii) Determine maximum normal concentration for each adsorber bed as the 99th percentile confidence level using the one-sided z-statistic test described in Equation 1 of this section.

$$P_{99} = \text{mean} + [(SD)*(t)] \quad \text{(Eq. 1)}$$

Where:

P_{99} = 99th percentile confidence level pollutant concentration in parts per million.

Mean = Arithmetic average of the volatile organic compound or regulated material concentration in the adsorber vent gas, calculated as specified in paragraph (d)(2)(ii) of this section.

SD = Standard deviation of the mean pollutant concentration, calculated as specified in paragraph (d)(2)(ii) of this section.

t = t distribution critical value for 99th percentile (0.01) probability for the appropriate degrees of freedom (number of samples minus one), as obtained from a Distribution Critical Value Table. Use a value of 3 if you have 8 samples.

(iv) You must reestablish your maximum normal concentration for an adsorber bed according to paragraphs (d)(2)(i) through (iii) of this section each time you replace the adsorbent in an adsorber bed.

(e) *Regenerative adsorber corrective action plan.* For regenerative adsorbers, except those monitored with CEMS, you must develop a corrective action plan describing corrective actions to be taken and the timing of those actions when a weekly measurement is above the maximum normal concentration. The plan must specify that you will initiate procedures to identify the cause and take corrective action no later than 8 hours after the weekly measurement. Three consecutive weekly measurements greater than the maximum normal concentration is a deviation. Examples of corrective actions that could be included in your plan are listed in paragraphs (e)(1) through (6) of this section.

(1) Analyze the adsorber inlet vent to determine if inlet concentrations are in the expected range.

(2) Obtain samples at other locations in the system to determine if conditions are normal.

(3) Verify the system temperatures, regeneration stream mass and other operational parameters are within normal ranges.

(4) Test the operation of valves in the system, verify the valves are working as intended and not allowing gas to pass through when closed.

(5) Obtain a sample of the carbon to check for bed poisoning or deterioration of the carbon.

(6) Replace the adsorbent in the adsorber bed with fresh adsorbent.

(f) *Regenerative adsorber performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless any of the general control measures specified in § 65.702(e) are used.

(g) *Regenerative adsorber design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the absorber meets the applicable emission limit, address the following characteristics, as applicable. For an adsorption system that regenerates the adsorber bed directly onsite in the control device, such as a fixed-bed adsorber, the design evaluation must consider the vent stream mass flow rate, vent stream composition and concentrations, relative humidity, and temperature and must establish the design exhaust vent stream organic compound concentration level, adsorption cycle time, number and capacity of adsorber beds, type and working capacity of adsorbent used for adsorber beds, design total regeneration stream mass flow over the period of each complete adsorber bed regeneration cycle, design adsorber bed temperature after regeneration, design adsorber bed regeneration time and design service life of adsorbent. For vacuum desorption, the lowest required vacuum level and duration needed to assure regeneration of the beds must be considered.

(h) *Regenerative adsorber performance test records.* If you are required to conduct a performance test, you must keep readily accessible records of the data specified in paragraphs (h)(1) through (5) of this section, as applicable, measured during each performance test conducted, pursuant to §§ 65.820 through 65.829.

(1) For non-vacuum regenerative adsorbers, you must record the total regeneration stream mass flow during each adsorber bed regeneration cycle during the period of the performance test, and temperature of the adsorber bed after each regeneration during the period of the performance test (and within 15 minutes of completion of any cooling cycle or cycles).

(2) For non-vacuum regeneration adsorbers, you must record the adsorber bed temperature during regeneration, except for any temperature regulating (cooling or warming to bring bed temperature closer to vent gas temperature) portion of the regeneration cycle.

(3) For vacuum regenerative adsorbers, you must record the vacuum profile over time during each regeneration cycle, and the period of time the vacuum level is below the minimum target level during the period of the performance test.

(4) You must record regeneration frequency and duration during the period of the performance test.

(5) You must record the observations of the verification of the adsorber operation during the period of the performance test.

(i) *Regenerative adsorber monitoring records.* You must keep the records specified in paragraphs (i)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters and emissions required to be monitored under paragraph (b) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

(j) *Regenerative adsorber other records.* For regenerative adsorbers, except those monitored with CEMS, you must also maintain records, as specified in paragraphs (j)(1) through (6) of this section.

(1) The corrective action plan required in paragraph (e) of this section.

(2) For the adsorber verification required in paragraph (c) of this section, you must maintain daily records of the verification inspections, including the visual observations and/or any activation of an automated alarm or shutdown system with a written entry into a log book or other permanent form of record.

(3) For the monitoring required in paragraph (d) of this section, you must record the weekly volatile organic compound or regulated material outlet concentration observed over the last 5 minutes of the adsorption cycle for each adsorber bed.

(4) If the measured concentration obtained during the monitoring required in paragraph (d) of this section is greater than the maximum normal concentration for 3 consecutive weekly measurements, you must keep a record of these periods, including the date of the third measurement and the date and time when the concentration becomes less than the maximum normal concentration, or when the adsorbent is replaced.

(5) You must keep records of the measurements used to determine the maximum normal concentrations established for each adsorber bed.

(6) You must keep records of the date and time the adsorbent is replaced and which adsorbent bed was replaced.

§ 65.744 What monitoring requirements must I meet for non-regenerative adsorbers?

(a) *Non-regenerative adsorber monitoring.* You must install the monitoring equipment and meet the requirements specified for non-regenerative adsorbers in either Table 1 or Table 2 to this subpart. Non-regenerative adsorbers include adsorbers that cannot be regenerated and regenerative adsorbers that are regenerated offsite. For non-regenerative adsorbers for which you have selected the monitoring specified in Table 2 to this subpart, you must also comply with paragraph (a)(1) of this section, and you may reduce your monitoring frequency according to paragraphs (a)(2) of this section.

(1) The first adsorber in series must be replaced immediately when breakthrough, as defined in § 65.295, is detected between the first and second adsorber. The original second adsorber (or a fresh canister) will become the new first adsorber and a fresh adsorber will become the second adsorber. For purposes of this paragraph, ''immediately'' means within 8 hours of the detection of a breakthrough for adsorbers of 55 gallons or less, and within 24 hours of the detection of a breakthrough for adsorbers greater than 55 gallons.

(2) In lieu of the daily monitoring, as specified in Table 3 to this subpart, you may reduce your monitoring frequency by establishing the average adsorber bed life. To establish the average adsorber bed life, you must conduct daily monitoring of the outlet volatile organic compound or regulated material concentration of the first adsorber bed in series until breakthrough, as defined in § 65.295, occurs for the first three adsorber bed change-outs. You must re-establish an average adsorber bed life if you change the adsorbent brand or type,

or if any process changes are made that would lead to a lower bed lifetime. You must measure the outlet concentration of volatile organic compounds or outlet concentration of regulated material(s) in accordance with Table 2 to this subpart. Once the average life of the bed is determined, you may conduct ongoing monitoring, as specified in paragraphs (a)(2)(i) and (ii) of this section.

(i) You may conduct monthly monitoring if the adsorbent has more than 2 months of life remaining, based on the average adsorber bed life, as established in paragraph (a)(2) of this section, and the date the adsorbent was last replaced.

(ii) You may conduct weekly monitoring if the adsorbent has more than 2 weeks of life remaining, based on the average adsorber bed life, established in paragraph (a)(2) of this section, and the date the adsorbent was last replaced.

(b) *Non-regenerative adsorber performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless any of the general control measures specified in § 65.702(e) are used.

(c) *Non-regenerative adsorber design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the absorber meets the applicable emission limit, address the following characteristics, as applicable. For an adsorption system that does not regenerate the adsorber bed directly on site in the control device, such as a carbon canister, the design evaluation must consider the vent stream mass flow rate, vent stream composition and concentrations, relative humidity and temperature and must establish the design exhaust vent stream organic compound concentration level, capacity of adsorber bed, type and working capacity of adsorbent used for the adsorber bed and design adsorbent replacement interval, based on the total adsorbent working capacity of the control device and source operating schedule.

(d) *Non-regenerative adsorber performance test records.* If you are required to conduct a performance test, you must keep readily accessible records of the outlet volatile organic compound or regulated material concentration for each adsorber bed, as provided in Table 2 to this subpart, measured during each performance test conducted, pursuant to §§ 65.820 through 65.829. You must also keep records of the date and time you last replaced the adsorbent.

(e) *Non-regenerative adsorber monitoring records.* You must keep the records specified in paragraphs (e)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

(f) *Non-regenerative adsorber other records.* For non-regenerative adsorbers for which you have selected the monitoring specified in Table 2 to this subpart, you must also maintain records, as specified in paragraph (f)(1) and (2) of this section.

(1) Records of the date and time you replace the adsorbent.

(2) If you conduct monitoring less frequently than daily, as specified in Table 2 to this subpart, you must record the average life of the bed.

§ 65.746 What requirements must I meet for condensers?

(a) *Condenser monitoring.* You must install the monitoring equipment and meet the requirements specified for condensers in either Table 1 or Table 2 to this subpart.

(b) *Condenser performance test.* You are not required to conduct a performance test, pursuant to §§ 65.820 through 65.829, unless required by a referencing subpart. Instead, you must conduct a design evaluation, as specified in paragraph (c) of this section, unless you choose to use a CEMS meeting the requirements in § 65.711 to monitor the performance of the condenser.

(c) *Condenser design evaluation.* If you chose to do a design evaluation in lieu of using CEMS meeting the requirements in § 65.711, you must meet the requirements of § 65.850 and, in demonstrating that the condenser meets the applicable emission limit, address the characteristics specified in paragraphs (c)(1) and (2) of this section, as applicable.

(1) The design evaluation must consider the vent stream flow rate, relative humidity, temperature and conditions under which entrainment of the condensing liquid could occur, and must establish the design outlet organic regulated material compound concentration level, design average temperature of the condenser exhaust vent stream and the design average temperatures of the coolant fluid at the condenser inlet and outlet.

(2) You must establish your operating limit for temperature of the condensate receiver and calculate the resulting regulated material concentration using the methodologies in § 65.835(d) to demonstrate compliance with the emissions standard of the referencing subpart.

(d) *Condenser monitoring records.* You must keep the records specified in paragraphs (d)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

(e) *Condenser other records.* If you chose to do a design evaluation in lieu of using CEMS meeting the requirements in § 65.711, you must calculate and record the regulated material concentration using continuous and direct measurements of the condensate receiver temperature and the methodology in § 65.835(d).

§ 65.748 What requirements must I meet for biofilters?

(a) *Biofilter monitoring.* You must install the monitoring equipment and meet the requirements specified for biofilters in either Table 1 or Table 2 to this subpart.

(b) *Biofilter performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, and paragraphs (b)(1) through (3) of this section, unless one of the provisions in paragraph (c) of this section is met.

(1) The operating temperature limit must be based on only the temperatures measured during the performance test; these data may not be supplemented by engineering assessments or manufacturer's recommendations, as otherwise allowed in § 65.713(a).

(2) You may expand the biofilter bed temperature operating limit by conducting a repeat performance test that demonstrates compliance with the percent reduction requirement or outlet concentration limit, as applicable.

(3) You must conduct a repeat performance test using the applicable methods specified in § 65.825 within 2 years following the previous

performance test and within 150 days after each replacement of any portion of the biofilter bed media with a different type of media or each replacement of more than 50 percent (by volume) of the biofilter bed media with the same type of media.

(c) *Biofilter performance test exemptions.* You are not required to conduct a performance test if any of the general control measures specified in § 65.702(e) are used. If the operating limit is established using data from previous performance tests in accordance with § 65.702(e)(4), replacement of the biofilter media with the same type of media is not considered a process change and would not require a new performance test; however, you are still subject to the repeat performance test requirements, as specified in paragraph (b)(3) of this section.

(d) *Biofilter design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the biofilter meets the applicable emission limit, address the characteristics specified in the referencing subpart.

(e) *Biofilter performance test records.* If you are required to conduct a performance test, you must record the biofilter bed temperature and moisture content, and the pressure drop through the biofilter bed measured during each performance test conducted, pursuant to §§ 65.820 through 65.829. You must record the biofilter bed temperature, moisture content and the pressure drop through the biofilter bed at least every 15 minutes and average these operating parameters over each run of the performance test.

(f) *Biofilter monitoring records.* You must keep the records specified in paragraphs (f)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (a) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

§ 65.760 What requirements must I meet for sorbent injection and collection systems?

(a) *General.* If you use sorbent injection as an emission control technique, you must operate the sorbent injection system in accordance with this section. You must also meet the requirements in § 65.762 for the fabric filters used for sorbent collection.

(b) *Sorbent injection monitoring.* You must install the monitoring equipment and meet the requirements specified for sorbent injection in either Table 1 or Table 2 to this subpart.

(c) *Sorbent injection performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, and paragraphs (c)(1) and (2) of this section, unless one of the general control measures specified in § 65.702(e) is used. A performance test conducted to meet the requirements of this section also satisfies the performance test requirements of § 65.762(b) provided that you monitor and record the appropriate fabric filter operating parameters during the performance test.

(1) You must conduct the performance test at the outlet of the fabric filter used for sorbent collection.

(2) If the sorbent is replaced with a different brand and type of sorbent that was used during the performance test, you must conduct a new performance test.

(d) *Sorbent injection design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850 and, in demonstrating that the sorbent injection system meets the applicable emission limit, address the characteristics specified in paragraphs (d)(1) and (2) of this section, as applicable.

(1) For a sorbent injection system, the design evaluation must consider the vent stream flow rate and temperature, levels of regulated materials to be adsorbed in the vent stream, sorbent type and brand, sorbent mass injection rate, sorbent injection carrier gas system, design of the injection system, location of sorbent injection site, downstream collection device (fabric filter or other device to capture the sorbent), residence time of the gas-sorbent mixture and contact characteristics of the gas-sorbent mixture.

(2) For a sorbent injection system that is controlling dioxins, furans, total hazardous air pollutants (HAP) or total organic HAP, as specified in Table 2 to this subpart, you must consider the temperature in the combustion device and in any particulate control devices upstream of injection system.

(e) *Sorbent injection performance test records.* If you are required to conduct a performance test, you must keep readily accessible records of the data specified in paragraphs (e)(1) and (2) of this section, as applicable, measured during each performance test conducted, pursuant to §§ 65.820 through 65.829.

(1) Record the brand and type of sorbent used during the performance test.

(2) If you have chosen to monitor operating parameters in Table 2 to this subpart, you must record the parameters, as specified in paragraphs (e)(2)(i) through (iii) of this section, as applicable.

(i) Record the rate of sorbent injection measured during the performance test at least every 15 minutes and average the injection rate over each run of the performance test.

(ii) Record the carrier gas flow rate measured during the performance test at least every 15 minutes and average the flow rate over each run of the performance test.

(iii) Record the temperature downstream of the combustion device and/or downstream of any particulate control devices, as applicable, measured during the performance test. Record the temperature(s) at least every 15 minutes and average the temperature(s) over each run of the performance test.

(f) *Sorbent injection monitoring records.* You must keep the records specified in paragraphs (f)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) Continuous records of the control device operating parameters or emissions specified to be monitored under paragraph (b) of this section, as applicable.

(2) Records of the daily average value, or for batch operations, operating block average value, of each continuously monitored operating parameter or records of continuous emissions according to the procedures specified in § 65.860(a).

(g) *Sorbent injection other records.* You must keep records of the type and brand of sorbent used. If the type or brand of sorbent is changed, you must record the date the sorbent was changed, and maintain documentation that the substitute will provide the same or better level of control as the original sorbent.

§ 65.762 What requirements must I meet for fabric filters?

(a) Fabric filter monitoring. You must equip fabric filters with a bag leak detection system that is installed, calibrated, maintained and continuously operated according to the requirements in paragraphs (a)(1) through (10) of this section. Monitoring systems associated with bag leak detection are also subject to the requirements of § 65.710.

(1) Install a bag leak detection sensor(s) in a position(s) that will be representative of the relative or absolute particulate matter loadings for each exhaust stack, roof vent or compartment (*e.g.*, for a positive pressure fabric filter) of the fabric filter.

(2) Use a bag leak detection system certified by the manufacturer to be capable of detecting particulate matter emissions at concentrations of 1 milligram per actual cubic meter (0.00044 grains per actual cubic foot) or less.

(3) Conduct a performance evaluation of the bag leak detection system in accordance with paragraph (b) of this section and consistent with the guidance provided in EPA–454/R–98–015 (incorporated by reference, see § 65.265).

(4) Use a bag leak detection system equipped with a device to continuously record the output signal from the sensor.

(5) Use a bag leak detection system equipped with a system that will sound an alarm when an increase in relative particulate material emissions over a preset level is detected. The alarm must be located such that the alert is observed readily by plan operating personnel.

(6) Install a bag leak detection system in each compartment or cell for positive pressure fabric filter systems that do not duct all compartments or cells to a common stack. Install a bag leak detector downstream of the fabric filter if a negative pressure or induced air filter is used. If multiple bag leak detectors are required, the system's instrumentation and alarm may be shared among detectors.

(7) Calibration of the bag leak detection system must, at a minimum, consist of establishing the baseline output level by adjusting the range and the averaging period of the device and establishing the alarm set points and the alarm delay time.

(8) Following initial adjustment, you must not adjust the sensitivity or range, averaging period, alarm set points or alarm delay time, except as established in a CPMS monitoring plan required in § 65.712 and paragraph (e)(1) of this section. In no event may the sensitivity be increased more than 100 percent or decreased by more than 50 percent over a 365-day period unless such adjustment follows a complete baghouse inspection that demonstrates the baghouse is in good operating condition.

(9) Each bag leak detection system must be operated and maintained such that the alarm does not sound more than 5 percent of the operating time during a 6-month period. If the alarm sounds more than 5 percent of the operating time during a 6-month period, it is considered an operating parameter exceedance and, therefore, a deviation, as specified in § 65.710(e)(2). You must calculate the alarm time, as specified in paragraphs (a)(9)(i) through (iv) of this section.

(i) If inspection of the fabric filter demonstrates that no corrective action is required, no alarm time is counted.

(ii) If corrective action is required, each alarm time is counted as a minimum of 1 hour.

(iii) If you take longer than 1 hour to initiate corrective action, each alarm time (*i.e.*, time that the alarm sounds) is counted as the actual amount of time taken by you to initiate corrective action.

(iv) Your maximum alarm time is equal to 5 percent of the operating time during a 6-month period.

(10) If the alarm on a bag leak detection system is triggered, you must, within 1 hour of an alarm, initiate procedures to identify the cause of the alarm and take corrective action, as specified in the corrective action plan required in paragraph (e)(2) of this section.

(b) *Fabric filter performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, unless one of the general control measures specified in § 65.702(e) is used. A performance test conducted to meet the requirements of this section also satisfies the performance test requirements of § 65.760(c) provided that § 65.760(c)(1) and (2) are followed and the appropriate sorbent injection operating parameters are monitored and recorded.

(c) *Fabric filter design evaluation.* If a referencing subpart allows you to conduct a design evaluation in lieu of a performance test, and you chose to do a design evaluation, you must meet the requirements of § 65.850. The design evaluation must include the pressure drop through the device and the ratio of volumetric gas flow to surface area of the cloth.

(d) *Fabric filter performance test records.* You must document the bag leak detection system's sensitivity to detecting changes in particulate matter emissions, range, averaging period and alarm set points during each performance test conducted, pursuant to §§ 65.820 through 65.829.

(e) *Fabric filter monitoring records.* For each bag leak detector used to monitor regulated material emissions from a fabric filter, you must maintain the records specified in paragraphs (e)(1) through (3) of this section.

(1) A CPMS monitoring plan, as specified in § 65.712. You must also include performance evaluation procedures and acceptance criteria (*e.g.,* calibrations) in your CPMS monitoring plan, including how the alarm set-point will be established.

(2) A corrective action plan describing corrective actions to be taken and the timing of those actions when the bag leak detection alarm sounds. You must initiate corrective action no later than 48 hours after a bag leak detection system alarm. Failure to take action within the prescribed time period is considered a deviation. Corrective actions may include, but are not limited to, the actions listed in paragraphs (e)(2)(i) through (vi) of this section.

(i) Inspecting the fabric filter for air leaks, torn or broken bags or filter media, or any other conditions that may cause an increase in regulated material emissions.

(ii) Sealing off defective bags or filter media.

(iii) Replacing defective bags or filter media or otherwise fixing the control device.

(iv) Sealing off a defective fabric filter compartment.

(v) Cleaning the bag leak detection system probe or otherwise fixing the bag leak detection system.

(vi) Shutting down the process producing the regulated material emissions.

(3) Records of any bag leak detection system alarm, including the date, time, duration and the percent of the total operating time during each 6-month period that the alarm sounds, with a brief explanation of the cause of the alarm, the corrective action taken and the schedule and duration of the corrective action.

(f) You must submit analyses and supporting documentation demonstrating conformance with EPA–454/R–98–015 (incorporated by reference, see § 65.265) and specifications for bag leak detection systems as part of the Notification of Compliance Status Report, as required, pursuant to § 65.880(f).

§ 65.800 What requirements must I meet for other control devices?

(a) *Other control device monitoring.* If you use a control device other than those listed in this subpart, you must

meet the requirements of paragraphs (a)(1) and (2) of this section.

(1) You must submit to the Administrator for approval the planned operating parameters to be monitored, and the recordkeeping and reporting procedures, as specified in § 65.884(h). You must also include a rationale for the proposed monitoring in your submittal. The Administrator will approve, deny or modify the proposed monitoring, reporting and recordkeeping requirements as part of the review of the plan or through the review of the permit application or by other appropriate means.

(2) If you receive approval from the Administrator for the information required in paragraph (a)(1) of this section, you must then establish an operating limit for the operating parameters that indicates proper operation of the control device. The information required in § 65.880(d) must be submitted in the Notification of Compliance Status Report. The operating limit may be based upon a prior performance test meeting the specifications of § 65.702(e)(4).

(b) *Other control device performance test.* You must conduct a performance test, pursuant to §§ 65.820 through 65.829, as applicable, unless any of the general control measures specified in § 65.702(e) are used.

(c) *Other control device performance test records.* If you are required to conduct a performance test, you must keep readily accessible records of the approved operating parameters, as established in paragraph (a) of this section measured during the performance test and any other records as may be necessary to determine the conditions of the performance test conducted, pursuant to §§ 65.820 through 65.829.

(d) *Other control device records.* You must keep the records specified in paragraphs (d)(1) and (2) of this section up-to-date and readily accessible, as applicable.

(1) You must keep records of the operating parameter(s) monitored, pursuant to the approved plan established in paragraph (a) of this section.

(2) Records of flow/no flow, as provided in § 65.860(i).

Performance Testing

§ 65.820 What are the performance testing requirements?

For each control device for which a performance test is required, you must conduct a performance test according to the schedule specified by the referencing subpart and the procedures in this section §§ 65.820 through 65.829, as applicable, unless any of the general control measures specified in § 65.702(e) are used. For all performance tests, a notification of the performance test and a performance test plan are also required, as specified in paragraphs (a) through (c) of this section. You must also provide the performance testing facilities, as specified in paragraph (d) of this section.

(a) *Notification of performance test.* You must notify the Administrator of your intention to conduct a performance test, as specified in § 65.884(a).

(b) *Performance test plan.* Before conducting a required performance test, you must develop and submit a performance test plan to the Administrator for approval. The test plan must include a test program summary, the test schedule, data quality objectives and both an internal and external quality assurance program. Data quality objectives are the pretest expectations of precision, accuracy and completeness of data, as specified in paragraphs (b)(1) through (4) of this section.

(1) The internal quality assurance program must include, at a minimum, the activities planned by routine operators and analysts to provide an assessment of test data bias and precision; an example of internal quality assurance to measure precision is the sampling and analysis of replicate samples.

(2) You must perform a test method performance audit during the performance test, as specified in § 60.8(g), § 61.13(e), or § 63.7(c)(2)(iii) of this chapter.

(3) You must submit the performance test plan to the Administrator at least 60 calendar days before the performance test is scheduled to take place, that is, simultaneously with the notification of intention to conduct a performance test required under paragraph (a) of this section, or on a mutually agreed upon date.

(4) The Administrator may request additional relevant information after the submittal of a performance test plan.

(5) If you would like to use an alternative test method or a change to a test method, you must follow the requirements of § 65.250, except for minor test method changes. You may propose minor test method changes in your performance test plan. Approval of the test plan is approval of any minor test method changes included in the test plan.

(c) *Approval of performance test plan.*

(1) The Administrator will notify you of approval or intention to deny approval of the performance test plan within 30 calendar days after receipt of the original plan and within 30 calendar days after receipt of any supplementary information that is submitted under paragraph (c)(1)(ii) of this section. An intention to disapprove the plan will include the information provided in (c)(1)(i) and (ii) of this section and will be provided to you before the Administrator disapproves a performance test plan.

(i) Notice of the information and findings on which the intended disapproval is based.

(ii) Notice of opportunity for you to present, within 30 calendar days after you have been notified of the intended disapproval, additional information to the Administrator before final action on the plan.

(2) If the Administrator does not approve or disapprove the performance test plan within the time period specified in paragraph (c)(1) of this section, then you must conduct the performance test within the time specified in this subpart using the specified method(s) and any minor changes to the test methods proposed in the test plan.

(d) *Performance testing facilities.* If required to do performance testing, you must provide performance testing facilities, as specified in paragraphs (d)(1) through (5) of this section.

(1) Sampling ports adequate for the applicable test methods, including meeting the provisions of paragraphs (d)(1)(i) and (ii) of this section, as applicable.

(i) Constructing the air pollution control system such that volumetric flow rates and pollutant emission rates can be accurately determined by applicable test methods and procedures; and

(ii) Providing a stack or duct free of cyclonic flow during performance tests, as demonstrated by applicable test methods and procedures.

(2) Safe sampling platform(s).

(3) Safe access to sampling platform(s).

(4) Utilities for sampling and testing equipment.

(5) Any other facilities that the Administrator deems necessary for safe and adequate testing of a source.

§ 65.821 At what process conditions must I conduct performance testing?

You must conduct performance tests under the conditions specified in paragraphs (a) through (d) of this section, as applicable, unless the Administrator specifies or approves alternate operating conditions. Upon request, you must make available to the Administrator such records as may be

necessary to determine the conditions of performance tests performed, pursuant to this section.

(a) *Continuous process operations.* For continuous process operations, you must conduct all performance tests at maximum representative operating conditions for the process.

(b) *Batch process operations.* For batch process operations, testing must be conducted at absolute worst-case conditions or hypothetical worst-case conditions, as specified in § 65.822.

(c) *Combination of both continuous and batch unit operations.* For combined continuous and batch process operations, you must conduct performance tests when the batch process operations are operating at absolute worst-case conditions or hypothetical worst-case conditions, as specified in paragraph (b) of this section, and the continuous process operations are operating at maximum representative operating conditions for the process, as specified in paragraph (a) of this section.

(d) You must not conduct a performance test during startup, shutdown, periods when the control device is bypassed or periods when the process, monitoring equipment or control device is not operating properly.

§ 65.822 At what process conditions must I conduct performance testing for batch process operations?

If you choose to conduct testing at absolute worst-case conditions for batch process operations, you must characterize the conditions by the criteria presented in paragraph (a) of this section. If you choose to conduct testing at hypothetical worst-case conditions for batch process operations, you must characterize the conditions by the criteria presented in paragraph (b) of this section. In all cases, a performance test plan must be submitted to the Administrator for approval prior to testing in accordance with § 65.820(a) through (d). The performance test plan must include the emission profile described in paragraph (c) of this section.

(a) *Absolute worst-case conditions.* You must consider all relevant factors, including load and compound-specific characteristics, in defining absolute worst-case conditions. Absolute worst-case conditions are defined by the criteria presented in paragraph (a)(1) or (2) of this section if the maximum load is the most challenging condition for the control device. Otherwise, absolute worst-case conditions are defined by paragraph (a)(3) of this section.

(1) The period in which the inlet to the control device will contain the maximum projected regulated material load and will always contain at least 50 percent of the maximum regulated material load (in pounds) capable of being vented to the control device over any 8-hour period. An emission profile, as described in paragraph (c)(1) of this section, must be used to identify the 8-hour period that includes the maximum projected regulated material load.

(2) A 1-hour period of time in which the inlet to the control device will contain the highest regulated material mass loading rate, in lb/hr, capable of being vented to the control device. An emission profile, as described in paragraph (c)(1) of this section, must be used to identify the 1-hour period of maximum regulated material loading.

(3) The period of time when the regulated material loading or stream composition (including non-regulated material) is most challenging for the control device. These conditions include, but are not limited to, paragraphs (a)(3)(i) through (iii) of this section.

(i) Periods when the stream contains the highest combined regulated material load, in lb/hr, described by the emission profiles in paragraph (c) of this section.

(ii) Periods when the stream contains regulated material constituents that approach limits of solubility for scrubbing media.

(iii) Periods when the stream contains regulated material constituents that approach limits of adsorptivity for adsorption systems.

(b) *Hypothetical worst-case conditions.* Hypothetical worst-case conditions are simulated test conditions that, at a minimum, contain the highest hourly regulated material load of emissions that would be predicted to be vented to the control device from the emissions profile described in paragraphs (c)(2) or (3) of this section.

(c) *Emission profile.* For batch process operations, you must develop an emission profile for the vent to the control device that describes the characteristics of the vent stream at the inlet to the control device under worst-case conditions. The emission profile is an analysis of regulated material emissions versus time and must be developed, based on any one of the procedures described in paragraphs (c)(1) through (3) of this section.

(1) *Emission profile by process.* The emission profile by process must consider all emission episodes (for example, but not limited to, vessel filling, empty vessel purging, gas sweep of a partially filled vessel, vacuum operations, gas evolution, depressurization, heating and evaporation) that could contribute to the vent stack for a period of time that is sufficient to include all processes venting to the stack and must consider production scheduling. The emission profile by process must describe the regulated material load to the device that equals the highest sum of emissions from the episodes that can vent to the control device in any given hour. Emissions per episode must be calculated using the procedures specified in § 65.835(b).

(2) *Emission profile by process equipment.* The emission profile by process equipment must consist of emissions that meet or exceed the highest emissions, in lb/hr, that would be expected under actual processing conditions. The emission profile by process equipment must describe component configurations used to generate the emission events, volatility of materials processed in the process equipment and the rationale used to identify and characterize the emission events. The emissions may be based on using a compound more volatile than compounds actually used in the process(es), and the emissions may be generated from all process equipment in the process(es) or only selected process equipment.

(3) *Emission profile by capture and control device limitation.* The emission profile by capture and control device must consider the capture and control system limitations and the highest emissions, in lb/hr, that can be routed to the control device, based on maximum flow rate and concentrations possible because of limitations on conveyance and control components (*e.g.,* fans and lower explosive level alarms).

§ 65.823 How do I sample from vent streams?

You must conduct the applicable sampling, as specified in paragraphs (a) through (d) of this section.

(a) You must use Method 1 or 1A at 40 CFR part 60, appendix A–1, as appropriate, to select the sampling sites.

(1) For determination of compliance with a percent reduction requirement of regulated material or total organic compounds, sampling sites must be located at the outlet of the control device, and with the exception noted in § 65.724(b)(2), the control device inlet sampling site must be located at the exit from the unit operation before any control device.

(2) For determining compliance with a ppmv total regulated material or total organic compounds emissions limit in a referencing subpart, the sampling site

must be located at the outlet of the control device.

(3) For determining compliance with an emission limit requirement of a vent stream halogen atom mass emission rate prior to a combustion device, or to demonstrate that a vent stream is not halogenated, pursuant to § 65.702(c), collect samples prior to the combustion device.

(b) For determining compliance with percent reduction emission limits, you must collect samples simultaneously at the inlet and outlet of the control device during the performance test.

(c) For correcting concentrations to specified percent oxygen, the sampling site for the measurement of oxygen concentration must be the same as that of the regulated material samples, and the samples must be taken concurrently.

(d) For each test run, you must take either real-time measurements, an integrated sample or a minimum of four grab samples per hour. If grab sampling is used, then the samples must be taken at approximately equal intervals in time, such as 15-minute intervals during the run.

§ 65.824 What is the performance test duration?

(a) Except as provided in paragraph (c) of this section, for continuous process operations, a performance test must consist of three runs of at least 1 hour in length; and must be conducted under the conditions specified in § 65.821(a).

(b) Except as provided in paragraph (c) of this section, for batch process operations, a performance test must consist of three runs; and must be conducted under the conditions specified in § 65.821(b). Each run must occur over the same absolute or hypothetical worst-case conditions, as defined in § 65.822, and be tested over the length of the episode, at a minimum of 1 hour and not to exceed 8 hours.

(c) For control devices used to control emissions from transfer racks (except low throughput transfer racks that are capable of continuous vapor processing, but do not handle continuous emissions or multiple loading arms of a transfer rack that load simultaneously), each run must represent at least one complete tank truck or tank car loading period, during which regulated materials are loaded.

§ 65.825 What performance test methods do I use?

You must conduct the performance test using the applicable test methods and procedures specified in Table 5 to this subpart and paragraphs (a) through (e) of this section, as applicable, unless you request an alternative test method or a change to a test method, as specified in § 65.250.

(a) If you use ASTM D6420–99(2010), ''Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry'' (incorporated by reference, see § 65.265) in lieu of Method 18 at 40 CFR part 60, appendix A–6 or Method 320 at 40 CFR part 63, appendix A to measure specific organic regulated material compound concentration, as applicable, at the inlet and/or outlet of a control device, then you must meet the conditions specified in paragraphs (a)(1) through (3) of this section.

(1) The target compound(s) must be listed in Section 1.1 of ASTM D6420–99 (2010), ''Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry'' (incorporated by reference, see § 65.265), and the target concentration is between 150 parts per billion by volume and 100 ppmv.

(2) If one (or more) target compound(s) is not listed in Section 1.1 of ASTM D6420–99 (2010), ''Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry'' (incorporated by reference, see § 65.265), but is potentially detected by mass spectrometry, an additional system continuing calibration check after each run, as detailed in Section 10.5.3 of ASTM D6420–99, must be followed, met, documented and submitted with the performance test report, even if a moisture condenser is not used or the compound is not considered soluble.

(3) A minimum of one sample/analysis cycle must completed at least every 15 minutes.

(b) If using Method 25A at 40 CFR part 60, appendix A–7 to determine compliance with a total organic compounds outlet concentration or percent reduction limit specified in a referencing subpart, you must follow the procedures in paragraphs (b)(1) through (3) of this section.

(1) Calibrate the instrument on propane.

(2) When demonstrating compliance with an outlet concentration emission limit specified in the referencing subpart, you must use a span value of the analyzer between 1.5 and 2.5 times the applicable emission limit in the referencing subpart. When demonstrating compliance with a percent reduction by making measurements at the inlet and outlet of the control device, you must use a span value of the analyzer of between 1.5 and 2.5 times the highest expected total organic compounds concentration at each location.

(3) Report the results as carbon, calculated according to Equation 25A–1 of Method 25A at 40 CFR part 60, appendix A–7.

(c) If you are using Method 320 at 40 CFR part 63, appendix A, pursuant to Table 5 to this subpart, you must follow the validation procedure of section 13.0 of EPA Method 320 unless the validation procedure was conducted at another source and it can be shown that the exhaust gas characteristics are similar at both sources. When demonstrating compliance with an emission limit for hydrogen halides and halogens, EPA Method 320 may only be used if you can show that there are no diatomic halogen molecules present in the vent stream being tested.

(d) If the uncontrolled or inlet gas stream to the control device contains formaldehyde, you must conduct emissions testing according to paragraph (d)(1) or (2) of this section.

(1) If you elect to comply with a percent reduction requirement and formaldehyde is the principal regulated material compound (*i.e.,* the highest concentration for any regulated compound in the stream by volume), you must use Method 320 at 40 CFR part 63, appendix A, to measure formaldehyde at the inlet and outlet of the control device, unless the vent stream being tested has entrained water droplets. If the vent stream contains entrained water droplets, you must use EPA Method 316 instead of EPA Method 320 to measure formaldehyde concentration. Use the percent reduction in formaldehyde as a surrogate for the percent reduction in total regulated material emissions.

(2) If you elect to comply with an outlet total organic regulated material concentration or total organic compounds concentration limit, and the uncontrolled or inlet gas stream to the control device contains greater than 10 percent (by volume) formaldehyde, you must use Method 320 at 40 CFR part 63, appendix A, to determine the formaldehyde concentration, unless the vent stream being tested has entrained water droplets. If the vent stream contains entrained water droplets, you must use EPA Method 316 instead of EPA Method 320 to measure formaldehyde concentration. Calculate the total organic regulated material concentration or total organic compounds concentration by totaling the formaldehyde emissions measured using EPA Method 316 or EPA Method 320 and the other regulated material

compound emissions measured using Method 18 at 40 CFR part 60, appendix A–6, Method 25A at 40 CFR part 60, appendix A–7, EPA Method 320 or ASTM D6420–99(2010), ''Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry'' (incorporated by reference, see § 65.265).

(e) If the uncontrolled or inlet gas stream to the control device contains carbon disulfide, you must conduct emissions testing according to paragraph (e)(1) or (2) of this section.

(1) If you elect to comply with a percent reduction requirement and carbon disulfide is the principal regulated material compound (i.e., the highest concentration for any regulated compound in the stream by volume), you must use Method 18 at 40 CFR part 60, appendix A–6 or Method 15 at 40 CFR part 60, appendix A–5, to measure carbon disulfide at the inlet and outlet of the control device. Use the percent reduction in carbon disulfide as a surrogate for the percent reduction in total regulated material emissions.

(2) If you elect to comply with an outlet total organic regulated material concentration or total organic compounds concentration limit, and the uncontrolled or inlet gas stream to the control device contains greater than 10 percent (by volume) carbon disulfide, you must use Method 18 at 40 CFR part 60, appendix A–6 or Method 15 at 40 CFR part 60, appendix A–5, to determine the carbon disulfide concentration. Calculate the total organic regulated material concentration or total organic compounds concentration by totaling the carbon disulfide emissions measured using Method 15 at 40 CFR part 60, appendix A–5 or Method 18 at 40 CFR part 60, appendix A–6 and the other regulated material compound emissions measured using Method 18 at 40 CFR part 60, appendix A–6, or Method 25A at 40 CFR part 60, appendix A–7, Method 320 at 40 CFR part 63, appendix A or ASTM D6420–99(2010), ''Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry'' (incorporated by reference, see § 65.265), as applicable.

(f) You must not use Method 26 at 40 CFR part 60, appendix A–8, to test gas streams with entrained water droplets.

§ 65.826 How do I calculate emissions in parts per million by volume concentration?

Use the procedures specified in paragraph (a) of this section to calculate ppmv concentration. The calculated concentration must be corrected to a standard percent oxygen, if required by the referencing subpart, using the procedures specified in paragraph (b) of this section.

(a) *Concentration calculation.* The concentration of either total organic compounds (minus methane or ethane) or total organic regulated material must be calculated according to paragraph (a)(1) or (2) of this section.

(1) The total organic compounds concentration (CTOC) is the sum of the concentrations of the individual components and must be computed for each run using Equation 2 of this section.

$$C_{TOC} = \frac{1}{x}\left(\sum_{i=1}^{x}\sum_{j=1}^{n} C_{ji}\right) \qquad \text{(Eq. 2)}$$

Where:

C_{TOC} = Concentration of total organic compounds (minus methane and ethane), dry basis, ppmv.

x = Number of samples in the sample run.

n = Number of components in the sample.

C_{ji} = Concentration of sample component j (where j is not methane or ethane) of sample i, dry basis, ppmv.

(2) You must compute the total organic regulated material (CREG) according to Equation 2 of this section except that you need only sum the regulated species.

(b) *Concentration correction calculation.* If a referencing subpart requires the concentration of total organic compounds or organic regulated material to be corrected to standard oxygen, the correction must be made, as specified in paragraph (b)(1) of this section. For batch process operations, you must correct the concentration for supplemental gases, as specified in paragraph (b)(2) of this section.

(1) Determine the concentration corrected to a standard percent oxygen (Cc) specified by the referencing subpart, using Equation 3 of this section.

$$C_c = C_{TOC}\left(\frac{20.9 - \%O_{2s}}{20.9 - \%O_{2d}}\right) \qquad \text{(Eq. 3)}$$

Where:

C_c = Concentration of total organic compounds or organic regulated material corrected to a standard percent oxygen, dry basis, ppmv.

C_{TOC} = Concentration of total organic compounds (minus methane and ethane) or organic regulated material, dry basis, ppmv.

$\%O_{2s}$ = Concentration of oxygen specified by the referencing subpart, percentage by volume.

$\%O_{2d}$ = Measured concentration of oxygen, dry basis, percentage by volume.

(2) For batch process operations, correct the measured concentration for any supplemental gases using Equation 4 of this section.

$$C_a = C_m\left(\frac{Q_s + Q_a}{Q_a}\right) \qquad \text{(Eq. 4)}$$

Where:

C_a = Corrected outlet concentration of regulated material, dry basis, ppmv.

C_m = Actual concentration of regulated material measured at control device outlet, dry basis, ppmv.

Q_a = Total volumetric flow rate of all gas streams vented to the control device, except supplemental gases, cubic meters per minute.

Q_s = Total volumetric flow rate of supplemental gases, cubic meters per minute.

§ 65.827 How do I demonstrate compliance with a percent reduction requirement?

(a) To demonstrate compliance with a percent reduction requirement for a control device specified in a referencing subpart, you must comply with § 65.828.

(b) To meet a process aggregated percent reduction emission requirement specified in a referencing subpart for a batch process, you must follow the provisions, as specified in § 65.835.

(c) For combined streams of continuous and batch process operations subject to a process aggregated percent reduction emission requirement in a referencing subpart, you must demonstrate that the control device meets the percent reduction requirements for both batch and continuous process operations by following the provisions specified in §§ 65.828 and 65.835.

§ 65.828 How do I determine percent reduction?

To determine a percent reduction for a control device, you must use the procedures specified in paragraphs (a) and (b) of this section. For small boilers and process heaters, you must follow the provisions of § 65.724(b)(1) and (2).

(a) *Mass rate of total organic compounds or regulated material.* Compute the mass rate of either total organic compounds (minus methane and ethane) or regulated material (E_i, E_o), as applicable. Use Equations 5 and 6 of this section.

$$E_i = K_2 \left(\sum_{j=1}^{n} C_{ij} M_{ij} \right) Q_i \qquad \text{(Eq. 5)}$$

$$E_o = K_2 \left(\sum_{j=1}^{n} C_{oj} M_{oj} \right) Q_o \qquad \text{(Eq. 6)}$$

Where:

E_i, E_o = Emission rate of total organic compounds (minus methane and ethane) or emission rate of regulated material in the sample at the inlet and outlet of the control device, respectively, dry basis, kilogram per hour.

K_2 = Constant, $2.494 \times 10 - 6$ $(\text{ppmv})^{-1}$ (g-mol per standard cubic meter) (kilogram per gram) (minute per hour), where standard temperature is 20 degrees Celsius (68 degrees Fahrenheit).

N = Number of compounds in the sample.

C_{ij}, C_{oj} = Concentration on a dry basis of organic compound j (where j is not methane or ethane) in ppmv of the gas stream at the inlet and outlet of the control device, respectively. If the total organic compounds emission rate is being calculated, C_{ij} and C_{oj} include all organic compounds measured minus methane and ethane; if the regulated material emissions rate is being calculated, all organic regulated material are included.

M_{ij}, M_{oj} = Molecular weight of compound j, gram per g-mol, of the gas stream at the inlet and outlet of the control device, respectively.

Q_i, Q_o = Vent stream flow rate, dry standard cubic meter per minute, at a temperature of 20 degrees Celsius (68 degrees Fahrenheit), at the inlet and outlet of the control device, respectively.

(b) *Percent reduction in total organic compounds or regulated material.* Determine the percent reduction in total organic compounds (minus methane and ethane) or regulated material using Equation 7 of this section.

$$R = \frac{E_i - E_o}{E_i} (100) \qquad \text{(Eq. 7)}$$

Where:

R = Control efficiency of control device, percent.

E_i = Mass rate of total organic compounds (minus methane and ethane) or regulated material at the inlet to the control device as calculated under paragraph (a) of this section, kilograms total organic compounds per hour or kilograms regulated material per hour.

E_o = Mass rate of total organic compounds (minus methane and ethane) or regulated material at the outlet of the control device, as calculated under paragraph (a) of this section, kilograms total organic compounds per hour or kilograms regulated material per hour.

§ 65.829 How do I demonstrate compliance with a hydrogen halide and halogen emission limit specified in a referencing subpart?

You must conduct a performance test, pursuant to § 65.820, and follow the procedures in paragraphs (a) through (d) of this section, as applicable, when determining compliance with a hydrogen halide and halogen emission limit specified in a referencing subpart.

(a) To determine compliance with a halogen atom mass emission rate emission limit requirement, you must use Equation 8 of this section to calculate the mass emission rate of halogen atoms:

$$E = K_2 Q \left(\sum_{j=1}^{n} \sum_{i=1}^{m} C_j L_{ji} M_{ji} \right) \qquad \text{(Eq. 8)}$$

Where:

E = Mass of halogen atoms, dry basis, kilogram per hour.

K_2 = Constant, 2.494×10^{-6} (ppmv)$^{-1}$ (g-mol per standard cubic meter) (kilogram per gram) (minute per hour), where standard temperature is 20 degrees Celsius (68 degrees Fahrenheit).

Q = Flow rate of gas stream, dry standard cubic meters per minute, determined according to an engineering assessment, as specified in § 65.830 or, pursuant to Table 5 to this subpart.

n = Number of halogenated compounds j in the gas stream.

m = Number of different halogens i in each compound j of the gas stream.

j = Halogenated compound in the gas stream.

i = Halogen atom in compound j of the gas stream.

C_j = Concentration of halogenated compound j in the gas stream, dry basis, ppmv.

L_{ji} = Number of atoms of halogen i in compound j of the gas stream.

M_{ji} = Molecular weight of halogen atom i in compound j of the gas stream, kilogram per kilogram-mol.

(b) Calculate the mass emissions rate of each hydrogen halide and halogen compound as the summation of the measured concentrations and the gas stream flow rate, as shown in Equations 9 and 10 of this section. To determine compliance with an outlet mass emission rate limit specified in a referencing subpart, only Equation 10 is required.

$$E_i = kQ_i \sum C_{ij} \qquad \text{(Eq. 9)}$$

$$E_o = kQ_o \sum C_{oj} \qquad \text{(Eq. 10)}$$

Where:

E_i, E_o = Total mass rate of hydrogen halide and halogen compounds, in kilograms per hour.

K = $6 \times 10 - 5$, Conversion factor of milligrams per minute to kilograms per hour.

C_{ij}, C_{oj} = Concentration of each hydrogen halide and halogen compound in the gas stream, in milligrams per dry standard cubic meter at the inlet and outlet of the control device, respectively.

Q_i, Q_o = Vent stream flow rate, dry standard cubic meter per minute, at a temperature of 20 degrees Celsius (68 degrees Fahrenheit), at the inlet and outlet of the control device, respectively.

(c) Calculate the percent reduction of hydrogen halide and halogen compounds using the inlet and outlet mass emission rates calculated in paragraph (b) of this section and Equation 7 of this section.

(d) To demonstrate compliance with a mass rate (*e.g.,* kilogram per hour) outlet emission limit, the test results must show that the mass emission rate of total hydrogen halides and halogens measured at the outlet of the absorber or other halogen reduction device is below the mass rate outlet emission limit specified in a referencing subpart.

§ 65.830 When can an engineering assessment be used and what does it include?

(a) You may conduct an engineering assessment if you perform any of the actions described in paragraphs (a)(1) through (6) of this section.

(1) Determine whether a vent stream is halogenated, as specified in § 65.702(c)(2).

(2) Supplement your performance test, as specified in § 65.713(a).

(3) Establish your operating limit on ranges or limits previously established under a referencing subpart, as specified in § 65.713(d).

(4) Determine flow rate of a gas stream, as specified in Equation 8 of § 65.829(a).

(5) Calculate regulated material emissions for each emission episode that is not described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265), as specified in § 65.835(b)(2) or § 65.835(d)(3).

(6) Calculate regulated material emissions for each emission episode that you can demonstrate to the Administrator that the emission estimation techniques in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265) are not appropriate, as specified in § 65.835(e).

(b) An engineering assessment includes, but is not limited to, the information specified in paragraphs (b)(1) through (4) of this section.

(1) Previous test results, provided the tests are representative of current operating practices at the process unit.

(2) Bench-scale or pilot-scale test data representative of the process under representative operating conditions.

(3) Maximum flow rate, regulated material emission rate, concentration or other relevant parameter specified or implied within a permit limit applicable to the vent stream.

(4) Design analysis, based on accepted chemical engineering principles, measurable process parameters or physical or chemical laws or properties. Examples of analytical methods include, but are not limited to, the methods specified in paragraphs (b)(4)(i) through (iii) of this section.

(i) Use of material balances, based on process stoichiometry to estimate maximum organic regulated material concentrations.

(ii) Estimation of maximum flow rate, based on physical process equipment design such as pump or blower capacities.

(iii) Estimation of regulated material concentrations, based on saturation conditions.

Batch Emission Calculations

§ 65.835 What emissions calculations must I use for batch process operations for purposes of compliance with an aggregated percent reduction?

(a) *General.* To demonstrate compliance with a process aggregated percent reduction emission limit in a referencing subpart for batch process operations, including batch process operations in combined streams of continuous and batch unit operations, you must compare the sums of the controlled and uncontrolled emissions for the batch vent streams subject to control within the process, and show that the specified reduction is met. The emission reduction must be calculated as shown in Equation 11 of this section using parameters from Equations 12 and 13 of this section.

$$R = \frac{E_u - E_c}{E_u} \qquad \text{(Eq. 11)}$$

$$E_u = \sum_i E_i \qquad \text{(Eq. 12)}$$

$$E_c = \sum_i D_i + \sum_i (E_i)(1 - Z_i) \qquad \text{(Eq. 13)}$$

Where:

E_u = Uncontrolled emissions for batch vent streams.

E_c = Controlled emissions for batch vent streams.

E_i = Uncontrolled emissions for each emission episode, as determined, pursuant to § 65.835(b).

i = Each emission episode that applies to the batch process (for example, but not limited to, vessel filling, empty vessel purging, gas sweep of a partially filled vessel, vacuum operations, gas evolution, depressurization, heating and evaporation).

D_i = Controlled emissions for each emission episode from a condenser, as determined, pursuant to paragraph (d) of this section.

Z_i = Emission percent reduction for a control device other than a condenser used during an emission episode (i), as determined, pursuant to § 65.828.

(b) *Uncontrolled emissions.* You must calculate uncontrolled emissions from all process equipment according to the procedures described in paragraphs (b)(1) and (2) of this section to demonstrate initial compliance with a percent reduction emission limit in a referencing subpart for batch process operations, including operations in combined streams of continuous and batch unit operations. You must also use these procedures if you choose to develop an emission profile by process, as specified in § 65.822(c)(1).

(1) Except as provided in paragraph (e) of this section, you must determine uncontrolled emissions of regulated material using measurements and/or calculations for each batch emission episode within each unit operation using the emission estimation techniques described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265). Chemical property data can be obtained from standard reference texts.

(2) You must conduct an engineering assessment according to § 65.830 in order to calculate uncontrolled regulated material emissions for each emission episode that is not described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265). You may also conduct an engineering assessment according to § 65.830 if you meet the requirements of paragraphs (d)(3) or (e) of this section. Data or other information supporting a finding that the emissions estimation equations are inappropriate are subject to preapproval by the Administrator and must be reported in the batch pre-compliance report.

(c) *Controlled emissions.* Except as provided in paragraph (d) of this section, you must calculate controlled emissions using the percent reduction for the control device, as determined from the performance test required in § 65.828 to demonstrate initial compliance with a percent reduction emission limit in a referencing subpart for batch process operations, including batch process operations in combined streams of continuous and batch unit operations.

(d) *Controlled emissions from condensers.* For a condenser used as control, you may calculate controlled emissions from the condenser using the procedures specified in paragraphs (d)(1) through (4) of this section to demonstrate initial compliance with a percent reduction emission limit in a referencing subpart for batch process operations, including batch process operations in combined streams of continuous and batch unit operations.

(1) Except as provided in paragraph (d)(2) of this section, you must determine controlled emissions from the condenser using calculations for each batch emission episode within each unit operation according to the emission estimation techniques described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265). You must use the temperature and regulated material partial pressures that are determined at the exit temperature and exit pressure conditions of the condenser. Chemical property data can be obtained from standard reference texts.

(2) For heating and depressurization episodes, you must determine controlled emissions from the condenser using the procedures, as specified in paragraphs (d)(2)(i) through (iii) of this section.

(i) You must determine the average molecular weight of regulated material in vapor exiting the receiver using Equation 14 of this section.

$$MW_{RM} = \sum_{i=1}^{n} \frac{\left((P_i)_{T_1} + (P_i)_{T_2}\right) MW_i}{\sum_{i=1}^{n} \left((P_i)_{T_1} + (P_i)_{T_2}\right)} \qquad \text{(Eq. 14)}$$

Where:

MW_{RM} = Average molecular weight of regulated material in vapor exiting the receiver.

$(P_i)_{T1}$ = Partial pressure of each regulated material in the vessel headspace at initial temperature of the receiver.

$(P_i)_{T2}$ = Partial pressure of each regulated material in the vessel headspace at final temperature of the receiver.

MW_i = Molecular weight of the individual regulated material.

n = Number of regulated material compounds in the emission stream.

i = Identifier for a regulated material compound.

(ii) You must determine the number of moles of non-condensable gas displaced from the vessel using Equation 15 of this section for heating episodes; and Equation 16 of this section for depressurization episodes, as applicable.

$$\Delta\eta = \frac{V}{R}\left(\left(\frac{P_{nc1}}{T_1}\right) - \left(\frac{P_{nc2}}{T_2}\right)\right) \qquad \text{(Eq. 15)}$$

$$\Delta\eta = \frac{V}{RT}\left(P_{nc1} - P_{nc2}\right) \qquad \text{(Eq. 16)}$$

Where:

$\Delta\eta$ = Number of moles of non-condensable gas displaced from the vessel being heated or depressurized.
V = Volume of free space in the vessel being heated or depressurized.
R = Ideal gas law constant.
P_{nc1} = Initial partial pressure of the non-condensable gas in the headspace of the vessel being heated or depressurized.
P_{nc2} = Final partial pressure of the non-condensable gas in the headspace of the vessel being heated or depressurized.
T_1 = Initial temperature of the vessel contents being heated.
T_2 = Final temperature of the vessel contents being heated.
T = Exit temperature of the receiver.

(iii) You must determine the mass of regulated material emitted from the receiver due to the vessel being heated or depressurized using Equation 17 of this section.

$$E = \Delta\eta \bullet \left(\frac{\sum_{i=1}^{n} P_i MW_{RM}}{P_T - \sum_{j=1}^{m}\left(P_j\right)}\right) \qquad \text{(Eq. 17)}$$

Where:

E = Mass of regulated material emitted from the receiver due to the vessel being heated or depressurized.
$\Delta\eta$ = The number of moles of non-condensable displaced from the vessel being heated or depressurized, as calculated for heating episodes using Equation 15 of this section; or as calculated for depressurization episodes using Equation 16 of this section.
P_T = Pressure in the receiver.
P_i = Partial pressure of each individual regulated material determined at the temperature of the receiver.
P_j = Partial pressure of each individual condensable (including regulated material) determined at the temperature of the receiver.
n = Number of regulated material compounds in the emission stream.
i = Identifier for a regulated material compound.
j = Identifier for a condensable compound.
MW_{RM} = Average molecular weight of regulated material in vapor exiting the receiver, as calculated using Equation 14 of this section.
m = Number of condensable compounds (including regulated material) in the emission stream.

(3) You must conduct an engineering assessment, as specified in paragraph (b)(2) of this section, for each emission episode that is not described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265).

(4) You may elect to conduct an engineering assessment, as specified in paragraph (e) of this section, if you demonstrate to the Administrator that the methods described in paragraphs (d)(1) or (2) of this section are not appropriate.

(e) *Modified emission estimation technique.* Instead of calculating uncontrolled emissions, as specified in § 65.835(b)(1) of this section, or instead of calculating controlled emissions from a condenser used as a control device, as specified in § 65.835(d)(1) and (2) of this section, you may conduct an engineering assessment, as specified in paragraph (b)(2) of this section, if you can demonstrate to the Administrator that the emission estimation techniques in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265) are not appropriate. The engineering assessment can result in modified versions of the emission estimation techniques described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265) if you demonstrate that they have been used to meet other regulatory obligations, and they do not affect applicability assessments or compliance determinations under the referencing subpart. One criterion you could use to demonstrate that the emission estimation techniques described in Section 3 of EPA EIIP Volume II: Chapter 16 (incorporated by reference, see § 65.265) are not appropriate is if previous test data are available that show a greater than 20-percent discrepancy between the test value and the estimated value.

Design Evaluation

§ 65.850 How do I demonstrate compliance through design evaluation?

(a) For each non-flare control device for which a design evaluation, as allowed by the referencing subpart, is used as an alternative to a performance test, as specified in § 65.702(e)(1), you must conduct the design evaluation according to the procedures in paragraphs (b) through (e) of this section.

(b) You must prepare a design evaluation, as specified in paragraph (c) of this section. Also, unless you are using a CEMS to monitor the emissions to demonstrate compliance with the emission standard of the referencing subpart, you must prepare a monitoring description, as specified in paragraph (d) of this section. The design

evaluation and monitoring description must be submitted with the Notification of Compliance Status Report, as specified in § 65.880(c). You must comply with § 63.711 for all CEMS.

(c) The design evaluation must include documentation demonstrating that the control device being used achieves the required emission limit of a referencing subpart. You must identify in the design evaluation, each emission point routed to the control device and the applicable emission limit. The design evaluation must also address the composition of the vent stream entering the control device, including flow and regulated material concentration, and the information specified in paragraphs (c)(1) through (4) of this section and § 65.724(d) for boilers and process heaters, § 65.726(c) for thermal oxidizers, § 65.728(c) for catalytic oxidizers, § 65.740(c) for absorbers, § 65.742(d) for adsorbers regenerated onsite, § 65.744(c) for non-regenerative adsorbers, § 65.746(c) for condensers, § 65.748(d) for biofilters, § 65.760(d) for sorbent injection and § 65.762(c) for fabric filters, as applicable.

(1) For storage vessels, the design evaluation must include documentation demonstrating that the control device being used achieves the required control efficiency during reasonably expected maximum filling rate.

(2) For transfer racks, the design evaluation must demonstrate that the control device achieves the required control efficiency during the reasonably expected maximum transfer loading rate.

(3) For a non-flare control device used to control emissions from batch process operations, establish emission profiles and conduct the evaluation under worst-case conditions, as determined, pursuant to § 65.822.

(4) If the vent stream is not the only inlet to the control device, the efficiency demonstration also must consider all other vapors, gases and liquids other than fuels received by the control device.

(d) The monitoring description must include the information specified in paragraphs (d)(1) and (2) of this section to identify the operating parameters that you will monitor to assure proper operation of the control device such that the control device is meeting the specified emission limit of the referencing subpart.

(1) A description of the operating parameter or parameters to be monitored, an explanation of the criteria used for selection of that parameter (or parameters) and when the monitoring will be performed (*e.g.,* when the liquid level in the storage vessel is being raised). If continuous records are specified, indicate whether the provisions of §§ 65.712 and 65.713 apply.

(2) The operating limit, monitoring frequency (*e.g.,* every 15 minutes), and averaging time for each operating parameter identified in paragraph (d)(1) of this section. The specified operating limit must represent the conditions for which the control device is being properly operated and maintained such that the control device is meeting the specified emission limit of the referencing subpart.

(e) You must operate and maintain the non-flare control device so that the monitored operating parameters, as determined in paragraph (d) of this section, remain within the operating limits specified in the Notification of Compliance Status whenever emissions of regulated material are routed to the control device.

Recordkeeping

§ 65.855 How do I calculate monitoring data averages?

(a) *Data averages for compliance.* You must calculate monitoring data averages, as specified in paragraphs (a)(1) through (4) of this section, as applicable.

(1) Except as specified in paragraphs (a)(2) through (4) of this section, daily average values of continuously monitored emissions and operating parameters must be calculated for each operating day using all continuously monitored data, except the data specified in paragraph (b) of this section must be excluded from the average. The operating day must be the period defined in the operating permit or in the Notification of Compliance Status.

(2) For batch process operations and as an alternative to the requirement for daily averages in paragraph (a)(1) of this section, you may determine averages for operating blocks while excluding the data specified in paragraph (b) of this section.

(3) If all values of a monitored operating parameter, during an operating day or operating block, are below the operating limit established, pursuant to § 65.713, you do not have to calculate the daily average for the operating parameter. In such cases, you may not discard the recorded values, as allowed in § 65.860(a)(2).

(4) If all values of monitored continuous emissions, during an operating day or operating block, reduced, as specified in § 65.711(j), are below the emission limit specified in the referencing subpart, you do not have to calculate the daily or block average of the emissions. In such cases, you may not discard the recorded values, as allowed in § 65.860(a)(2).

(b) *Excluded data.* In computing averages to determine compliance, as specified in paragraph (a) of this section, you must exclude monitoring data recorded during periods identified in paragraphs (b)(1) through (3) of this section.

(1) Periods of non-operation of the process unit (or portion thereof), resulting in cessation of the emissions to which the monitoring applies.

(2) Periods of no flow to a control device, as recorded, pursuant to paragraph § 65.860(i).

(3) Any monitoring data recorded during CEMS or CPMS system breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments.

(c) *Data averages for recording.* For the purposes of recording and in addition to the averages specified in paragraph (a) of this section, you may calculate hourly averages of continuous parameter monitoring and continuous emissions data from all measured values or, if measured more frequently than once per minute, from at least one measured value per minute. The hourly averages may include values of excluded periods, as specified in paragraph (b) of this section. The hourly averages may be retained as an alternative to retaining records of all measured values if the provisions of § 65.860(a)(2) are met.

§ 65.860 What records must I keep?

(a) *Continuous monitoring data records.* You must maintain records, as specified in paragraphs (a)(1) through (6) of this section, as applicable.

(1) Except as provided in paragraph (a)(2) of this section, you must maintain a record of each measured value measured at least once every 15 minutes.

(2) Except as provided in paragraph (a)(3) of this section, or in § 65.855(a)(4) through (6), you may calculate and record block hourly average values calculated, as specified in § 65.855(c) and discard all but the most recent 3 hours of continuous (15-minute or shorter) records that do not include deviations that are specified in § 65.710(e). If you select this method for retaining monitoring data, you must also meet the provisions of paragraphs (a)(2)(i) through (iii) of this section.

(i) You must retain a file that contains a hard copy of the data acquisition

system algorithm used to reduce the measured data into the reportable form of the standard and calculate the hourly averages.

(ii) The 1-hour averages may include measurements taken during periods of CEMS or CPMS system breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments. However, you must not include these periods for any average computed to determine compliance, as specified in § 65.855(a).

(iii) A record must be maintained stating whether the calculated 1-hour averages include, or do not include, measurements taken during periods of CEMS or CPMS breakdowns, out-of-control periods, repairs, maintenance periods, instrument adjustments or checks to maintain precision and accuracy, calibration checks, and zero (low-level), mid-level (if applicable) and high-level adjustments.

(3) The Administrator, upon notification to you, may require you to maintain all measurements, as required by paragraph (a)(1) of this section, if the Administrator determines these records are required to more accurately assess the compliance status of the regulated source.

(4) You must keep records of all applicable daily and operating block averages, as calculated, pursuant to § 65.855(a).

(5) You must keep records of periods of operation during which the daily average of monitored operating parameters, calculated as specified in § 65.855(a), is outside the operating limits established, pursuant to § 65.713.

(6) You must keep records of periods of operation during which the daily average of continuous emissions, calculated as specified in § 65.855(a), is above the emission standard specified in the referencing subpart.

(b) *Non-continuous monitoring records.* You must keep up-to-date and readily accessible records, as specified in § 65.728(f) for catalytic oxidizers, § 65.742(j) for adsorbers regenerated onsite, § 65.744(k) for non-regenerative adsorbers, § 65.746(e) for condensers, § 65.760(g) for sorbent injection and § 65.762(e) for fabric filters.

(c) *Performance test records.* For each performance test conducted, pursuant to §§ 65.820 through 65.829, and for any prior performance test that is accepted in place of a performance test conducted, pursuant to §§ 65.820 through 65.829, you must keep readily accessible records of the data specified in paragraphs (c)(1) through (3) of this section, as applicable, recorded over the full period of the performance test, as well as averages calculated over the full period of the performance test.

(1) The records specified in § 65.724(e) for boilers and process heaters, § 65.726(d) for thermal oxidizers, § 65.728(d) for catalytic oxidizers, § 65.740(d) for absorbers, § 65.742(h) for adsorbers regenerated onsite, § 65.744(d) for non-regenerative adsorbers, § 65.746(e) for condensers, § 65.748(e) for biofilters, § 65.760(e) for sorbent injection, § 65.762(d) for fabric filters and § 65.800(c) for other control devices.

(2) The concentration of regulated material or total organic compounds (ppmv, by compound), as applicable, at the outlet of the control device, as specified in § 65.826; or the percent reduction of regulated material or total organic compounds, as applicable, achieved by the control device, as specified in § 65.828.

(3) You must retain copies of the performance test reports during the period that the performance tests are applicable to the operating limits being complied with and 5 years after the time they become obsolete. A complete test report must include the items listed in paragraphs (c)(3)(i) through (xvii) of this section. A performance test is ''completed'' when field sample collection is terminated.

(i) The purpose of the test.

(ii) A brief process description.

(iii) A complete unit description, including a description of feed streams and control devices.

(iv) Sampling site description.

(v) Pollutants measured.

(vi) Description of sampling and analysis procedures and any modifications to standard procedures.

(vii) Quality assurance procedures.

(viii) Record of operating conditions during the test, including the records required by paragraph (c)(1) of this section.

(ix) Record of preparation of standards.

(x) Record of calibrations.

(xi) Raw data sheets for field sampling.

(xii) Raw data sheets for field and laboratory analyses.

(xiii) Chain-of-custody documentation.

(xiv) Explanation of laboratory data qualifiers.

(xv) Example calculations of all applicable stack gas parameters, emission rates, percent reduction rates and analytical results, as applicable.

(xvi) Any other information required by the test method or the Administrator.

(xvii) Any additional information necessary to determine the conditions of performance tests.

(d) *CMS records.* You must maintain the records specified in paragraphs (d)(1) through (4) of this section.

(1) The CEMS performance evaluation and monitoring plan and the CPMS monitoring plan, as applicable, developed and implemented, as specified in §§ 65.711 and 65.712, respectively.

(2) Results of all CEMS evaluations, as specified in the CEMS performance evaluation and monitoring plan and, as specified in § 65.711, including the information listed in paragraphs (d)(2)(i) through (v) of this section.

(i) Raw CEMS evaluation measurements.

(ii) All measurements necessary to determine the conditions of the CEMS evaluation.

(iii) Raw performance testing measurements associated with relative accuracy tests and audits.

(iv) Cylinder gas certifications.

(v) Information specified to be recorded in the applicable performance specification.

(3) Records of all calibrations, certifications, audits, adjustments and other quality control procedures required in the CEMS performance evaluation and monitoring plan or CPMS monitoring plan.

(4) If you use more than one CEMS to measure the regulated materials from one emissions unit (*e.g.*, multiple breechings, multiple outlets), you must maintain records for both CEMS. However, if you use one CEMS as a backup to another CEMS, you must maintain records for the CEMS used to meet the monitoring requirements of this part.

(e) *General process records.* You must maintain records of the information specified in paragraphs (e)(1) through (8) of this section.

(1) A description of the process and the type of process equipment used, including a description of storage vessels, wastewater, transfer operations or heat exchangers that are subject to this subpart.

(2) An identification of related vent streams, including, for batch operations, their associated emissions episodes.

(3) The applicable control requirements of this subpart, including the level of required control for each emission point.

(4) The control device(s) and/or methods used on each regulated emission point to meet the emission standard, including a description of the operating conditions of the control device.

(5) Combined emissions that are routed to the same control device.

(6) The applicable monitoring requirements of this subpart and the operating limit(s) that apply for each emission point routed to the control device.

(7) Calculations and engineering analyses required to demonstrate compliance.

(8) Actual total monthly process operating time.

(f) *Batch process records.* You must keep records for batch process operations, as specified in paragraphs (f)(1) through (5) of this section.

(1) You must keep a schedule or log of operating scenarios, updated each time you put a different operating scenario into effect. You must maintain records in your daily schedule or log of processes indicating each point at which an emission episode with a different operating limit begins and ends, even if the duration of the emission episode and the monitoring for an operating limit is less than 15 minutes.

(2) For each operating scenario, you must record a justification demonstrating that the operating limit selected for the operating scenario (or operating limits selected for the individual emission episodes of the operating scenario) will not result in emissions in excess of the emissions standards. All calculations and engineering analyses performed to develop the operating limits must be included in the records. For the purposes of this paragraph, a revised operating scenario for an existing process is considered a different operating scenario when one or more of the data elements listed in paragraphs (e)(1) through (7) of this section have changed.

(3) You must keep records of all emission profiles you develop according to § 65.822(c). You must include descriptions and documentation of worst-case operating and/or testing conditions for control devices.

(4) Calculations used to demonstrate compliance according to §§ 65.820 through 65.829 and, if applicable, § 65.835. You must include data and rationale used to support an engineering assessment to calculate uncontrolled emissions in accordance with § 65.835(b)(2), if applicable.

(5) You must keep records of the information specified in paragraphs (f)(5)(i) and (ii) of this section for the collection of all batch vent streams at the regulated source in compliance with an aggregated percent reduction emission limit specified in the referencing subpart if some of the vents are controlled to less than the percent reduction requirement.

(i) Records of each batch operated and whether it was considered a standard or nonstandard batch.

(ii) The estimated uncontrolled and controlled emissions for each nonstandard batch.

(g) *Records of CMS, process and control changes.* You must maintain records of changes in CMS, processes and controls, including a description of the change.

(h) *Closed vent system bypass records.* For closed vent systems subject to the requirements of § 65.720, you must maintain records of the information specified in paragraphs (h)(1) and (2) of this section, as applicable.

(1) All times when flow was detected in the bypass line, the vent stream was diverted from the control device or the flow indicator was not operating, as specified in § 65.720(d)(1).

(2) All occurrences of periods when a bypass of the system was indicated (the seal mechanism is broken, the bypass line valve position has changed, or the key for a lock-and-key type lock has been checked out and records of any car-seal that has been broken), as specified in § 65.720(d)(2).

(i) *Records of flow/no flow to a control device.* You must keep records of periods of no flow, or no flow of regulated material to the control device, including the start and stop time and dates of periods of flow and no flow. If flow to the control device is not intermittent, you must record that flow is not intermittent and flow/no flow records are not required.

(j) *Records of excess emissions, operating parameters exceeding their limits, out-of-control periods and periods when CMS, processes or controls are inoperative or not operating properly.* You must identify each occurrence of the periods specified in paragraphs (j)(1) through (6) of this section, include the date and time of commencement and completion of each period and the total duration (recorded in hours).

(1) Periods of excess emissions.

(2) Periods when the daily average of an operating parameter is outside the established operating limit.

(3) Periods when CEMS or CPMS are out-of-control.

(4) Periods when a CEMS or CPMS is not operating properly or is inoperative, except for zero (low-level), mid-level (if applicable) and high-level checks.

(5) Periods when the process is not operating properly.

(6) Periods when a control device is not working properly.

(k) *Records demonstrating compliance with a waiver of recordkeeping or reporting requirements.* You must keep a record of any information demonstrating whether you are meeting the requirements for a waiver of recordkeeping or reporting requirements under this part, if the source has been granted a waiver under § 65.235.

(l) *Fabric filter plan.* You must maintain a record of your corrective action plan, as specified in § 65.762(e)(2).

(m) *Adsorber corrective action plan.* You must maintain a record of the corrective action plan, as specified in § 65.742(e).

(n) *Records of submittals to the Administrator.* You must maintain copies of all reports, notifications and requests (*e.g.*, requests or applications for alternative monitoring, test methods, test method changes, recordkeeping or reporting and waivers) submitted to the Administrator associated with this part and applicable referencing subparts. You must also maintain all documentation supporting submitted notifications and reports.

(o) *Other records.* You must keep records of all information specified to be recorded in design evaluations prepared, pursuant to § 65.850; all data, assumptions and procedures used in the engineering assessment, pursuant to § 65.830; requests and approvals for other control devices, pursuant to § 65.800; and alternative requests and the Administrator's approvals of alternative requests, as specified in § 65.235 for recordkeeping waivers, § 65.240 for alternative monitoring (including alternative operating parameters) and recordkeeping, § 65.245 for performance test waivers and § 65.250 for alternative test methods.

Reporting

§ 65.880 What information do I submit as part of my Notification of Compliance Status?

You must include the information listed in paragraphs (a) through (g) of this section, as applicable, in the Notification of Compliance Status that you submit according to the procedures in § 65.225.

(a) *Batch operations.* You must submit the information specified in § 65.860(f)(2) through (4).

(b) *Routing emissions to a fuel gas system.* If you elect to comply by routing emissions to a fuel gas system, you must submit a statement that the emission stream is connected to the fuel gas system.

(c) *Design evaluation and monitoring description.* If you conduct a design

evaluation instead of a performance test to demonstrate compliance with a referencing subpart, you must submit the information specified in paragraphs (c)(1) through (3) of this section.

(1) The design evaluation and monitoring description specified in § 65.850(c) and (d), respectively.

(2) Any data and calculations used to select the operating parameters and establish the operating limits specified in 65.850(d).

(3) The information specified in paragraphs (d)(3) and (4) of this section, as applicable.

(d) *Operating limit for monitored operating parameters.* You must submit the information in paragraphs (d)(1) through (3) of this section, for each control device requiring operating limits, as applicable.

(1) The operating limit and averaging time for each operating parameter identified for each control device, as determined, pursuant to § 65.713 or § 65.884(h), and the emission point(s) routed to each control device.

(2) The rationale for the established operating limit for each operating parameter for each emission point, including any data and calculations used to develop the operating limit and a description of why the operating limit indicates proper operation of the control device.

(3) A definition of the source's operating day for purposes of determining daily average values of monitored operating parameters. The definition must specify the times at which an operating day begins and ends. The operating day must cover a 24-hour period if operation is continuous. It may be from midnight to midnight or another daily period. For batch process operations, you may define the operating blocks, as specified in § 65.295, instead of an operating day.

(e) *Designating a halogen vent stream.* You must submit a list of the vent streams designated as halogenated, pursuant to § 65.702(c)(2).

(f) *Bag leak detection system documentation.* You must submit the bag leak detection system information specified in § 65.762(f).

(g) *Biofilter thermocouple placement rationale.* If you use multiple thermocouples in representative locations throughout the biofilter bed to calculate the average biofilter bed temperature across these thermocouples prior to reducing the temperature data to 15 minute (or shorter) averages for purposes of establishing operating limits for the biofilter, you must submit rationale for their site selection.

§ 65.882 What information must I submit in my semiannual periodic report?

You must include the information listed in paragraphs (a) through (e) of this section, as applicable, in the semiannual periodic report that you submit, according to the procedures in § 65.225.

(a) The beginning and ending dates of the reporting period and the total operating time of the regulated source during the reporting period.

(b) For any information reported in a semiannual periodic report, provide the identification of the process unit and/or emission unit the information, using the same terminology and identification numbers used in the Notification of Compliance Status or subsequent periodic report.

(c) For CEMS and CPMS, include the information specified in paragraphs (c)(1) through (6) of this section, as applicable.

(1) For each period when a CEMS or CPMS is out of control, inoperative or not operating properly, include the date, the start time and the stop time of the period.

(2) For each period when your CEMS or CPMS data does not meet the data availability requirements defined in § 65.710(e)(4) and (5), include the date, the start time and the stop time of the period.

(3) The daily average emission value, as calculated in § 65.855, for each day when the calculated daily average emission value indicated excess emissions, include the date, the start time and the stop time of the period.

(4) The block average emission value, as calculated in § 65.855, for each block when the calculated block average value indicated excess emissions, include the date, the start time and the stop time of the period.

(5) The daily average value of each monitored operating parameter, as calculated in § 65.855, that is outside the operating limit established according to § 65.713 and documented in your Notification of Compliance Status or subsequent periodic report, include the date, the start time and the stop time of the period.

(6) The block average value of each monitored operating parameter, as calculated in § 65.855, that is outside the operating limit established according to § 65.713 and documented in your Notification of Compliance Status or subsequent periodic report, include the date, the start time and the stop time of the period.

(d) For closed vent systems, include the records of periods when vent steam flow was detected in the bypass line or diverted from the control device, a flow indicator was not operating or a bypass of the system was indicated, as specified in § 65.860(h).

(e) All records of daily and operating block averages, required in § 65.860(a)(4).

§ 65.884 What other reports must I submit and when?

You must submit the reports specified in paragraphs (a) through (j) of this section, as applicable, according to the procedures in § 65.225. You must provide the identification of the process unit and/or emission unit information, using the same terminology and identification numbers used in the Notification of Compliance Status or subsequent report.

(a) *Performance test notification.* At least 60 calendar days before a performance test is initially scheduled, you must notify the Administrator of your intention to conduct a performance test to allow the Administrator to have an observer present during the test. You must include the performance test plan required in § 65.820(b) with your notification to allow the Administrator time to review and approve the performance test plan. For batch process operations, you must include the emission profile(s) required in § 65.822(c). If you are unable to conduct the performance test on the date specified in a performance test notification, due to unforeseeable circumstances beyond your control, you must notify the Administrator as soon as practicable and without delay prior to the scheduled performance test date and specify the date when the performance test is rescheduled.

(b) *Submission of performance test reports.* Within 60 calendar days of completing a performance test, you must submit a performance test report with the information specified in § 65.860(c)(3).

(c) *CEMS performance evaluation notification and monitoring plan.* If you use a CEMS, you must submit a notification of the date the CEMS performance evaluation under § 65.711(c) is scheduled to begin, along with the CEMS performance evaluation and monitoring plan. The notification and plan must be submitted according to the schedule specified in paragraphs (c)(1) through (3) of this section.

(1) If you are conducting a performance test, you must submit the notification and plan simultaneously with the notification of the performance test date required in paragraph (a) of this section.

(2) If you are not conducting a performance test, you must submit the notification and plan at least 60

calendar days before the CEMS performance evaluation is scheduled to begin, as specified by the referencing subpart, or on a mutually agreed upon date.

(3) If you are unable to conduct the CEMS performance evaluation on the date specified in the notification specified in paragraph (c)(1) or (2) of this section, due to unforeseeable circumstances beyond your control, you must notify the Administrator as soon as practicable and without delay prior to the scheduled CEMS performance evaluation date and specify the date when the evaluation is rescheduled.

(d) *Submission of CEMS performance evaluations.* Within 60 calendar days of completing a CEMS performance evaluation, pursuant to § 65.711, and your CEMS performance evaluation and monitoring plan, you must submit the results of the CEMS performance evaluation.

(e) *CPMS monitoring plan submittal.* If you use a CPMS, you must submit the CPMS monitoring plan required in § 65.712(c), 60 days prior to the performance test, with the performance test notification and test plan specified in paragraph (a) of this section, except as specified in paragraphs (e)(1) through (3) of this section.

(1) If no performance test is required, submit your CPMS monitoring plan 60 days prior to your compliance date.

(2) If you submit an application specified in § 65.884(f) to use a prior performance test, submit your CPMS monitoring plan with the application to use the prior performance test.

(3) If you are making a change to a previously submitted monitoring plan, submit the revised monitoring plan 60 days before you intend to implement the revised plan.

(f) *Application to substitute a prior performance test.* You must submit an application to the Administrator for approval if you would like to substitute a prior performance test for an initial performance test, as allowed by § 65.702(e)(4). The application must be submitted no later than 90 days before the performance test is required. The application must include all documentation required by the applicable test methods specified in § 65.825 and all documentation of monitoring during the performance test that supports the operating parameters for which you establish limits. Your application must document that the prior test was conducted using the same sample times or volumes required by the referencing subpart and the methods required by the referencing subpart or Table 5 of this subpart. Your prior test report must include all of the information required by § 65.860(c). The application must also include information demonstrating that no process changes were made since the test, or that the results of the performance test or compliance assessment reliably demonstrates compliance despite process changes.

(g) *Batch pre-compliance report.* You must submit a batch pre-compliance report, which includes a description of the test conditions, data, calculations and other information used to establish operating limits according to § 65.713 for all batch operations, and a description of why each operating limit indicates the control device is meeting the specified emission limit of the referencing subpart during each specific emission episode. If you use an engineering assessment, as specified in § 65.835(b)(2), you must also include data or other information supporting a finding that the emissions estimation equations in § 65.835 are inappropriate. You must submit the batch pre-compliance report according to the schedule in paragraph (g)(1) of this section. The Administrator will approve or disapprove your report, as specified in paragraph (g)(2) of this section. You must notify the Administrator of any changes to the report according to the schedule in paragraph (g)(3) of this section.

(1) You must submit the report for approval at least 6 months prior to the compliance date of the referencing subpart, or with the permit application for modification, construction or reconstruction.

(2) We will either approve or disapprove the report within 90 days after we receive it. If we disapprove the report, you must still be in compliance with the emission limitations and work practice standards of the referencing subpart by the compliance date of the referencing subpart.

(3) To change any of the information submitted in the report, you must submit a revised report 60 days before the planned change is to be implemented in order to allow time for review and approval by the administrator before the change is implemented.

(h) *Requests for approval of different operating parameters.* You may request approval to monitor a different operating parameter than those specified for control devices in this subpart; and you must propose operating parameters for any control device not specified in this subpart, as specified in § 65.800. These requests must contain the information specified in paragraphs (h)(1) through (8) of this section, and you must comply with paragraph (h)(9) of this section.

(1) A description of the operating parameter(s) to be monitored to ensure the control technology or pollution prevention measure is operated in conformance with its design and achieves the emission limit, as specified in the referencing subpart. Specify the applicable averaging time(s) for the operating parameter(s) and an explanation of the criteria used to select the operating parameter(s) and averaging times.

(2) A description of the methods and procedures that will be used to demonstrate that the operating parameter indicates proper operation of the control device and the schedule for this demonstration.

(3) For parameter monitoring that does not generate continuous data, include the monitoring results that demonstrate that the device is outside the established limit.

(4) The frequency and content of monitoring, recording and reporting.

(5) If continuous records are specified, indicate whether the provisions of §§ 65.712 and 65.713 apply.

(6) The rationale for the proposed monitoring, recordkeeping and reporting system.

(7) If your request includes a proposal to use a control device other than those listed in this subpart, your request must include a description of the proposed control device and your proposed operating parameters.

(8) A statement that you will establish an operating limit for the monitored operating parameter(s) as part of the Notification of Compliance Status or a semiannual periodic report.

(9) You must submit the request for this approval according to the procedures specified for alternative monitoring in § 65.240.

(i) *Changes in CMS, processes or controls.* For changes specified in § 65.702(f), or whenever you change any of the information submitted in the Notification of Compliance Status Report or a subsequent report, you must report the information specified in paragraphs (i)(1) and (2) of this section, within 30 days of completing the process change.

(1) A description of the change.

(2) Revisions to any of the information reported in the Notification of Compliance Status Report specified in § 65.880, or subsequent report.

(j) *New operating scenarios for batch operations.* For batch operations, you must report the information specified in § 65.860(f)(2) for each new operating scenario that has not been reported in the Notification of Compliance Status or

a previous report, within 30 days of implementing the new operating scenario.

List of Tables in Subpart M of Part 65

TABLE 1 TO SUBPART M OF PART 65—CEMS MONITORING

For all control devices, you must . . .	If . . .	At this location . . .	To . . .	And the monitoring equipment must . . .
Install CEMS ..	The referencing subpart requires the use of CEMS or you choose not to conduct the monitoring according to Table 2 to this subpart.	At a spot representative of the exhaust stream of the control device.	Measure the compound required by the referencing subpart.	Be capable of measuring the compounds required by the referencing subpart; and meet the requirements in § 65.711.

TABLE 2 TO SUBPART M OF PART 65—MONITORING EQUIPMENT AS AN ALTERNATIVE TO CEMS MONITORING

You must do the following . . .	If . . .	And you must monitor . . .	And . . .
Small Boilers and Process Heaters			
Install a CPMS for temperature in the fire box.		Temperature in the firebox.	
Thermal Oxidizers			
Install a CPMS for temperature in the fire box or in the ductwork immediately downstream of the fire box in a position before any substantial heat exchange occurs.		Temperature in the firebox or ductwork.	
Catalytic Oxidizers			
Install a CPMS for temperature in the gas stream immediately before and after the catalyst bed.	You choose to monitor the temperature differential across the catalyst bed, rather than temperature at the inlet of the catalyst bed.	Temperature differential across the catalyst bed.	
Install a CPMS for temperature at the inlet of the catalyst bed.	You choose to monitor the temperature at the inlet of the catalyst bed, rather than the temperature differential across the catalyst bed; and the temperature differential between the inlet and outlet of the catalytic oxidizer during normal operating conditions is less than 10 degrees Celsius (18 degrees Fahrenheit).	Temperature at the inlet of the catalyst bed.	You must conduct catalyst checks according to § 65.728(a)(1) and (2).
All Absorbers			
Install a CPMS for liquid flow at the inlet of the absorber.	You choose to monitor only the influent liquid flow, rather than the liquid-to-gas ratio.	Influent liquid flow.	
Install CPMS for liquid and gas flow at the inlet of the absorber.	You choose to monitor the liquid-to-gas ratio, rather than only the influent liquid flow; and you want the ability to lower liquid flow with changes in gas flow.	Liquid-to-gas ratio as determined by dividing the influent liquid flow rate by the inlet gas flow rate. The units of measure must be consistent with those used to calculate this ratio during the performance test.	You must measure the gas stream by: (A) Measuring the gas stream flow at the absorber inlet; or (B) Using the design blower capacity, with appropriate adjustments for pressure drop; or (C) If the absorber is subject to regulations in 40 CFR parts 264 through 266 that require a determination of the liquid-to-gas ratio prior to the applicable compliance date, as specified in a referencing subpart, determine the gas stream flow by the method that had been used to comply with those regulations if it is still representative.

TABLE 2 TO SUBPART M OF PART 65—MONITORING EQUIPMENT AS AN ALTERNATIVE TO CEMS MONITORING—Continued

You must do the following . . .	If . . .	And you must monitor . . .	And . . .
Install CPMS for pressure at the gas stream inlet and outlet of the absorber.	Your pressure drop through the absorber is greater than 5 inches of water.	Pressure drop through the absorber.	
Acid Gas Absorbers			
Install a CPMS for pH at the absorber liquid effluent.		pH of the absorber liquid effluent.	
Absorbers Controlling Particulate and/or Metal Regulated Materials			
Install CPMS for temperature at the absorber gas stream outlet.	Your pressure drop through the absorber is 5 inches of water or less.	Exit gas temperature of the absorber.	
Install CPMS for temperature at the absorber gas stream inlet.	Your pressure drop through the absorber is 5 inches of water or less, and you choose not to monitor the specific gravity of liquid stream at inlet and exit of the absorber, or liquid inlet feed pressure of the absorber.	Inlet gas temperature of the absorber.	
Install CPMS for specific gravity at the absorber liquid stream inlet and outlet.	The difference between the specific gravity of the saturated scrubbing fluid and specific gravity of the fresh scrubbing fluid is greater than 0.02 specific gravity units; and your pressure drop through the absorber is 5 inches of water or less; and you choose not to monitor the inlet gas temperature of the absorber, or liquid inlet feed pressure of the absorber.	Specific gravity of liquid stream at inlet and exit of the absorber.	
Install CPMS for pressure at the absorber liquid stream inlet.	Your pressure drop through the absorber is 5 inches of water or less, and you choose not to monitor the inlet gas temperature of the absorber, or specific gravity of liquid stream at inlet and exit of the absorber.	Liquid inlet feed pressure of the absorber.	
Absorbers Not Controlling Acid Gas, Particulates and Metal Regulated Materials			
Install CPMS for chemical strength at the inlet liquid stream of the absorber.	You are using a scrubbing liquid other than water.	Chemical strength at the inlet liquid stream to the absorber.	
Install CPMS for flow rate of the chemical at the chemical stream inlet.	You are using a scrubbing liquid other than water.	Chemical flow rate.	
Install CPMS for temperature at the absorber gas stream outlet.	You are using water as the scrubbing liquid; and your pressure drop through the absorber is 5 inches of water or less.	Exit gas temperature of the absorber.	
Install CPMS for temperature at the absorber gas stream inlet.	You are using water as the scrubbing liquid; and your pressure drop through the absorber is 5 inches of water or less; and you choose not to monitor the liquid inlet feed pressure of the absorber.	Inlet gas temperature of the absorber.	
Install CPMS for pressure at the absorber liquid stream inlet.	You are using water as the scrubbing liquid; and your pressure drop through the absorber is 5 inches of water or less; and you choose not to monitor the inlet gas temperature of the absorber.	Liquid inlet feed pressure of the absorber.	

TABLE 2 TO SUBPART M OF PART 65—MONITORING EQUIPMENT AS AN ALTERNATIVE TO CEMS MONITORING—Continued

You must do the following . . .	If . . .	And you must monitor . . .	And . . .
Adsorbers Regenerated On Site			
Install a CPMS for mass flow	You operate a non-vacuum regeneration system.	Total regeneration stream mass flow for each regeneration cycle.	
Install a CPMS for temperature in the adsorber bed..	You operate a non-vacuum regeneration system.	The adsorber bed temperature after each regeneration and within 15 minutes of completing any temperature regulation (cooling or warming to bring bed temperature closer to vent gas temperature) portion of the regeneration cycle.	
Install a CPMS for temperature in the adsorber bed..	You operate a non-vacuum regeneration system.	The adsorber bed temperature during regeneration, except during any temperature regulating (cooling or warming to bring bed temperature closer to vent gas temperature) portion of the regeneration cycle.	
Install a CPMS for pressure in the vacuum pump suction line.	You operate a vacuum regeneration system.	Vacuum level for each minute during regeneration. You must establish a minimum target and a length of time at which the vacuum must be below the minimum target during regeneration.	
Install a frequency monitoring device.	You operate any type of regeneration system.	Regeneration frequency (i.e., operating time since last regeneration) and duration.	
Non-Regenerative Adsorbers			
Install a system of dual adsorber units in series.		The concentration of volatile organic compounds or regulated material(s) through a sample port at the outlet of the first adsorber bed in series.	Measure the concentration of volatile organic compounds through a sample port using a portable analyzer, in accordance with Method 21 of 40 CFR part 60, appendix A–7, for open-ended lines. Measure the concentration of regulated material(s) through a sample port using either: Chromatographic analysis and Method 18 of 40 CFR part 60, appendix A using a calibration gas or gas mixture containing the compounds present in the adsorber vent gas; or a flame ionization analyzer and Method 25A at 40 CFR part 60, appendix A–7 using propane as the calibration gas.
Condensers			
Install a CPMS for temperature in the condensate receiver.		Temperature of the condensate receiver.	
Biofilters			
Install CPMS for temperature in the biofilter bed.		Biofilter bed temperature	You must include the rationale for the placement of the CPMS for temperature in the Notification of Compliance Status Report, pursuant to § 65.880(g).
Install CPMS for moisture content in the biofilter bed.		Biofilter bed moisture content.	
Install CPMS for pressure at the inlet and outlet of the biofilter bed.		Pressure drop through the biofilter bed.	

TABLE 2 TO SUBPART M OF PART 65—MONITORING EQUIPMENT AS AN ALTERNATIVE TO CEMS MONITORING—Continued

You must do the following . . .	If . . .	And you must monitor . . .	And . . .
Sorbent Injection			
Install a CPMS for flow		Sorbent injection rate.	
Install a CPMS for flow		Sorbent injection carrier gas flow rate.	
Install a CPMS for temperature	You are operating a combustion device upstream of the sorbent injection system.	Temperature in the ductwork immediately downstream of the fire box of the combustion device.	
Install a CPMS for temperature	You are using a particulate matter control device upstream of the adsorbent injection system.	Temperature in the ductwork immediately downstream of the particulate matter control device.	

TABLE 3 TO SUBPART M OF PART 65—OPERATING PARAMETERS, OPERATING LIMITS AND DATA MONITORING, RECORDKEEPING AND COMPLIANCE FREQUENCIES

For the operating parameter applicable to you, as specified in Table 2 to this subpart, you must monitor . . .	Establish the following operating limit during your performance test . . .	Monitor, record, and demonstrate continuous compliance using these minimum frequencies.		
		Data measurement	Data recording	Data averaging period for compliance
Small Boilers and Process Heaters				
Temperature in the fire box	Minimum temperature	Continuous	Every 15 minutes	Daily.
Thermal Oxidizers				
Temperature in the fire box or downstream ductwork prior to heat exchange.	Minimum temperature	Continuous	Every 15 minutes	Daily.
Catalytic Oxidizers				
Temperature differential across catalyst bed.	Minimum temperature differential.	Continuous	Every 15 minutes	Daily.
Temperature at the inlet to catalyst bed and condition of the catalyst.	Minimum inlet temperature and catalyst condition as specified in § 65.728(a)(1) and (2).	Continuous for temperature; frequency determined in accordance with § 65.728(a)(1)(ii) for sampling and analysis of the catalyst; and annual for internal inspections of catalyst bed.	Every 15 minutes for temperature; frequency determined in accordance with § 65.728(a)(1)(ii) for sampling and analysis of the catalyst; and annual for internal inspections of catalyst bed.	Daily for temperature; frequency determined in accordance with § 65.728(a)(1)(ii) for sampling and analysis of the catalyst; and annual for internal inspections of catalyst bed.
All Absorbers				
Influent liquid flow	Minimum inlet liquid flow ...	Continuous	Every 15 minutes	Daily.
Influent liquid flow rate and gas stream flow rate.	Minimum influent liquid-to-gas ratio.	Continuous	Every 15 minutes	Daily.
Pressure drop	Pressure drop range	Continuous	Every 15 minutes	Daily.
Acid Gas Absorbers				
pH of effluent liquid	Minimum pH	Continuous	Every 15 minutes	Daily.
Absorbers Controlling Particulate and/or Metal Regulated Materials				
Exit gas temperature	Maximum exit gas temperature.	Continuous	Every 15 minutes	Daily.
Inlet gas temperature	Temperature range of temperature difference between inlet and exit gas.	Continuous	Every 15 minutes	Daily.
Specific gravity	Range of specific gravity difference between inlet and outlet scrubbing liquid.	Continuous	Every 15 minutes	Daily.
Liquid feed pressure	Pressure range	Continuous	Every 15 minutes	Daily.

TABLE 3 TO SUBPART M OF PART 65—OPERATING PARAMETERS, OPERATING LIMITS AND DATA MONITORING, RECORDKEEPING AND COMPLIANCE FREQUENCIES—Continued

For the operating parameter applicable to you, as specified in Table 2 to this subpart, you must monitor . . .	Establish the following operating limit during your performance test . . .	Monitor, record, and demonstrate continuous compliance using these minimum frequencies.		
		Data measurement	Data recording	Data averaging period for compliance
Absorbers Not Controlling Acid Gas, Particulates, and Metal Regulated Materials				
Chemical strength of influent liquid stream.	Minimum chemical strength.	Continuous	Every 15 minutes	Daily.
Chemical flow rate	Minimum flow rate	Continuous	Every 15 minutes	Daily.
Exit gas temperature	Maximum exit gas temperature.	Continuous	Every 15 minutes	Daily.
Inlet gas temperature	Temperature range of temperature difference between inlet and exit gas.	Continuous	Every 15 minutes	Daily.
Liquid feed pressure	Pressure range	Continuous	Every 15 minutes	Daily.
Adsorbers Regenerated On Site				
Total regeneration stream mass flow for each generation cycle.	Minimum total flow per regeneration cycle.	Continuous	Every 15 minutes during regeneration cycle.	Total flow for each regeneration cycle.
Adsorber bed temperature after each regeneration.	Maximum temperature	Continuously after regeneration and within 15 minutes of completing any temperature regulation.	Every 15 minutes after regeneration and within 15 minutes of completing any temperature regulation.	Daily.
Adsorber bed temperature during regeneration.	Minimum temperature	Continuously during regeneration except during any temperature regulating portion of the regeneration cycle.	Every 15 minutes during regeneration cycle.	Average of regeneration cycle.
Vacuum and duration of regeneration.	Minimum vacuum and period of time for regeneration.	Continuous	Every 15 minutes during regeneration cycle.	Average vacuum and duration of regeneration.
Regeneration frequency	Minimum regeneration frequency and duration.	Continuous	Every 15 minutes during regeneration cycle.	Date and time of regeneration start and stop.
Adsorber operation valve sequencing and cycle time.	Correct valve sequencing and minimum cycle time.	Daily	Daily	N/A.
Non-Regenerative Adsorbers				
Outlet VOC concentration or regulated material concentration of the first adsorber bed in series.	Breakthrough limit as determined by the referencing subpart.	Daily, except as provided in § 65.744(a)(2).	Daily, except as provided in § 65.744(a)(2).	N/A.
Average adsorber bed life	N/A	Daily until breakthrough for 3 adsorber bed changeouts.	Calculated average bed life.	N/A.
Condensers				
Gas temperature at the exit of the condenser.	Maximum outlet gas temperature.	Continuous	Every 15 minutes	Daily.
Sorbent Injection				
Sorbent injection rate	Minimum injection rate	Continuous	Every 15 minutes	Daily.
Sorbent injection carrier gas flow rate.	Minimum carrier gas flow rate.	Continuous	Every 15 minutes	Daily.
Temperature in the ductwork immediately downstream of the firebox of the combustion device.	Minimum temperature	Continuous	Every 15 minutes	Daily.
Temperature in the ductwork immediately downstream of the particulate matter control device.	Minimum temperature	Continuous	Every 15 minutes	Daily.

TABLE 3 TO SUBPART M OF PART 65—OPERATING PARAMETERS, OPERATING LIMITS AND DATA MONITORING, RECORDKEEPING AND COMPLIANCE FREQUENCIES—Continued

For the operating parameter applicable to you, as specified in Table 2 to this subpart, you must monitor . . .	Establish the following operating limit during your performance test . . .	Monitor, record, and demonstrate continuous compliance using these minimum frequencies.		
		Data measurement	Data recording	Data averaging period for compliance
Fabric Filters				
Alarm time	Maximum alarm time is not established on a site-specific basis but is specified in § 65.762(a)(9).	Continuous	Each date and time of alarm start and stop.	Maximum alarm time specified in § 65.762(a)(9).
Biofilter				
Biofilter bed temperature	Temperature range	Continuous	Every 15 minutes; if you use multiple temperature monitoring devices, you must calculate the average biofilter bed temperature across the temperature devices prior to reducing the temperature data to 15 minute averages.	Daily.
Biofilter bed moisture content.	Moisture content range	Continuous	Every 15 minutes	Daily.
Pressure drop through the biofilter bed.	Minimum pressure drop	Continuous	Every 15 minutes	Daily.

TABLE 4 TO SUBPART M OF PART 65—CALIBRATION AND QUALITY CONTROL REQUIREMENTS FOR CPMS

If you monitor this parameter . . .	Your accuracy requirements are . . .	Your calibration requirements are . . .
Temperature	±1 percent over the normal range of temperature measured or 2.8 degrees Celsius (5 degrees Fahrenheit), whichever is greater, for non-cryogenic temperature ranges. ±2.5 percent over the normal range of temperature measured or 2.8 degrees Celsius (5 degrees Fahrenheit), whichever is greater, for cryogenic temperature ranges.	Performance evaluation annually and following any period of more than 24 hours throughout which the temperature exceeded the maximum rated temperature of the sensor, or the data recorder was off scale. Visual inspections and checks of CPMS operation every 3 months, unless the CPMS has a redundant temperature sensor. Select a representative measurement location.
Flow Rate	±2 percent over the normal range of flow measured or 1.9 liters per minute (0.5 gallons per minute), whichever is greater, for liquid flow rate. ±2 percent over the normal range of flow measured or 28 liters per minute (10 cubic feet per minute), whichever is greater, for gas flow rate. ±2 percent over the normal range measured for mass flow rate.	Performance evaluation annually and following any period of more than 24 hours throughout which the flow rate exceeded the maximum rated flow rate of the sensor, or the data recorder was off scale. Checks of all mechanical connections for leakage monthly. Visual inspections and checks of CPMS operation every 3 months, unless the CPMS has a redundant flow sensor. Select a representative measurement location where swirling flow or abnormal velocity distributions due to upstream and downstream disturbances at the point of measurement are minimized.
pH	±0.2 pH units.	Performance check daily. Performance evaluation, including a two-point calibration with one of the two buffer solutions having a pH within 1 of the pH of the operating limit, every 3 months. Visual inspections and checks of CPMS operation monthly, unless the CPMS has a redundant pH sensor. Select a measurement location that provides a representative sample of absorber effluent and that ensures the fluid is properly mixed.

TABLE 4 TO SUBPART M OF PART 65—CALIBRATION AND QUALITY CONTROL REQUIREMENTS FOR CPMS—Continued

If you monitor this parameter . . .	Your accuracy requirements are . . .	Your calibration requirements are . . .
Pressure	±1 percent over the normal range measured or 0.12 kilopascals (0.5 inches of water column), whichever is greater.	Checks for obstructions at least once each process operating day (*e.g.,* pressure tap pluggage). Performance evaluation annually and following any period of more than 24 hours throughout which the pressure exceeded the maximum rated pressure of the sensor, or the data recorder was off scale. Checks of all mechanical connections for leakage monthly. Visual inspection of all components for integrity, oxidation and galvanic corrosion every 3 months, unless the CPMS has a redundant pressure sensor. Select a representative measurement location that minimizes or eliminates pulsating pressure, vibration, and internal and external corrosion.
Sorbent Injection Rate	±5 percent over the normal range measured	Performance evaluation annually. Visual inspections and checks of CPMS operation every 3 months, unless the CPMS has a redundant sensor. Select a representative measurement location that provides measurement of total sorbent injection.

TABLE 5 TO SUBPART M OF PART 65—METHODS AND PROCEDURES FOR CONDUCTING PERFORMANCE TESTS FOR VENT STREAMS

For each control device used to meet . . .	You must use . . .	And you must . . .
Specific organic regulated material compound outlet concentration or percent reduction emission limit specified in a referencing subpart.	Method 18 at 40 CFR part 60, appendix A–6; or. ASTM D6420–99(2010) Standard Test Method for Determination of Gaseous Organic Compounds by Direct Interface Gas Chromatography-Mass Spectrometry. (incorporated by reference, see § 65.265), under the conditions specified in § 65.825(a); or Method 320 at 40 CFR part 63, appendix A under the conditions specified in § 65.825(c).	Follow the exceptions provided in § 65.825(d) and (e), as applicable.
A total organic compounds emission limit (either outlet concentration or percent reduction) specified in a referencing subpart.	Method 25A at 40 CFR part 60, appendix A–7 under the conditions specified in § 65.825(b).	Follow the exceptions provided in § 65.825(d) and (e), as applicable.
A metal regulated material emission limit specified in a referencing subpart.	Method 29 at 40 CFR part 60, appendix A–8.	
A filterable particulate matter emission limit specified in a referencing subpart.	Method 5 at 40 CFR part 60, appendix A–3.	
A total (filterable plus condensable) particulate matter emission limit specified in a referencing subpart.	Method 5 at 40 CFR part 60, appendix A–3 and Method 202 at 40 CFR part 51, appendix M.	
A total (filterable plus condensable) fine particulate matter ($PM_{2.5}$) emission limit specified in a referencing subpart.	Methods 201A and 202 at 40 CFR part 51, appendix M, if no entrained water droplets exist in the stack. If the stack contains entrained water droplets (e.g., immediately after a wet scrubber), use Method 5 at 40 CFR part 60, appendix A–3 with a filter temperature of 320 degrees Fahrenheit ± 25 degrees Fahrenheit and Method 202 at 40 CFR part 51, appendix M.	
A hydrogen halide and halogen emission limit specified in a referencing subpart (either outlet concentration or percent reduction).	Method 26 at 40 CFR part 60, appendix A–8, under conditions specified in § 65.825(f); or Method 26A at 40 CFR part 60, appendix A–8; or Method 320 at 40 CFR part 63, appendix A under the conditions specified in § 65.825(c).	
Halogen atom mass emission rate or percent reduction emission limit specified in a referencing subpart.	Method 26 at 40 CFR part 60, under conditions specified in § 65.825(f); or 26A at 40 CFR part 60, appendix A–8; or Method 320 at 40 CFR part 63, appendix A under the conditions specified in § 65.825(c); and Method 18 at 40 CFR part 60, appendix A–6.	
A dioxins/furans emission limit specified in a referencing subpart.	Method 23 at 40 CFR part 60, appendix A–7.	

TABLE 5 TO SUBPART M OF PART 65—METHODS AND PROCEDURES FOR CONDUCTING PERFORMANCE TESTS FOR VENT STREAMS—Continued

For each control device used to meet . . .	You must use . . .	And you must . . .
An emission limit for a batch and/or continuous process operation.	Method 2, 2A, 2C, 2D, 2F or 2G at 40 CFR part 60, appendix A–2.	Determine gas velocity and volumetric flow rate.
	Method 3, 3A or 3B at 40 CFR part 60, appendix A–2; or ANSI/ASME PTC 19.10–1981, Flue and Exhaust Gas Analyses [Part 10, Instruments and Apparatus] (incorporated by reference, see § 65.265).	Conduct gas molecular weight analysis and correction to standard percent oxygen (if applicable).
	Method 4 at 40 CFR part 60, appendix A–3 ...	Measure gas moisture content.

[FR Doc. 2012–5760 Filed 3–23–12; 8:45 am]

BILLING CODE 6560–50–P

FEDERAL REGISTER

Vol. 77 Monday,
No. 58 March 26, 2012

Part IV

Environmental Protection Agency

40 CFR Part 52
Approval and Promulgation of Implementation Plans; State of Colorado; Regional Haze State Implementation Plan; Proposed Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 52

[EPA–R08–OAR–2011–0770, FRL–9650–7]

Approval and Promulgation of Implementation Plans; State of Colorado; Regional Haze State Implementation Plan

AGENCY: Environmental Protection Agency.

ACTION: Proposed rule.

SUMMARY: EPA is proposing to approve a State implementation plan (SIP) revision submitted by the State of Colorado on May 25, 2011 that addresses regional haze (RH). EPA is proposing to determine that the plan submitted by Colorado satisfies the requirements of the Clean Air Act (CAA or ''the Act'') and our rules that require states to prevent any future and remedy any existing man-made impairment of visibility in mandatory Class I areas caused by emissions of air pollutants from numerous sources located over a wide geographic area (also referred to as the ''regional haze program''). States are required to assure reasonable progress toward the national goal of achieving natural visibility conditions in Class I areas. EPA is taking this action pursuant to section 110 of the CAA.

DATES: Written comments must be received at the address below on or before May 25, 2012.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R08–OAR–2011–0770, by one of the following methods:

- *http://www.regulations.gov.* Follow the on-line instructions for submitting comments.
- *Email: dygowski.laurel@epa.gov.*
- *Fax:* (303) 312–6064 (please alert the individual listed in the **FOR FURTHER INFORMATION CONTACT** if you are faxing comments).
- *Mail:* Carl Daly, Director, Air Program, Environmental Protection Agency (EPA), Region 8, Mailcode 8P–AR, 1595 Wynkoop Street, Denver, Colorado 80202–1129.
- *Hand Delivery:* Carl Daly, Director, Air Program, Environmental Protection Agency (EPA), Region 8, Mailcode 8P–AR, 1595 Wynkoop, Denver, Colorado 80202–1129. Such deliveries are only accepted Monday through Friday, 8 a.m. to 4:30 p.m., excluding Federal holidays. Special arrangements should be made for deliveries of boxed information.

Instructions: Direct your comments to Docket ID No. EPA–R08–OAR–2011–0770. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *http://www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *http://www.regulations.gov* or email. The *http://www.regulations.gov* Web site is an ''anonymous access'' system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to EPA, without going through *http://www.regulations.gov,* your email address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. For additional instructions on submitting comments, go to Section I, ''General Information'' of the **SUPPLEMENTARY INFORMATION** section of this document.

Docket: All documents in the docket are listed in the *http://www.regulations.gov* index. Although listed in the index, some information is not publicly available, e.g., CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly-available docket materials are available either electronically in *http://www.regulations.gov* or in hard copy at the Air Program, Environmental Protection Agency (EPA), Region 8, Mailcode 8P–AR, 1595 Wynkoop, Denver, Colorado 80202–1129. EPA requests that if at all possible, you contact the individual listed in the **FOR FURTHER INFORMATION CONTACT** section to view the hard copy of the docket. You may view the hard copy of the docket Monday through Friday, 8 a.m. to 4 p.m., excluding Federal holidays.

FOR FURTHER INFORMATION CONTACT: Laurel Dygowski, Air Program, U.S. Environmental Protection Agency, Region 8, Mailcode 8P–AR, 1595 Wynkoop, Denver, Colorado 80202–1129, (303) 312–6144, *dygowski.laurel@epa.gov.*

Definitions

For the purpose of this document, we are giving meaning to certain words or initials as follows:

i. The words or initials *Act* or *CAA* mean or refer to the Clean Air Act, unless the context indicates otherwise.

ii. The initials *BACT* mean or refer to Best Available Control Technology.

iii. The initials *BART* mean or refer to Best Available Retrofit Technology.

iv. The initials *CAMx* mean or refer to Comprehensive Air Quality Model.

v. The initials *CMAQ* mean or refer to Community Multi-Scale Air Quality modeling system.

vi. The initials *CEMS* mean or refer to continuous emission monitoring systems.

vii. The words *Colorado* and *State* mean the State of Colorado.

viii. The initials *EC* mean or refer to elemental carbon.

ix. The initials *EGUs* mean or refer to Electric Generating Units.

x. The words *EPA, we, us* or *our* mean or refer to the United States Environmental Protection Agency.

xi. The initials *FETS* mean or refer to the Fire Emission Tracking System.

xii. The initials *FGD* mean or refer to flue gas desulfurization.

xiii. The initials *FGR* mean or refer to external flue gas recirculation.

xiv. The initials *FLMs* mean or refer to Federal Land Managers.

xv. The initials *FS* mean or refer to the U.S. Forest Service.

xvi. The initials *IMPROVE* mean or refer to Interagency Monitoring of Protected Visual Environments monitoring network.

xvii. The initials *IWAQM* mean or refer to Interagency Workgroup on Air Quality Modeling.

xviii. The initials *LB* mean or refer to lean burn.

xix. The initials *LNB* mean or refer to low NO_X burner.

xx. The initials *LTS* mean or refer to Long-Term Strategy.

xxi. The initials *MACT* mean or refer to Maximum Achievable Control Technology.

xxii. The initials NH_3 mean or refer to ammonia.

xxiii. The initials NO_X mean or refer to nitrogen oxides.

xxiv. The initials *NPS* mean or refer to National Park Service.

xxv. The initials *OC* mean or refer to organic carbon.

xxvi. The initials *OFA* mean or refer to overfire air.

xxvii. The initials $PM_{2.5}$ mean or refer to particulate matter with an aerodynamic diameter of less than 2.5 micrometers.

xxviii. The initials PM_{10} mean or refer to particulate matter with an aerodynamic diameter of less than 10 micrometers.

xxix. The initials *PSAT* mean or refer to Particle Source Apportionment Technology

xxx. The initials *PSD* mean or refer to Prevention of Signification Deterioration.

xxxi. The initials *RAVI* mean or refer to Reasonably Attributable Visibility Impairment.

xxxii. The initials *RB* mean or refer to rich burn.

xxxiii. The initials *RH* mean or refer to regional haze.

xxxiv. The initials *RH SIP* mean or refer to Colorado's RH State Implementation Plan.

xxxv. The initials *RHR* mean or refer to the Regional Haze Rule.

xxxvi. The initials *RMC* mean or refer to the Regional Modeling Center at the University of California Riverside.

xxxvii. The initials *ROFA* mean or refer to rotating overfire air.

xxxviii. The initials *RP* mean or refer to Reasonable Progress.

xxxix. The initials *RPGs* mean or refer to Reasonable Progress Goals.

xl. The initials *RPOs* mean or refer to regional planning organizations.

xli. The initials *RRI* mean or refer to rich reagent injection.

xlii. The initials *SCR* mean or refer to selective catalytic reduction.

xliii. The initials *SIP* mean or refer to State Implementation Plan.

xliv. The initials *SNCR* mean or refer to selective non-catalytic reduction.

xlv. The initials SO_2 mean or refer to sulfur dioxide.

xlvi. The initials *SOFA* mean or refer to separated overfire air.

xlvii. The initials *TSD* mean or refer to Technical Support Document.

xlviii. The initials *URP* mean or refer to Uniform Rate of Progress.

xlix. The initials *VOC* mean or refer to volatile organic compounds.

l. The initials *WEP* mean or refer to Weighted Emissions Potential.

li. The initials *WRAP* mean or refer to the Western Regional Air Partnership.

I. General Information

A. What should I consider as I prepare my comments for EPA?

1. *Submitting CBI.* Do not submit CBI to EPA through *http://www.regulations.gov* or email. Clearly mark the part or all of the information that you claim to be CBI. For CBI information in a disk or CD ROM that you mail to EPA, mark the outside of the disk or CD ROM as CBI and then identify electronically within the disk or CD ROM the specific information that is claimed as CBI. In addition to one complete version of the comment that includes information claimed as CBI, a copy of the comment that does not contain the information claimed as CBI must be submitted for inclusion in the public docket. Information so marked will not be disclosed except in accordance with procedures set forth in 40 CFR part 2.

2. *Tips for Preparing Your Comments.* When submitting comments, remember to:

a. Identify the rulemaking by docket number and other identifying information (subject heading, **Federal Register** date and page number).

b. Follow directions—The agency may ask you to respond to specific questions or organize comments by referencing a Code of Federal Regulations (CFR) part or section number.

c. Explain why you agree or disagree; suggest alternatives and substitute language for your requested changes.

d. Describe any assumptions and provide any technical information and/or data that you used.

e. If you estimate potential costs or burdens, explain how you arrived at your estimate in sufficient detail to allow for it to be reproduced.

f. Provide specific examples to illustrate your concerns, and suggest alternatives.

g. Explain your views as clearly as possible, avoiding the use of profanity or personal threats.

h. Make sure to submit your comments by the comment period deadline identified.

II. What action is EPA proposing to take?

EPA is proposing to approve a SIP revision submitted by the State of Colorado on May 25, 2011 that addresses RH. In so doing, EPA is proposing to determine that the plan submitted by Colorado satisfies the requirements of 40 CFR 51.308.

III. Background

A. Regional Haze

RH is visibility impairment that is produced by a multitude of sources and

activities which are located across a broad geographic area and emit fine particles ($PM_{2.5}$) (e.g., sulfates, nitrates, organic carbon (OC), elemental carbon (EC), and soil dust), and their precursors (e.g., sulfur dioxide (SO_2), nitrogen oxides (NO_X), and in some cases, ammonia (NH_3) and volatile organic compounds (VOC)). Fine particle precursors react in the atmosphere to form $PM_{2.5}$, which impairs visibility by scattering and absorbing light. Visibility impairment reduces the clarity, color, and visible distance that one can see. $PM_{2.5}$ can also cause serious health effects and mortality in humans and contributes to environmental effects such as acid deposition and eutrophication.

Data from the existing visibility monitoring network, the ''Interagency Monitoring of Protected Visual Environments'' (IMPROVE) monitoring network, show that visibility impairment caused by air pollution occurs virtually all the time at most national park and wilderness areas. The average visual range [1] in many Class I areas (*i.e.,* national parks and memorial parks, wilderness areas, and international parks meeting certain size criteria) in the western United States is 100–150 kilometers, or about one-half to two-thirds of the visual range that would exist without anthropogenic air pollution. In most of the eastern Class I areas of the United States, the average visual range is less than 30 kilometers, or about one-fifth of the visual range that would exist under estimated natural conditions. 64 FR 35715 (July 1, 1999).

B. Requirements of the CAA and EPA's Regional Haze Rule (RHR)

In section 169A of the 1977 Amendments to the CAA, Congress created a program for protecting visibility in the nation's national parks and wilderness areas. This section of the CAA establishes as a national goal the ''prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Class I Federal areas [2] which impairment results from manmade air pollution.'' On December 2, 1980, EPA promulgated regulations to address visibility impairment in Class I areas that is ''reasonably attributable'' to a single source or small group of sources, *i.e.,* ''reasonably attributable visibility impairment.'' 45 FR 80084. These regulations represented the first phase in addressing visibility impairment. EPA deferred action on RH that emanates from a variety of sources until monitoring, modeling and scientific knowledge about the relationships between pollutants and visibility impairment were improved.

Congress added section 169B to the CAA in 1990 to address RH issues. EPA promulgated a rule to address RH on July 1, 1999. 64 FR 35714 (July 1, 1999), codified at 40 CFR part 51, subpart P. The RHR revised the existing visibility regulations to integrate into the regulation provisions addressing RH impairment and established a comprehensive visibility protection program for Class I areas. The requirements for RH, found at 40 CFR 51.308 and 51.309, are included in EPA's visibility protection regulations at 40 CFR 51.300–309. Some of the main elements of the RH requirements are summarized in section III of this preamble. The requirement to submit a RH SIP applies to all 50 states, the District of Columbia and the Virgin Islands. 40 CFR 51.308(b) requires states to submit the first implementation plan addressing RH visibility impairment no later than December 17, 2007.[3]

Few states submitted a RH SIP prior to the December 17, 2007 deadline, and on January 15, 2009, EPA found that 37 states (including Colorado), the District of Columbia, and the Virgin Islands, had failed to submit SIPs addressing the RH requirements. 74 FR 2392. Once EPA has found that a state has failed to make a required submission, EPA is required to promulgate a FIP within two years unless the state submits a SIP and the Agency approves it within the two-year period. CAA § 110(c)(1).

C. Roles of Agencies in Addressing Regional Haze

Successful implementation of the RH program will require long-term regional coordination among states, tribal governments and various federal agencies. As noted above, pollution affecting the air quality in Class I areas can be transported over long distances, even hundreds of kilometers. Therefore, to effectively address the problem of visibility impairment in Class I areas, states need to develop strategies in coordination with one another, taking into account the effect of emissions from one jurisdiction on the air quality in another.

Because the pollutants that lead to RH can originate from sources located across broad geographic areas, EPA has encouraged the states and tribes across the United States to address visibility impairment from a regional perspective. Five regional planning organizations (RPOs) were developed to address RH and related issues. The RPOs first evaluated technical information to better understand how their states and tribes impact Class I areas across the country, and then pursued the development of regional strategies to reduce emissions of particulate matter (PM) and other pollutants leading to RH.

The Western Regional Air Partnership (WRAP) RPO is a collaborative effort of state governments, tribal governments, and various federal agencies established to initiate and coordinate activities associated with the management of RH, visibility and other air quality issues in the western United States. WRAP member State governments include: Alaska, Arizona, California, Colorado, Idaho, Montana, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming. Tribal members include Campo Band of Kumeyaay Indians, Confederated Salish and Kootenai Tribes, Cortina Indian Rancheria, Hopi Tribe, Hualapai Nation of the Grand Canyon, Native Village of Shungnak, Nez Perce Tribe, Northern Cheyenne Tribe, Pueblo of Acoma, Pueblo of San Felipe, and Shoshone-Bannock Tribes of Fort Hall.

IV. Requirements for Regional Haze SIPs

The following is a summary of the requirements of the RHR. See 40 CFR 51.308 for further detail regarding the requirements of the rule.

A. The CAA and the Regional Haze Rule

RH SIPs must assure reasonable progress (RP) towards the national goal of achieving natural visibility conditions in Class I areas. Section 169A of the CAA and EPA's implementing regulations require states to establish long-term strategies for making RP toward meeting this goal. Implementation plans must also give

[1] Visual range is the greatest distance, in kilometers or miles, at which a dark object can be viewed against the sky.

[2] Areas designated as mandatory Class I Federal areas consist of national parks exceeding 6000 acres, wilderness areas and national memorial parks exceeding 5000 acres, and all international parks that were in existence on August 7, 1977. 42 U.S.C. 7472(a). In accordance with section 169A of the CAA, EPA, in consultation with the Department of Interior, promulgated a list of 156 areas where visibility is identified as an important value. 44 FR 69122 (November 30, 1979). The extent of a mandatory Class I area includes subsequent changes in boundaries, such as park expansions. 42 U.S.C. 7472(a). Although states and tribes may designate as Class I additional areas which they consider to have visibility as an important value, the requirements of the visibility program set forth in section 169A of the CAA apply only to ''mandatory Class I Federal areas.'' Each mandatory Class I Federal area is the responsibility of a ''Federal Land Manager.'' 42 U.S.C. 7602(i). When we use the term ''Class I area'' in this action, we mean a ''mandatory Class I Federal area.''

[3] EPA's regional haze regulations require subsequent updates to the regional haze SIPs. 40 CFR 51.308(g)–(i).

specific attention to certain stationary sources that were in existence on August 7, 1977, but were not in operation before August 7, 1962, and require these sources, where appropriate, to install BART controls for the purpose of eliminating or reducing visibility impairment. The specific RH SIP requirements are discussed in further detail below.

B. Determination of Baseline, Natural, and Current Visibility Conditions

The RHR establishes the deciview (dv) as the principal metric or unit for expressing visibility. See 70 FR 39104, 39118. This visibility metric expresses uniform changes in the degree of haze in terms of common increments across the entire range of visibility conditions, from pristine to extremely hazy conditions. Visibility expressed in dvs is determined by using air quality measurements to estimate light extinction and then transforming the value of light extinction using a logarithm function. The dv is a more useful measure for tracking progress in improving visibility than light extinction itself because each dv change is an equal incremental change in visibility perceived by the human eye. Most people can detect a change in visibility at one dv.[4]

The dv is used in expressing Reasonable Progress Goals (RPGs) (which are interim visibility goals towards meeting the national visibility goal), defining baseline, current, and natural conditions, and tracking changes in visibility. The RH SIPs must contain measures that ensure ''reasonable progress'' toward the national goal of preventing and remedying visibility impairment in Class I areas caused by anthropogenic air pollution by reducing anthropogenic emissions that cause RH. The national goal is a return to natural conditions, i.e., anthropogenic sources of air pollution would no longer impair visibility in Class I areas.

To track changes in visibility over time at each of the 156 Class I areas covered by the visibility program (40 CFR 81.401–437), and as part of the process for determining RP, states must calculate the degree of existing visibility impairment at each Class I area at the time of each RH SIP submittal and periodically review progress every five years midway through each 10-year implementation period. To do this, the RHR requires states to determine the degree of impairment (in dvs) for the average of the 20 percent least impaired (''best'') and 20 percent most impaired (''worst'') visibility days over a specified time period at each of their Class I areas. In addition, states must also develop an estimate of natural visibility conditions for the purpose of comparing progress toward the national goal. Natural visibility is determined by estimating the natural concentrations of pollutants that cause visibility impairment and then calculating total light extinction based on those estimates. We have provided guidance to states regarding how to calculate baseline, natural and current visibility conditions.[5]

For the first RH SIPs that were due by December 17, 2007, ''baseline visibility conditions'' were the starting points for assessing ''current'' visibility impairment. Baseline visibility conditions represent the degree of visibility impairment for the 20 percent least impaired days and 20 percent most impaired days for each calendar year from 2000 to 2004. Using monitoring data for 2000 through 2004, states are required to calculate the average degree of visibility impairment for each Class I area, based on the average of annual values over the five-year period. The comparison of initial baseline visibility conditions to natural visibility conditions indicates the amount of improvement necessary to attain natural visibility, while the future comparison of baseline conditions to the then current conditions will indicate the amount of progress made. In general, the 2000–2004 baseline period is considered the time from which improvement in visibility is measured.

C. Determination of Reasonable Progress Goals

The vehicle for ensuring continuing progress towards achieving the natural visibility goal is the submission of a series of RH SIPs from the states that establish two RPGs (i.e., two distinct goals, one for the ''best'' and one for the ''worst'' days) for every Class I area for each (approximately) 10-year implementation period. See 40 CFR 51.308(d), (f). The RHR does not mandate specific milestones or rates of progress, but instead calls for states to establish goals that provide for ''reasonable progress'' toward achieving natural visibility conditions. In setting RPGs, states must provide for an improvement in visibility for the most impaired days over the (approximately) 10-year period of the SIP, and ensure no degradation in visibility for the least impaired days over the same period. *Id.*

In establishing RPGs, states are required to consider the following factors established in section 169A of the CAA and in our RHR at 40 CFR 51.308(d)(1)(i)(A): (1) The costs of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of any potentially affected sources. States must demonstrate in their SIPs how these factors are considered when selecting the RPGs for the best and worst days for each applicable Class I area. In setting the RPGs, states must also consider the rate of progress needed to reach natural visibility conditions by 2064 (referred to as the ''uniform rate of progress'' (URP) or the ''glidepath'') and the emission reduction measures needed to achieve that rate of progress over the 10-year period of the SIP. Uniform progress towards achievement of natural conditions by the year 2064 represents a rate of progress, which states are to use for analytical comparison to the amount of progress they expect to achieve. In setting RPGs, each state with one or more Class I areas (''Class I state'') must also consult with potentially ''contributing states,'' i.e., other nearby states with emission sources that may be affecting visibility impairment at the state's Class I areas. 40 CFR 51.308(d)(1)(iv). In determining whether a state's goals for visibility improvement provide for RP toward natural visibility conditions, EPA is required to evaluate the demonstrations developed by the state pursuant to paragraphs 40 CFR 51.308(d)(1)(i) and (d)(1)(ii). 40 CFR 51.308(d)(1)(iii).

D. Best Available Retrofit Technology (BART)

Section 169A of the CAA directs states to evaluate the use of retrofit controls at certain larger, often uncontrolled, older stationary sources in order to address visibility impacts from these sources. Specifically, section 169A(b)(2)(A) of the CAA requires states to revise their SIPs to contain such measures as may be necessary to make RP towards the natural visibility goal, including a requirement that certain categories of existing major stationary

[4] The preamble to the RHR provides additional details about the dv. 64 FR 35714, 35725 (July 1, 1999).

[5] *Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule,* September 2003, EPA–454/B–03–005, available at *http://www.epa.gov/ttncaaa1/t1/memoranda/Regional Haze _envcurhr_gd.pdf,* (hereinafter referred to as ''our 2003 Natural Visibility Guidance''); and *Guidance for Tracking Progress Under the Regional Haze Rule,* (September 2003, EPA–454/B–03–004, available at *http://www.epa.gov/ttncaaa1/t1/memoranda/rh_tpurhr_gd.pdf,* (hereinafter referred to as our ''2003 Tracking Progress Guidance'').

sources[6] built between 1962 and 1977 procure, install, and operate the ''Best Available Retrofit Technology'' as determined by the state. Under the RHR, states are directed to conduct BART determinations for such ''BART-eligible'' sources that may be anticipated to cause or contribute to any visibility impairment in a Class I area. Rather than requiring source-specific BART controls, states also have the flexibility to adopt an emissions trading program or other alternative program as long as the alternative provides greater RP towards improving visibility than BART.

On July 6, 2005, EPA published the *Guidelines for BART Determinations Under the Regional Haze Rule* at appendix Y to 40 CFR part 51 (hereinafter referred to as the ''BART Guidelines'') to assist states in determining which of their sources should be subject to the BART requirements and in determining appropriate emission limits for each applicable source. 70 FR 39104. In making a BART determination for a fossil fuel-fired electric generating plant with a total generating capacity in excess of 750 megawatts (MW), a state must use the approach set forth in the BART Guidelines. A state is encouraged, but not required, to follow the BART Guidelines in making BART determinations for other types of sources. Regardless of source size or type, a state must meet the requirements of the CAA and our regulations for selection of BART, and the state's BART analysis and determination must be reasonable in light of the overarching purpose of the RH program.

The process of establishing BART emission limitations can be logically broken down into three steps: first, states identify those sources which meet the definition of ''BART-eligible source'' set forth in 40 CFR 51.301;[7] second, states determine which of such sources ''emits any air pollutant which may reasonably be anticipated to cause or contribute to any impairment of visibility in any such area'' (a source which fits this description is ''subject to BART''); and third, for each source subject to BART, states then identify the best available type and level of control for reducing emissions.

States must address all visibility-impairing pollutants emitted by a source in the BART determination process. The most significant visibility impairing pollutants are SO_2, NO_X, and PM. EPA has stated that states should use their best judgment in determining whether VOC or NH_3 compounds impair visibility in Class I areas.

Under the BART Guidelines, states may select an exemption threshold value for their BART modeling, below which a BART-eligible source would not be expected to cause or contribute to visibility impairment in any Class I area. The state must document this exemption threshold value in the SIP and must state the basis for its selection of that value. Any source with emissions that model above the threshold value would be subject to a BART determination review. The BART Guidelines acknowledge varying circumstances affecting different Class I areas. States should consider the number of emission sources affecting the Class I areas at issue and the magnitude of the individual sources' impacts. Any exemption threshold set by the state should not be higher than 0.5 dv. 40 CFR part 51, appendix Y, section III.A.1.

In their SIPs, states must identify the sources that are subject to BART and document their BART control determination analyses for such sources. In making their BART determinations, section 169A(g)(2) of the CAA requires that states consider the following factors when evaluating potential control technologies: (1) The costs of compliance; (2) the energy and non-air quality environmental impacts of compliance; (3) any existing pollution control technology in use at the source; (4) the remaining useful life of the source; and (5) the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.

A RH SIP must include source-specific BART emission limits and compliance schedules for each source subject to BART. Once a state has made its BART determination, the BART controls must be installed and in operation as expeditiously as practicable, but no later than five years after the date of EPA approval of the RH SIP. CAA section 169(g)(4) and 40 CFR 51.308(e)(1)(iv). In addition to what is required by the RHR, general SIP requirements mandate that the SIP must also include all regulatory requirements related to monitoring, recordkeeping, and reporting for the BART controls on the source. See CAA section 110(a). As noted above, the RHR allows states to implement an alternative program in lieu of BART so long as the alternative program can be demonstrated to achieve greater RP toward the national visibility goal than would BART.

E. Long-Term Strategy (LTS)

Consistent with the requirement in section 169A(b) of the CAA that states include in their RH SIP a 10 to 15 year strategy for making RP, section 51.308(d)(3) of the RHR requires that states include a LTS in their RH SIPs. The LTS is the compilation of all control measures a state will use during the implementation period of the specific SIP submittal to meet applicable RPGs. The LTS must include ''enforceable emissions limitations, compliance schedules, and other measures as necessary to achieve the reasonable progress goals'' for all Class I areas within, or affected by emissions from, the state. 40 CFR 51.308(d)(3).

When a state's emissions are reasonably anticipated to cause or contribute to visibility impairment in a Class I area located in another state, the RHR requires the impacted state to coordinate with the contributing states in order to develop coordinated emissions management strategies. 40 CFR 51.308(d)(3)(i). In such cases, the contributing state must demonstrate that it has included, in its SIP, all measures necessary to obtain its share of the emission reductions needed to meet the RPGs for the Class I area. *Id.* at (d)(3)(ii). The RPOs have provided forums for significant interstate consultation, but additional consultations between states may be required to sufficiently address interstate visibility issues. This is especially true where two states belong to different RPOs.

States should consider all types of anthropogenic sources of visibility impairment in developing their LTS, including stationary, minor, mobile, and area sources. At a minimum, states must describe how each of the following seven factors listed below are taken into account in developing their LTS: (1) Emission reductions due to ongoing air pollution control programs, including measures to address RAVI; (2) measures to mitigate the impacts of construction activities; (3) emissions limitations and schedules for compliance to achieve the RPG; (4) source retirement and replacement schedules; (5) smoke management techniques for agricultural and forestry management purposes including plans as currently exist within the state for these purposes; (6) enforceability of emissions limitations and control measures; and (7) the anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period

[6] The set of ''major stationary sources'' potentially subject to BART is listed in CAA section 169A(g)(7).

[7] BART-eligible sources are those sources that have the potential to emit 250 tons or more of a visibility-impairing air pollutant, were not in operation prior to August 7, 1962, but were in existence on August 7, 1977, and whose operations fall within one or more of 26 specifically listed source categories. 40 CFR 51.301.

addressed by the LTS. 40 CFR 51.308(d)(3)(v).

F. Coordinating Regional Haze and Reasonably Attributable Visibility Impairment (RAVI)

As part of the RHR, EPA revised 40 CFR 51.306(c) regarding the LTS for RAVI to require that the RAVI plan must provide for a periodic review and SIP revision not less frequently than every three years until the date of submission of the state's first plan addressing RH visibility impairment, which was due December 17, 2007, in accordance with 40 CFR 51.308(b) and (c). On or before this date, the state must revise its plan to provide for review and revision of a coordinated LTS for addressing RAVI and RH, and the state must submit the first such coordinated LTS with its first RH SIP. Future coordinated LTS's, and periodic progress reports evaluating progress towards RPGs, must be submitted consistent with the schedule for SIP submission and periodic progress reports set forth in 40 CFR 51.308(f) and 51.308(g), respectively. The periodic review of a state's LTS must report on both RH and RAVI impairment and must be submitted to EPA as a SIP revision.

G. Monitoring Strategy and Other Implementation Plan Requirements

Section 51.308(d)(4) of the RHR includes the requirement for a monitoring strategy for measuring, characterizing, and reporting of RH visibility impairment that is representative of all mandatory Class I Federal areas within the state. The strategy must be coordinated with the monitoring strategy required in section 51.305 for RAVI. Compliance with this requirement may be met through ''participation'' in the IMPROVE network, i.e., review and use of monitoring data from the network. The monitoring strategy is due with the first RH SIP, and it must be reviewed every five years. The monitoring strategy must also provide for additional monitoring sites if the IMPROVE network is not sufficient to determine whether RPGs will be met.

The SIP must also provide for the following:

- Procedures for using monitoring data and other information in a state with mandatory Class I areas to determine the contribution of emissions from within the state to RH visibility impairment at Class I areas both within and outside the state;
- Procedures for using monitoring data and other information in a state with no mandatory Class I areas to determine the contribution of emissions from within the state to RH visibility impairment at Class I areas in other states;
- Reporting of all visibility monitoring data to the Administrator at least annually for each Class I area in the state, and where possible, in electronic format;
- Developing a statewide inventory of emissions of pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any Class I area. The inventory must include emissions for a baseline year, emissions for the most recent year for which data are available, and estimates of future projected emissions. A state must also make a commitment to update the inventory periodically; and
- Other elements, including reporting, recordkeeping, and other measures necessary to assess and report on visibility.

The RHR requires control strategies to cover an initial implementation period extending to the year 2018, with a comprehensive reassessment and revision of those strategies, as appropriate, every 10 years thereafter. Periodic SIP revisions must meet the core requirements of section 51.308(d) with the exception of BART. The requirement to evaluate sources for BART applies only to the first RH SIP. Facilities subject to BART must continue to comply with the BART provisions of section 51.308(e), as noted above. Periodic SIP revisions will assure that the statutory requirement of RP will continue to be met.

H. Consultation With States and Federal Land Managers (FLMs)

The RHR requires that states consult with FLMs before adopting and submitting their SIPs. 40 CFR 51.308(i). States must provide FLMs an opportunity for consultation, in person and at least 60 days prior to holding any public hearing on the SIP. This consultation must include the opportunity for the FLMs to discuss their assessment of impairment of visibility in any Class I area and to offer recommendations on the development of the RPGs and on the development and implementation of strategies to address visibility impairment. Further, a state must include in its SIP a description of how it addressed any comments provided by the FLMs. Finally, a SIP must provide procedures for continuing consultation between the state and FLMs regarding the state's visibility protection program, including development and review of SIP revisions, five-year progress reports, and the implementation of other programs having the potential to contribute to impairment of visibility in Class I areas.

V. EPA's Evaluation of Colorado's Regional Haze SIP

The State of Colorado submitted a revision to its SIP to address the requirements for RH on May 25, 2011. The following is a discussion of our evaluation of the revision.

A. Affected Class I Areas

Pursuant to 40 CFR 51.308(d), the State identified 12 mandatory Class I areas in Colorado: Black Canyon of the Gunnison National Park, Eagles Nest Wilderness Area, Flat Tops Wilderness Area, Great Sand Dunes National Park, La Garita Wilderness Area, Maroon Bells-Snowmass Wilderness Area, Mesa Verde National Park, Mount Zirkel Wilderness Area, Rawah Wilderness Area, Rocky Mountain National Park, Weminuche Wilderness Area, and West Elk Wilderness Area. The State developed and submitted as part of its RH SIP technical support documents (TSDs) for each of the Class I areas. The Class I area TSDs include a detailed description of each area, along with photographs, summaries of monitoring data, an overview of current visibility conditions, and sources of pollution.

The State also identified in the TSD areas outside of the State that modeling shows may be impacted from emissions from Colorado.[8] These areas include: Upper Buffalo Wilderness in Arkansas; Petrified Forest National Park, Grand Canyon National Park, and Sycamore Canyon Wilderness in Arizona; Hercules-Glade Wilderness in Missouri; San Pedro Parks Wilderness, Bandelier National Monument, and Wheeler Peak in New Mexico; Wichita Mountains National Wildlife Refuge in Oklahoma; Wind Cave National Park and Badlands National Park in South Dakota; Canyonlands National Park and Capitol Reef National Park in Utah; and Bridger Wilderness in Wyoming.

B. Baseline Visibility, Natural Visibility, and Uniform Rate of Progress

As required by 40 CFR 51.308(d)(2), Colorado determined baseline visibility, natural visibility, and the URP for each Class I area in the State. Natural background visibility, as defined in our 2003 Natural Visibility Guidance, is estimated by calculating the expected light extinction using default estimates of natural concentrations of fine particle components adjusted by site-specific estimates of humidity. This calculation uses the IMPROVE equation, which is a

[8] See Colorado TSD document titled *Colorado Visibility Impacts on nearby Class I Areas.*

formula for estimating light extinction from the estimated natural concentrations of fine particle components (or from components measured by the IMPROVE monitors). As documented in our 2003 Natural Visibility Guidance, EPA allows states to use ''refined'' or alternative approaches to this guidance to estimate the values that characterize the natural visibility conditions of Class I areas.

One alternative approach is to develop and justify the use of alternative estimates of natural concentrations of fine particle components. Another alternative is to use the ''new IMPROVE equation'' that was adopted for use by the IMPROVE Steering Committee in December 2005.[9] The purpose of this refinement to the ''old IMPROVE equation'' is to provide more accurate estimates of the various factors that affect the calculation of light extinction.

Colorado used the new IMPROVE equation to calculate natural conditions and baseline visibility. The natural condition for each Class I area represents the visibility goal expressed in dvs for the 20% worst days and the 20% best days that would exist if there were only naturally occurring visibility impairment. In accordance with 40 CFR 51.308(d)(2)(iii), the State calculated natural visibility conditions based on available monitoring information and appropriate data analysis techniques and in accordance with our 2003 Natural Visibility Guidance. The State also calculated the number of dvs by which baseline conditions exceed natural conditions at each of its Class I areas to meet the requirements of 40 CFR 51.308(d)(2)(iv)(A).

Colorado has established baseline visibility for the best and worst visibility days for each Class I area based on data from the IMPROVE monitoring sites. Each IMPROVE monitor collects particulate concentration data which are converted into reconstructed light extinction through a complex calculation using the IMPROVE equation (see Class I area TSDs for more information on reconstructed light extinction and the IMPROVE equation). Per 40 CFR 51.308(d)(2)(i), the State calculated baseline visibility using a five-year average (2000 to 2004) of IMROVE data for both the 20% best and 20% worst days. The State's baseline calculations were made in accordance with our 2003 Tracking Progress Guidance.

Pursuant to 40 CFR 51.308(d)(1)(i)(B), the State calculated the URP for each of its Class I areas. For the 20% worst days, the URP is the calculation of the dv reduction needed to achieve natural conditions by 2064. For the 20% worst days, the State calculated the URP in dvs per year using the following formula: URP = [Baseline Condition − Natural Condition]/60 years. In order to determine the uniform progress needed by 2018 to be on the path to achieving natural visibility conditions by 2064, the State multiplied the URP by the 14 years in the first planning period (2004–2018).

Table 1 shows the baseline visibility, natural conditions, and URP for each of the Class I areas.

TABLE 1—BASELINE VISIBILITY, NATURAL CONDITIONS, AND UNIFORM RATE OF PROGRESS FOR COLORADO CLASS I AREAS

Colorado class I areas	Monitor name	20% Worst Days					20% Best days
		2000–2004 Baseline (dv)	2018 URP (dv)	Reduction needed to reach 2018 URP (delta dv)	2064 Natural conditions (dv)	Delta Baseline—2064 Natural Conditions (dv)	2000–2004 Baseline (dv)
Great Sand Dunes National Park and Preserve	GRSA1	12.78	11.35	1.43	6.66	6.12	4.50
Mesa Verde National Park	MEVE1	13.03	11.58	1.45	6.81	6.22	4.32
Mount Zirkel and Rawah Wilderness Area	MOZI1	10.52	9.48	1.04	6.08	4.44	1.61
Rocky Mountain National Park	RMHQ1	13.83	12.27	1.56	7.15	6.68	2.29
Weminuche Wilderness, Black Canyon of Gunnison, and La Garita Wilderness	WEMI1	10.33	9.37	0.96	6.21	4.12	3.11
Eagles Nest Wilderness, Flat Tops Wilderness, Maroon Bells-Snowmass Wilderness, and West Elk Wilderness	WHRI1	9.61	8.78	0.83	6.06	3.55	0.70

We have reviewed Colorado's calculations of baseline visibility, natural conditions, and URP. We find they have been calculated correctly and are proposing to approve them.

C. BART Determinations

BART is an element of Colorado's LTS for the first implementation period. As discussed in more detail in section IV.D of this notice, the BART evaluation process consists of three components: (1) An identification of all the BART-eligible sources; (2) an assessment of whether those BART-eligible sources are in fact subject to BART; and (3) a determination of any BART controls. Colorado addressed these steps as follows:

1. BART Eligible Sources

The first step of a BART evaluation is to identify all the BART-eligible sources within the State's boundaries. Colorado identified the BART-eligible sources in Colorado by utilizing the approach set out in the BART Guidelines (70 FR 39158). This approach provides three criteria for identifying BART-eligible sources: (1) One or more emission units at the facility fit within one of the 26 categories listed in the BART Guidelines; (2) the emission unit or units began operation on or after August 6, 1962, and were in existence on August 6, 1977; and (3) combined potential emissions of any visibility-impairing pollutant from the units that meet the criteria in (1) and (2) are 250

[9] The IMPROVE program is a cooperative measurement effort governed by a steering committee composed of representatives from Federal agencies (including representatives from EPA and the FLMs) and regional planning organizations. The IMPROVE monitoring program was established in 1985 to aid the creation of Federal and State implementation plans for the protection of visibility in Class I areas. One of the objectives of IMPROVE is to identify chemical species and emission sources responsible for existing anthropogenic visibility impairment. The IMPROVE program has also been a key participant in visibility-related research, including the advancement of monitoring instrumentation, analysis techniques, visibility modeling, policy formulation and source attribution field studies.

tons or more per year. Colorado reviewed source permits and emission data from 2001–2003 to identify facilities in the BART source categories with potential emissions of 250 tons per year or more for any visibility-impairing pollutant from any unit or units that were in existence on August 7, 1977 and began operation on or after August 7, 1962. The BART Guidelines direct States to address SO_2, NO_X, and direct PM (including both coarse particulate matter (PM_{10}) and fine particulate matter ($PM_{2.5}$)) emissions as visibility-impairing pollutants and to exercise their ''best judgment to determine whether VOC or NH_3 emissions from a source are likely to have an impact on visibility in an area.'' (70 FR 39162).

The State analyzed the emissions from VOC and NH_3 from sources in the State. VOC is a precursor to OC. The State eliminated VOC from further consideration in the RH SIP as it determined statewide point source emissions of VOC constitute a negligible portion of the emission inventory for OC (3 tons per year (tpy)). Colorado also determined that statewide point sources of NH_3 emissions are small. The State's emission inventory for 2001–2003 shows that point sources emitted 453 tpy of NH_3, while total State NH_3 emissions are 67,686 tpy. Thus, the State has eliminated NH_3 from further consideration.[10] We have reviewed this information and propose to accept this determination.

Table 2 lists the 12 sources that Colorado determined were BART-eligible.

2. Sources Subject to BART

The second step of the BART evaluation is to identify those BART-eligible sources that may reasonably be anticipated to cause or contribute to any visibility impairment at any Class I area, i.e., those sources that are subject to BART. The BART Guidelines allow states to consider exempting some BART-eligible sources from further BART review because they may not reasonably be anticipated to cause or contribute to any visibility impairment in a Class I area. Consistent with the BART Guidelines, Colorado performed dispersion modeling on the BART-eligible sources to assess the extent of their contribution to visibility impairment at surrounding Class I areas.

a. Modeling Methodology

The BART Guidelines provide that states may use the CALPUFF[11] modeling system or another appropriate model to predict the visibility impacts from a single source on a Class I area and to, therefore, determine whether an individual source is anticipated to cause or contribute to impairment of visibility in Class I areas, i.e., ''is subject to BART.'' The Guidelines state that CALPUFF is the best regulatory modeling application currently available for predicting a single source's contribution to visibility impairment (70 FR 39162).

The BART Guidelines also recommend that states develop a modeling protocol for making individual source attributions, and suggest that states may want to consult with EPA and their RPO to address any issues prior to modeling. Colorado used the CALPUFF model for Colorado BART sources in accordance with a protocol it developed titled *CALMET/CALPUFF BART Protocol for Class I Federal Area Individual Source Attribution Visibility Impairment Modeling Analysis,* October 24, 2005, which was approved by EPA and is included in the Supporting and Related Materials section of the docket. The Colorado protocol follows recommendations for long-range transport described in appendix W to 40 CFR part 51, *Guideline on Air Quality Models,* and in EPA's *Interagency Workgroup on Air Quality Modeling (IWAQM) Phase 2 Summary Report and Recommendations for Modeling Long Range Transport Impacts* as recommended by the BART Guidelines. (40 CFR part 51, appendix Y, section III.A.3).

To determine if each BART-eligible source has a significant impact on visibility, Colorado used the CALPUFF model to estimate daily visibility impacts above estimated natural conditions at each Class I area within 300 km of any BART-eligible facility, based on maximum actual 24-hour emissions over a three year period (2000–2002).

b. Contribution Threshold

For states using modeling to determine the applicability of BART to single sources, the BART Guidelines note that the first step is to set a contribution threshold to assess whether the impact of a single source is sufficient to cause or contribute to visibility impairment at a Class I area. The BART Guidelines state that, ''[a] single source that is responsible for a 1.0 deciview change or more should be considered to 'cause' visibility impairment.'' (70 FR 39104, 39161). The BART Guidelines also state that ''the appropriate threshold for determining whether a source contributes to visibility impairment may reasonably differ across states,'' but, ''[a]s a general matter, any threshold that you use for determining whether a source 'contributes' to visibility impairment should not be higher than 0.5 deciviews.'' Id. Further, in setting a contribution threshold, states should ''consider the number of emissions sources affecting the Class I areas at issue and the magnitude of the individual sources' impacts.'' The Guidelines affirm that states are free to use a lower threshold if they conclude that the location of a large number of BART-eligible sources in proximity to a Class I area justifies this approach.

Colorado used a contribution threshold of 0.5 dvs for determining which sources are subject to BART. The State's decision was based on the following factors: 0.5 dvs equates to the 5% extinction threshold for new sources under the Prevention of Significant Deterioration (PSD) New Source Review rules, and 0.5 dvs represents the limit of perceptible change. Although we do not agree with Colorado that these factors are always the appropriate ones to consider in determining which BART-eligible sources should be subject to BART in Colorado, we propose to approve the State's threshold of 0.5 dvs based on our own evaluation, discussed below. As shown in Table 2 below, Colorado exempted three of the 12 BART-eligible sources in the State from further review under the BART requirements. These three sources are Lamar Light and Power, Suncor Denver Refinery, and Ray D. Nixon Unit 1. According to Colorado's modeling, each of these sources had a visibility impact less than 0.5 dvs. As shown in Table 2, the visibility impact attributable to each of these sources is 0.06, 0.48, and 0.24 dvs, respectively. Given the relatively limited combined impact on visibility from these three sources, we propose to agree with Colorado that 0.5 dvs is a reasonable threshold for determining

[10] More details on the State's emission inventory can be found in *Colorado Emission Inventories Plan 2002d and PRP 2018b* in the Supporting and Related Materials section of the docket.

[11] Note that our reference to CALPUFF encompasses the entire CALPUFF modeling system, which includes the CALMET, CALPUFF, and CALPOST models and other pre and post processors. The different versions of CALPUFF have corresponding versions of CALMET, CALPOST, etc. which may not be compatible with previous versions (e.g., the output from a newer version of CALMET may not be compatible with an older version of CALPUFF). The different versions of the CALPUFF modeling system are available from the model developer at *http://www.src.com/verio/download/download.htm.*

whether its BART-eligible sources are subject to BART.

Because our recommended modeling approach already incorporates choices that tend to lower peak daily visibility impact values,[12] our BART Guidelines state that a state should compare the 98th percentile (as opposed to the 90th or lower percentile) of CALPUFF modeling results against the ''contribution'' threshold established by the state for purposes of determining BART applicability. Colorado used a 98th percentile comparison that we find appropriate. Further explanation on use of the 98th versus 90th percentile value is provided at 70 FR 39121.

c. Sources Identified by Colorado as BART-Eligible and Subject to BART

Table 2 shows the sources that the State identified as BART-eligible and the results of the State's CALPUFF modeling. Colorado determined that the BART-eligible facilities with modeled impacts at all Class I areas less than 0.5 dvs were not subject to BART and those with impacts greater than 0.5 dvs were subject to BART (see Chapter 6.3 of the SIP).

TABLE 2—COLORADO BART-ELIGIBLE SOURCES AND SUBJECT-TO-BART MODELING RESULTS

Unit name	Owner	Source type	State modeling results—98th percentile delta-Dv	Subject to BART?
Cemex—Lyons Cement Kiln and Dryer	Cemex	Portland Cement	1.53	Yes.
CENC (Trigen-Colorado) Units 4 & 5	Colorado Energy Nations Company (CENC)	EGU	1.26	Yes.
Cherokee Station—Unit 4	Public Service Company of Colorado (PSCO).	EGU	1.46	Yes.
Comanche Station—Units 1 & 2	PSCO	EGU	0.7	Yes.
Craig Station—Units 1 & 2	Tri-State Generation and Transmission, Inc. (Tri-State).	EGU	2.69	Yes.
Hayden Station—Units 1 & 2	PSCO	EGU	2.54	Yes.
Lamar Light and Power—Unit 6	City of Lamar	EGU	0.06	No.
Martin Drake Power Plant—Units 5, 6, & 7	Colorado Springs Utilities (CSU)	EGU	1.04	Yes.
Pawnee Station—Unit 1	PSCO	EGU	1.19	Yes.
Ray D. Nixon Power Plant—Unit 1	CSU	EGU	[13] 0.48	No.
Suncor Denver Refinery	Suncor	Refinery	0.24	No.
Valmont Station—Unit 5	PSCO	EGU	1.59	Yes.

[13] The State of Colorado originally modeled an impact of 0.57 dvs for Ray D. Nixon Power Plant. The source submitted refined modeling that showed an impact of 0.48 dvs. Both the State and EPA agree with the refined modeling submitted by the source.

3. BART Determinations and Federally Enforceable Limits

The third step of a BART evaluation is to perform the BART analysis. The BART Guidelines (70 FR 39164) describe the BART analysis as consisting of the following five steps:

- Step 1: Identify All Available Retrofit Control Technologies;
- Step 2: Eliminate Technically Infeasible Options;
- Step 3: Evaluate Control Effectiveness of Remaining Control Technologies;
- Step 4: Evaluate Impacts and Document the Results; and
- Step 5: Evaluate Visibility Impacts.

In determining BART, the State must consider the five statutory factors in section 169A of the CAA: (1) The costs of compliance; (2) the energy and non-air quality environmental impacts of compliance; (3) any existing pollution control technology in use at the source; (4) the remaining useful life of the source; and (5) the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology. See also 40 CFR 51.308(e)(1)(ii)(A). The five-factor analysis occurs during steps 4 and 5 of the BART analysis.

Colorado performed BART determinations for all of the sources subject to BART for NO_X, SO_2, and PM. We find that Colorado adequately considered all five steps above in its BART determinations.

State NO_X Control Criteria

For NO_X, the State developed criteria to assist in the selection of post-combustion controls for BART. For the highest-performing NO_X post-combustion control options (i.e., selective catalytic reduction (SCR) systems for electric generating units) that do not exceed a cost of $5,000 per ton and which provide a modeled visibility benefit of 0.50 dv or greater at the primary Class I Area affected, the State views that level of control as generally reasonable for BART. For lesser-performing NO_X post-combustion control options (*e.g.,* selective non-catalytic reduction (SNCR) technologies for electric generating units) that do not exceed a cost of $5,000 per ton which provide a modeled visibility benefit of 0.20 dv or greater at the primary Class I Area affected, the State views that level of control as generally reasonable for BART.

EPA does not necessarily agree that the State's criteria for selecting NO_X controls would always be appropriate. First, the criteria appear to discriminate against SCR as a potential control option. Under the criteria, if the cost of SCR is under $5,000/ton and the modeled visibility benefit is 0.20 delta-dv or greater but less than 0.50 delta-dv, the State would reject SCR. Using the State's criteria, the State would find SNCR reasonable with the same $/ton and delta-dv values. We are not aware of a valid basis for applying different criteria to the two control options. In addition, we are aware of no basis for establishing benchmarks for post-combustion controls but not for other types of NO_X controls. The criteria may also preclude a reasonable weighing of the five factors where the delta dv benefit is over 0.5 but the cost is higher than $5,000/ton.

While we do not necessarily agree that the criteria used by the State would always be appropriate to select NO_X controls, we agree with the State's determinations for NO_X BART controls on the BART sources as discussed below.

[12] See our BART Guidelines, Section III.A.3.

SO_2 Controls—Wet and Dry Scrubbing

Scrubbing is one of the most common ways to control emissions of SO_2 from stationary sources. Scrubbing can consist of either wet flue gas desulfurization (FGD) or dry FGD. The State eliminated wet FGD from consideration as a BART control because of negative non-air quality environmental impacts. The main non-air quality environmental impact that the State identified for wet FGDs is very heavy water usage. Wet FGDs consume approximately 23% more water than dry FGDs depending on boiler size.[14] In Colorado, water law is based upon the doctrine of prior appropriation or ''first in time-first in right,'' and the priority date is established by the date the water was first put to a beneficial use. The State reasoned that, depending upon whether and when a power plant first secured a water appropriation and whether such appropriation is adequate to supply the demand, there may be insufficient water appropriations available in some areas of the State, particularly in the Front Range area, to accommodate the added demands of wet FGD controls. The State also found that the water demands of wet FGDs would compete for what is already a scarce resource needed for Colorado's domestic, agricultural, and industrial demands.

Generally, wet FGD controls can achieve a slightly higher level of SO_2 control than dry FGDs on a percent capture basis. Considering this, the State determined that the non-air quality environmental impacts outweigh any incremental improvement in SO_2 emission reductions that would result from the use of wet FGDs rather than dry FGDs (see Chapter 6.4.1.3 of the SIP). EPA is proposing that the State provided adequate justification to eliminate the consideration of wet FGDs as SO_2 BART controls.

a. Visibility Improvement Modeling

The BART Guidelines provide that states may use the CALPUFF modeling system or another appropriate model to determine the visibility improvement expected at a Class I area from potential BART control technologies applied to the source. Colorado performed CALPUFF modeling to determine the degree of visibility improvement expected at a Class I area based on the controls evaluated for BART for the subject-to-BART sources, with the exception of Cemex. For Cemex, the State relied on modeling submitted by the source based on a modeling protocol approved by the State.

The BART Guidelines also recommend that states develop a modeling protocol for modeling visibility improvement, and suggest that states may want to consult with EPA and their RPO to address any issues prior to modeling. Colorado used the CALPUFF model for Colorado BART sources in accordance with a protocol it developed titled Supplemental BART Analysis *CALPUFF Protocol for Class I Federal Area Visibility Improvement Modeling Analysis,* revised August 19, 2010, which was approved by EPA and is included in the Supporting and Related Materials section of the docket. The Colorado protocol follows recommendations for long-range transport described in appendix W to 40 CFR part 51, *Guideline on Air Quality Models,* and in EPA's *Interagency Workgroup on Air Quality Modeling (IWAQM) Phase 2 Summary Report and Recommendations for Modeling Long Range Transport Impacts,* as recommended by the BART Guidelines. (40 CFR part 51, appendix Y, section III.D.5).

b. Summary of BART Determinations and Federally Enforceable Limits

In lieu of individual BART determinations, the State submitted a BART alternative as allowed for by 40 CFR 51.308(e)(2) for three of the subject-to-BART sources: Cherokee Station Unit 4, Pawnee Station Unit 1, and Valmont Station Unit 5. We provide a summary of the BART alternative in section IV.C.3.b.vii of this notice. We are proposing to approve the BART alternative. For the rest of the subject-to-BART sources, the State provided analyses that took into consideration the five factors as required by section 169A(g)(2) of the CAA. The State's five factor analyses, as well as additional technical information and materials, are included in Appendix C of the SIP. Chapter 6 of the SIP provides a summary of the five factor analyses. EPA is proposing to approve the BART determinations submitted by the State for Cemex Lyons Kiln and Dryer, CENC Unit 4 and Unit 5, Comanche Unit 1 and Unit 2, Craig Unit 2, Hayden Unit 1 and Unit 2, and Martin Drake Unit 5, Unit 6, and Unit 7. A summary of the BART determination for each source is provided below.

i. Cemex Lyons Dryer and Kiln

Background

The Cemex facility manufactures Portland cement and is located in Lyons, Colorado, approximately 20 miles from Rocky Mountain National Park. There are two BART-eligible units at the facility: The dryer and the kiln. The Lyons plant was originally constructed with a long dry kiln. In 1980, the kiln was cut to one-half its original length, and a flash vessel was added with a single-stage preheater. The permitted kiln feed rate is 120 tons per hour of raw material (kiln feed), and on average yields approximately 62 tons of clinker per hour. The kiln is the main source of SO_2 and NO_X emissions. The raw material dryer emits minor amounts of SO_2 and NO_X. The State's BART determination can be found in Chapter 6.4.3.1 and Appendix C of the SIP.

Baseline Emissions

The State has emissions data for the dryer from 1999, 2003, 2008, and 2009. The 1999 emissions are based on emission factors, whereas the 2003, 2008 and 2009 emissions are based on a stack test. The State has determined that the 2008 emissions best represent baseline emissions for the dryer since the State considers stack test data more reliable than emission factors. Furthermore, the 2008 clinker production is representative of typical operations because it falls within the normal range of the historical average. The 2008 baseline emissions for the dryer are: 10.41 tpy for NO_X; 0.89 tpy for SO_2; and 5.12 tpy for PM.

The State has determined that the 2002 emissions best represent baseline emissions for the kiln because they correspond to the high range for SO_2 emissions (which can vary significantly due to pyrites in the limestone) and the normal historical range for NO_X emissions and clinker production. The 2002 baseline emissions for the kiln are: 1,747 tpy for NO_X; 95 tpy for SO_2; and 8.5 tpy for PM.

SO_2 and NO_X BART Determination for the Dryer

CALPUFF modeling provided by the source, using a maximum SO_2 emission rate of 123.4 lbs/hour for both the dryer and kiln combined, shows a 98th percentile visibility impact of 0.78 delta dv at the most impacted Class I area, Rocky Mountain National Park. The State determined the modeling was performed correctly and EPA agrees with the State's assessment. The modeled 98th percentile visibility impact from the kiln is 0.76 dv. Thus, the visibility impact of the dryer alone

[14] ''*Revised BART Analysis for Unit 1 & 2 Gerald Gentleman Station Sutherland, Nebraska: Nebraska Public Power District.''* Prepared by: HDF 701 Xenia Avenue South, Suite 600 Minneapolis, MN 55416 With control technology costs provided by: Sargent & Lundy.

is the resultant difference of 0.02 dv. Because of the extremely low visibility impact and emissions from the dryer, the State has determined that no meaningful visibility improvements would result from any conceivable controls on the dryer. The State has determined that SO_2 and NO_X BART for the Cemex dryer are the following existing emission limits: 36.7 tpy for SO_2 and 13.9 tpy for NO_X on a 12-month rolling average.

EPA is proposing to approve the State's SO_2 and NO_X BART determinations for the Cemex Lyons dryer. EPA agrees with the State that no significant visibility improvements would result from the application of controls on the dryer.

SO_2 BART Determination for the Kiln

The kiln has no current SO_2 controls, but approximately 80% of the SO_2 emissions are captured as part of the inherent control of the kiln process. The State determined that lime addition to kiln feed, fuel substitution (coal with tire-derived fuel), dry sorbent injection (DSI), and wet lime scrubbing (WLS) were technically feasible for reducing SO_2 emissions from the Cemex kiln. The State determined raw materials substitution was technically infeasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, and there are no remaining-useful-life issues for this source. A summary of the State's SO_2 BART analysis and the visibility impacts derived from modeling conducted by the source is provided in Table 3 below.

TABLE 3—SUMMARY OF CEMEX-LYONS KILN SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Annual controlled hourly SO_2 emissions (lbs/hr)	Emission reduction (tpy)	Annualized cost	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Lime Addition to Kiln Feed	25	19	23.8	$3,640,178	$153,271	0.033
Fuel Substitution	40	15.2	38	172,179	4,531	0.034
DSI	50	12.7	47.5	.....	.....	0.036
WLS	90	2.5	85.5	2,529,018	29,579	0.040

Based upon its consideration and weighing of the five factors, the State has determined that no additional SO_2 emissions control on the kiln is reasonable for BART. The State determined that the added expense of any of the potential SO_2 controls was not reasonable for the small visibility improvement of 0.04 dvs or less. Despite not having cost information on DSI, the State determined that the minimal visibility improvement of 0.036 dv does not justify further consideration of this control technology. The State has determined that emissions from the 2002 baseline period represent BART for SO_2 emissions for the kiln. The State determined that the SO_2 BART emission limits for the kiln are 25.3 lbs/hour and 95.0 tpy of SO_2 (12-month rolling average).

We are proposing to approve the State's SO_2 BART determination for the Cemex Lyons kiln. The State's weighing of the factors was reasonable and resulted in a reasonable determination for SO_2 BART.

NO_X BART Determination for the Kiln

The kiln is currently uncontrolled for NO_X emissions. The State determined that water injection, firing coal supplemented with tire-derived fuel (TDF), indirect firing with low NO_X burners (LNBs), SNCR, and the combination of SNCR and LNBs were technically feasible and appropriate for reducing NO_X emissions from the Cemex kiln. The State determined that SCR is not commercially available for Portland cement kilns. EPA does not agree with the State's assertion that SCR is not commercially available for Portland cement kilns.

Although we disagree with the State's conclusion on the commercial availability of SCR for cement kilns, we accept the State's decision, for purposes of RH, not to analyze this control technology further. We note that EPA has acknowledged, in the context of establishing the New Source Performance Standards (NSPS) for Portland Cement Plants, substantial uncertainty regarding the cost effectiveness associated with the use of SCR at such plants. See 75 FR 54995. We expect the State to reevaluate this technology in subsequent RP planning periods.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, and there are no remaining-useful-life issues for this facility. A summary of the State's NO_X BART analysis and the visibility impacts derived from modeling conducted by the source is provided in Table 4 below.

TABLE 4—SUMMARY OF CEMEX-LYONS KILN NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Annual controlled hourly NO_X emissions (lbs/hr)	Emission reduction (tpy)	Annualized cost	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile Impact)
Water Injection	7	431.8	122.3	$43,598	$356	0.22
Firing TDF	10	417.8	174.7	172,179	986	0.23
Indirect Firing with LNBs	20	371.4	349.4	710,179	2,034	0.28
SNCR	45	255.3	786.2	1,636,636	2,082	0.39
SNCR	48.5	239.4	846.1	1,636,636	1,934	0.41
SNCR with LNBs	55	208.9	960.9	1,686,395	1,755	0.44

As the table shows, SNCR with LNB could potentially achieve the greatest emission reductions for the control technologies evaluated. The Cemex-Lyons facility is a unique kiln system most accurately described as a modified long dry kiln. The characteristics of a modified long dry kiln system are not similar to either a long wet kiln or a multi-stage preheater/precalciner kiln. The temperature profile in a long dry kiln system (>1500°F) is significantly higher at the exit than a more typical preheater/precalciner kiln (650 °F). This limits the location and residence time available for an effective NO_X control system. Because of this unique design, the State determined that SNCR and the combination of SNCR with LNBs have an uncertain level of control. Because the design of the Cemex kiln is unlike that for other kilns where SNCR has been successfully applied, it is uncertain whether SNCR can achieve emission reductions of 48.5%. The incremental reduction in visibility associated with SNCR in combination with LNBs would be 0.05 dv over just SNCR alone. Based on the uncertainty concerning the control efficiency of SNCR alone and SNCR with LNBs, and based on the small incremental visibility improvement that would result from SNCR in combination with LNBs over just SNCR, the State determined that BART for NO_X equates to an emission limit consistent with SNCR at 45% control. The State determined that the NO_X BART emission limits for the Cemex kiln are 255.3 pounds per hour (30-day rolling average) and 901.0 tons per year (12-month rolling average). The State assumes the emission limits can be met with the installation and operation of SNCR.

We agree with the State's conclusion, and we are proposing to approve the State's NO_X BART determination for the Cemex-Lyons kiln.

PM BART Determination

PM emissions from the kiln and dryer are currently controlled by fabric filter baghouses and wet dust suppression techniques. Current PM emission limits are in compliance with the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Source Categories; Portland Cement Manufacturing Industry, 40 CFR part 63, subpart LLL. The existing NESHAP regulatory emission limits for the kiln are 0.275 lb/ton of dry feed and 20% opacity. For the dryer, the emission limit is 22.8 tpy and 10% opacity. For sources already regulated by a NESHAP standard, EPA stated the following in the BART guidelines: ''We believe that, in many cases, it will be unlikely that States will identify emission controls more stringent than the MACT standards without identifying control options that would cost many thousands of dollars per ton. Unless there are new technologies subsequent to the MACT standards which would lead to cost effective increases in the level of control, you may rely on the MACT standards for purposes of BART.'' (70 FR 39163) (MACT means Maximum Achievable Control Technology).

The State determined that no new PM control methodologies could be identified that would improve upon the PM controls required in the NESHAP. The State determined that the current emission limit and control technology represent the most stringent level of control and are BART for PM for the Cemex-Lyons kiln and dryer. Per the BART Guidelines, if the BART source has the most stringent control technology and limit in place, a full five-factor analysis is not required (70 FR 39165). The State determined that PM BART emission limits for the kiln are 0.275 lb/ton of dry feed and 20% opacity and the emission limits for the dryer are 22.8 tpy (12-month rolling average) and 10% opacity. The State assumes the limits can be achieved with the operation of the current fabric filter baghouses.

We are proposing to approve the State's PM BART determinations for the Cemex-Lyons kiln and dryer. We agree with the State that the existing controls and emission limits represent the most stringent level of PM control for this type of facility.

ii. CENC Boilers 4 and 5

Background

This CENC facility is located adjacent, and supplies steam and electrical power, to the Coors Brewery in Golden, Colorado. The facility consists of five boilers and the associated equipment for coal and ash handling. Boilers 4 and 5 are the only units that are subject to BART. Boiler 4 mainly fires coal, but can also fire natural gas. Fuel oil may be used as a backup fuel, but has not been used in recent years. Boiler 5 fires coal, but uses oil as a backup fuel. Either boiler may also fire ethanol or sludge from the Coors Brewery. Boiler 4 is rated at 360 MMBtu/hr and Boiler 5 at 650 MMBtu/hr. Both boilers are pulverized-coal dry-bottom tangentially-fired boilers. The BART determination for CENC Boilers 4 and 5 can be found in Chapter 6.4.3.2 and Appendix C of the SIP.

SO_2 BART Determination

Boilers 4 and 5 are currently uncontrolled for SO_2. The State determined that DSI and SO_2 emission management were technically feasible for reducing SO_2 emissions from Boilers 4 and 5. The State determined that dry FGD controls were not technically feasible due to space constraints at the facility. Emissions management for SO_2 encompasses a variety of options to reduce SO_2 emissions, including dispatching natural gas-fired capacity, reducing total system load, and/or reducing coal firing rate to maintain a new peak SO_2 limit. The State also evaluated tightening the emission limits for Boiler 4 and 5 based on current operations.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for the source. A summary of the State's SO_2 BART analysis and the visibility impacts is provided in Tables 5 and 6 below. The State did not model the visibility improvement of SO_2 emissions management because the emission reduction from the control technology is negligible. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis. Baseline SO_2 emissions are 781 tpy for Boiler 4 and 1,406 tpy for Boiler 5 based on the average of 2006–2008 actual emissions.

TABLE 5—SUMMARY OF CENC BOILER 4 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu)	Emission reduction (tpy)	Annualized cost	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
SO_2 Emissions Management	0.13	.74	1	$44,299	$43,600	NA

TABLE 5—SUMMARY OF CENC BOILER 4 SO_2 BART ANALYSIS—Continued

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu)	Emission reduction (tpy)	Annualized cost	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
DSI	60	.30	468	1,766,000	3,774	0.08

TABLE 6—SUMMARY OF CENC BOILER 5 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu)	Emission reduction (tpy)	Annualized cost	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
SO_2 Emissions Management	0.063	.82	0.8	$65,882	$78,095	NA
DSI	60	.33	844	2,094,000	2,482	0.13

Based on its consideration of the five factors, the State determined that SO_2 emissions management and DSI are not reasonable for BART. The State further evaluated emissions limit tightening based on current operations, which is a no-cost control option. The State determined that it would be appropriate to evaluate a lower emission limit based on percent sulfur and heat content. Based on the boiler sulfur to SO_2 conversions, the State has determined that the SO_2 BART emission limit for CENC Boiler 4 is 1.0 lb/MMBtu (30-day rolling average) and for Boiler 5 is 1.0 lb/MMBtu (30-day rolling average). The details of the State's calculation can be found in the State's BART analysis.

We agree with the State's conclusions, and we are proposing to approve its SO_2 BART determinations for CENC Boiler 4 and Boiler 5.

NO_X BART Determination

Boilers 4 and 5 are currently uncontrolled for NO_X. The State determined that LNBs, LNBs plus separated overfire air (SOFA), SNCR, SNCR plus LNB plus SOFA, and SCR were technically feasible for reducing NO_X emissions at CENC Boilers 4 and 5. The State determined rich reagent injection (RRI), ECO System, and coal reburn with SNCR were technically infeasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Tables 7 and 8 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis. Baseline NO_X emissions are 600 tpy for Boiler 4 and 691 tpy for Boiler 5, based on the average of 2006–2008 actual emissions.

TABLE 7—SUMMARY OF CENC BOILER 4 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
LNBs	[15] 7	.52	59.9	$193,433	$3,227	0.05
SNCR	30	.40	179.8	694,046	3,860	0.07
LNBs + SOFA	18.5	.37	209.8	678,305	3,234	0.08
LNB + SOFA + SNCR	51	.22	368	1,372,351	3,729	0.12
SCR	79.6	.08	515.4	4,201,038	8,150	0.18

TABLE 8—SUMMARY OF CENC BOILER 5 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
LNBs	7	.37	48.4	$249,858	$5,166	0.17
SNCR	30	.32	127.3	815,829	6,383	0.21
LNBs + SOFA	18.5	.28	207.3	923,996	4,458	0.21
LNBs + SOFA + SNCR	51	.19	353.7	1,739,825	4,918	0.26
SCR	79.6	.08	550.0	6,469,610	11,764	0.31

Based on its consideration of the five factors, the State determined BART is LNBs + SOFA for Boiler 4 and LNBs + SOFA + SNCR for Boiler 5. Although SCR achieves better emissions reductions, the State determined that SCR is not reasonable based on the high cost effectiveness values and the low visibility improvement afforded by this control. The State has determined that the NO_X BART emission limit for CENC Boiler 4 is 0.37 lb/MMBtu (30-day rolling average) and for Boiler 5 is 0.19 lb/MMBtu (30-day rolling average). The State assumes the BART emission limits can be achieved by the installation and operation of LNBs with SOFA on Boiler 4 and LNBs + SOFA + SNCR on Boiler 5.

Per the BART Guidelines, states may consider allowing sources to average emissions across any set of BART eligible emissions units within a fenceline, so long as the emission reductions from each pollutant being controlled for BART would be equal to those reductions that would be obtained by simply controlling each of the BART-eligible sources (70 FR 39172). Pursuant to this, the State also established a combined NO_X BART limit for CENC Boiler 4 and Boiler 5 of 0.26 lb/MMBtu on a 30-day rolling average.

We agree with the State's conclusions, and we are proposing to approve the State's NO_X BART determinations for CENC Boiler 4 and Boiler 5.

PM BART Determination

CENC Boilers 4 and 5 are each equipped with fabric filter baghouses to control PM emissions with a current emission limit of 0.07 lb/MMBtu. Fabric filter baghouses are the most stringent control technology for controlling PM emissions, and stack tests show that the fabric filter baghouses are achieving a 98% reduction in PM. The State determined that PM BART for Boiler 4 and Boiler 5 is an emission limit of 0.07 lb/MMBtu. The State assumes the BART emission limit can be met with the operation of the current fabric filter baghouses.

While we do not agree with all of the State's assumptions and conclusions in arriving at a PM BART limit of 0.07 lb/MMBtu, we are proposing to approve the State's PM BART determinations for CENC Boiler 4 and Boiler 5. Based on our review/analysis, CENC is capable of achieving a lower emission limit than 0.07 lb/MMBtu with existing equipment. However, we anticipate that the visibility improvement that would result from lowering the limit from 0.07 lb/MMBtu to 0.03 lb/MMBtu would be insignificant. Under these circumstances, we propose to find that the State's BART determination was reasonable.

iii. PSCO Comanche Station Units 1 and 2

Background

Comanche Station is located in Pueblo, Colorado. It consists of three coal-fired EGUs, Units 1, 2, and 3. Unit 1 is rated at 325 megawatts (MW) and Unit 2 is rated at 335 MW. Unit 1 and Unit 2 are the only subject-to-BART units at Comanche Station. The boilers burn sub-bituminous coal as fuel and use natural gas for startup, shutdown, and flame stabilization. Both units are dry-bottom pulverized coal-fired boilers. Unit 1 is tangentially fired and Unit 2 is wall-fired.

In August of 2004, PSCO proposed to construct and operate Unit 3 at Comanche Station. As part of the project, PSCO proposed to install NO_X and SO_2 control devices on Unit 1 and Unit 2 and take new emission limits on those units. In November 2008, PSCO installed LNBs with OFA and a lime spray dryer (LSD) on Unit 1, and in November 2007, PSCO installed LNBs with OFA and a LSD on Unit 2. Operation of the LSDs did not commence until June 3, 2009 for Unit 1 and January 10, 2009 for Unit 2. The State's BART determination for Comanche Station Units 1 and 2 can be found in Chapter 6.4.3.3 and Appendix C of the SIP.

SO_2 BART Determination

The State determined that the LSD on Unit 1 is achieving 76.1% control and the LSD on Unit 2 is achieving 81.9% control. Baseline SO_2 emissions are 1,557 tpy for Unit 1 and 1,244 tpy for Unit 2 based on 2009 actual emissions. The current emission limit for Units 1 and 2 is 0.12 lb/MMBtu each on a 30-day rolling average and a combined annual average of 0.10 lb/MMBtu. Per the BART Guidelines, for EGUs with preexisting post-combustion SO_2 controls achieving removal efficiencies of at least 50 percent, states should consider cost effective scrubber upgrades designed to improve the system's overall SO_2 removal efficiency (70 FR 39171). Under the BART Guidelines, a state is not required to evaluate the replacement of the current SO_2 controls if their removal efficiency is over 50%. The State's BART analysis evaluated numerous LSD upgrades including: (1) Use of performance additives; (2) use of more reactive sorbent; (3) increasing the pulverization level of sorbent; (4) engineering redesign of atomizer or slurry injection system; and (5) additional equipment and maintenance. The State analyzed the potential upgrades and determined all upgrades were either technically infeasible or would not achieve a decrease in current SO_2 emissions.

The State also assessed emissions limit tightening based on current operations. The State reviewed available SO_2 emissions data from EPA's Clean Air Markets Division (CAMD) for 2009 and for part of 2010 (January–October 2010). Since the LSDs only recently commenced full operation, there was limited data available for the State to determine post-control achievable emissions. In its submittal to the State, PSCO provided additional information pertaining to emissions limit tightening. PSCO stated that during low-load operations the inlet temperature at the baghouse approaches the minimum acceptable level, lowering the overall SO_2 control efficiency during low-load operations. PSCO indicated that, due to the increased use of wind resources, the boilers will be required to cycle more frequently to accommodate intermittent wind resources, and, therefore, the units will run at low loads more frequently. As a result, the SO_2 reduction levels will be lower during those times.

Based on this information, the State determined that the limited emissions data from 2009 and 2010 may not accurately represent future plant emissions. In addition, since the LSDs only came on line recently, the State recognized that PSCO has limited operating experience with these units. Although PSCO has other units that are equipped with LSDs, Comanche Station Units 1 and 2 are the first such units in PSCO's system that are firing Powder River Basin coal. After startup of the LSDs in 2009, both units have had a number of days indicating zero emissions, presumably due to a unit shutdown. In many cases, emissions data shows that for one or more days following these events, the daily SO_2 emission rate is frequently well above 0.12 lb/MMBtu. In looking at the data, the State also found that both units have historically lower inlet temperatures to the scrubbers in the winter months, resulting in increased SO_2 emissions.

Based on the information discussed above, the State concluded that a tighter 30-day rolling average and annual average SO_2 emission limit is not feasible at this time for either unit.

[15] EPA's AP–42 emission factor tables estimate that LNBs can control 35–55%, and LNB with OFA can control 40–60%, of NO_X emissions. However, due to the size and configuration (e.g. furnace dimensions) of the CENC boilers, the State has determined that the estimated control efficiency for LNBs and LNBs with OFA used in the analysis are reasonable.

Based on its analysis, the State determined that the SO_2 BART emission limit for Comanche Station Unit 1 is 0.12 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.12 lb/MMBtu (30-day rolling average). The State also established a SO_2 BART emission limit of 0.10 lb/MMBtu, combined annual average for both units.

We agree with the State's conclusions and are proposing to approve its SO_2 BART determinations for Comanche Station Unit 1 and Unit 2.

NO_X BART Determination

Comanche Station Units 1 and 2 currently have a NO_X permit limit of 0.20 lb/MMBtu on a 30-day rolling average for each unit and a combined annual average limit of 0.15 lb/MMBtu. The State determined that SCR and SNCR were technically feasible at Unit 1 and SCR was technically feasible for Unit 2. PSCO conducted testing in the fall of 2008 on Unit 2 using a temporary SNCR system. PSCO performed the testing following the installation of LNBs and OFA to determine if additional reductions could be achieved. PSCO primarily conducted testing at full load over a seven-day period using a single-level urea based SNCR system. The SNCR system is sensitive to temperature and average exhaust temperature in the injection area for Unit 2 was nearly 2,200 °F, which exceeds the optimal temperature for the technology. During the test periods, NO_X reductions were less than 10%, and in some cases during testing, an actual increase in NO_X emissions was observed by PSCO. Based on the results of PSCO's test of SNCR on Unit 2, the State did not evaluate SNCR further as a control option for Unit 2. The State also determined that ECO system and RRI were technically infeasible for both units. The State did not evaluate rotating opposed fire air (ROFA) and reburning because they do not achieve better emission reductions than the current controls.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline NO_X emissions from the 2009 calendar year are 1,511 tpy for Unit 1 and 2,349 tpy for Unit 2. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Tables 9 and 10 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis.

TABLE 9—SUMMARY OF COMANCHE STATION UNIT 1 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
SNCR	29.5	0.10	446	$1,624,100	$3,644	0.11
SCR	51	0.07	770	12,265,014	15,290	0.14

TABLE 10—SUMMARY OF COMANCHE STATION UNIT 2 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
SCR	63	0.07	1480	$14,650,885	$9,900	0.17

Based on its consideration of the five factors, the State has determined that the NO_X BART emission limit for Comanche Station Unit 1 is 0.20 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.20 lb/MMBtu (30-day rolling average). The State also established a NO_X BART emission limit of 0.15 lb/MMBtu, combined annual average for both units.

The State assumes that the BART emission limits can be achieved through the operation of existing LNBs. Although the other alternatives achieve better emissions reductions, the State determined that the added expense of achieving lower limits through different controls was not reasonable based on the high cost effectiveness coupled with the low visibility improvement (under 0.2 dv) afforded.

We agree with the State's conclusions, and we are proposing to approve the State's NO_X BART determinations for Comanche Station Unit 1 and Unit 2.

PM BART Determination

Comanche Station Units 1 and 2 are each equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 99% reduction in PM. Fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent Best Available Control Technology (BACT) determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. Consistent with the BART Guidelines, the State did not provide a full five-factor analysis because the State determined BART to be the most stringent control technology and limit. The State determined that the PM BART limit for Comanche Station Units 1 and 2 is 0.03 lb/MMBtu (30-day rolling average). The State assumes the BART limit can be met with the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM BART determinations for Comanche Station Unit 1 and Unit 2.

iv. Tri-State Craig Units 1 and 2

Background

The Tri-State Generation & Transmission Association, Inc. (Tri-State) Craig Station is located in Moffat County approximately 2.5 miles southwest of the town of Craig,

Colorado. This facility is a coal-fired power plant with a total net electric generating capacity of 1264 MW, consisting of three units. Only Units 1 and 2 are BART-eligible. Units 1 and 2 are dry-bottom pulverized coal-fired boilers and are each rated at a net capacity of 428 MW. The State's BART determination for Craig Units 1 and 2 can be found in Chapter 6.4.3.4 and Appendix C of the SIP.

SO_2 BART Determination

Craig Unit 1 and Unit 2 are currently controlled with wet FGD. The units have a current SO_2 emission limit of 0.16 lb/MMBtu on a 30-day rolling average and a requirement to achieve a 90% reduction of SO_2 (90-day rolling average). Per the BART Guidelines, for EGUs with preexisting post-combustion SO_2 controls achieving removal efficiencies of at least 50 percent, states should consider cost effective scrubber upgrades designed to improve the system's overall SO_2 removal efficiency (70 FR 39171). Under the BART Guidelines, a state is not required to evaluate the replacement of the current SO_2 controls if their removal efficiency is over 50%.

The State evaluated the following wet FGD upgrades: (1) Elimination of bypass reheat; (2) installation of liquid distribution rings; (3) installation of perforated trays; (4) use of organic acid additives; (5) improve or upgrade scrubber auxiliary equipment; and (6) redesign spray header or nozzle configuration. Tri-State performed numerous upgrades at Units 1 and 2 during 2003–2004. The State determined that Tri-State had installed all of the above upgrades with the exception of liquid distribution rings and use of organic additives. The State determined that the installation of perforated trays achieved the same objective as these upgrades.

The State evaluated emission limit tightening based on current operations. The State analyzed the baseline period (2006–2008) emission data from EPA's CAMD to determine the maximum and average 30-day rolling emission rates. The emissions data shows that the maximum 30-day rolling average was 0.08 lb/MMBtu for Unit 1 and 0.09 lb/MMBtu for Unit 2. The average 30-day rolling emission rate was 0.05 lb/MMBtu for Unit 1 and 0.08 for Unit 2. The daily maximum over the three-year period was 0.17 lb/MMBtu for Unit 1 and 0.16 lb/MMBtu for Unit 2. Table 11 shows the visibility improvement modeled by the State for possible lower SO_2 emission limits.

TABLE 11—CRAIG UNIT 1 AND UNIT 2 SO_2 VISIBILITY IMPROVEMENT

SO_2 Control	Emission rate (lb/MMBtu) (30-day rolling average)	Craig unit 1—visibility improvement (delta dv for the maximum 98th percentile impact)	Craig unit 2—visibility improvement (delta dv for the maximum 98th percentile impact)
Wet FGD	0.11	0.03	0.03
Wet FGD	0.07	0.05	0.05

The State determined that an emission limit of 0.11 lb/MMBtu would be achievable without additional capital investment. The State determined that an emission limit lower than 0.11 lb/MMBtu would likely require additional capital expenditure and determined it was not reasonable for the incremental visibility improvement of 0.02. The State has determined that the SO_2 BART emission limit for Craig Unit 1 is 0.11 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.11 lb/MMBtu (30-day rolling average). The State assumes that the BART emission limits can be achieved through the operation of the existing wet FGD.

We agree with the State's conclusions, and we are proposing to approve its SO_2 BART determinations for Craig Unit 1 and Unit 2.

NO_X BART Determination

Craig Units 1 and 2 are currently controlled with ultra low NO_X burners (ULNBs) plus OFA, achieving emission reductions of about 54 percent each. The State determined that combustion control refinements, neural network systems, SNCR, and SCR were technically feasible.[16] The State determined that ECO, RRI, ROFA, and coal reburn plus SNCR were not technically feasible. The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline NO_X emissions are 5,190 tpy for Unit 1 and 5,372 tpy for Unit 2 based on the average of 2006–2008 actual emissions. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Tables 12 and 13 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis. Due to the very small percent control achieved with combustion control refinements and neural network systems, the State did not perform visibility modeling for these two control options. Thus, Tables 12 and 13 do not show a value for visibility improvement for these options.

[16] Although not reflected in the SIP, the State's five-factor analysis in Appendix C of the SIP contains information on combustion control refinements and neural network systems.

TABLE 12—SUMMARY OF CRAIG UNIT 1 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Combustion Control Refinements	2	0.31	104	$122,000	$1,175	.....
Neural Network System	5	0.30	260	280,000	1,079	.....
SNCR	15	0.27	779	3,797,000	4,877	0.31
SCR	74.9	0.08	3,893	25,036,709	6,432	1.01

TABLE 13—SUMMARY OF CRAIG UNIT 2 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Combustion Control Refinements	2	0.31	104	$122,000	$1,136	.....
Neural Network System	5	0.30	260	280,000	1,043	.....
SNCR	15	0.27	779	3,797,000	4,712	0.31
SCR	74	0.07	3,893	25,036,709	6,299	1.01

The State determined that SNCR was reasonable for BART for both Unit 1 and Unit 2 based on the cost effectiveness and visibility improvement associated with this level of control. The State determined SCR was not reasonable because of the high cost effectiveness value. Based upon its consideration of the five factors, the State determined that the NO_X BART emission limit for Craig Unit 1 is 0.27 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.27 lb/MMBtu (30-day rolling average). The State assumed that the BART emission limits can be achieved through the operation of SNCR. We agree with the State's BART determination that an emission limit of 0.27 lb/MMBtu is NO_X BART for Craig Unit 1 and Unit 2. The State arrived at this limit based on a reasonable consideration of the five factors.

Although the State determined that 0.27 lb/MMBtu was NO_X BART for Craig Unit 1 and Unit 2, the State adopted a more stringent emission limit for Craig Unit 2 in its SIP and a slightly less stringent limit for Unit 1. Tri-State and the State agreed to a NO_X emissions control plan for Craig Unit 1 and Unit 2 that is more stringent overall. It consists of emission limits associated with the operation of SNCR for Unit 1 and the operation of SCR for Unit 2. These NO_X emission limits are 0.28 lb/MMBtu (30-day rolling average) for Craig Unit 1 and 0.08 lb/MMBtu (30-day rolling average) for Craig Unit 2. The State adopted these emission limits in its SIP, and these are the emission limits Tri-State must meet for purposes of the RH program. We are proposing to approve the State's NO_X emission limits for Craig Unit 1 and for Craig Unit 2 as satisfying the requirements of 40 CFR 51.308(e).

PM BART Determination

Craig Units 1 and 2 are each equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 99% reduction in PM. Fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. Consistent with the BART Guidelines, the State did not provide a full five-factor analysis because the State determined BART to be the most stringent control technology and limit. The State determined that the PM BART emission limit is 0.03 lb/MMBtu (30-day rolling average) at Craig Unit 1 and Craig Unit 2. The State assumes the BART emission limits can be met through the operation of the current fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM BART determinations for Craig Unit 1 and Unit 2.

v. PSCO Hayden Station Units 1 and 2

Background

The Hayden facility is located four miles east of Hayden, Colorado in Routt County. This facility consists of two steam driven turbine/generator units, Units 1 and 2, and the associated equipment needed for generating electricity. Unit 1 is a pulverized-coal front-fired dry-bottom boiler, firing coal, with natural gas and No. 2 fuel oil used for startup, shutdown, and/or flame stabilization. Unit 2 is a pulverized-coal tangentially-fired dry-bottom boiler, firing coal, with No. 2 fuel oil used for startup, shutdown, and/or flame stabilization. Units 1 and 2 are the only subject-to-BART units at the facility. The State's BART determination for Hayden Units 1 and 2 can be found in Chapter 6.4.3.5 and Appendix C of the SIP.

SO_2 BART Determination

PSCO Hayden Units 1 and 2 are currently controlled with LSDs. Both units have a current SO_2 emission limit of 0.16 lb/MMBtu (30-day rolling average) and a requirement to achieve an 82% reduction of SO_2 (30-day rolling average). As mentioned earlier, if a BART source has current SO_2 controls achieving at least 50% control, then the state needs to evaluate upgrades to the existing control technology but does not need to consider the replacement of that technology. The State's BART analysis evaluated numerous LSD upgrades including: (1) Use of performance additives; (2) use of more reactive sorbent; (3) increasing the pulverization

level of sorbent; (4) engineering redesign of atomizer or slurry injection system (including an additional scrubber vessel); and (5) additional equipment and maintenance. The State determined that the application of the first three upgrades in the list above would not result in lower SO_2 emissions. The State determined that engineering redesign using an additional scrubber vessel and additional equipment and maintenance were technically feasible and would potentially achieve SO_2 emissions reductions.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline SO_2 emissions are 1,172 tpy for Unit 1 and 1,469 tpy for Unit 2 based on the average of 2006–2008 actual emissions. A summary of the State's SO_2 BART analysis and the visibility impacts is provided in Tables 14 and 15 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis.

TABLE 14—SUMMARY OF HAYDEN UNIT 1 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Additional Equipment and Maintenance ..	5.2	0.13	61	$141,150	$2,317	.10
Additional Scrubber Vessel	41.7	0.08	488	4,142,538	8,490	0.14

TABLE 15—SUMMARY OF HAYDEN UNIT 2 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Additional Equipment and Maintenance ..	2.7	0.13	39	$141,150	$3,626	0.21
Additional Scrubber Vessel	40.1	0.08	589	4,808,896	8,164	0.26

The State determined that the cost of an additional scrubber vessel was not reasonable for BART controls. The State determined that additional equipment and maintenance was reasonable for SO_2 BART controls and that a more stringent 30-day rolling SO_2 limit represents an appropriate level of emissions control for BART for Hayden Units 1 and 2. Based on its consideration of the five factors, the State has determined that the SO_2 BART emission limit for Hayden Unit 1 is 0.13 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.13 lb/MMBtu (30-day rolling average). The State assumes the BART emission limit can be met with the operation of the existing LSD.

We agree with the State's conclusions, and we are proposing to approve its SO_2 BART determinations for Hayden Unit 1 and Unit 2.

NO_X BART Determination

Hayden Units 1 and 2 are currently controlled with LNBs plus OFA, achieving emission reductions of 54 percent and 33 percent, respectively. The State determined that upgrades to the existing LNBs, SNCR, and SCR were technically feasible. The State determined that ECO, RRI, ROFA, and coal reburn plus SNCR were not technically feasible. The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline NO_X emissions are 3,750 tpy for Unit 1 and 3,743 tpy for Unit 2 based on the average of 2006–2008 actual emissions. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Tables 16 and 17 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis.

TABLE 16—SUMMARY OF HAYDEN UNIT 1 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
LNBs	37	0.30	1,391	$572,010	$411	0.69
SNCR	37	0.30	1,391	1,353,500	973	0.69
SCR	83	0.08	3,120	10,560,612	3,385	1.12

TABLE 17—SUMMARY OF HAYDEN UNIT 2 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
LNBs	35	0.24	1,303	$992,729	$762	0.40
SNCR	43	0.21	1,610	1,893,258	1,176	0.48
SCR	81	0.07	3,032	12,321,491	4,064	0.85

Based on its consideration of the five factors, the State has determined that the NO_X BART emission limit for Hayden Unit 1 is 0.08 lb/MMBtu (30-day rolling average) and for Unit 2 is 0.07 lb/MMBtu (30-day rolling average). The State assumes the BART emission limit can met through the installation and operation of SCR.

We agree with the State's conclusions, and we are proposing to approve its NO_X BART determinations for Hayden Unit 1 and Unit 2.

PM BART Determination

Hayden Units 1 and 2 are each equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 99% reduction in PM. Fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. Consistent with the BART Guidelines, the State did not provide a full five-factor analysis because the State determined BART to be the most stringent control technology and limit. The State has determined that the PM BART emission limit is 0.03 lb/MMBtu (30-day rolling average) for Hayden Unit 1 and Unit 2. The State assumes the BART emission limit can be met through the operation of the current fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM BART determinations for Hayden Unit 1 and Unit 2.

vi. CSU Martin Drake Units 5, 6, and 7

Background

The CSU's Martin Drake facility is located in Colorado Springs, Colorado. This facility consists of three steam driven turbine/generator units, Units 5, 6, and 7, and the associated equipment needed for generating electricity. Units 5, 6, and 7 are the only BART-eligible units at the facility. These units fire coal as the primary fuel and use natural gas for backup and startup. All three boilers are pulverized-coal, dry-bottom, front-fired boilers. The State's BART determination for CSU Martin Drake can be found in Chapter 6.4.3.6 and Appendix C of the SIP.

SO_2 BART Determination

Martin Drake Units 5, 6, and 7 are currently uncontrolled for SO_2. The State determined that DSI was technically feasible for all three units and that dry FGD was technically feasible for Units 6 and 7. The State determined dry FGD was not technically feasible for Unit 5 because of space constraints surrounding this unit. The State also examined emission limit tightening based on current operations for Unit 5.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline SO_2 emissions are 1,269 tpy for Unit 5, 2,785 tpy for Unit 6, and 4,429 tpy for Unit 7 based on an average of 2006–2008 actual emissions. A summary of the State's SO_2 BART analysis and the visibility impacts is provided in Tables 18, 19, and 20 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis.

TABLE 18—SUMMARY OF MARTIN DRAKE UNIT 5 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost Effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
DSI	60	0.26	762	$1,340,663	$1,760	0.12

TABLE 19—SUMMARY OF MARTIN DRAKE UNIT 6 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
DSI	60	0.34	1,671	$2,234,438	$1,741	0.18
Dry FGD	82	0.15	3,632	6,186,854	2,709	0.24
Dry FGD	85	0.13	2,368	6,647,835	2,808	0.25

TABLE 19—SUMMARY OF MARTIN DRAKE UNIT 6 SO_2 BART ANALYSIS—Continued

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Dry FGD	90	0.09	2,507	7,452,788	4,064	0.26

TABLE 20—SUMMARY OF MARTIN DRAKE UNIT 7 SO_2 BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
DSI	60	0.35	2,657	$3,732,826	$1,405	0.29
Dry FGD	82	0.16	3,632	8,216,863	2,263	0.39
Dry FGD	85	0.13	3,764	8,829,321	2,345	0.40
Dry FGD	90	0.09	3,986	9,898,382	2,483	0.41

The State also examined emission limits tightening based on current operations for Unit 5. (The State did not evaluate emissions limit tightening on Units 6 and 7 because the State determined BART to be the most stringent control technology). In order to evaluate emissions limit tightening, the State analyzed actual emission data for Unit 5 from the baseline period of 2006–2008. The State found that the maximum 30-day rolling emission rate for Unit 5 was 0.83 lb/MMBtu. The State applied a 5 percent buffer to the maximum 30-day rolling emission rate because the Drake facility has limited coal storage capacity and blends four different types of coals. These factors can lead to a greater fluctuation in emissions. Assuming no new control technology for Unit 5 and a 5 percent buffer, the State determined that an appropriate SO_2 emission limit would be 0.9 lb/MMBtu on a 30-day rolling average, which is less control than would be achieved with DSI.

Based upon its consideration of the five factors, the State determined that the following are the SO_2 BART limits for Drake Units 5, 6, and 7: 0.26 lb/MMBtu (30-day rolling average) for Unit 5; 0.13 lb/MMBtu (30-day rolling average) for Unit 6; and 0.13 lb/MMBtu (30-day rolling average) for Unit 7. The State assumes the BART emission limits can be met with the installation and operation of DSI on Unit 5 and the installation and operation of dry FGD on Unit 6 and Unit 7. The State determined that a lower emissions limit (0.09 lb/MMBtu) for Units 6 and 7 was not reasonable because the increased control costs to achieve such an emissions limit would not provide significant improvements in visibility (0.01 delta dv for each unit respectively).

We agree with the State's conclusions, and we are proposing to approve its SO_2 BART determinations for Martin Drake Unit 5, Unit 6, and Unit 7.

NO_X BART Determination

Martin Drake Units 5, 6, and 7 are currently controlled with LNBs achieving 54.7%, 52.8%, and 57.7% control, respectively. The State's BART analysis shows that OFA, ULNBs, ULNBs plus OFA, SNCR, SNCR plus ULNBs, and SCR are technically feasible for reducing NO_X emissions at Drake Units 5, 6 and 7. The State determined that RRI, ECO, and coal reburn plus SNCR were technically infeasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline NO_X emissions are 768 tpy for Unit 5, 1,413 tpy for Unit 6, and 2,081 tpy for Unit 7 based on an average of 2006–2008 actual emissions. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Tables 21, 22, and 23 below. The emission rate for each control option in the tables is reflective of the 30-day rolling average contained in the State's BART analysis.

TABLE 21—SUMMARY OF MARTIN DRAKE UNIT 5 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
OFA	20	0.35	154	$141,844	$923	0.07
ULNBs	26	0.32	200	147,000	736	0.08
ULNBs + OFA	28	0.31	215	288,844	1,342	0.08
SNCR	30	0.30	231	1,011,324	4,387	0.08
ULNB/SCR layered approach	81.5	0.08	626	4,467,000	7,133	0.12
SCR	81.5	0.08	626	4,580,349	7,314	0.12

TABLE 22—SUMMARY OF MARTIN DRAKE UNIT 6 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (Delta dv for the maximum 98th percentile impact)
OFA	20	0.38	283	$104,951	$371	0.18
SNCR	30	0.33	424	1,208,302	2,851	0.19
ULNBs	32	0.32	452	232,800	515	0.20
ULNBs + OFA	36	0.31	509	337,751	664	0.19
ULNB/SCR layered approach	83	0.08	1,175	6,182,800	5,260	0.27
SCR	83	0.08	1,175	6,340,797	5,395	0.27

TABLE 23—SUMMARY OF MARTIN DRAKE UNIT 7 NO_X BART ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (Delta dv for the maximum 98th percentile impact)
OFA	20	0.36	416	$75,217	$181	0.22
SNCR	28	0.33	583	386,000	662	0.24
ULNBs	30	0.32	624	2,018,575	3,233	0.26
ULNBs + OFA	36	0.29	749	461,217	616	0.24
ULNB/SCR layered approach	80	0.08	1,709	8,196,000	4,797	0.37
SCR	80	0.08	1,709	8,510,067	4,981	0.37

The State determined that ULNBs plus OFA constitute BART based on the low dollars-per-ton control costs and the visibility improvement afforded by this control technology. The State did not choose SNCR as that technology provides a similar level of NO_X reduction and visibility improvement as ULNBs plus OFA, but at a higher cost per ton of pollutant removed. The State determined SCR was not cost effective for any of the units when compared with the visibility improvement.

Based upon its consideration of the five factors, the State determined that the following are the NO_X BART limits for Drake Units 5, 6, and 7: 0.31 lb/MMBtu (30-day rolling average) for Unit 5 and Unit 6; and 0.29 lb/MMBtu (30-day rolling average) for Unit 7. The State assumes that the BART emission limits can be achieved through the installation and operation of ULNBs plus OFA.

We agree with the State's conclusions, and we are proposing to approve the State's NO_X BART determinations for Martin Drake Units 5, 6, and 7.

PM BART Determination

Martin Drake Units 5, 6, and 7 are each equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 95% reduction in PM. Fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. Consistent with the BART Guidelines, the State did not provide a full five-factor analysis because the State determined BART to be the most stringent control technology and limit.

The State has determined that 0.03 lb/MMBtu (30-day rolling average) is the PM BART limit for Martin Drake Units 5, 6, and 7. The State assumes the limits can be met with the operation of the current fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM BART determinations for Martin Drake Units 5, 6, and 7.

Summary of Colorado's BART Determinations

Table 24 provides a summary of the State's BART determinations that we are proposing to approve.

TABLE 24—SUMMARY OF THE STATE'S BART DETERMINATIONS EPA IS PROPOSING TO APPROVE

Emission unit	Assumed NO_X control type	NO_X emission limit	Assumed SO_2 control type	SO_2 emission limit	Assumed particulate control and emission limit
Cemex-Lyons Kiln	SNCR	255.3 lbs/hr (30-day rolling average) 901.0 tpy (12-month rolling average).	None	25.3 lbs/hr (12-month rolling average) 95.0 tpy (12-month rolling average).	Fabric Filter Baghouse * 0.275 lb/ton of dry feed 20% opacity.
Cemex-Lyons Dryer	None	13.9 tpy	None	36.7 tpy	Fabric Filter Baghouse * 22.8 tons/yr 10% opacity.

TABLE 24—SUMMARY OF THE STATE'S BART DETERMINATIONS EPA IS PROPOSING TO APPROVE—Continued

Emission unit	Assumed NO_X control type	NO_X emission limit	Assumed SO_2 control type	SO_2 emission limit	Assumed particulate control and emission limit
CENC Unit 4	LNBs with OFA	0.37 lb/MMBtu (30-day rolling average) Or 0.26 lb/MMBtu Combined Average for Units 4 & 5 (30-day rolling average).	None	1.0 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.07 lb/MMBtu.
CENC Unit 5	LNBS with SOFA and SNCR.	0.19 lb/MMBtu (30-day rolling average) Or 0.26 lb/MMBtu Combined Average for Units 4 & 5 (30-day rolling average).	None	1.0 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.07 lb/MMBtu.
Comanche Unit 1	LNBs *	0.20 lb/MMBtu (30-day rolling average) 0.15 lb/MMBtu (combined annual average for units 1 & 2).	Lime Spray Dryer *	0.12 lb/MMBtu (30-day rolling average) 0.10 lb/MMBtu (combined annual average for units 1 & 2).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Comanche Unit 2	LNBs*	0.20 lb/MMBtu (30-day rolling average) 0.15 lb/MMBtu (combined annual average for units 1 & 2).	Lime spray Dryer *	0.12 lb/MMBtu (30-day rolling average) 0.10 lb/MMBtu (combined annual average for units 1 & 2).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Craig Unit 1	SNCR	0.28 lb/MMBtu (30-day rolling average).	Wet Limestone scrubber *.	0.11 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Craig Unit 2	SCR	0.08 lb/MMBtu (30-day rolling average).	Wet Limestone scrubber *.	0.11 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Hayden Unit 1	SCR	0.08 lb/MMBtu (30-day rolling average).	Lime Spray Dryer *	0.13 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Hayden Unit 2	SCR	0.07 lb/MMBtu (30-day rolling average).	Lime Spray Dryer *	0.13 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Martin Drake Unit 5	ULNBs with OFA	0.31 lb/MMBtu (30-day rolling average).	Dry Sorbent Injection.	0.26 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Martin Drake Unit 6	ULNBs with OFA	0.31 lb/MMBtu (30-day rolling average).	Lime Spray Dryer or Equivalent Control Technology.	0.13 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Martin Drake Unit 7	ULNBs with OFA	0.29 lb/MMBtu (30-day rolling average).	Lime Spray Dryer or Equivalent Control Technology.	0.13 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.

* Indicates controls that are already installed.

vii. PSCO BART Alternative

Colorado has adopted the PSCO BART Alternative Program (BART alternative) to meet the requirements for BART for PSCO Cherokee Unit 4, Valmont Unit 5, and Pawnee Station Unit 1 and RP for PSCO Arapahoe Units 3 and 4 and Cherokee Units 1, 2, and 3. Under 40 CFR 51.308(e)(2), states may choose to meet the BART requirements with a BART alternative. Section 51.308(e)(2) specifies the requirements that a state must meet to show that the alternative measure or alternative program achieves greater RP than would be achieved through the installation and operation of BART. Section 51.308(e)(3) contains additional requirements that states must address pertaining to their alternative program. Table 25 provides a summary of the units covered under the BART alternative, as well as the required control or shutdown date for the facility.

TABLE 25—SOURCES COVERED UNDER THE PSCO BART ALTERNATIVE

Unit	BART eligible?	NO_X control type	NO_X emission uimit	SO_2 control type	SO_2 emission limit	Particulate type and limit
Cherokee Unit 1	No	Shutdown by 7/1/2012.	0	Shutdown by 7/1/2012.	0	Shutdown by 7/1/2012.
Cherokee Unit 2	No	Shutdown by 12/31/2011.	0	Shutdown by 12/31/2011.	0	Shutdown by 12/31/2011.
Cherokee Unit 3	No	Shutdown by 12/31/2016.	0	Shutdown by 12/31/2016.	0	Shutdown by 12/31/2016.

TABLE 25—SOURCES COVERED UNDER THE PSCO BART ALTERNATIVE—Continued

Unit	BART eligible?	NO_X control type	NO_X emission uimit	SO_2 control type	SO_2 emission limit	Particulate type and limit
Cherokee Unit 4	Yes	Natural Gas Operation by 12/31/2017.	0.12 lb/MMBtu (30-day rolling average) by 12/31/2017.	Natural Gas Operation by 12/31/2017.	7.81 tpy (12 month rolling average).	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Valmont Unit 5	Yes	Shutdown by 12/31/2017.	0	Shutdown by 12/31/2017.	0	Shutdown by 12/31/2017.
Pawnee Unit 1	Yes	SCR **	0.07 lb/MMBtu (30-day rolling average) by 12/31/2014.	Lime Spray Dryer **	0.12 lb/MMBtu (30-day rolling average) by 12/31/2014.	Fabric Filter Baghouse * 0.03 lb/MMBtu.
Arapahoe Unit 3	No	Shutdown by 12/31/2013.	0	Shutdown by 12/31/2013.	0	Shutdown by 12/31/2013.

* Controls are already installed.
** The State assumes this is the control technology the source will use to meet the limit.

A summary of Colorado's BART alternative and the requirements under 40 CFR 51.308(e)(2) and (e)(3) are discussed below. The State's analysis of the PSCO BART alternative can be found in Chapter 6.4.3.7 of the SIP.

i. A List of All BART-Eligible Sources

Pursuant to 40 CFR 51.308(e)(2)(i)(A), the State included a list of all BART-eligible sources in the State in Chapter 6, Table 6–3 of the SIP. A list of BART-eligible sources can also be found in Table 2 of this notice.

ii. A List of All Sources Covered by the Alternative

Pursuant to 40 CFR 51.308(e)(2)(i)(B), the State included in the SIP a list of the BART-eligible sources that are included in the BART alternative, as well as the RP sources covered under the program.

iii. Best System of Continuous Emission Control Technology

As required by 40 CFR 51.308(e)(2)(i)(C), the State determined the best system of continuous emission control for sources that are subject to BART and that are covered by the BART alternative program. Because the State's BART alternative program was designed to meet requirements other than BART,[17] our regulation allowed the State to use simplifying assumptions to determine the best system of continuous emission control for the BART sources in the State's BART alternative program. 40 CFR 51.308(e)(2)(i)(C); 71 FR 60619. We have indicated that our BART presumptive limits for SO_2 and NO_X, set forth in our BART Guidelines (70 FR 39171–39172), represent appropriate simplifying assumptions for determining the best system of continuous emission control for EGUs. The presumptive limit for SO_2 is 0.15 lb/MMBtu. The presumptive limits for NO_X vary depending on boiler and coal type. The State used the presumptive limits in the BART Guidelines for calculating the best system of continuous emission control for the BART sources in the State's BART alternative program. The State also used the presumptive limits as a benchmark for control levels that might have been anticipated from the non-BART sources that are included in the BART alternative, if the State had not adopted the BART alternative.

iv. Projected Emissions Reductions

Pursuant to 40 CFR 51.308(e)(2)(i)(D), the State provided a calculation of the emission reductions expected from the BART alternative compared to emissions reductions that would be achieved by the application of the presumptive limits to sources covered under the alternative. Tables 26 and 27 show the relative emissions.

TABLE 26—SO_2 REDUCTIONS UNDER THE BART ALTERNATIVE

Unit	SO_2 average emissions 2006–2008 (tpy)	SO_2 emissions with presumptive limits (0.15 lb/MMBtu)	SO_2 emissions under BART alternative in 2018 (tpy)
Arapahoe Unit 3	924.97	328.51	0.00
Arapahoe Unit 4	1,764.70	640.93	1.28
Cherokee Unit 1	2,220.80	623.35	0.00
Cherokee Unit 2	1,888.37	418.95	0.00
Cherokee Unit 3	743.00	611.99	0.00
Cherokee Unit 4	2,135.43	1,953.57	7.81
Valmont Unit 5	758.47	1,029.19	0.00
Pawnee Unit 1	13,472.07	3,007.03	2,405.63
Total	23,908	8,614	2,415

[17] Specifically, the program was designed to help the State achieve its overarching reasonable progress goals and to meet the requirements of Colorado House Bill 10–1365 and § 40–3.2–202, C.R.S.—Colorado's Clean Air-Clean Jobs Act.

TABLE 27—NO_X REDUCTIONS UNDER THE BART ALTERNATIVE

Unit	NO_X average emissions 2006–2008 (tpy)	NO_X presumptive limit (lb/MMBtu)	NO_X emissions with presumptive limits (tpy)	NO_X emissions under BART alternative in 2018 (tpy)
Arapahoe Unit 3	1,770.47	0.23	503.71	0.00
Arapahoe Unit 4	1,147.67	0.23	982.77	900.00
Cherokee Unit 1	1,556.23	0.39	1,620.71	0.00
Cherokee Unit 2	2,895.20	0.39	1,089.27	0.00
Cherokee Unit 3	1,865.50	0.39	1,591.18	0.00
Cherokee Unit 4	4,274.00	0.28	3,646.67	2,062.86
Valmont Unit 5	2,313.73	0.28	1,921.15	0.00
Pawnee Unit 1	4,537.73	0.23	4,610.78	1,403.28
Total	20,361	.....	15,996	4,366

v. Evidence That the Alternative Program Achieves Greater RP Than BART

Tables 26 and 27 demonstrate that the State's BART Alternative achieves greater RP than would be achieved through the installation of BART. By applying presumptive limits to the sources, the resulting emissions would be 8,614 tpy for SO_2 and 15,996 tpy for NO_X. Under the BART alternative, the emissions from the sources in 2018 will be 2,415 tpy for SO_2 and 4,366 tpy for NO_X. Thus, EPA concludes that the BART alternative achieves greater RP than would be achieved through the installation of BART and meets the requirements of 40 CFR 51.308(e)(2)(i)(E).

vi. All Emission Reductions Take Place During First Planning Period

Pursuant to 40 CFR 51.308(e)(2)(ii), Table 25 shows that all controls under the BART alternative will occur by December 17, 2017, within the first planning period, which ends in December 2018.

vii. Reductions Are Surplus

As required by 40 CFR 51.308(e)(2)(iv), the State has concluded that emission controls associated with the BART alternative have not been used for other SIP purposes and are only a requirement under the RH SIP. The State has thus determined they are surplus. EPA agrees with the State's assessment.

viii. Distribution of Emissions

The State has determined that the distribution of emissions under the BART alternative is not substantially different than under source-by-source BART or RP. The BART alternative includes only sources that are BART or RP sources and does not include any sources that would not have been included in the RH SIP. All of the units in the BART alternative are located within or adjacent to the 8-hour ozone non-attainment area in the Front Range of Colorado. Pursuant to 40 CFR 51.308(e)(3), since the State has determined that the geographic distribution of emissions is not substantially different under the alternative program, the State is not required to perform visibility modeling. We agree that the BART alternative will not result in a significant shift in the distribution of emissions.

EPA is proposing to approve the State's BART alternative as it meets the requirements for alternative programs under 40 CFR 51.308(e)(2) and (e)(3).

D. Reasonable Progress Requirements

In order to establish RPGs for its Class I areas, and to determine the controls needed for the long-term strategy, Colorado followed the process established in the RHR. First, Colorado identified the anticipated visibility improvement in 2018 in all its Class I areas using the WRAP Community Multi-Scale Air Quality (CMAQ) modeling results. This modeling identified the extent of visibility improvement from the baseline by pollutant for each Class I area. The modeling relied on projected source emission inventories, which included enforceable Federal and State regulations already in place and anticipated BART controls.

Colorado then identified sources and source categories (other than BART sources) in Colorado that are major contributors to visibility impairment and considered whether these sources should be controlled based on a consideration of the factors identified in the CAA and EPA's regulations. *See* CAA 169A(g)(1) and 40 CFR 51.308(d)(1)(i)(A).

The SIP includes Colorado's analysis and conclusion that reasonable progress will be made by 2018, including an analysis of pollutant trends, emission reductions, and improvements expected. The RP discussion and analyses are included in Chapter 8 and Appendix D of the SIP. We are proposing to approve Colorado's submitted RP goals as described more fully below.

1. Visibility Impairing Pollutants and Sources

a. Source Regions of Pollutants

In order to determine the significant sources contributing to haze in Colorado's Class I areas, Colorado relied upon two source apportionment analysis techniques developed by the WRAP. The first technique was regional modeling using the Comprehensive Air Quality Model (CAMx) and the PM Source Apportionment Technology (PSAT) tool, used for the attribution of sulfate and nitrate sources only. The second technique was the Weighted Emissions Potential (WEP) tool, used for attribution of sources of OC, EC, $PM_{2.5}$, and PM_{10}. The WEP tool is based on emissions and residence time, not modeling.

PSAT uses the CAMx air quality model to show nitrate-sulfate-ammonia chemistry and apply this chemistry to a system of tracers or ''tags'' to track the chemical transformations, transport, and removal of NO_X and SO_2. These two pollutants are important because they tend to originate from anthropogenic sources. Therefore, the results from this analysis can be useful in determining contributing sources that may be controllable, both in-state and in neighboring states.

WEP is a screening tool that helps to identify source regions that have the potential to contribute to haze formation at specific Class I areas. Unlike PSAT, this method does not account for chemistry or deposition. The WEP combines emissions inventories, wind patterns, and residence times of air

masses over each area where emissions occur, to estimate the percent contribution of different pollutants. Like PSAT, the WEP tool compares baseline values (2000–2004) to 2018 values, to show the improvement expected by 2018, for sulfate, nitrate, OC, EC, $PM_{2.5}$, and PM_{10}. More information on the WRAP modeling methodologies is available in the document *Technical Support Document for Technical Products Prepared by the Western Regional Air Partnership (WRAP) in Support of Western Regional Haze Plans* in the Supporting and Related Materials section of the docket. Table 28 shows Colorado's contribution to extinction at its own Class I areas. Sulfate and nitrate contribution is based on PSAT results and OC, EC, $PM_{2.5,}$ PM_{10}, and sea salt contributions are based on WEP.

TABLE 28—COLORADO SOURCES EXTINCTION CONTRIBUTION 2000–2004 FOR 20% WORST DAYS

Class I area	Pollutant species	2000–2004 extinction (Mm^{-1})	Species contribution to total extinction (%)	CO sources contribution to species extinction (%) [1]

* Not modeled by the WRAP.

Table 29 shows influences from sources both inside and outside of Colorado per the PSAT modeling for 2018. As indicated, boundary conditions or outside domain are the highest contributor to sulfate at all Colorado Class I areas. The boundary conditions represent the background concentrations of pollutants that enter the edge of the modeling domain. Depending on meteorology and the type of pollutant (particularly sulfate), these emissions can be transported great distances that can include regions such as Canada, Mexico, and the Pacific Ocean.

Colorado appears to be a major contributor of particulate sulfate at those Class I areas near significant sources of SO_2, specifically Rocky Mountain National Park, Mount Zirkel, and Rawah Wilderness. For nitrate, Colorado appears to be a major contributor at most of its Class I areas except for the Weminuche Wilderness, La Garita Wilderness, and Black Canyon of Gunnison National Park. Boundary conditions are also a major contributor of nitrate at all Colorado Class Iareas.

[18] OD denotes Outside Domain; MEX denotes the country of Mexico; CEN denotes the Central Regional Air Partnership; PO denotes Pacific Offshore.

TABLE 29—PSAT SOURCE REGION APPORTIONMENT FOR 20% WORST DAYS

b. Source Categories

The State conducted a detailed evaluation of six visibility impairing pollutants: nitrates, sulfates, OC, EC, fine soil and coarse mass (CM) (fine soil and CM are collectively known as PM) contributing to visibility impairment at Colorado's Class I areas.[19] The State relied on WRAP emission inventory information and modeling to determine what pollutants and sources were contributing to visibility impairment at its Class I areas. Once the State determined what sources were contributing to visibility impairment and by what amount, it determined whether the source/source category was significant and if it was reasonable to control.

Based on its analysis, the State determined that the sources of OC, EC, and area source PM are not well documented because of emission inventory limitations associated with natural sources (predominantly wildfires), uncertainty of windblown emissions, and poor model performance for these constituents. The State determined it would defer on addressing these pollutants until science and emission inventories are improved for consideration in future RH SIPs. The State determined that RP controls would be evaluated for SO_2, NO_X, and stationary source PM.

The State's analysis evaluated the projected sources of SO_2 and NO_X in 2018. The State's analysis shows that 78% of 2018 total statewide SO_2 emissions are from point sources, mainly coal-fired boilers. Area source SO_2 emissions (14% of total SO_2 emissions) are mainly comprised of thousands of small commercial boilers and internal combustion engines spread throughout the State that burn distillate fuel. The State determined there is no practical way to control thousands of small boilers and engines. The State determined SO_2 emissions from natural fires constitute 6% of total SO_2 emissions and are considered uncontrollable. Both off-road and on-road mobile sources each constitute 1% of SO_2 emissions and are subject to federal ultra-low sulfur diesel fuel requirements that limit sulfur content to 15 ppm. Ultra-low sulfur diesel fuel was in widespread use after June 2010 for off-road mobile sources and after June 2006 for on-road mobile sources. The State has determined that point sources are the dominant source of emissions and, for this planning period, the only practical category to evaluate under RP for SO_2.

Colorado's analysis shows that point sources comprise 36% of total NO_X emissions; these emissions are primarily from coal-fired external combustion boilers and natural gas-fired internal combustion engines (in oil and gas compression service). On-road and off-road mobile sources comprise 16% and 14% of Statewide NO_X emissions, respectively. Because mobile exhaust emissions are primarily addressed, and will continue to be addressed, through federal programs, the State did not evaluate mobile sources for RP control in this planning period. Emissions of NO_X from biogenic activity and natural fire are considered uncontrollable and vary from year-to-year. Non-oil and gas area sources comprise about 6% of NO_X emissions and involve thousands of combustion sources that the State determined are not reasonable to control in this planning period. Area oil and gas emissions contribute 12% of total NO_X emissions.

The State has determined that large point sources are the dominant source of NO_X emissions and are practical to evaluate under RP in this planning period. The State determined that smaller point sources (combustion turbines) and area oil and gas emissions, specifically heater-treaters and reciprocating internal combustion engines (RICE), significantly contribute to visibility impairment in Colorado's Class I areas and are also practical to evaluate for RP controls in this planning period.

c. Stationary Sources

The State used a RP screening methodology called ''Q/d'' to determine which stationary (point) sources would be candidates for controls under RP. The methodology Q/d is a calculated ratio that evaluates stationary source emissions (mathematical sum of actual SO_2, NO_X and PM emissions in tons per year, denoted as ''Q'') divided by the distance (in kilometers, denoted as ''d'') of the point source from the nearest Class I area. The State evaluated the visibility impact sensitivity of different Q/d thresholds and determined that a Q/d ratio equal to or greater than 20 approximated a delta dv impact ranging from 0.06 dv to 0.56 dv. The resultant average of the range is about 0.3 dv, which is a more conservative RP threshold than the 0.5 dv that was used in determining which sources would be subject-to-BART under the federal BART regulations. Since the threshold is more conservative than the subject-to-BART threshold, the State determined that a Q/d value of 20 is reasonable for determining which RP sources the State should consider for RP controls.

[19] See *Significant Source Categories Contributing to Regional Haze at Colorado Class I Areas,* October 2, 2007, located in the Supplemental and Related Materials section of the docket.

The evaluation of potential RP sources involved all Colorado stationary sources with actual SO_2, NO_X, or PM_{10} emissions over 100 tpy in 2007. The State identified 113 sources as exceeding the 100 tpy threshold for any of the three pollutants and further analyzed these sources using the Q/d analysis. The State determined that there were seven sources that had a Q/d equal to or greater than the threshold of 20 that were not already being controlled under BART.[20] The State deemed these seven sources to be subject to RP and the State completed a RP analysis for each of the sources.

Table 30 shows the subject-to-RP sources identified by the State.

TABLE 30—RP SOURCES EVALUATED FOR CONTROLS

Source	Q (tpy based on 2007 actual emissions)	Nearest Class I area	Q/d value
Platte River Power Authority—Rawhide Station	2,796	Rocky Mountain National Park	49.9
CENC—Unit 3	4,453	Rocky Mountain National Park	81.7
CSU-Nixon Power Plant—Nixon Unit 1	6,668	Great Sand Dunes National Park	63.9
Black Hills Energy Clark Power Plant Units 1 and 2	2,393	Great Sand Dunes National Park	40.8
Holcim—Kiln and Dryer	3,250	Great Sand Dunes National Park	49.2
Tri-State—Nucla	3,327	Black Canyon National Park	47.1
Tri-State—Craig Unit 3	20,628	Flat Tops Wilderness Area	432.4
PSCO—Cameo Station	3,750	Black Canyon National Park	53.2

We agree with the State's analysis on appropriate source categories and stationary sources to be evaluated under RP.

2. Four Factor Analyses

In determining the measures necessary to make RP, states must take into account the following four factors and demonstrate how they were taken into consideration in selecting RP goals for a Class I area:

- Costs of Compliance;
- Time Necessary for Compliance;
- Energy and Non-air Quality Environmental Impacts of Compliance; and
- Remaining Useful Life of any Potentially Affected Sources. CAA § 169A(g)(1) and 40 CFR 308(d)(1)(i)(A).

The State performed a four factor analysis for each of the RP sources pursuant to 40 CFR 51.308(d)(1)(i)(A).

State NO_X Control Criteria

For potential NO_X controls in the RP context, the State adopted the same screening criteria as used to evaluate potential NO_X BART controls. For further detail, see section V.C.3 above. We have some of the same concerns regarding the use of these criteria for RP as we expressed concerning their use in BART determinations. Nonetheless, as discussed below, we agree with the State's determinations concerning NO_X controls on the RP sources.

SO_2 Controls—Wet and Dry Scrubbing

As it did in the BART context, the State eliminated wet FGD from consideration as a potential RP control for the same reasons—because of negative non-air quality environmental impact on water usage. EPA is proposing that the State has provided adequate justification to eliminate wet FGD as a potential SO_2 RP control.

a. Visibility Improvement Modeling

Colorado concluded that it is also appropriate to consider a fifth factor for evaluating potential RP control options—the degree of visibility improvement that may reasonably be anticipated from the use of the RP controls. Our RP guidance contemplates that states may be able to consider other relevant factors for RP sources (see EPA's *Guidance for Setting Reasonable Progress Goals under the Regional Haze Program,* (''Reasonable Progress Guidance''), pp. 2–3, July 1, 2007), and we find it appropriate to consider visibility improvement when evaluating potential RP controls.

For the RP modeling, the State followed the BART Guidelines. The BART Guidelines provide that states may use the CALPUFF modeling system or another appropriate model to determine the visibility improvement expected at a Class I area from the potential BART control technology applied to the source. Colorado performed CALPUFF modeling to determine the degree of visibility improvement expected at a Class I area based on the controls evaluated for RP for the subject-to-RP sources.

The BART Guidelines also recommend that states develop a modeling protocol for making individual source attributions, and suggest that states may want to consult with EPA and their RPO to address any issues prior to modeling. Colorado used the CALPUFF model for Colorado RP sources in accordance with a protocol it developed titled ''Supplemental BART Analysis CALPUFF Protocol for Class I Federal Area Visibility Improvement Modeling Analysis, revised August 19, 2010,'' which was approved by EPA and is included in the Supplemental Information section of the docket. The Colorado protocol follows recommendations for long range transport described in appendix W to 40 CFR part 51, ''Guideline on Air Quality Models,'' and in EPA's ''Interagency Workgroup on Air Quality Modeling (IWAQM) Phase 2 Summary Report and Recommendations for Modeling Long Range Transport Impacts,'' as recommended by the BART Guidelines. (40 CFR part 51, appendix Y, section III.D.5).

b. Summary of RP Determinations and Limits

For the subject-to-RP sources, the State provided analyses that took into consideration the four factors as required by section 169A(g)(1) of the CAA. The State also included visibility improvement as a fifth factor in its RP analyses for most sources. The State elected to consider EPA's BART Guidelines as relevant to its RP evaluations, in addition to EPA's Reasonable Progress Guidance. A summary of the RP analysis for each source is included in Chapter 8 of the SIP. The State's complete RP analyses, as well as additional technical information and materials, are included in Appendix D of the SIP. EPA is

[20] The State has concluded that it need not reanalyze a source for RP controls for which it has already made a BART determination. This conclusion is consistent with our RP guidance.

proposing to approve the RP determinations submitted by the State for: Platte River Power Authority (PRPA), Rawhide Unit 101; CENC Unit 3; CSU Nixon Power Plant, Nixon Unit 1; Black Hills Energy Clark Power Plant, Units 1 and 2; Holcim Florence Cement Plant; Tri-State Generation, Nucla; Tri-State Generation, Craig Unit 3; and PSCO Cameo Station. A summary of the RP determination for each source is provided below.

i. Platte River Power Authority—Rawhide Unit 101

Background

The PRPA Rawhide Energy Station is located in Larimer County approximately 10 miles north of the town of Wellington, Colorado. Rawhide Unit 101 is a coal-fired steam-driven EGU with a rated electric generating capacity of 305 MW (gross). The Rawhide Station also has five natural-gas-fired combustion turbines. The primary use of these units is to meet PRPA's energy reliability and peak load requirements. The turbines operate on limited, intermittent, and unpredictable schedules as peak loading units. Additionally, the facility includes a number of fugitive dust sources. The State did not do a RP analysis for the turbines or fugitive dust sources since these units fall below the de minimis threshold established by the State.[21] Unit 101 is the only subject-to-RP unit at the facility. The State's RP determination can be found in Chapter 8.5.2.1 and Appendix D of the SIP.

SO_2 RP Determination

Rawhide Unit 101 is currently controlled with a dry FGD achieving over 72 percent SO_2 reduction with a current permit limit of 0.09 lb/MMBtu (annual average). Per the BART Guidelines, for EGUs with preexisting post-combustion SO_2 controls achieving removal efficiencies greater than 50 percent, states should consider cost effective scrubber upgrades designed to improve the system's overall SO_2 removal efficiency (70 FR 39171). Under the BART Guidelines, a state is not required to evaluate the replacement of the current SO_2 controls if the removal efficiency is over 50% (70 FR 39171). We conclude that it is reasonable to follow this approach for evaluating potential RP controls in this initial planning period. Colorado should consider replacement of existing scrubbers in future planning periods. The State's RP analysis evaluated numerous dry FGD upgrades including: (1) Use of performance additives; (2) use of more reactive sorbent; (3) increase the pulverization level of sorbent; and (4) engineering redesign of atomizer or slurry injection system. The State analyzed each possible upgrade and determined that all were technically infeasible for Rawhide Unit 101. The State determined that fuel switching from coal to natural gas was a technically feasible option for Rawhide Unit 101.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source.

Baseline SO_2 emissions are 913 tpy based on an average of 2006–2008 actual emissions. A summary of the State's SO_2 RP analysis and the visibility impacts for fuel switching is provided in Table 31 below.

TABLE 31—SUMMARY OF RAWHIDE UNIT 101 SO_2 RP ANALYSIS

Control technology	Emission rate (lb/MMBtu) (30-day rolling average)	Emission Reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Fuel Switching	0.00	906	$237,424,331	$262,169	0.87

The State determined it would take PRPA approximately 2–3 years to switch from coal to natural gas. The State determined fuel switching was not reasonable based on the high cost effectiveness value.

The State also assessed emissions limit tightening based on current operations. Rawhide Unit 101's average 30-day rolling emission rate during the baseline period (2006–2008) was 0.09 lb/MMBtu. The maximum 30-day rolling emission rate during this period was 0.11 lb/MMBtu. The State evaluated both these levels as potential emissions limits. The State also evaluated an emission limit of 0.07 lb/MMBtu. Emissions limit tightening to emissions levels currently achieved is a no-cost control option. The State modeled visibility improvement for SO_2 emission limits lower than 0.11 lb/MMBtu. The modeling showed that, compared to an emission limit of 0.11 lb/MMBtu, an emission limit of 0.09 lb/MMBtu would result in 0.01 dvs of visibility improvement, and an emission limit of 0.07 lb/MMBtu would result in 0.03 dvs of visibility improvement.

The State has determined that the SO_2 RP emission limit for Rawhide Unit 101 is 0.11 lb/MMBtu (30-day rolling average), reflecting the actual performance of the current controls. It represents a more stringent limit than the current limit of 0.13 lb/MMBtu (30-day rolling average). The State assumes the RP limit can be achieved by the operation of the current LSD. The State determined a lower SO_2 limit was not reasonable as it would not result in significant visibility improvement (less than 0.02 dv) and would likely result in frequent non-compliance events.

We agree with the State's conclusions, and we are proposing to approve its SO_2 RP determination for PRPA Rawhide Unit 101.

NO_X RP Determination

Rawhide Unit 101 is currently controlled with LNB+ close coupled over fire air + SOFA achieving a 49.6% control. The State determined that enhanced combustion controls (ECC), SNCR, fuel switching from coal to natural gas, and SCR were technically feasible NO_X controls for Rawhide Unit 101. The State determined that RRI, ECO, and coal reburn + SNCR were not technically feasible.

The State did not identify any energy or non-air quality environmental

[21] For the purposes of evaluating RP, the State has elected to set de minimis thresholds for any emission unit at a subject-to-RP source with actual baseline emissions of SO_2, NO_X, or PM_{10} less than the federal Prevention of Significant Deterioration (PSD) significance levels. These *de minimis* levels are as follows: NOx—40 tons per year; SO_2—40 tons per year; PM_{10}—15 tons per year. Any unit emitting below these levels is not subject to an RP analysis. The BART Guidelines allow for states to set de minimis levels (see 70 FR 39161), and we think it was reasonable for the State to set *de minimis* levels for RP sources.

impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. Baseline NO_X emissions are 1,866 tpy based on an average of 2006–2008 actual emissions. A summary of the State's NO_X BART analysis and the visibility impacts is provided in Table 32 below. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis.

TABLE 32—SUMMARY OF RAWHIDE UNIT 101 NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
ECC	24	0.145	448	$288,450	$644	0.45
SNCR	27	0.140	504	1,596,000	3,168	0.46
Fuel Switching	29	0.135	545	237,424,331	435,681	0.47
SCR	63.5	.07	1,185	12,103,000	10,214	0.59

The State estimates that the time necessary for compliance after SIP approval would be approximately 2–3 years for SNCR and 3–4 years for SCR. ECC could be functional within 6 months of SIP approval.

The State eliminated switching to natural gas and SCR from consideration due to the high cost effectiveness values and associated degree of visibility improvement. The State determined that ECC was reasonable for RP control. The State made this determination based on the cost effectiveness and visibility improvement associated with ECC. SNCR would achieve similar emissions reductions to ECC and would afford a minimal additional visibility benefit (0.01 delta dv), but it would do so at a significantly higher dollar-per-ton control cost compared to the selected ECC. Thus, the State determined that SNCR was not reasonable. Based upon its consideration of the five factors that it used for RP, the State determined that the NO_X RP emission limit for Rawhide Unit 101 is 0.145 lb/MMBtu (30-day rolling average). The State assumes that the RP emission limit can be achieved through the operation of ECC.

We agree with the State's conclusions, and we are proposing to approve its NO_X RP determination for PRPA Rawhide Unit 101.

PM RP Determination

Rawhide Unit 101 is equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 99% reduction in PM. Fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. The State did not provide a full four-factor analysis plus visibility improvement modeling because the State determined RP to be the most stringent control technology and limit.

The State has determined that the PM RP emission limit for Rawhide Unit 101 is 0.03 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for PRPA Rawhide Unit 101.

ii. CENC Boiler 3

Background

The CENC facility includes five coal-fired boilers (Boilers 1–5) that supply steam and electrical power to Coors Brewery. Of these five Boilers, Boilers 4 and 5 are subject to BART and Boiler 3 is subject to RP. Boiler 3 is a 225 MMBtu/hr boiler. The State did not evaluate Boiler 1, Boiler 2, or fugitive dust sources at the facility for RP controls since emissions from these units were below the State's de minimis levels. The State's RP determination for CENC Boiler 3 can be found in Chapter 8.5.2.2 and Appendix D of the SIP.

SO_2 RP Determination

CENC Boiler 3 is currently uncontrolled for SO_2. The State determined that DSI and fuel switching to natural gas were technically feasible for reducing SO_2 emissions from Boiler 3. The State determined that dry FGD is not technically feasible for Boiler 3 due to space constraints onsite. Boiler 3's load range varies from low loads (ready to respond in the event of a malfunction in Boiler 4 or Boiler 5), medium loads (increased customer steam loads) to high loads (during Boiler 4 or Boiler 5 overhauls). The load range varies within the month and has patterns throughout the year. Because of the varying loads, the State has reasoned that a longer-than-three-year average of emissions is needed to determine baseline emissions. The State determined that a baseline average from 2000–2008 represents a reasonable depiction of actual emissions from this unit.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. The baseline SO_2 emissions are 257 tpy. A summary of the State's SO_2 RP analysis is provided in Table 33 below. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis.

TABLE 33—SUMMARY OF CENC BOILER 3 SO_2 RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)
DSI	60	0.11	147	$1,340,661	$9,114
Fuel Switching	100	0.00	245	1,428,911	5,828

The State determined it would take CENC five years after SIP approval to install any controls.

The State used modeling results from CENC Boiler 4 to determine the projected visibility improvement for Boiler 3 because the units are similar and located at the same facility. CALPUFF modeling indicates a 0.08 dv improvement for DSI applied to Boiler 4. DSI controls for Boiler 4 would reduce SO_2 emissions by approximately 268 tons per year. DSI controls for Boiler 3 would reduce SO_2 emissions by about 147 tons per year. Fuel switching to natural gas would reduce SO_2 emissions by an estimated 245 tons annually. The State inferred that either control applied to Boiler 3 would yield visibility improvements of less than 0.10 dv.

The State determined that fuel switching and DSI were not reasonable to select as RP controls due to the high cost effectiveness values and low visibility improvement associated with these controls. Based on a fuel analysis, the State determined that the maximum SO_2 emissions rate from 2000–2010 is 0.99 lb/MMBtu. In establishing an RP emission limit, the State determined a 20% contingency factor is warranted for CENC Boiler 3 due to the different load factors discussed above. Based upon its consideration of the five factors that it used for RP, the State has determined that the SO_2 RP emission limit for CENC Boiler 3 is 1.2 lbs/MMBtu (annual average).

We agree with the State's conclusions, and we are proposing to approve its SO_2 RP determination for CENC Boiler 3.

NO_X RP Determination

The State determined that flue gas recirculation (FGR), SNCR, ROFA, fuel switching to natural gas, and three options for SCR (regenerative SCR (RSCR), high temperature SCR (HTSCR), and low temperature SCR (LTSCR)) were technically feasible for reducing NO_X emissions at CENC Boiler 3. The State determined that LoTOx™, ECO, RRI, and coal reburn plus SNCR were not technically feasible. The State determined that because CENC Boiler 3 is a coal stoker boiler, LNBs are also not technically feasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X RP analysis is provided in Table 34 below. Baseline NO_X emissions are 205 tpy. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis.

TABLE 34—SUMMARY OF CENC BOILER 3 NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)
FGR	20	0.17	34	$1,042,941	$30,292
SNCR	30	0.15	51	513,197	10,146
Fuel Switching	35	0.14	84	1,428,911	16,950
ROFA w/Rotamix	57	0.09	77	978,065	9,496
RSCR	75	0.05	96	978,065	10,160
HTSCR	86	0.03	126	1,965,929	15,651
LTSCR	86	0.03	145	2,772,286	19,187

The State estimates that the source would need at least five years after SIP approval to install the control equipment.

The State used modeling results from CENC Boiler 4 to determine the projected visibility improvement for Boiler 3 since the units are similar and located at the same facility. CALPUFF modeling indicates a 0.12 dv improvement for LNB + SOFA + SNCR applied to Boiler 4. LNB + SOFA + SNCR controls for Boiler 4 would reduce NO_X emissions by approximately 368 tons per year. The highest performing SCR controls for Boiler 3 would reduce NO_X emissions by about 145 tons per year. Based on this information, the State has inferred that any control applied to Boiler 3 would yield visibility improvements of less than 0.12 dv. The State determined that none of the evaluated controls were reasonable because of the high cost effectiveness values and low visibility improvement for each of the controls.

Based on a review of historical load characteristics of this boiler, the State determined that RP for Boiler 3 is an annual NO_X limit based on 50% annual capacity utilization using the maximum capacity year in the last decade. Included in this annual capacity utilization, there is a 20% contingency factor for reasons explained above. The State determined that the NO_X RP emission limit for Boiler 3 is 246 tons/year (12-month rolling total).

We agree with the State's conclusions, and we are proposing to approve its NO_X RP determination for CENC Boiler 3.

PM RP Determination

CENC Boiler 3 is equipped with a fabric filter baghouse to control PM emissions with a current emission limit of 0.07 lb/MMBtu. Fabric filter baghouses are the most stringent control technology for controlling PM emissions, and stack tests show that the fabric filter baghouses are achieving a 98% reduction in PM. The State determined that PM RP for Boiler 3 is an emission limit of 0.07 lb/MMBtu.

The State assumes the RP emission limit can be met with the operation of the current fabric filter baghouses.

While we do not agree with all of the State's assumptions and conclusions in arriving at a PM RP limit of 0.07 lb/MMBtu, we are proposing to approve the State's PM RP determination for CENC Boiler 3. Based on our review/analysis, it appears CENC is capable of achieving a lower emission limit than 0.07 lb/MMBtu with existing equipment. However, we anticipate that the visibility improvement that would result from lowering the limit to a value below 0.07 lb/MMBtu would be insignificant. Under these circumstances, we are proposing to find that the State's RP determination was reasonable.

We find that an emission limit of 0.07 lb/MMBtu is reasonable, as a lower emission limit would not result in significant visibility improvement. Thus, we are proposing to approve the State's PM RP determination for CENC Boiler 3.

iii. CSU—Nixon Unit 1

Background

The Nixon facility is located in Fountain, Colorado. This facility consists of one coal fired boiler (Unit 1), an auxiliary boiler, the associated equipment needed for generating electricity, and two natural-gas-fired simple cycle combustion turbines driving electricity generators. The facility also includes the various processes necessary to handle the coal, flyash and bottom ash. The State determined that Unit 1 and the two combustion turbines were subject to RP. The State determined the rest of the units at this facility had emissions below the de minimis thresholds set by the State. The boiler is a 227 MW unit with a pulverized-coal, dry-bottom, front-fired boiler that fires low sulfur western coal as the primary fuel. It can currently use No. 2 distillate oil or natural gas for an ignition fuel. The State's RP determination can be found in Chapter 8.5.2.3 and Appendix D of the SIP. The analysis for the combustion turbines can be found in section V.D.2.b.x of this notice.

SO_2 RP Determination

Nixon Unit 1 is currently uncontrolled for SO_2. The State determined that DSI and dry FGD were technically feasible for reducing SO_2 emissions from Nixon Unit 1. The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's SO_2 RP analysis is provided in Table 35 below. Baseline SO_2 emissions are 4,121 tpy based on the average of 2006–2008 actual emissions. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis.

TABLE 35—SUMMARY OF NIXON UNIT 1 SO_2 RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
DSI—Trona	60	0.19	2,473	$9,438,692	$1,997	0.44
Dry FGD	78	0.11	3,215	12,036,604	3,744	0.46
Dry FGD	85	0.08	3,392	13,399,590	3,950	0.50

The State estimates it would take 3–5 years after SIP approval for the source to install controls on Nixon Unit 1.

The State determined that dry FGD was reasonable for RP control for Nixon Unit 1. Based upon its consideration of the five factors that it used for RP, the State determined that the SO_2 RP emission limit for CSU Nixon Unit 1 is 0.11 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved with dry FGD. The State determined that a lower emissions limit (85% control efficiency) for Unit 1 was not reasonable as increased control costs to achieve such an emissions rate would not provide appreciable incremental improvements in visibility (0.04 delta dv).

We agree with the State's conclusions, and we are proposing to approve its SO_2 RP determination for CSU Nixon Unit 1.

NO_X RP determination

Nixon Unit 1 is currently controlled for NO_X emissions with LNBs. The State determined ULNB, OFA, SNCR, SNCR plus ULNB, and SCR were technically feasible for reducing NO_X emissions at Nixon Unit 1. The State determined ECO, RRI, and coal reburn plus SNCR were not technically feasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X RP analysis is provided in Table 36 below. Baseline NO_X emissions are 2,356 tpy based on the average of 2006–2008 actual emissions. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis.

TABLE 36—SUMMARY OF NIXON UNIT 1 NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
ULNBs	20	0.24	471	$567,000	$1,203	0.15
OFA	25	0.22	589	403,000	684	0.15
ULNBs + OFA	30	0.21	707	907,000	1,372	0.16
SNCR	30	0.21	707	3,266,877	4,564	0.16

TABLE 36—SUMMARY OF NIXON UNIT 1 NO_X RP ANALYSIS—Continued

Control technology	Control efficiency (%)	Emission rate (lb/MMBtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
ULNBs + SCR	73	0.08	1,720	11,007,000	6,398	0.24
SCR	73	0.08	1,720	11,010,000	6,400	0.24

The State estimates it would take CSU 2–3 years to install SNCR and 3–4 years to install SCR after SIP approval.

The State determined NO_X RP is ULNBs plus OFA. The State eliminated SNCR, ULNBs plus SCR, and SCR from consideration due to the high cost effectiveness values and low visibility improvement for these controls. Based upon its consideration of the five factors that it used for RP, the State determined that the NO_X RP emission limit for Nixon Unit 1 is 0.21 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved with ultra-low NO_X burners with overfire air control. The State did not choose SNCR as it would achieve the same emissions reductions at a greater expense.

We agree with the State's conclusions, and we are proposing to approve the State's NO_X RP determination for CSU Nixon Unit 1.

PM RP Determination

Nixon Unit 1 is equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving greater than a 95% reduction in PM. The State determined that fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. The State did not provide a full four-factor analysis plus visibility improvement modeling because the State determined RP to be the most stringent control technology and limit.

The State has determined that the PM RP emission limit for CSU Nixon Unit 1 is 0.03 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for CSU Nixon Unit 1.

iv. Black Hills Energy Clark Power Plant, Units 1 and 2

Black Hills/Colorado Electric Utility Company informed the State that the Clark Units 1 and 2 will be shut down by December 31, 2013. The shutdown will result in SO_2, NO_X and PM reductions of approximately 1,457 tpy, 861 tpy, and 72 tpy, respectively. The State determined that the shutdown of Clark Power Plant Units 1 and 2 by December 31, 2013 is RP for this source. The State did not provide a RP analysis for this facility since the shutdown of the facility represents the most stringent control. The State's discussion for the source can be found in Chapter 8.5.2.4 of the SIP. The shutdown of Black Hills Energy Clark Power Plant Unit 1 and Unit 2 is required by the RH SIP (see section 8.5.2 of the SIP and Regulation No. 3, Part F, Section VI.B).

v. Holcim Florence Cement Plant

Background

The Holcim Florence Cement Plant is a Portland cement plant located in Florence, Colorado. In May 2002, a newly constructed cement kiln commenced operation at the plant. This more energy-efficient 5-stage preheater/precalciner kiln replaced three older wet process kilns. The Florence Plant includes a quarry where major raw materials used to produce Portland cement, such as limestone, translime and sandstone, are mined, crushed and then conveyed to the plant site. Emissions from the kiln system, raw mill, coal mill, alkali bypass and clinker cooler are all routed through a common main stack for discharge to the atmosphere. The kiln system is rated at 950 MMBtu per hour of fuel input with a nominal clinker production rate of 5,950 tons per day. It is permitted to burn the following fuel types: Coal, tire derived fuel, petroleum coke, natural gas, dried cellulose, and oil, including non-hazardous used oil. The State determined that the kiln system, quarry, and finish mill were subject to RP and that all other units at this facility fall below the State's de minimis threshold. The quarry and finish mill only have PM emissions. The State RP determination for the Holcim Florence Cement Plant can be found in Chapter 8.5.2.5 and Appendix D of the SIP.

SO_2 RP Determination

The kiln system is currently controlled with a wet FGD with a current SO_2 permit limit of 1006.5 tpy. The wet FGD, in conjunction with good combustion practices and the inherent recycling and scrubbing of acid gases in the manufacturing process, achieves a 98.3% reduction in SO_2 emissions as measured by the total sulfur input into the system versus the amount of sulfur emitted to atmosphere. The State estimates that the wet FGD itself achieves an overall SO_2 removal efficiency of greater than 90%.

On August 9, 2010, EPA finalized changes to the NSPS for Portland Cement Plants. The NSPS requires new, modified, or reconstructed cement kilns to meet an emission standard of 0.4 pound of SO_2 per ton of clinker on a 30-day rolling average or a 90% reduction as measured at the inlet and outlet of the control device. While the new NSPS does not apply to the Holcim Portland Plant because it is an existing facility, the State determined that 90 percent control represents the most stringent level of control and wet FGD the most stringent control technology for Portland cement plants. Therefore, the State did not complete a full RP analysis.

The State did evaluate emissions limit tightening based on current operations. As a part of its submittals to the State, Holcim analyzed continuous hourly emission data for SO_2. The State used the hourly emission data from 2004 to 2008 to calculate the daily emission rates. The State calculated a 30-day rolling average emission rate by dividing the total emissions from the previous 30 operating days by the total clinker production from the previous 30 operating days. The State established two RP limits for the Holcim Florence Cement Plant. The State used the 99th percentile of the 30-day rolling average data to establish a short-term SO_2 RP emission limit of 1.30 pounds per ton of clinker (30-day rolling average). The State calculated the long-term annual

limit by multiplying the long-term baseline SO_2 value of 0.77 lb/ton clinker (the mean of 0.51 pound per ton plus one standard deviation of 0.26 pound per ton) by the annual clinker limit of 1,873,898 tpy, and then dividing by 2,000 pounds per ton. The State determined that the SO_2 RP long-term limit is 721.4 tpy (12-month rolling total). The State assumes that the emission limits can be achieved through the operation of the existing wet FGD.

We agree with the State's conclusions, and we are proposing to approve its SO_2 RP determination for the Holcim Florence Cement Kiln.

NO_X RP Determination

NO_X emissions from the kiln are currently controlled by a number of technologies, including LNBs. The State determined water injection (the injection of water into the main flame of the kiln to act as a heat sink and reduce the flame temperature) and SNCR were technically feasible. The State determined that SCR is not commercially available for Portland cement kilns.

Although we disagree with the State's conclusion on the commercial availability of SCR for cement kilns, we accept the State's decision, for purposes of RH, not to analyze this control technology further. We note that EPA has acknowledged, in the context of establishing NSPS for Portland Cement Plants, substantial uncertainty regarding the cost effectiveness associated with the use of SCR at such plants. See 75 FR 54995. We expect the State to reevaluate this technology in subsequent RP planning periods.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X RP analysis is provided in Table 37 below. Baseline NO_X emissions are 1,931 tpy based on the average of 2007–2009 actual emissions. The emission rate in the table is reflective of the 30-day rolling average contained in the State's RP analysis. The State estimates that water injection would result in a 7 percent or less emission reduction and SCNR could achieve about 45 percent control.[22] Since the State's initial analysis indicated that SNCR would be reasonable for RP control, the State did not analyze water injection further.

TABLE 37—SUMMARY OF HOLCIM FLORENCE CEMENT KILN NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/ton of clinker) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
SNCR	45	2.73	1098.9	$2,520,000	$2,293	0.29

The State has determined that Holcim will need five years from SIP approval to install SNCR controls.

The State determined that NO_X RP control is SNCR. The State has determined that the NO_X RP emission limits for the Holcim Florence Cement Kiln are 2.73 pounds per ton of clinker (30-day rolling average) and 2086.8 tpy (12-month rolling average). The State assumes that the emission limits can be achieved through the operation of the existing LNBs and the installation and operation of SNCR.

The State calculated the 30-day rolling average short-term limit by adjusting upward by 10% (to account for the use of tire-derived fuel) the short-term baseline emission rate of 4.47 pounds of NO_X per ton clinker, and by then accounting for SNCR at 45% control efficiency [4.47/0.9*(1–0.45) = 2.73]. The State calculated the long-term annual limit by adjusting the annual baseline emission rate of 3.64 lbs/ton clinker (the mean of 3.43 pounds per ton plus one standard deviation of 0.21 pound per ton) in a similar fashion [3.64/0.9*(1–0.45) = 2.23 lb/ton]. The State took the calculated value of 2.23 pounds per ton, multiplied it by the annual clinker limit of 1,873,898 tpy, and then divided by 2,000 pounds per ton to arrive at the 2,086.8 tpy NO_X limit.

We agree with the State's conclusions, and we are proposing to approve its NO_X RP determination for the Holcim Florence Cement Kiln.

PM RP Determination for the Kiln

The kiln system is currently controlled with fabric filter baghouses with an emission limit of 246.3 tpy. The units are exceeding a PM control efficiency of 95%. The State has determined that the existing fabric filter baghouses installed on the kiln system represent the most stringent control technology.

The 246.3 tpy limit equates to an annual average of 0.26 pound of PM per ton of clinker. The State evaluated the impact on visibility of a lower emission rate. The State modeled possible visibility improvements associated with two emission rates: an emission rate of 0.08 pound of PM per ton of clinker (19.83 lbs/hour) and a rate of 0.04 pound of PM per ton of clinker (9.92 lbs/hour). This analysis assumed the emissions were all attributable to the kiln (i.e., no contribution from the clinker cooler) to assess the impact of a possible reduction of the kiln emission limit. The 98th percentile impact for all pollutants is 0.435 dv. The modeling showed no change to this value when the State modeled the lower emission limits. The State's modeling demonstrates that PM is an insignificant contributor to visibility impairment.

Given the very limited impact of PM emissions from the kiln system on visibility impairment, the State determined that no additional PM emissions control is warranted. The State has determined that the PM RP emission limit for the Holcim Florence Cement Kiln is 246.3 tpy of PM (12-month rolling total) from the kiln system main stack (including emissions from the clinker cooler). The State assumes that the emission limit can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for the Holcim Florence Cement Kiln.

[22] An SNCR control efficiency of 50% is feasible for the Portland Plant kiln. However, to achieve the necessary system configuration and temperature profile, SNCR will be applied at the top of the preheater tower and thus the alkali bypass exhaust stream cannot be treated. To achieve the proper cement product specifications, the Portland Plant alkali bypass varies from 0–30% of main kiln gas flow. Adjusting by 10%, for the alkali bypass to account for the exhaust gas that is not treated (*i.e.,* bypassed) by the SNCR system, the State determined the overall SNCR control efficiency for the main stack will be 45%.

PM RP Determination for the Quarry[23]

The quarry has a current PM emission limit of 47.9 tpy. The State has determined that the existing fugitive dust control plan and associated control measures represent the most stringent controls for the quarry emission sources. The control measures include: watering and the use of chemical stabilizers, compaction and re-vegetation of stockpiles, vehicle speed limitations, reclamation and sequential extraction of materials, paving, graveling and cleaning of haul roads, sequential blasting, wet drilling, and the suspension of activities during high wind events. The State also determined that additional controls would result in no additional visibility benefit based on the low permitted emissions.

The State has determined that the PM RP emission limit for the Holcim Florence Cement Quarry is 47.9 tpy fugitive PM (12-month rolling total).

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for the Holcim Florence Cement Quarry.

PM RP Determination for the Finish Mill

The finish mill is currently controlled with fabric filter baghouses with an emission limit of 34.3 tpy of PM (12-month rolling total). The units are exceeding a PM control efficiency of 95%. The State determined that the current control technology and limit represent the most stringent level of control for the finish mill. Accordingly, the State did not provide a four-factor analysis plus visibility improvement modeling for the finish mill.

The State has determined that the PM RP emission limit for the Holcim Florence Cement Finish Mill is 34.3 tpy (12-month rolling total). The State assumes that the emission limit can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for the Holcim Florence Cement Finish Mill.

vi. Tri-State Generation Nucla Facility

Background

The Tri-State Nucla facility is located in Montrose County approximately 3 miles southeast of the town of Nucla, Colorado. The Nucla facility consists of one coal-fired steam-driven electric generating unit, Unit 4, with a rated electric generating capacity of 110 MW (gross). The Nucla facility is an atmospheric circulating fluidized bed (CFB) unit. Additionally, the facility includes a number of fugitive dust sources. Unit 4 is the only unit subject to RP as the fugitive dust sources fall below the de minimis levels set by the State. The State's RP determination for the Nucla facility can be found in Chapter 8.5.2.6 and Appendix D of the SIP.

SO_2 RP Determination

Unit 4 is currently controlled for SO_2 emissions by limestone injection achieving a 70% reduction in emissions. Unit 4 has a current permit limit of 0.4 lbs/MMBtu (30-day rolling average). The State determined that limestone injection improvements (LII), dry FGD, DSI, and LII with a dry FGD were technically feasible. Study-level information for hydrated ash reinjection (HAR) systems at Nucla or any other EGU in the western United States were not available for use in evaluating costs. Based on the lack of cost information, the State does not consider this option to be commercially available and did not consider HAR in this analysis. The State did not evaluate DSI, as this technology would achieve less than a 50% reduction in emissions, which is less than the current SO_2 controls.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's SO_2 RP analysis is provided in Table 38 below. Baseline SO_2 emissions are 1,335 tpy based on the average of 2006–2008 actual emissions. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis. Costs for SO_2 control options (and NO_X) were evaluated based on analyses for similar systems proposed at other western CFB boiler units, specifically Spiritwood in North Dakota[24] and Bonanza in Utah.[25] The State did not model visibility improvement due to time constraints.

TABLE 38—SUMMARY OF NUCLA UNIT 4 SO_2 RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/mmbtu) (30-day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)
LII	39.4	0.19	526	$914,290	4,161
Dry FGD	87.0	0.04	1,162	7,604,627	6,547
LII + dry FGD	93.9	0.02	1,254	9,793,222	7,808

The State's analysis assumes that the LII will not require any construction or capital improvements and compliance time will be minimal. The State anticipates that the time necessary for installing dry FGD or dry FGD plus LII would be 3–5 years after SIP approval.

The State eliminated dry FGD and dry FGD plus limestone injection improvements from consideration due to the high cost effectiveness values. The State originally asserted in the Nucla RP analysis that limestone injection improvements are technically feasible. However, Tri-State provided additional information on November 29, 2011 in the Colorado Air Quality Control Commission hearing that introduced significant uncertainty regarding the technical feasibility of LII for Unit 4 at Nucla Station. The State determined upon further evaluation that LII beyond current operations were not feasible in all operating conditions.

Based upon its consideration of the four factors, the State has determined that the SO_2 RP emission limit for Nucla Unit 4 is 0.5 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved through the operation of the current limestone injection system.

[23] The summary of the RP analysis was not included in the SIP. Please see the State's full RP analysis for information on the quarry and finish mill.

[24] Barr, July 2007. ''Application for a Permit to Construct a Combined Heat and Power (CHP) Plant.'' Prepared for Great River Energy—Spiritwood Station, Spiritwood, ND.

[25] EPA, August 30, 2007. ''Deseret Power Electric Cooperative, Bonanza Power Plant, Waste Coal Fired Unit: Prevention of Significant Deterioration Permit to Construct—Final Statement of Basis for Permit No. PSD–00–0002.01.00. ''

We agree with the State's conclusions, and we are proposing to approve the State's SO_2 RP determination for Nucla Unit 4.

NO_X RP Determination

In 2006, Tri-State installed a small-scale SNCR system on Unit 4 that injects anhydrous ammonia to achieve NO_X reductions. Tri-State does not operate the SNCR system frequently. It is used on occasions when NO_X emissions approach 0.4 lb/MMBtu. Operation above this level at high unit capacity factors results in levels that approach the annual NO_X limit of 1,987.9 tpy (12-month rolling average).

The State determined full-scale SNCR and SCR were technically feasible for reducing NO_X emissions at Nucla Unit 4. Though the SIP states SCR is not technically feasible on a CFB coal-fired boiler, the State's RP analysis contains a discussion on SCR being technically feasible, and we agree with the State's assessment in the RP analysis. With respect to SNCR, the State has asserted that there is substantial uncertainty surrounding the potential control efficiency achievable by a full-scale SNCR system at a CFB boiler burning western coal. The State's estimates for control efficiency vary between 10–40% for NO_X reduction potential.

The State determined that the costs for SCR would likely be excessive, and the State did not further evaluate this control option. The State estimated that the incremental cost of using SCR versus SNCR on a CFB Boiler as $25,315 per ton per the Spiritwood BACT analysis and $40,297 per ton per the Bonanza BACT analysis. The State expects a SCR system at the Nucla Station to have even higher costs due to the retrofit factor and small size of Unit 4.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of the remaining control evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X RP analysis is provided in Table 39 below. Baseline NO_X emissions are 1,760 tpy based on the average of 2006–2008 actual emissions. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis. The State did not model visibility improvement due to time constraints. The State evaluated SNCR at two different control efficiencies due to the uncertainty of SNCR control on this type of boiler.

TABLE 39—SUMMARY OF NUCLA UNIT 4 NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/mmbtu) (30–day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)
SNCR	10.3	0.40	173	$2,238,592	12,974
SNCR	43.6	0.25	730	2,238,592	3,065

The State anticipates that the time necessary to install and operate SNCR would be approximately 3–5 years after SIP approval.

Based on its consideration of the four factors, the State has determined that NO_X RP for Nucla Unit 4 is the following NO_X emission limit: 0.5 lb/MMBtu (30-day rolling average). Due to the uncertainty of the control efficiency of SNCR control, the State determined that it was not reasonable for NO_X RP control at this time.

We agree with the State's conclusions, and we are proposing to approve its NO_X RP determination for Tri-State Nucla Unit 4.

PM RP Determination

Nucla Unit 4 is equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.03 lb/MMBtu. Stack tests show that the fabric filter baghouses are achieving a 99.9% reduction in PM. The State determined that fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that an emission limit of 0.03 lb/MMBtu represents the most stringent level of control for this type of source. The State did not provide a full four-factor analysis because the State determined RP to be the most stringent control technology and limit.

The State has determined that the PM RP emission limit for Tri-State Nucla Unit 4 is 0.03 lb/MMBtu (30-day rolling average). The State assumes that the emission limit can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for Tri-State Nucla Unit 4.

vii. Tri-State Craig Unit 3

Background

The Tri-State Craig Station is located in Moffat County about 2.5 miles southwest of the town of Craig, Colorado. This facility is a three unit coal-fired power plant with a total net electric generating capacity of 1264 MW. Craig Units 1 and 2 are subject to BART. The State determined Craig Unit 3 was subject to RP. Craig Unit 3 is a dry-bottom pulverized coal-fired boiler. The Craig facility also includes two cooling towers, coal handling systems, ash handling systems, limestone handling system, and the staging/landfill area. In addition to Craig Unit 3, the State determined that the ash handling system and the limestone hauling system were subject to RP (they only emit PM emissions, not SO_2 or NO_X). The State determined the other systems were not subject to RP as their emissions were below the de minimis threshold set by the State. The State's RP determination can be found in Chapter 8.5.2.7 and Appendix D of the SIP.

SO_2 RP Determination

Craig Unit 3 is currently controlled with a dry FGD currently achieving over 80 percent SO_2 reduction. The current emission limits are .20 lb/MMBtu (calendar day average), 80% reduction (30-day rolling average). As mentioned earlier, if a BART source has current SO_2 controls achieving at least a 50% reduction in emissions, the state needs to evaluate upgrades to the existing control technology but does not need to consider the replacement of that technology (70 FR 39171). We conclude that it is reasonable to follow this approach for evaluating potential RP controls in this initial planning period. Colorado should consider replacement of existing scrubbers in future planning periods. The State considered the following dry FGD upgrades: (1) Use of performance additives; (2) use of more reactive sorbent or increasing the pulverization level of sorbent; (3)

engineering redesign of atomizer or slurry injection system. Based on the design of Unit 3, the State could not identify any performance additives that could be used and determined that Tri-State cannot use a more reactive sorbent or increase the pulverization level of sorbent. The source recently redesigned the slurry injection system, and the State could not identify any other feasible upgrades. Based on its analysis, the State determined that no upgrades are technically feasible. We agree with the State's assessment of possible upgrades. The State determined that fuel switching and DSI were technically feasible, but did not further analyze these controls as they would achieve less emission reductions than the current controls.

The State analyzed emission limit tightening based on current operations. Tri-State made upgrades to the dry FGD between 2007 and 2009. The maximum 30-day rolling emission rate post-upgrade (June 2009–June 2010) was 0.14 lbs/MMBtu and the average 30-day rolling average was 0.11 lbs/MMBtu. The State modeled the visibility improvement that would result from a 0.15 lbs/MMBtu emission limit and 0.07 lbs/MMBtu emission limit. The visibility improvement was 0.26 dv and 0.38 dv, respectively.

Based on its analysis, the State determined that a more stringent 30-day rolling SO_2 limit of 0.15 lbs/MMBtu represents an appropriate and reasonable level of emissions control for this dry FGD control technology. Upon review of 2009 emissions data from EPA's CAMD Web site, the State has determined that this emissions rate is achievable without additional capital investment. The State has determined that the SO_2 RP emission limit for Craig Unit 3 is 0.15 lb/MMBtu (30-day rolling average). The State assumes the emission limit is achievable with the current dry FGD controls.

The State has determined that a SO_2 limit lower than 0.15 lbs/MMBtu would not result in significant visibility improvement (0.12 dv), would likely result in frequent non-compliance events, and, would, thus, not be reasonable.

We agree with the State's conclusions, and we are proposing to approve its SO_2 RP determination for Tri-State Craig Unit 3.

NO_X RP Determination

Craig Unit 3 is currently controlled with LNBs and OFA that were installed in 2009. The State determined that combustion control refinements, neural network system (NNS) combustion controls, SNCR, and SCR were technically feasible. The State determined that ROFA, ECO, RRI, and coal reburn plus SNCR were not technically feasible.

The State did not identify any energy or non-air quality environmental impacts that would preclude the selection of any of the controls evaluated, nor are there any remaining-useful-life issues for this source. A summary of the State's NO_X RP analysis is provided in Table 40 below. Baseline NO_X emissions are 6,402 tpy based on the average of 2006–2008 actual emissions. The emission rate for each control option in the table is reflective of the 30-day rolling average contained in the State's RP analysis. The State did not model combustion control refinements or NNS because of the extremely low control efficiency for these two control options.

TABLE 40—SUMMARY OF TRI-STATE CRAIG UNIT 3 NO_X RP ANALYSIS

Control technology	Control efficiency (%)	Emission rate (lb/mmbtu) (30–day rolling average)	Emission reduction (tpy)	Annualized costs	Cost effectiveness ($/ton)	Visibility improvement (delta dv for the maximum 98th percentile impact)
Combustion Control Refinements	2	0.32	114	$122,000	$1,071	.....
NNS	5	0.31	285	280,000	984	.....
SNCR	15	0.28	858	4,173,000	4,887	0.32
SCR	75	0.08	4,281	239,762,387	6,952	0.79

The State eliminated SCR from consideration due to the high cost effectiveness value and the visibility improvement associated with this control. The State determined SNCR was reasonable for RP control. Based upon its consideration of the five factors that it used for RP, the State has determined that the NO_X RP emission limit for Craig Unit 3 is 0.28 lb/MMBtu (30-day rolling average). The State assumes that the RP emission limit can be achieved through the operation of SNCR.

We agree with the State's conclusions, and we are proposing to approve its NO_X RP determination for Tri-State Craig Unit 3.

PM RP Determination

Craig Unit 3 is equipped with fabric filter baghouses to control PM emissions with an emission limit of 0.013 lb/MMBtu for PM filterable and 0.012 lb/MMBtu for PM_{10}. Stack tests show that the fabric filter baghouses are achieving over a 95% reduction in PM. The State determined that fabric filter baghouses are the most stringent control technology for controlling PM emissions. The State also evaluated what would constitute the most stringent level of control for PM by looking at recent BACT determinations. Based on this evaluation, the State determined that the current emission limits represents the most stringent level of control for this type of source. The State did not provide a full four-factor analysis plus visibility improvement modeling because the State determined RP to be the most stringent control technology and limit.

The State has determined that the PM RP emission limits for Tri-State Craig Unit 3 are 0.013 lb/MMBtu for filterable PM (30-day rolling average) and 0.012 lb/MMBtu for PM_{10} (30-day rolling average). The State assumes that the emission limits can be achieved through the operation of the existing fabric filter baghouses.

We agree with the State's conclusions, and we are proposing to approve its PM RP determination for Tri-State Craig Unit 3.

viii. PSCO Cameo Station

PSCO informed the State that the Cameo Station east of Grand Junction, Colorado would be shut down by December 31, 2011, resulting in SO_2, NO_X, and PM reductions of approximately 2,618, 1,140, and 225 tons per year, respectively. The State did not perform a RP analysis for this source since a shutdown is the most stringent control. The State determined that the shutdown of Cameo Station by

December 31, 2011 is RP for this source. We agree with the State's conclusions, and we are proposing to approve its RP determination for PSCO Cameo Station. The State's discussion of RP for Cameo Station can be found in Chapter 8.5.2.8 of the SIP. The shutdown of PSCO Cameo Station is required by the RH SIP (see Chapter 8.5.2 of the SIP and Regulation No. 3, Part F, Section VI.B).[26]

Summary of State's RP Determinations

TABLE 41—SUMMARY OF THE STATE'S RP DETERMINATIONS FOR STATIONARY SOURCES

Emission unit	Assumed NO_X control type	NO_X Emission limit	Assumed SO_2 control type	SO_2 Emission limit	Assumed particulate control and emission limit
Rawhide Unit 101	Enhanced Combustion Control*.	0.145 lb/MMBtu (30-day rolling average).	Lime Spray Dryer*	0.11 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse* 0.03 lb/MMBtu.
CENC Unit 3	No Control	246 tons per year (12-month rolling total).	No Control	1.2 lbs/MMBtu	Fabric Filter Baghouse* 0.07 lb/MMBtu.
Nixon Unit 1	ULNBS with OFA	0.21 lb/MMBtu (30-day rolling average).	Lime Spray Dryer	0.11 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse* 0.03 lb/MMBtu.
Clark Units 1 &2	Shutdown by 12/31/2013.	0	Shutdown by 12/31/2013.	0	Shutdown by 12/31/2013.
Holcim—Florence Kiln	SNCR	2.73 lbs/ton clinker (30-day rolling average). 2,086.8 tons/year	Wet Lime Scrubber*	1.30 lbs/ton clinker (30-day rolling average). 721.4 tons/year	Fabric Filter Baghouse* 246.3 tons/year.
Nucla	No Control	0.5 lb/MMBtu (30-day rolling average).	Limestone Injection*	0.4 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse* 0.03 lb/MMBtu.
Craig Unit 3	SNCR	0.28 lb/MMBtu (30-day rolling average).	Lime Spray Dryer*	0.15 lb/MMBtu (30-day rolling average).	Fabric Filter Baghouse* 0.013 lb/MMBtu filterable PM 0.012 lb/MMBtu PM_{10}.
Cameo	Shutdown by 12/31/2011.	0	Shutdown by 12/31/2011.	0	Shutdown by 12/31/2011.

*Controls already operating.

ix. Area Oil and Gas Sources

Because the area source oil and gas category is made up of numerous smaller sources, the State determined it is only practical to evaluate the category for RP control as a whole. When reviewing oil and gas area sources, the State identified heater-treaters and RICE as the largest NO_X emission sources.

a. Oil and Gas Heater-Treaters

A heater-treater is a device used to remove contaminants from the natural gas or oil at or near the wellhead before the gas is sent down the production line to a natural gas processing plant or the oil is collected in storage tanks. The latest 2018 emissions inventory for the State assumes approximately 23,000 tons of NO_X per year from 26,000 natural gas and oil heater-treaters. This equates to approximately 0.88 tpy of NO_X per gas/oil well heater-treater.

The State's research shows that emission controls and control applications for this source category are not well developed and have focused primarily on methane reductions. Though the State identified some technically feasible control options, the State determined that the costs of compliance and the control effectiveness could not be confidently determined. Because of the uncertainty of controls, the State has determined that additional controls under RP are not reasonable in this initial planning period.

b. RICE

Background

Power generated by large RICE is generally used to compress natural gas or to generate electricity in remote locations. The designation large RICE refers to engines have a rating of at least 100 horsepower (hp) for the purpose of this RP analysis. Large RICE produce power by combustion of fuel and are operated at various air-to-fuel ratios. RICE are operated with either fuel-rich ratios, which are called rich-burn (RB) engines, or air-rich ratios, which are called lean-burn (LB) engines. The State's 2018 emission inventory shows that large RICE represent 16% of the Statewide point source NO_X emission inventory, with 2018 emissions expected to be 16,199 tpy.

The State determined the following were technically feasible for controlling NO_X emissions from RICE: (1) Air/fuel ratio adjustment for LB engines; (2) ignition/spark timing retard for LB engines; (3) 3-way non-selective catalytic reduction (NSCR) for RB engines; (4) SNCR for RB and LB engines; (5) SCR for LB engines; and 6) replace RICE with electric motors for LB and RB engines.

A summary of the State's RP analysis for RICE engines is provided in Table 42 below. Because control effectiveness and cost effectiveness is dependent on a number of engine-specific factors, the State has provided a range for these factors. Due to a lack of available information, the State did not provide the cost effectiveness for SNCR.

[26] PSCO Cameo Station was shut down in December 2010.

TABLE 42—SUMMARY OF RICE CONTROLS FOR RP

Control technology	Control effectiveness (%)	Cost effectiveness ($/ton)
Lean Burn (Air/Fuel Ratio Adjustment)	5–30	$320–8,300.
Lean Burn (Ignition/Spark Timing Retard)	20	$310–2,000.
Rich Burn NSCR w/an air to fuel ratio (ATF) controller	80–90	$571.
Rich/Lean Burn SNCR	50–95	
Lean Burn SCR	80–90	$430–4,900.
Replace RICE with electric motors	60–100	4,700 or more.

For RICE NO_X control under the RHR, the State determined that the installation of NSCR plus ATF controllers on all RB RICE greater than 500 hp throughout the State satisfies RP requirements. Additional NO_X control for lean burn RICE throughout the State is not reasonable for this planning period. For existing RICE less than 500 hp, the State determined that no additional control is necessary for RP in this planning period. Colorado's emission inventory indicates that in the 2007–2008 timeframe, there were 538 engines with less than 500 hp in the State, and these engines emitted 5,464 tpy of NO_X. At an average of about 10 tons of NO_X emissions per year, the State determined controlling engines of this size is not reasonable.

In addition, for new and modified RICE of 100 hp or greater, the State is relying on emissions controls that are required by EPA's NSPS subpart JJJJ, 40 CFR part 60, and EPA's NESHAP subpart ZZZZ, 40 CFR part 63. The State determined that these federal control requirements satisfy RP for these sources in this planning period.

Colorado adopted regulations to control NO_X emissions from RICE in 2004. For the Denver metro area/North Front Range ozone control area, the State revised Regulation No. 7 to require the installation of controls on new and existing rich burn RICE larger than 500 hp by May 1, 2005. EPA approved the revisions to Regulation No. 7 as part of the Colorado SIP on August 19, 2005 (70 FR 48652).

In December 2008, Colorado adopted section XVII.E.3.a into Regulation No. 7. Section XVII.E.3.a applies to all existing RB RICE over 500 hp throughout the State. The revisions to Regulation No. 7 required that by July 1, 2010 all existing RB RICE over 500 hp in Colorado had to install NSCR with an ATF controller. Sources subject to emission controls under a MACT, BACT, or NSPS are not subject to the requirements of section XVII.E.3.a. In addition, sources that fall below State permitting thresholds are not subject to the requirements of section XVII.E.3.a. An exemption from control for RB RICE can be obtained upon demonstration that the cost of emission control would exceed $5,000 per ton. The State has included Regulation No. 7, section XVII.E.3.a, as part of the RH SIP to become federally enforceable upon EPA approval.

We are proposing to approve the State's RP determination for RICE engines. We are also proposing to approve Regulation No. 7, section XVII.E.3.a, as part of the SIP.

x. Combustion Turbines

Combustion turbines fueled by natural gas are either co-located with coal-fired electric generating units or are stand-alone facilities. These units are primarily used to supplement power supply during peak demand periods when electricity use is highest. Typical emissions for this source type may be significant for NO_X, but usually have very low SO_2 and PM_{10} emissions.

The State evaluated combustion turbines that are co-located at subject-to-BART or subject-to-RP sources. The State determined there are five BART and RP facilities with combustion turbines: PSCO Valmont Generating Station, PSCO Arapahoe Generating Station, CSU—Nixon Power Plant, PRPA Rawhide Energy Station, and PSCO Pawnee Generating Station. Of these, only two turbines located at the Nixon Front Range Power Plant (Turbine #1 and Turbine #2) emit levels of pollutants above the State de minimis levels for NO_X. Baseline NO_X emissions based on the average of 2006–2008 actual emissions are 159.6 tpy for Turbine #1 and 148 tpy for Turbine #2.

The combustion turbines at the Nixon Front Range Power Plant were installed with advanced dry-low-NO_X combustion systems, which are achieving a control efficiency of 89.4% on Turbine #1 and 90.1% on Turbine #2. The State determined that the following were technically feasible controls for NO_X: 1) dry controls using advanced combustor design to suppress NO_X formation and/or promote CO burnout (already installed); and (2) post-combustion controls (SNCR, SCR). Although post-combustions controls are technically feasible, the State's search of the EPA's RACT/BACT/LAER Clearinghouse database revealed SCR is the predominant post-combustion control technology for combustion turbines and did not find any examples of SNCR post-combustion technology applied to combustion turbines. The State could not find any instances of commercial scale SNCR applied at combustion turbines, so the State eliminated SNCR.

The State analyzed SCR for RP control. The State determined that applying SCR at a 90% control efficiency to both turbines would result in about 275 tons of NO_X reduced annually with a capital expenditure of at least $15 million. The State estimated that SCR for these turbines would range from approximately $57,000–$62,000 per ton of NO_X reduced annually. Based on the cost effectiveness value, the State determined that SCR was not reasonable for RP control. Combustion turbines are subject to 40 CFR part 60, subpart GG—Standards of Performance for Stationary Gas Turbines, which limits nitrogen oxides to 117.8 percent by volume at 15 percent oxygen on a dry basis (60.332(a)(1)), supported by monitoring and testing. The State determined that the limits of 40 CFR part 60, subpart GG are NO_X RP for combustion turbines.

We agree with the State's analysis and are proposing to approve its RP determination for combustion turbines and for the CSU—Nixon Power Plant Turbine #1 and Turbine #2.

3. Reasonable Progress Goals

40 CFR 51.308(d)(1) requires states to ''establish goals (in dvs) that provide for RP towards achieving natural visibility conditions'' for each Class I area of the State. These RP goals are interim goals that must provide for incremental visibility improvement for the most impaired visibility days, and ensure no degradation for the least impaired visibility days. The RP goals for the first planning period are goals for the year 2018. The State's discussion of RP and RPGs can be found in Chapter 8 and section 9.5 of the SIP.

Colorado is relying on the WRAP's CMAQ regional modeling performed in 2009 to establish its RP goals for 2018. As part of the 2009 CMAQ modeling, WRAP included all western states' reasonably foreseeable control measures in the projections of 2018 visibility levels.

The Regional Modeling Center at the University of California Riverside, under the oversight of the WRAP Modeling Forum, performed modeling used for the RH long-term strategy for the WRAP member states, including Colorado. The modeling analysis is a complex technical evaluation that began with selection of the modeling system. The Regional Modeling Center primarily used the CMAQ photochemical grid model to estimate 2018 visibility conditions in Colorado and all western Class I areas, based on application of the RH strategies in the various state plans, including assumed controls on BART sources.

The Regional Modeling Center developed air quality modeling inputs, including annual meteorology and emissions inventories for: (1) A 2002 actual emissions base case; (2) a planning case to represent the 2000–2004 RH baseline period using averages for key emissions categories; and (3) a 2018 base case of projected emissions determined using factors known at the end of 2005. Each of these inventories underwent a number of revisions throughout the development process to arrive at the final versions used in CMAQ modeling. The WRAP states' modeling was developed in accordance with our guidance.[27] A more detailed description of the CMAQ modeling performed for the WRAP can be found in the Colorado Class I area TSDs.

The photochemical modeling of RH for the WRAP states for 2002 and 2018 was conducted on the 36-km resolution national regional planning organization domain that covered the continental United States, portions of Canada and Mexico, and portions of the Atlantic and Pacific Oceans along the east and west coasts. The Regional Modeling Center examined the model performance of the regional modeling for the areas of interest before determining whether the CMAQ model results were suitable for use in the RH assessment of the long-term strategy and for use in the modeling assessment. The 2002 modeling efforts were used to evaluate air quality/visibility modeling for a historical episode, in this case, for calendar year 2002, to demonstrate the suitability of the modeling systems for subsequent planning, sensitivity, and emissions control strategy modeling. Model performance evaluation compares output from model simulations with ambient air quality data for the same time period to determine whether model performance is sufficiently accurate to justify using the model to simulate future conditions.

Once the Regional Modeling Center determined that model performance was acceptable, it used the model to determine the 2018 RP goals using the current and future year air quality modeling predictions, and compared the RP goals to the uniform rate of progress.

The State determined that the WRAP 2018 projections represent significant visibility improvement and RP toward natural visibility based upon the State's consideration of the factors required for BART and RP. The State is adopting the WRAPs 2018 projections as its RPG for each Class I area in Colorado. Table 43 shows the URP and the 2018 RPG adopted by the State for such areas.

TABLE 43—COLORADO'S URP AND RP GOAL FOR 2018

Colorado class I areas	20% Worst days				20% Best days	
	2000–2004 Baseline (dv)	2018 URP (dv)	Reduction needed to reach URP goal (delta dv)	2018 CMAQ Modeling projection—state's RP goal	2000–2004 Baseline (dv)	2018 CMAQ Modeling projection
Great Sand Dunes National Park and Preserve	12.78	11.35	1.43	12.20	4.5	4.16
Mesa Verde National Park	13.03	11.58	1.45	12.5	4.32	4.10
Mount Zirkel & Rawah Wilderness Area	10.52	9.48	1.04	9.91	1.61	1.29
Rocky Mountain National Park	13.83	12.27	1.56	12.83	2.29	2.06
Weminuche Wilderness, Black Canyon of Gunnison, and La Garita Wilderness	10.33	9.37	0.96	9.83	3.11	2.93
Eagles Nest Wilderness, Flat Tops Wilderness, Maroon Bells-Snowmass Wilderness, and West Elk Wilderness	9.61	8.78	0.83	8.98	0.70	0.53

Table 43 shows that the State's RH SIP will provide for improvement in visibility for the most-impaired days over the period ending in 2018 and will allow for no degradation in visibility for the least-impaired days.

Table 43 also shows that Colorado is not meeting the URP to meet natural visibility conditions by 2064 because the projected 2018 RPG is greater than the 2018 URP. The State finds that the RPGs established in this SIP are reasonable for this planning period and that achieving the URP in this planning period is not reasonable. Pursuant to 40 CFR 51.308(d)(1)(ii), the State has determined and presented detailed analyses to show why certain controls for specified RP sources are reasonable, and why additional controls during this planning period are not reasonable based upon its consideration of the required factors for RP (40 CFR 51.308(d)(1)(i)(A)). The State has determined and presented detailed analyses to show why certain controls for specified BART sources are reasonable based upon its consideration of the five-factors (40 CFR 51.308(e)(1)(A)). In addition, sources outside of the modeling domain are the single largest contributor to sulfate or nitrate at many Class I areas (see Table 29 in section V.D.1 of this notice). These sources are not under the control of Colorado or the surrounding States, and

[27] Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$, and Regional Haze, (EPA–454/B–07–002), April 2007, located at *http://www.epa.gov/scram001/guidance/guide/final-03-pm-rh-guidance.pdf*. Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations, August 2005, updated November 2005 (''our Modeling Guidance''), located at *http://www.epa.gov/ttnchie1/eidocs/eiguid/index.html,* EPA–454/R–05–001.

will not be significantly controlled by 2018. As discussed below, the State consulted with other states on RP.

Since the State is not meeting the URP, the State is required by 40 CFR 51.308(d)(1)(ii) to assess the number of years it would take to reach natural conditions if visibility improvement continues at the current rate of progress. The State has calculated the year and the length of time to reach natural visibility as follows: Great Sand Dunes: 2152 (148 years); Mesa Verde: 2168 (164 years); Zirkel and Rawah: 2106 (102 years); Rocky Mountain: 2098 (94 years); Black Canyon, Weminuche, and La Garita: 2119 (115 years); and Eagles Nest, Flat Tops, Maroon Bells and West Elk: 2083 (79 years).

We note that the WRAP 2018 reasonable progress projections did not reflect the additional RH controls that Colorado adopted in 2010. These controls included additional BART requirements, the PSCO BART alternative, and RP limits as described above. These additional controls will produce about 44,500 tpy of NO_X and SO_2 reductions that were not included in the WRAP CMAQ modeling. Thus, it is likely that the State is closer to the URP than is indicated by the WRAP modeling.

EPA has evaluated Colorado's demonstrations concerning the RPGs and finds that they provide for reasonable progress towards natural visibility conditions for the first planning period. Based on the RP factors, Colorado has demonstrated that it is not reasonable to attain the URPs for Colorado's Class I areas in the first planning period, and that Colorado's RPGs (as augmented by the additional measures that Colorado adopted in 2010) are reasonable. Colorado has adopted BART, BART alternative, and RP controls that will achieve substantial reductions of NO_X and SO_2 emissions by 2018. We find that Colorado, considering the statutory BART and RP factors, has reasonably evaluated and rejected more stringent controls in this first planning period. We also find that Colorado has focused on an appropriate set of sources and source categories in considering potential reasonable progress controls in this first planning period. Finally, we agree that sources outside of the modeling domain are the single largest contributor to sulfate or nitrate at many Class I areas, that these sources are not under the control of Colorado or the surrounding states, and that they will not be significantly controlled by 2018. This is another major reason that it is not reasonable for the Class I areas in Colorado to attain the URPs in 2018. For these reasons, EPA is proposing that the State's RPGs are reasonable.

E. Long Term Strategy

1. Emission Inventories

40 CFR 51.308(d)(3)(iii) requires that Colorado document the technical basis, including modeling, monitoring, and emissions information, on which it relied to determine its apportionment of emission reduction obligations necessary for achieving RP in each mandatory Class I Federal area it affects. Colorado must identify the baseline emissions inventory on which its strategies are based. 40 CFR 51.308(d)(3)(iv) requires that Colorado identify all anthropogenic (human-caused) sources of visibility impairment it considered in developing its long-term strategy. This includes major and minor stationary sources, mobile sources, and area sources.

In order to meet these requirements, Colorado relied on the emission inventory developed by the WRAP. The pollutants inventoried by the WRAP that Colorado used for this SIP include SO_2, NO_X, VOC, OC, EC, $PM_{2.5}$, PM_{10}, and ammonia. WRAP developed an inventory for the baseline year 2002 and provided projections of future emissions in 2018 based on expected controls, growth, or other factors. The emission inventories developed by the WRAP were calculated using best available data and approved EPA methods.[28]

There are a number of emission inventory source categories identified in the Colorado SIP: point, area, on-road mobile, off-road mobile, anthropogenic fire, natural fire, road dust, fugitive dust, area source oil and gas, and biogenic emissions. The State provided the 2002 baseline, the 2018 projected emissions, and the net change of emissions between 2002 and 2018 for SO_2, NO_X, VOC, OC, EC, $PM_{2.5}$, PM_{10}, and ammonia for each of the above source categories. Following is a summary of the emission inventory for each pollutant by source.

SO_2

Sulfur dioxide emissions come primarily from coal combustion at EGUs but smaller amounts come from natural gas combustion, mobile sources and wood combustion.

TABLE 44—COLORADO SO_2 EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	97,984	44,062	−55
Area	6,533	7,644	17
On-Road Mobile	4,389	677	−85
Off-Road Mobile	3,015	754	−75
WRAP Area O & G	118	11	−91
Road Dust	4	6	34
Fugitive Dust	6	5	−13
Anthropogenic Fire	108	91	−15
Natural Fire	3,335	3,335	0
Biogenic	.....	.....	.....
Total	115,492	56,585	−51

Overall, SO_2 emission source categories are expected to decline statewide by 51% by 2018. Area sources is the only source category expected to increase by 2018 (we are discounting the 2 tpy increase in road-dust). Increases in area source emissions are linked to population growth.

[28] The methods WRAP used to develop these emission inventories are described in more detail in *Technical Support Document for Technical Products Prepared by the Western Regional Air Partnership (WRAP) in Support of Western Regional Haze Plans;* February 28, 2011. This document is included in the Supporting and Related Materials section of the docket.

NO_X

NO_X emissions in Colorado come mostly from point sources and from on-road and off-road mobile sources.

TABLE 45—COLORADO NO_X EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	118,667	101,818	−14
Area	11,729	16,360	39
On-Road Mobile	141,883	45,249	−68
Off-Road Mobile	62,448	37,916	−39
WRAP Area O & G	23,518	33,517	43
Road Dust	1	1	0
Fugitive Dust	16	14	−13
Anthropogenic Fire	520	408	−21
Natural Fire	9,377	9,377	0
Biogenic	37,349	37,349	0
Total	405,507	282,010	−30

Overall, NO_X emissions in Colorado are expected to decline by 30% by 2018. Area source and oil and gas emissions are the only source categories expected to increase. Area source emissions increases are related to population growth, and increases in oil and gas emissions are attributable to increased oil and gas development.

VOCs

VOCs come from such sources as automobiles, industrial and commercial facilities, solvent use, and refueling automobiles. Substantial natural emissions of VOCs come from vegetation.

TABLE 46—COLORADO VOC EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	91,750	77,312	−16
Area	99,191	136,032	37
On-Road Mobile	100,860	41,489	−59
Off-Road Mobile	38,401	24,684	−36
WRAP Area O & G	27,259	43,639	60
Road Dust	.....	.....	.....
Fugitive Dust	.....	.....	.....
Anthropogenic Fire	915	666	−27
Natural Fire	20,404	20,404	0
Biogenic	804,777	804,777	0
Total	1,183,557	1,149,002	−3

Overall, VOC emissions are projected to decrease by 3% statewide, with a 37% increase in area source emissions and a 60% increase in oil and gas emissions. Area source emission increases are a result of increased population growth, and increases in oil and gas emissions are attributable to increased oil and gas development.

OC

OC are emitted directly from the combustion of organic material. A wide variety of sources contribute emissions to this pollutant, including diesel emissions and combustion byproducts from wood and agricultural burning.

TABLE 47—COLORADO OC EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	17	3	−83
Area	8,432	8,738	4
On-Road Mobile	1,280	1,288	1
Off-Road Mobile	1,286	843	−34
WRAP Area O & G	.....	.....	.....
Road Dust	102	135	33
Fugitive Dust	777	677	−13
Anthropogenic Fire	850	621	−27
Natural Fire	30,581	30,581	0

TABLE 47—COLORADO OC EMISSIONS—2002 AND 2018—Continued

Source category	Baseline 2002	Future 2018	Percent change
Biogenic	.....	.....	.....
Total	43,325	42,886	−1

Overall, OC emissions decrease by 1% in 2018. The main source category expected to increase by 2018 is road dust. The increase in road dust is associated with increases in population and more vehicle miles traveled.

EC

Elemental carbon, also known as soot, is a byproduct of incomplete combustion. Emissions and reductions in this category are dominated by mobile sources. Expected new federal emission standards for mobile sources, especially for diesel engines, along with fleet replacement, are the reasons for the reductions.

TABLE 48—COLORADO EC EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	.....	.....	.....
Area	1,264	1,325	5
On-Road Mobile	1,448	408	−72
Off-Road Mobile	3,175	1,344	−58
WRAP Area O & G	.....	.....	.....
Road Dust	9	11	33
Fugitive Dust	53	46	−13
Anthropogenic Fire	92	74	−20
Natural Fire	6,337	6,337	0
Biogenic	.....	.....	.....
Total	12,377	9,545	−23

Overall, this category is expected to decline by 23%, with on-road and off-road mobile sources expected to decline by 72% and 58%, respectively. The main source category expected to increase by 2018 is road dust. The increase in road dust is associated with increases in population and more vehicle miles traveled.

$PM_{2.5}$

Fine soil emissions are largely related to agricultural and mining activities, windblown dust from construction areas and emissions from unpaved and paved roads.

TABLE 49—COLORADO $PM_{2.5}$ EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	6	85	1,404
Area	4,170	4,311	3
On-Road Mobile	.....	.....	.....
Off-Road Mobile	.....	.....	.....
WRAP Area O & G	.....	.....	.....
Road Dust	1,082	1,435	33
Fugitive Dust	13,401	11,679	−13
Windblown Dust	15,105	15,105	0
Anthropogenic Fire	253	169	−33
Natural Fire	1,948	1,948	0
Biogenic	.....	.....	.....
Total	35,964	34,732	−3

Overall, $PM_{2.5}$ emissions are expected to decrease 3%. Increases in road dust emissions are tied to population growth and vehicle miles traveled.

PM_{10}

PM_{10} is closely related to the same sources as fine soil emissions, but other activities like rock crushing and processing, material transfer, open pit mining, and unpaved road emissions can be prominent sources.

TABLE 50—COLORADO PM_{10} EMISSIONS—2002 AND 2018

Source category	Baseline 2002	Future 2018	Percent change
Point	21,096	26,828	27
Area	1,363	1,388	2
On-Road Mobile	794	917	15
Off-Road Mobile	.....	.....	.....
WRAP Area O & G	.....	.....	.....
Road Dust	8,930	11,826	32
Fugitive Dust	67,642	67,910	0
Windblown Dust	135,945	135,945	0
Anthropogenic Fire	51	32	−37
Natural Fire	5,973	5,973	0
Biogenic	.....	.....	.....
Total	241,794	250,818	4

Overall, PM_{10} emissions are expected to increase by 4% in 2018. Increases in coarse mass are seen in the fugitive dust category. The increase in PM_{10} from road dust is associated with population growth and increased vehicle miles traveled. Point source emissions are addressed by the State for BART and RP sources.

2. Consultation and Emissions Reductions for Other States' Class I Areas

40 CFR 51.308(d)(3)(i) requires that Colorado consult with another state if its emissions are reasonably anticipated to contribute to visibility impairment at that state's Class I area(s), and that Colorado consult with other states if those other states' emissions are reasonably anticipated to contribute to visibility impairment at its Class I areas. Colorado consulted with other states during ongoing participation in the WRAP while developing its SIP. Through the WRAP consultation process, Colorado has reviewed and analyzed contributions from other states that reasonably may cause or contribute to visibility impairment in Colorado's Class I areas and Colorado's impact on other states' Class I areas. The State held specific discussions with states that have a primary impact on Colorado Class I areas. These include California, Utah, Nebraska, Wyoming, New Mexico, and Arizona.

40 CFR 51.308(d)(3)(ii) requires that if Colorado emissions cause or contribute to impairment in another state's Class I area, Colorado must demonstrate that it has included in its RH SIP all measures necessary to obtain its share of the emission reductions needed to meet the progress goal for that Class I area. Section 51.308(d)(3)(ii) also requires that, since Colorado participated in a regional planning process, it must ensure it has included all measures needed to achieve its apportionment of emission reduction obligations agreed upon through that process. As we state in the RHR, Colorado's commitments to participate in WRAP bind it to secure emission reductions agreed to as a result of that process.

Colorado analyzed the WRAP PSAT modeling and determined that emissions from the State do not significantly impact other states' Class I areas. Colorado's largest visibility impacts are at Canyonlands National Park in Utah and Bandelier National Monument in New Mexico. Colorado's total nitrate and sulfate contributions represent 1.0% and 0.5%, respectively, of total haze at these Class I areas. The State determined this is not a meaningful level of contribution. Colorado accepted and incorporated the WRAP-developed visibility modeling into its RH SIP, and the State's RH SIP includes the controls assumed in the modeling. Colorado satisfied the RHR's requirements for consultation and included controls in the SIP sufficient to address the relevant requirements of the RHR related to impacts on Class I areas in other states.

We are proposing to find that the State has met the requirements for consultation under 40 CFR 51.308(d)(3)(ii) and 40 CFR 51.308(d)(3)(iii).

3. Mandatory Long-Term Strategy Requirements

40 CFR 51.308(d)(3)(v) requires that Colorado, at a minimum, consider certain factors in developing its long-term strategy (the long-term strategy factors). These are: (a) Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment (RAVI); (b) measures to mitigate the impacts of construction activities; (c) emissions limitations and schedules for compliance to achieve the RPGs; (d) source retirement and replacement schedules; (e) smoke management techniques for agricultural and forestry management purposes including plans that currently exist within the state for these purposes; (f) enforceability of emissions limitations and control measures; and (g) the anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period addressed by the long-term strategy.

a. Reductions Due to Ongoing Air Pollution Programs

In addition to its BART and RP determinations, the State's long-term strategy contains other reductions due to ongoing air pollution programs. The State's long-term strategy contains both state only and federally enforceable programs. Some examples of these programs that are federally enforceable and the emission reductions they achieve include: (1) Oil and gas condensate tank control regulations for the Front Range region that have achieved approximately 52,000 tpy of VOC emission reductions by 2007 with additional projected reductions of 18,000 tpy by 2010 (Regulation No. 7); (2) existing industrial engine control regulations for the Front Range region that have achieved NO_X and VOC emissions reductions of approximately 8,900 tpy (Regulation No. 7); (3) PM_{10} emission reduction programs in PM_{10} maintenance areas throughout the State; and 4) fugitive dust control programs for construction, mining, vehicular traffic, and industrial sources state-wide (Regulation No. 1). The State has also adopted some of the federal NSPS and the New Source Review and PSD permit requirements for stationary sources. Additional information on ongoing air pollution programs is included in Chapter 9 of the State SIP.

b. Measures to Mitigate the Impacts of Construction Activities

Regulation No.1 *Particles, Smokes, Carbon Monoxide, and Sulfur Oxides* and Regulation No. 3 *Air Pollution Emission Notices—Permits* have requirements that pertain to controlling emissions from construction activity. EPA has approved both regulations into the Colorado SIP. Regulation No. 3 requires air pollution sources to file Air Pollutant Emission Notices with the State. It also requires that new or modified sources of air pollution, with certain exemptions, obtain preconstruction permits. Regulation No. 1 sets forth emission limitations, equipment requirements and work practices (abatement and control measures) intended to control the emissions of particles, smoke and sulfur oxides from new and existing stationary sources, including construction activities.

c. Smoke Management

Colorado addresses the requirements for smoke management in Regulation No. 9 *Open Burning, Prescribed Fire, and Permitting.* The intent of Regulation No. 9 is to prevent unacceptable smoke impacts, pertaining to both health and visibility. The rule applies to all open burning activity within Colorado, with the exception of agriculture open burning.[29] Section III.A of the regulation requires anyone seeking to conduct open burning to obtain a permit from the State before conducting a burn. Regulation No. 9 also contains a number of factors the State must consider in determining whether and, if so, under what conditions, a permit may be granted. Some of the factors the State must consider include: the potential contribution of such burning to air pollution in the area; the meteorological conditions on the day or days of the proposed burning; the location of the proposed burn and smoke-sensitive areas and Class I areas that might be impacted by the smoke and emissions from the burn; whether the applicant will conduct the burn in accordance with a smoke management plan or narrative that requires that best smoke management methods will be used to minimize or eliminate smoke impacts at smoke-sensitive receptors (including Class I areas); and that the burn will be scheduled outside times of significant visitor use in smoke-sensitive receptor areas that may be impacted by smoke and emissions from the fire.

The regulation requires all prescribed fire permitees to submit an application to the State. The State only grants a permit if the State's assessment demonstrates that under the prescribed meteorological conditions for the burn there will be no unacceptable air pollution, including visibility impacts. The regulation provides for the State to impose permit conditions necessary to ensure that the burn will be conducted to minimize the impacts of the fire on visibility and on public health and welfare. Permitted sources are also required to report actual activity to the State. Depending on the size and type of fire, reporting may be a daily requirement. At a minimum, permitted sources must report yearly to the State with information indicating whether or not there was any activity in the area covered by the permit and, if so, how many acres were burned.

Colorado inputs fire data into the WRAP Fire Emissions Tracking System (FETS). The FETS gives the State more precise information for future inventories and studies. The State commits in this SIP to continue administration of Regulation 9 as part of this LTS, and to input data into the FETS as long as it is operational.

d. Emission Limitations and Schedules for Compliance

The State has included the emission limitations and compliance schedules for those sources specifically identified for control in this RH SIP in Chapters 6 and 8, Regulation No. 3, Part F and Regulation No.7, Section XVII.E.3.a. For the BART sources, Regulation No. 3, section VI.A contains the emission limitations for each of the sources and provides that sources must comply as expeditiously as possible, but no later than five years from EPA approval of the SIP. For RP sources, Regulation No. 3, section VI.B, contains the emission limitations for each of the sources and provides that sources must comply no later than December 31, 2017. For the PSCO BART alternative, Regulation No. 3, section VI.C, contains the emission limitations and the compliance deadlines for sources covered by the PSCO BART alternative. Regulation No. 7, Section XVII.E.3.a contains the compliance schedule for RB RICE over 500 hp.

We are proposing to approve the emission limits and compliance schedules contained in Regulation No. 3, sections VI.A, VI.B, and VI.C.

e. Sources Retirement and Replacement Schedules

The State has included specific information on source retirement for those sources specifically identified for shutdown in its RH SIP. The State has identified the sources in the PSCO BART alternative that will shut down. Specifically, under the PSCO BART alternative, the following units will be retired: Arapahoe Unit 3 by December 31, 2013; Cherokee Unit 1 by July 1, 2012, Cherokee Unit 2 by December 31, 2011, Cherokee Unit 3 by December 31, 2016, and Valmont by December 31, 2017. The shutdown of the sources under the BART alternative is required by the RH SIP (see Chapter 6.4.3.7 of the SIP and Regulation No. 3, Part F, SectionVI.C). Under RP, PSCO Cameo Station and Black Hills Clark Facility Units 1 and 2 will be, or have already, shut down. The shutdown of these RP sources is required by the RH SIP (see Chapter 8.5.2 of the SIP and Regulation No. 3, Part F, Section VI.B). The State is assuming that all other stationary sources evaluated in the SIP will remain in operation through the end of this planning period.

The State is also assuming mobile source fleet turnover. For mobile sources, the turnover of the fleet from older, higher-emitting vehicles to newer, lower-emitting vehicles is captured in the emission inventory presented in section V.E.1 of this notice. The State developed the fleet turnover rate utilizing EPA-approved methodologies.

f. Enforceability of Colorado's Measures

Section 51.308(d)(3)(v)(f) of the RHR requires States to ensure that emission limitations and control measures used to meet RPGs are enforceable. In addition to what is required by the RHR, general SIP requirements mandate that the SIP must also include adequate monitoring, recordkeeping, and reporting requirements for the RH emission limits and requirements. (see CAA section 110(a)). As noted above, Chapters 6 and 8 of the SIP and Regulation No. 3, Part F, Sections VI.A, VI.B, and VI.C, specify BART, RP, and BART alternative emission limits and compliance schedules. The State is submitting Regulation No. 3, Part F, Section VI, as part of the RH SIP.

Regulation No. 3, Part F, Section VII, specifies monitoring, recordkeeping, and reporting requirements for BART, RP, and BART alternative units. The State is submitting Regulation No. 3, Part F, Section VII, as part of its RH SIP. Colorado worked closely with EPA in developing these requirements. For SO_2 and NO_X limits, Colorado has required

[29] The State has determined that agricultural burning is not a significant source of emissions related to regional haze impairment. For example, the State estimates that in 2004 only 503 tpy of PM_{10} were generated from agricultural burning in the entire State of Colorado. See Colorado TSD document ''Agricultural Burning in Colorado, 2003 and 2004 Inventories.''

sources to use continuous emission monitoring systems (CEMS) that must be operated and maintained in accordance with relevant EPA regulations, in particular, 40 CFR part 75 or 40 CFR part 60. For PM limits, Regulation No. 3 requires that sources perform testing in accordance with EPA approved test methods and that sources have a compliance assurance monitoring plan developed and approved in accordance with 40 CFR part 64. Regulation No. 3, Part F, Section VII, requires that sources keep relevant records for five years, and that sources report excess emissions on a semi-annual basis.

g. Anticipated Net Effect on Visibility Due to Projected Changes

The anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions during this planning period is addressed in section V.D.3 of this notice.

Based on our analysis, we have determined the State is meeting the long-term strategy requirements under 40 CFR 51.308(d)(3)(v). EPA is proposing to approve the State's long-term strategy found in Chapter 9 of the SIP. In addition, EPA is proposing to approve Regulation No. 3, Part F, Section VI and Section VII.

F. Coordination of RAVI and Regional Haze Rule Requirements

Our visibility regulations direct states to coordinate their RAVI long-term strategy and monitoring provisions with those for RH, as explained in section IV.F above. Under our RAVI regulations, the RAVI portion of a state SIP must address any integral vistas identified by the FLMs pursuant to 40 CFR 51.304 (see 40 CFR 51.302). An integral vista is defined in 40 CFR 51.301 as a view perceived from within the mandatory Class I Federal area of a specific landmark or panorama located outside the boundary of the mandatory Class I Federal area. Visibility in any mandatory Class I Federal area includes any integral vista associated with that area. The long-term strategy must have the capability of addressing current and future existing impairment situations as they face the state.

Regulation No. 3, Part D, Section XIV provides FLMs the opportunity to certify whether an existing stationary source(s) is reasonably attributable to existing visibility impairment and potentially subject to BART and provides the State's review schedule for the RAVI long-term strategy. The EPA previously approved the State's 2004 RAVI long-term strategy as meeting the requirements of 40 CFR 51.306 (see 71 FR 64465). In order to coordinate the RH long-term strategy and the RAVI long-term strategy, the State submitted revisions to Regulation No. 3, Part D, Section XIV. The State amended Regulation No. 3, Part D, Section XIV.F as part of this SIP action to change the current three-year RAVI long-term strategy review cycle to a five-year cycle (as required by the RH Rule) to coordinate the RAVI and RH elements together as intended by the RH rule.

We propose to find that the RH SIP appropriately supplements and augments Colorado's RAVI provisions by updating the monitoring and long-term strategy provisions to address RH. We discuss the relevant monitoring provisions further below. We are also proposing to approve the revision to Regulation No. 3, Part D, Section XIV.F, to change the review period from three years to five years to coordinate with the five-year periodic review required by the RH Rule.

G. Monitoring Strategy and Other Implementation Plan Requirements

40 CFR 51.308(d)(4) requires that the SIP contain a monitoring strategy for measuring, characterizing, and reporting RH visibility impairment that is representative of all mandatory Class I Federal areas within the state. This monitoring strategy must be coordinated with the monitoring strategy required in 40 CFR 51.305 for RAVI. As 40 CFR 51.308(d)(4) notes, compliance with this requirement may be met through participation in the IMPROVE network. 40 CFR 51.308(d)(4)(i) further requires the establishment of any additional monitoring sites or equipment needed to assess whether RPGs to address RH for all mandatory Class I Federal areas within the state are being achieved.

Consistent with EPA's monitoring regulations for RAVI and RH, Colorado indicates in Chapter 3 of the RH SIP that it will rely on the IMPROVE network for compliance purposes, in addition to any additional visibility impairment monitoring that may be needed in the future. The IMPROVE monitors at the Colorado Class I Areas are described in section IV.B of this notice.

Section 51.308(d)(4)(ii) requires that Colorado establish procedures by which monitoring data and other information are used in determining the contribution of emissions from within Colorado to RH visibility impairment at mandatory Class I Federal areas both within and outside the state. The IMPROVE monitoring program is national in scope, and other states have similar monitoring and data reporting procedures, ensuring a consistent and robust monitoring data collection system. As 40 CFR 51.308(d)(4) indicates, Colorado's participation in the IMPROVE program constitutes compliance with this requirement.

Section 51.308(d)(4)(iv) requires that the SIP provide for the reporting of all visibility monitoring data to the Administrator at least annually for each mandatory Class I Federal area in the state. To the extent possible, Colorado should report visibility monitoring data electronically. Section 51.308(d)(4)(vi) also requires that the SIP provide for other elements, including reporting, recordkeeping, and other measures, necessary to assess and report on visibility. We propose that Colorado's participation in the IMPROVE network ensures that the monitoring data is reported at least annually and is easily accessible; therefore, such participation complies with this requirement. IMPROVE data are centrally compiled and made available to EPA, states and the public via various electronic formats and Web sites including IMPROVE (*http://vista.cira.colostate.edu/improve/*) and VIEWS (*http://vista.cira.colostate.edu/views/*).

Section 51.308(d)(4)(v) requires that Colorado maintain a statewide inventory of emissions of pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any mandatory Class I Federal area. The inventory must include emissions for a baseline year, emissions for the most recent year for which data are available, and estimates of future projected emissions. The state must also include a commitment to update the inventory periodically. The State's emission inventory is discussed in section V.E.1 above. Chapter 3 of the SIP states that Colorado will update its portion of the regional inventory on the tri-annual cycle as dictated by the Air Emissions Reporting Rule in order to track emission change commitments and trends as well as for input to regional modeling exercises.

Section 51.308(d)(4)(vi) requires that states provide for any additional reporting, recordkeeping, and measures necessary to evaluate and report on visibility. The State has committed to provide any additional reporting, recordkeeping and measures necessary to evaluate and report on visibility but has concluded that it cannot identify a need for any specific commitment at this time. We agree with the State's conclusion that no specific additional measures are necessary at this time.

We propose to find that Colorado has satisfied the requirements in 40 CFR 51.308(d)(4).

H. Consultation With FLMs

Class I areas in Colorado are managed by either the U.S. Forest Service (FS) or the U.S. National Park Service (NPS). Although the FLMs are very active in participating in the regional planning organizations, the RHR grants the FLMs a special role in the review of the RH SIPs, summarized in section IV.H, above. The FLMs and the state environmental agencies are our partners in the RH process. Under 40 CFR 51.308(i)(2), Colorado was obligated to provide the FS and the NPS with an opportunity for consultation, in person and at least 60 days prior to holding a public hearing on the RH SIP. In development of its 2010 RH SIP submittal, Colorado met with the FS and NPS for consultation on June 2, 2010, August 12, 2010, and October 5, 2010.

Section CFR 51.308(i)(3) requires that Colorado provide in its RH SIP a description of how it addressed any comments provided by the FLMs. The FLMs formally commented on the 2010 proposed SIP in November and December of 2010. The NPS and FS provided support for the modeling approach used by the State in the BART determinations and complimented the State on thorough BART and RP analyses and area source evaluations. The FLMs also presented recommendations that the State reevaluate costs and emission limits for some of the BART and RP sources. Chapter 2.1 of the State's SIP provides more detailed information on the State's response to FLM comments.

Lastly, 40 CFR 51.308(i)(4) specifies the RH SIP must provide procedures for continuing consultation between the state and FLMs on the implementation of the visibility protection program required by 40 CFR 51.308. This includes development and review of implementation plan revisions and five-year progress reports and the implementation of other programs having the potential to contribute to impairment of visibility in mandatory Class I Federal areas. In Chapter 10 of the SIP, the State has included a commitment that it will provide the FLMs an opportunity to review and comment on SIP revisions, the five-year progress reports, and other developing programs that may contribute to Class I visibility impairment. Colorado will afford the FLMs with an opportunity for consultation in person and at least 60 days prior to holding any public hearing on a SIP revision. The FLM consultation must include the opportunity to discuss the FLMs' assessment of visibility impairment in each federal Class I area and to provide recommendations on the development and implementation of the visibility control strategies.

I. Periodic SIP Revisions and 5-Year Progress Reports

In accordance with the requirements listed in 40 CFR 51.308(g), Colorado commits in Chapter 10 of its SIP to submit a report on RP to EPA every five years following the initial submittal of the SIP. That report will be in the form of an implementation plan revision. The State's report will evaluate the progress made towards the RPGs for each mandatory Class I area located within Colorado and in each mandatory Class I area located outside Colorado, which have been identified as being affected by emissions from Colorado. The State will also evaluate the monitoring strategy adequacy in assessing RPGs.

Based on the findings of the five-year progress report, 40 CFR 51.308(h) requires a state to make a determination of adequacy of the current implementation plan. The State must take one or more of the actions listed in 40 CFR 51. 308(h)(1) through (4) that are applicable at the same time as the state submits a five-year progress report. Colorado commits in Chapter 10 of the SIP to determine the adequacy of the current SIP at the same time a five-year progress report is due.

Section CFR 51.308(f) requires a state to revise and submit its RH SIP to EPA by July 31, 2018, and every ten years thereafter. The State commits in Chapter 10 of the SIP to provide this revision and to evaluate and reassess elements required under 40 CFR 51.308(d), taking into account improvements in monitoring data collection and analysis, and control technologies.

VI. EPA's Proposed Action

EPA is proposing to approve a SIP revision submitted by the State of Colorado on May 25, 2011 that addresses RH. EPA is proposing to determine that the plan submitted by Colorado satisfies requirements of the CAA and our rules under 40 CFR 51.308 that require states to prevent any future and remedy any existing man-made impairment of visibility in mandatory Class I areas. We are proposing to approve the State's RH SIP, including revisions submitted as part of the RH SIP to:

- Regulation No. 3, Part F, Section VI and Section VII.
- Regulation No. 3, Part D, Section XIV.F.
- Regulation No. 7, Section XVII.E.3.a.

VII. Statutory and Executive Order Reviews

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations (42 USC 7410(k), 40 CFR 52.02(a)). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this proposed action merely approves state law as meeting Federal requirements; this proposed action does not impose additional requirements beyond those imposed by state law. For that reason, this proposed action:

- Is not a ''significant regulatory action'' subject to review by the Office of Management and Budget under Executive Order 12866 (58 FR 51735, October 4, 1993);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 USC 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 USC 601 *et seq.*);
- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have Federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of Section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 USC 272 note) because application of those requirements would be inconsistent with the CAA; and,
- Does not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

In addition, this rule does not have Tribal implications as specified by Executive Order 13175 (65 FR 67249, November 9, 2000), because the SIP is not approved to apply in Indian country located in the State, and EPA notes that it will not impose substantial direct costs on Tribal governments or preempt Tribal law.

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Intergovernmental relations, Nitrogen dioxide, Particulate matter, Reporting and recordkeeping requirements, Sulfur oxides, Volatile organic compounds.

Dated: March 8, 2012.

James B. Martin,

Regional Administrator, Region 8.

LIST OF PUBLIC LAWS

This is a continuing list of public bills from the current session of Congress which have become Federal laws. It may be used in conjunction with ''P L U S'' (Public Laws Update Service) on 202–741–6043. This list is also available online at *http://www.archives.gov/federal-register/laws*.

The text of laws is not published in the **Federal Register** but may be ordered in ''slip law'' (individual pamphlet) form from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402 (phone, 202–512–1808). The text will also be made available on the Internet from GPO's Federal Digital System (FDsys) at *http://www.gpo.gov/fdsys*. Some laws may not yet be available.

S. 1134/P.L. 112–100
St. Croix River Crossing Project Authorization Act (Mar. 14, 2012; 126 Stat. 268)

S. 1710/P.L. 112–101
To designate the United States courthouse located at 222 West 7th Avenue, Anchorage, Alaska, as the James M. Fitzgerald United States Courthouse. (Mar. 14, 2012; 126 Stat. 270)

Last List March 15, 2012

Public Laws Electronic Notification Service (PENS)

PENS is a free electronic mail notification service of newly enacted public laws. To subscribe, go to *http://listserv.gsa.gov/archives/publaws-l.html*

Note: This service is strictly for E-mail notification of new laws. The text of laws is not available through this service. **PENS** cannot respond to specific inquiries sent to this address.
