Endangered and Threatened Wildlife and Plants; Endangered Species Status for Cape Sable Thoroughwort, Florida Semaphore Cactus, and Aboriginal Prickly-Apple, and Designation of Critical Habitat for Cape Sable Thoroughwort; Proposed Rule
DEPARTMENT OF THE INTERIOR

Fish and Wildlife Service

50 CFR Part 17

RIN 1018–AY08

Endangered and Threatened Wildlife and Plants; Endangered Species Status for Cape Sable Thoroughwort, Florida Semaphore Cactus, and Aboriginal Prickly-Apple, and Designation of Critical Habitat for Cape Sable Thoroughwort

SUMMARY: We, the U.S. Fish and Wildlife Service, propose to list Chromolaena frustrata (Cape Sable thoroughwort), Consolea coralllica (Florida semaphore cactus), and Harrisia aboriginum (aboriginal prickly-apple) as an endangered species under the Endangered Species Act, and we propose to designate critical habitat for Chromolaena frustrata, Consolea coralllica, and Harrisia aboriginum. These are proposed regulations, and if finalized, their effect will be to add three species to the List of Endangered or Threatened Plants and to designate critical habitat for one species under the Endangered Species Act.

DATES: We will accept comments received or postmarked on or before December 10, 2012. Comments submitted electronically using the Federal eRulemaking Portal (see ADDRESSES section, below) must be received by 11:59 p.m. Eastern Time on the closing date. We must receive your comments on or before December 10, 2012. We will receive and consider your comments only by the methods described above.

ADDRESSES: You may submit comments by one of the following methods:

(1) Electronically: Go to the Federal eRulemaking Portal: http://www.regulations.gov. In the search box, enter Docket No. FWS–R4–ES–2012–0076, which is the docket number for this rulemaking. Then, click the Search button. You may submit a comment by clicking on “Comment Now!” If your comments will fit in the provided comment box, please use this feature of http://www.regulations.gov, as it is most compatible with our comment review procedures. If you attach your comments as a separate document, our preferred file format is Microsoft Word. If you attach multiple comments (such as form letters), our preferred format is a spreadsheet in Microsoft Excel.

(2) By hard copy: Submit by U.S. mail or hand–delivery to: Public Comments Processing, Attn: FWS–R4–ES–2012–0076; Division of Policy and Directives Management; U.S. Fish and Wildlife Service; 4401 N. Fairfax Drive, MS 2042–PDM; Arlington, VA 22203.

FOR FURTHER INFORMATION CONTACT: Larry Williams, Field Supervisor, U.S. Fish and Wildlife Service, South Florida Ecological Services Office, 1339 20th Street, Vero Beach, FL 32960; by telephone 772–562–3909; or by facsimile 772–562–4288. Persons who use a telecommunications device for the deaf (TDD) may call the Federal Information Relay Service (FIRS) at 800–877–8339.

SUPPLEMENTARY INFORMATION: This document consists of: (1) A proposed rule to list Chromolaena frustrata, Consolea coralllica, and Harrisia aboriginum as an endangered species; and (2) a proposed rule to designate critical habitat for Chromolaena frustrata.

Executive Summary

Why we need to publish a rule. Under the Endangered Species Act (Act), a species may warrant protection through listing if it is an endangered or threatened species throughout all or a significant portion of its range. Chromolaena frustrata, Consolea coralllica, and Harrisia aboriginum are highly restricted in their ranges and the threats occur throughout their ranges; therefore, these species qualify for listing. We are proposing to list these plants as endangered species. Their protection under the Act can only be done by issuing a rule.

• Chromolaena frustrata has been extirpated (no longer in existence) from half of the islands where it occurred in the Florida Keys, and threats of competition from nonnative plants and habitat loss still exist in the remaining populations.

• Consolea coralllica has been extirpated from half of the islands where it occurred in the Florida Keys, and threats of poaching, predation by a nonnative moth, competition from nonnative plant species, and habitat loss still exist in the remaining populations.

• Harrisia aboriginum has been extirpated from the northern extent of its range in Manatee County, and threats of poaching, competition from nonnative plant species, and habitat loss still exist in the remaining populations.

The basis for our action. Under the Act, a species may be determined to be an endangered or threatened species based on any of five factors: (A) The present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or manmade factors affecting its continued existence.

We have determined that threats to Chromolaena frustrata include destruction, modification, or curtailment of its habitat or range; inadequate existing regulatory mechanisms; and other natural or manmade factors, including climate change (sea level rise), small populations, and competition from nonnative plant species.

We have determined that threats to Consolea coralllica include destruction, modification, or curtailment of its habitat or range; overuse (poaching) and predation; inadequate existing regulatory mechanisms; and other natural or manmade factors, including climate change (sea level rise), small populations, low genetic diversity, and competition from nonnative plant species.

We have determined that threats to Harrisia aboriginum include destruction, modification, or curtailment of its habitat or range; overuse (poaching); inadequate existing regulatory mechanisms; and other natural or manmade factors, including climate change (sea level rise), small populations, and competition from nonnative plant species.
This rule proposes to designate critical habitat for *Chromolaena frustrata*.

- In total, approximately 3,466 hectares (8,565 acres) are being proposed for designation as critical habitat for *C. frustrata*. The proposed critical habitat is located in Miami-Dade and Monroe Counties, Florida.
- The proposed designation includes both occupied and unoccupied critical habitat, although those areas are not differentiated in the proposed rule or on the maps. Where the unit is not occupied by *Chromolaena frustrata*, we have concluded that the area is essential for the conservation of the species because the designation would allow for the expansion of *Chromolaena frustrata*’s range and reintroduction of individuals into areas where the species previously occurred.
- This rule does not propose critical habitat for *Consolea corallicola* or *Harrisia aboriginum*. We have determined that designation of critical habitat would not be prudent for either species.
- Designation would increase the likelihood and severity of illegal collection of *C. corallicola* and *H. aboriginum*, and in doing so make enforcement of take prohibitions more difficult.
- These threats outweigh the benefits of designation for the two species.

Peer Review

We are seeking comments from knowledgeable individuals with scientific expertise to review our technical assumptions, analysis of the best available science, and application of that science and to provide any additional scientific information to improve this proposed rule.

Information Requested

We intend that any final action resulting from this proposed rule will be based on the best scientific and commercial data available and be as accurate and as effective as possible. Therefore, we request comments or information from other concerned governmental agencies, Native American tribes, the scientific community, industry, or any other interested parties concerning this proposed rule. We particularly seek comments concerning:

1. The species’ biology, range, and population trends, including:
   (a) Habitat requirements for feeding, breeding, and sheltering;
   (b) Genetics and taxonomy;
   (c) Historical and current range, including distribution patterns;
   (d) Historical and current population levels, and current and projected trends; and
   (e) Past and ongoing conservation measures for the species, its habitat, or both.
2. The factors that are the basis for making a listing determination for a species under section 4(a) of the Act (16 U.S.C. 1531 *et seq.*), which are:
   (a) The present or threatened destruction, modification, or curtailment of its habitat or range;
   (b) Overutilization for commercial, recreational, scientific, or educational purposes;
   (c) Disease or predation;
   (d) The inadequacy of existing regulatory mechanisms; or
   (e) Other natural or manmade factors affecting its continued existence.
3. Biological, commercial trade, or other relevant data concerning any threats (or lack thereof) to these species and existing regulations that may be addressing those threats.
4. Additional information concerning the historical and current status, range, distribution, and population size of these species, including the locations of any additional occurrences or populations of these species.
5. Any information on the biological or ecological requirements of these species and ongoing conservation measures for these species and their habitats.
6. The reasons why we should or should not designate habitat as “critical habitat” under section 4 of the Act (16 U.S.C. 1531 *et seq.*), including whether there are threats to all the species from human activity, the degree of which can be expected to increase due to the designation, and whether that increase in threat outweighs the benefit of designation such that the designation of critical habitat is not prudent.
7. Specific information on:
   (a) The amount and distribution of *Chromolaena frustrata* habitat;
   (b) What areas, that were occupied at the time of listing (or are currently occupied) and maintain features essential to the conservation of the species, should be included in the designation and why;
   (c) What areas not occupied at the time of listing are essential for the conservation of the species and why.
8. Land use designations and current or planned activities in the areas occupied by *Chromolaena frustrata* or proposed to be designated as critical habitat, and possible impacts of these activities on the species and proposed critical habitat.
9. Information on the projected and reasonably likely impacts of climate change on *Chromolaena frustrata*, *Consolea corallicola*, and *Harrisia aboriginum*, and proposed critical habitat for *Chromolaena frustrata*.
10. Probable economic, national security, or other relevant impacts that may result from designating any area that may be included in the final designation. We are particularly interested in any impacts on small entities, and the benefits of including or excluding areas from the proposed designation that are subject to these impacts.
11. Whether our approach to designating critical habitat could be improved or modified in any way to provide for greater public participation and understanding, or to assist us in accommodating public concerns and comments.
12. The likelihood of adverse social reactions to the designation of critical habitat and how the consequences of such reactions, if likely to occur, would relate to the conservation and regulatory benefits of the proposed critical habitat designation.

Please include sufficient information with your submission (such as scientific journal articles or other publications) to allow us to verify any scientific or commercial information you include.

Please note that submissions merely stating support for or opposition to the action under consideration without providing supporting information, although noted, will not be considered in making a determination, as section 4(b)(1)(A) of the Act directs that determinations as to whether any species is an endangered or threatened species must be made “solely on the basis of the best scientific and commercial data available.”

You may submit your comments and materials concerning this proposed rule by one of the methods listed in the ADDRESSES section. We request that you send comments only by the methods described in the ADDRESSES section.

If you submit information via http://www.regulations.gov, your entire submission—including any personal identifying information—will be posted on the Web site. If your submission is made via a hardcopy that includes personal identifying information, you may request at the top of your document that we withhold this information from public review. However, we cannot guarantee that we will be able to do so. We will post all hardcopy submissions on http://www.regulations.gov. Please include sufficient information with your comments to allow us to verify any scientific or commercial information you include.
Comments and materials we receive, as well as supporting documentation we used in preparing this proposed rule, will be available for public inspection on http://www.regulations.gov, or by appointment, during normal business hours, at the U.S. Fish and Wildlife Service, South Florida Ecological Services Office, Vero Beach, Florida (see FOR FURTHER INFORMATION CONTACT).

Previous Federal Actions

Consolea corallicola was first recognized as a candidate species (under the species’ former name Opuntia spinosissima) on September 27, 1985 (50 FR 39526). It was removed from the candidate list from 1996 to 1998 because there was not sufficient information on the species’ biological vulnerability and threats to support issuance of a proposed rule. The 1999 Candidate Notice of Review (CNOR) published in the Federal Register on October 23, 1999 (64 FR 57534) included C. corallicola (under the species’ previous name Opuntia corallicola) as a candidate for listing under the Act. We determined that listing was warranted, but was precluded due to workloads and priorities, and we assigned a listing priority number (LPN) of 5 to the species (64 FR 57534). In 2001, C. frustrata remained on the candidate species with the LPN of 5 (66 FR 54808, October 30, 2001). In the 2002 and 2004 CNORS (67 FR 40657, June 13, 2002; 69 FR 24876, May 4, 2004) C. frustrata retained the LPN of 5. We published a finding for the species in the 2005 CNOR on May 11, 2005 (70 FR 24869), in response to a petition received on May 11, 2004. We also changed the LPN of C. frustrata from a 5 to a 2 because the threats to the species were found to be more imminent than previously known. The species remained on the candidate list as published in the CNORS from 2006 to 2011 with the LNP of 2 (71 FR 53756, September 12, 2006; 72 FR 69034, December 6, 2007; 73 FR 75176, December 10, 2008; 74 FR 57804, November 9, 2009; 75 FR 69222, November 10, 2010; 76 FR 66370, October 26, 2011).

On May 10, 2011, the Service announced a work plan to restore biological priorities and certainty to the Service’s listing process. As part of an agreement with one of the agency’s most frequent plaintiffs, the Service filed a work plan with the U.S. District Court for the District of Columbia. The work plan will enable the agency to, over a period of 6 years, systematically review and address the needs of more than 250 species listed within the 2010 Candidate Notice of Review, including Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum, to determine if these species should be added to the Federal Lists of Endangered and Threatened Wildlife and Plants. This work plan will enable the Service to again prioritize its workload based on the needs of candidate species, while also providing state wildlife agencies, stakeholders, and other partners clarity and certainty about when listing determinations will be made. On July 12, 2011, the Service reached an agreement with a second frequent plaintiff group and further strengthened the work plan, which will allow the agency to focus its resources on the species most in need of protection under the Act. These agreements were approved on September 9, 2011. The timing of this proposed listing is, in part, therefore, an outcome of the work plan.

Status Assessment for Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum

Background

It is our intent to discuss below only those topics directly relevant to the listing of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum as endangered in this section of the proposed rule.

Chromolaena frustrata

General Biology

Chromolaena frustrata (Family: Asteraceae) is a perennial herb. Mature plants are 15 to 25 centimeters (cm) (5.9 to 9.8 inches (in)) tall with erect stems. The leaves and stems are covered in short, fuzzy hairs. The leaves have three distinct veins, are roughly oval or egg shaped, and have toothed edges. The blue to lavender flowers are borne in heads usually in clusters of two to six. Flowers are produced mostly in the fall, though sometimes year round (Nesom 2006, pp. 544–545).

Taxonomy, Life History, and Distribution

Chromolaena frustrata was first reported by Chapman in 1886, from the Florida Keys, who called it Eupatorium heteroclinum (Chapman 1889, p. 626). Early authors assigned the species to the genus Osmio (Small 1913, p. 147; 1933, p. 1320). In 1970, R.M. King and H.E. Robinson placed this species in the genus Chromolaena (King and Robinson 1970, p. 201). Some authors continue to assign the species to the genus Eupatorium (i.e., Long and Lakela 1971, p. 873 and Cronquist 1980, p. 185). The authors of Vascular Plants of Florida recognize Chromolaena frustrata (Wunderlin and Hansen 2008, pp. 1–2). The Integrated Taxonomic Information System (ITIS) (2012, p. 1) indicates that the taxonomic standing for C. frustrata (B.L. Robinson) King and H.E. Robinson is accepted. Synonyms include Eupatorium frustratum B.L. Robinson

Chromolaena corallicola

...
and Osmia frustrata (B.L. Robinson) Small.

Climate

The climate of south Florida where Chromolaena frustrata occurs is classified as tropical savanna and is characterized by distinct wet and dry seasons, a monthly mean temperature above 18 °C (64.4 °F) in every month of the year, and annual rainfall averaging 75 to 150 cm (30 to 60 in) (Gabler et al. 1994, p. 211). Freezes can occur in the winter months, but are very infrequent at this latitude in Florida.

Habitat

Chromolaena frustrata grows in open canopy habitats, including coastal berms and coastal rock barrens, and in semi-open to closed canopy habitats, including buttonwood forests and rockland hammocks.

Coastal BERM

Coastal berms are landscape features found along low-energy coastlines in south Florida and the Florida Keys. Coastal berm is a short forest or shrub thicket found on long, narrow, storm-deposited ridges of loose sediment formed by a mixture of coarse shell fragments, pieces of coralline algae, and other coastal debris. These ridges parallel the shore and may be found on the seaward edge or landward edge of the mangroves or farther inland depending on the height of the storm surge that formed them. They range in height from 30 to 305 cm (1 to 10 feet (ft)). Structure and composition of the vegetation is variable depending on height and time since the last storm event. The most stable berms may share some tree species with rockland hammocks, but generally have a greater proportion of shrubs and herbs. Tree species may include Bursera simaruba (gumbo limbo), Coccoloba uvifera (seagrape), Coccothrinax argentata (silver palm), Guapira discolor (blolly), Drypetes diversifolia (milkbark), Genipa clusiifolia (seven year apple), and Metopium toxiferum (poisonwood). Characteristic tall shrub and short tree species include Eugenia foetida (Spanish stopper), Ximenia americana (hog plum), Randia aculeata (white indigoberry), Pithecellobium keyense (Florida Keys blackhead), and Sideroxylon celastrinum (plafon plum). Short shrubs and herbs include Hymenocallis latifolia (perfumed spiderily), Capparis flexuosa (bayleaf capertree), Lantana involucrata (buttonage), and Rivina humilis (rougeplant). More seaward berms or those more recently affected by storm deposition may support a suite of plants similar to beaches, including shoreline Sesuvium portulacastrum (sea purslane), Distichlis spicata (saltgrass), and Sporobolus virginicus (seashore dropseed), or scattered to dense shrub thickets with Conocarpus erectus (buttonwood), stunted Avicennia germinans (black mangrove), Rhizophora mangle (red mangrove), Laguncularia racemosa (white mangrove), Suriana maritima (bay cedar), Manilkara jaimiqui (wild dilly), Jacquinia keyensis (joeewood), and Borrichia frutescens (burly seaside oxeye) (Florida Natural Areas Inventory (FNAI) 2010a, p. 1).

Coastal berms are deposited by storm waves along low-energy coasts. Their distance inland depends on the height of the storm surge. Tall berms may be the product of repeated storm deposition. Coastal berms that are deposited far enough inland and remain long-undisturbed may in time succeed to hammock. This is a structurally variable community that may appear in various stages of succession following storm disturbance, from scattered herbaceous beach colonizers to a dense stand of tall shrubs (FNAI 2010a, p. 2).

Coastal Rock Barren

Also known as Keys tidal rock barren or Keys cactus barren, coastal rock barren is confined to the Florida Keys on limestone bedrock along shores facing both Florida Bay and the Straits of Florida. Coastal rock barrens are flat rocklands with much exposed and eroded limestone, little soil or leaf litter, and a sparse cover of stunted halophytic herbs and shrubs in tidal rock barrens (FNAI 2010b, p. 1), or a wide variety of herbs and succulents in cactus barrens (FNAI 2010c, p. 1). The amount of exposed rock varies from practically 0 to over 50 percent of the area.

In tidal rock barrens, patches of low, salt-tolerant herbaceous species include Borrichia frutescens and B. arborescens (seaside oxeye), Sarcocornia perennis (perennial glasswort), Batis maritima (saltwort), Monanthochloe littoralis (shoregrass), Distichlis spicata, Sporobolus virginicus, and Fimbristylis spadicea (marsh fimbry). Spiny species, particularly the rare Opuntia triacantha (three-spined pricklypear), are characteristic but their abundance is variable. Other spiny species include Agave decipiens (false sisal), Acanthocereus tetragonus, and Opuntia stricta (erect pricklypear). Scattered clumps of stunted trees may be present, including Bursera simaruba, Conocarpus erectus, Eugenia foetida, and Pithecellobium unguis-cati (cattaw blackhead) (FNAI 2010c, p. 1).

Coastal rock barren occurs above the daily tidal range, but is subject to flooding by seawater during extreme tides and storm events. Salt spray from coastal winds, as well as shallow soils, may limit height growth of woody plants. Aside from bare rock substrate, discontinuous patches of thin murl soils may be present. Fires are rare to non-existent in this community (FNAI 2010b, p. 2). The natural process giving rise to cactus barrens is not known, but because they occur on sites where the thin layer of organic soil over limestone bedrock is missing, they may have formed by soil erosion following destruction of the plant cover by fire, storm, or artificial clearing (FNAI 2010c, p. 2).

At its seaward edge, coastal rock barren borders mangrove swamp or salt marshes that are regularly inundated. At its upland edge, coastal rock barrens may grade into rockland hammock or pine rockland (FNAI 2010b, p. 2; 2010c, p. 2).

Buttonwood Forest

Forests dominated by buttonwood often exist in upper tidal areas, especially where mangrove swamp transitions to rockland hammock. These buttonwood forests have canopy dominated by Conocarpus erectus and often have a understory dominated by Borrichia frutescens, Lycium
Rockland Hammock

Rockland hammock is a species-rich tropical hardwood forest on upland sites in areas where limestone is very near the surface and often exposed. The forest floor is largely covered by leaf litter with varying amounts of exposed limestone and has few herbaceous species. Rockland hammocks typically have larger, more mature trees in the interior, while the margins can be almost impenetrable in places with dense growth of smaller shrubs, trees, and vines. Canopy and subcanopy species include Bursera simaruba, Lysiloma latisiliquum (false tamarind), Coccoloba diversifolia (pigeon plum), Sideroxylon foetidissimum (false mastic), Ficus aurea (strangler fig), Piscidia piscipula (Jamaican dogwood), Ocotea coriacea (lancewood), Drypetes diversifolia, Simarouba glauca (paradisetree), Sideroxylon salicifolium (willow bastick), Krugiodendron ferreum (false ironwood), Exothea paniculata (inkwood), Metopium toxiferum, and Swietenia mahagoni (West Indies mahogany). Mature hammocks can be open beneath a tall, well-defined canopy and subcanopy. More commonly, in less mature or disturbed hammocks, dense woody vegetation of varying heights from canopy to short shrubs is often present. Species that generally make up the shrub layers within rockland hammock include several species of Eugenia (stoppers), Thrinax morrisii and T. radiata (thatch palms), Amyris elemifera (sea torchwood), Ardisia escallonioides (marberry), Psychotria nervosa (wild coffee), Chrysophyllum oliviforme (satinal), Sabal palmetto (cabbage palm), Guaiacum sanctum (lignum-vitae), Ximenia americana, Colubrina elliptica (soldierwood), Pithecellobium unguis-cati and Pithecellobium keyense, Coccoloba uvifera, and Colubrina arborescens (greenheart). Vines can be common and include Toxocodendron radicans (eastern poison ivy), Smilax auriculata (earleaf greenbrier), Smilax havanaensis (Everyglades greenbrier), Parthenocissus quinquefolia (Virginia creeper), Hippocratea volubilis (medicine vine), and Morinda royoc (redgal). The typically sparse short shrub layer may include Zamia pumila (coontie) and Acanthocereus tetragonus. Herbaceous species are occasionally present and generally sparse in coverage. Characteristic species include Lasiacis divaricata (smallcane), Oplismenus hirtellus (basketgrass), and many species of ferns (FNAI 2010e, p.1).

Rockland hammock occurs on a thin layer of highly organic soil covering limestone on high ground that does not regularly flood, but it is often dependent upon a high water table to keep humidity levels high. Rockland hammocks are frequently located near wetlands; in the Everglades they can occur on organic matter that accumulates on top of the underlying limestone; in the Keys they occur inland from tidal flats (FNAI 2010e, p.1).

Rockland hammock is susceptible to fire, frost, canopy disruption, and ground water reduction. Rockland hammock can be the advanced successional stage of pine rockland, especially in cases where rockland hammock is adjacent to pine rockland. In such cases, when fire is excluded from pine rockland for 15 to 25 years, it can succeed to rockland hammock vegetation. Historically, rockland hammocks in south Florida evolved with fire in the landscape, fire most often extinguished near the edges when it encountered the hammock’s moist microclimate and litter layer. However, rockland hammocks are susceptible to damage from fire during extreme drought or when the water table is lowered. In these cases, fire can cause tree mortality and consume the organic soil layer (FNAI 2010e, p.2).

Rockland hammocks are also sensitive to the strong winds and storm surge associated with infrequent hurricanes. Canopy damage often occurs, which causes a change in the microclimate of the hammock. Decreased relative humidity and drier soils can leave rockland hammocks more susceptible to fire. Rockland hammock can grade into glades marsh, mangrove swamp, salt marsh, coastal rock barren, pine rockland, maritime hammock, or marl prairie (FNAI 2010e, p. 2).

The sparsely vegetated edges or interior portions laid open by canopy disruption are the areas of rockland hammock that have light levels sufficient to support Chromolaena frustrata. However, the dynamic nature of the habitat means that areas not currently open may become open in the future as a result of canopy disruption from fire, or the currently open may develop more dense canopy over time, eventually rendering that portion of the hammock unsuitable for C. frustrata.

The ecological communities and substrate upon which Chromolaena frustrata is found differ between the mainland populations and those in the Florida Keys. The mainland populations occur only in Everglades National Park (ENP), where C. frustrata occurs in rockland hammocks and buttonwood forest, often occupying the transitional areas (ecotone) between these habitats and salt marsh dominated by Conocarpus erectus and salt-tolerant species, on marl (an unconsolidated sedimentary rock or soil consisting of clay and lime) substrate (Sadle 2008 and 2012, pers. comm.). In the Florida Keys, C. frustrata occurs on coastal rock barrens, coastal berms, and rockland hammocks on exposed bare limestone rock or with a thin layer of leaf litter (Bradley and Gann 1999, p. 37).

Chromolaena frustrata is often found in the shade of associated canopy and subcanopy plant species; these canopies buffer C. frustrata from full exposure to the sun (Bradley and Gann 1999, p. 37).

**Historical Range**

Chromolaena frustrata was historically known from Monroe County, both on the Florida mainland and the Keys, and in Miami-Dade County along Florida Bay (Bradley and Gann 1999, p. 36). In mainland Monroe County, C. frustrata was known from the Flamingo area to the Madeira Bay area in what is now ENP. In the Florida Keys, C. frustrata was known from Key Largo to Boca Grande Key (Bradley and Gann 1999, p. 36; Bradley and Gann 2004, p. 2). The species was observed historically on Big Pine Key, Boca Grande Key, Fiesler Key, Key Largo, Key West, Knight’s Key, Lignumvitae Key, Long Key, Upper Matecumbe Key, and Lower Matecumbe Key (Bradley and Gann 1999, p. 36; Bradley and Gann 2004, pp. 4–7).

The common name of Chromolaena frustrata, Cape Sable thoroughwort, places it in a locality where it may have never occurred. Usage of this place name may have been referring to the greater Cape Sable-Flamingo area, and not specifically to Cape Sable itself. No additional specimens or verifiable reports have documented it on Cable Sable proper. Other reports of C. frustrata are also suspect. It was reported from “Turner’s River Hammock” in Collier County and the Ten Thousand Islands area of ENP, but no voucher specimen has ever been located for these collections (Bradley and Gann 2004, p. 7).
Current Range

In ENP, the species appears to have a distribution approaching what was reported historically. Eleven populations supporting approximately 1,500 to 2,500 plants occur in buttonwood forests and rockland hammocks from the Coastal Prairie Trail near the southern tip of Cape Sable to Madeira Bay (Sadle 2007 and 2012, pers. comm.). In the Florida Keys, Chromolaena frustrata has been extirpated from half of the islands where it occurred (Bradley and Gann 2004, p. 4). It no longer occurs on Key Largo, Big Pine Key, Fiesta Key, Knight’s Key, or Key West (Bradley and Gann 2004, pp. 4–6). The current range of C. frustrata includes a small portion of ENP, and six islands in the Florida Keys (Upper Matecumbe Key, Lower Matecumbe Key, Lignumvitae Key, Long Key, Big Munson Island, and Boca Grande Key) (Bradley and Gann 2004, pp. 3–4). Extant populations of C. frustrata are identified in Table 1 and discussed below.

Demographics

Little is known about the long-term demographics or population trends of Chromolaena frustrata. Populations may experience declines due to the effects of hurricanes and storm surges, but the species appears to be able to rebound at affected sites within a few years. For example, after Hurricane Wilma in 2005, some populations of C. frustrata vanished and the habitat at these sites was significantly altered due to hurricane storm surge (Duquesnel 2012, pers. comm.). However, it appears that the species is returning at these locations (Bradley 2009, pers. comm.). Furthermore, canopy disturbance may also benefit the species, as it has been speculated that the large number of plants observed at Big Munson Island in 2003 was due to thinning of the hammock canopy caused by Hurricane Georges in 1998 (Bradley and Gann 2004, p. 4).

Reproductive Biology and Genetics

The reproductive biology and genetics of Chromolaena frustrata have not been studied (Bradley and Gann 1999, p. 37). We have no other information available regarding the ecology of the species beyond the habitat preferences and demographic trends discussed above.

Consolaea corallicola

Consolaea corallicola (Family: Cactaceae) is a tree-like cactus; mature plants grow 2 meters (6 feet) tall with an erect main trunk, which is elliptical or oval in cross section and armed with spines. Near the top of the plant there is a dense cluster of branches. The stem branches (pads) are green, elliptical, relatively thin, often curved, and 12 to 30 cm (5 to 12 in) long. The spines are in clusters of five to nine, 7 to 11 cm (2.8 to 4.7 in) long, needle-like, with one of the spines much longer than the others. Spines on the main stems of older plants are enlarged. The flowers are bright red and 1.3 to 1.9 cm (0.50 to 0.75 in) wide, and the fruits are yellow, egg-shaped, and 2.5 to 5.1 cm (1 to 2 in) long (Small 1930, pp. 25–26; Anderson 2001, pp. 170–171). The climate of south Florida where Consolaea corallicola occurs is classified as tropical savanna, as described above for Chromolaena frustrata.

Habitat

Consolaea corallicola occurs in rockland hammocks near sea level (Small 1930, pp. 25–26; Benson 1982, p. 531) and in buttonwood forests in the transitional area between rockland hammocks and mangrove swamps (Bradley and Gann 1999, p. 77; Gann et al. 2002, p. 480; Higgins 2007, pers. comm.). These community types are described above for Chromolaena frustrata. Consolaea corallicola occurs on sandy soils and limestone rockland soils with little organic matter (Small 1930, pp. 25–26) and seems to prefer areas where canopy cover and sun exposure are moderate (Grahl and Bradley 2005, p. 4).
Historical Range

*Consolea corallicola* was known historically from three islands of the Florida Keys in Monroe County (Small 1930, pp. 25–26) and one small island in Biscayne Bay in Miami-Dade County (Bradley and Woodmansee 2002, p. 810). A population on the southeast portion of Big Pine Key in the Florida Keys (Small 1921, p. 50) was extirpated by the 1960s, as a result of road building and “collecting by cactus enthusiasts” (Bradley and Gann 1999, p. 77). A population known from Key Largo in the Florida Keys was also extirpated, although the cause of its loss is unknown (Bradley and Woodmansee 2002, p. 810).

Current Range

The current range of *Consolea corallicola* includes two naturally occurring populations, one in Biscayne National Park (BNP; Miami-Dade County) and one on a small island in the Florida Keys (Monroe County) (Bradley and Gann 1999, p. 77; Bradley and Woodmansee 2002, p. 810). These naturally occurring populations account for fewer than 1,000 plants. *Consolea corallicola* was also reintroduced at several sites in the Florida Keys, and plants survive at two of these sites on State-owned lands (Stiling 2009, pers. comm.; Stiling 2010, p. 1; Duquesnel 2011a, b, pers. comm.). Both sites together represent fewer than 50 plants. A survey of other areas containing suitable habitat in BNP was undertaken in 2002 and 2003, to locate additional populations, but none were found (Bradley and Koop 2003, p. 2).

Extant populations of *Consolea corallicola* are provided in Table 2 and are discussed below.

### Table 2—Extant Populations of *Consolea corallicola*

<table>
<thead>
<tr>

<th>Ownership</th>
<th>Size</th>
<th>Habitat</th>
<th>Trend</th>
</tr>
</thead>
</table>

Reintroductions

Experimental plantings of *Consolea corallicola* were conducted at several sites on State and Federal conservation lands in the Florida Keys from 1996 to 2004. However, these plantings were largely unsuccessful (with most plants succumbing to *Cactoblastis* moth damage or rot), and plants currently remain at only two of these sites, one of which is inundated too frequently during high tides to be favorable for population expansion (Duquesnel 2008, 2009, 2011a, b, pers. comm.; Stiling 2007, p. 2; Stiling 2009, pers. comm.; Stiling 2010, pp. 193–194).

Reproductive Biology and Genetics

*Consolea corallicola* flowering occurs throughout the year, but peaks in February and March (Bradley and Koop 2003, p. 2). Plants of *C. corallicola* are functionally dioecious (i.e., with male and female flowers on separate plants), but the flowers give the appearance of a species that is hermaphroditic with perfect flowers (i.e., each flower produces stamens and ovules) (Negrón-Ortíz and Strittmatter 2004, p. 22; Negrón-Ortíz 2007a, p. 3; 2007b, p. 1362).

Sexual reproduction has not been observed in *Consolea corallicola*. All documented *C. corallicola* reproduction has been vegetative (clonal), with new plants originating from pads that fall from larger plants and take root (Negrón-Ortíz 1998, p. 208). Survival rates of fallen pads in research populations are low due to rot and *Cactoblastis* moth damage (Stiling 2010, p. 193; see Summary of Factors Affecting the Species below). Production of seeds is rare and the few seeds that have been observed are thought to be the product of asexual seed reproduction (agamospermy) (Negrón-Ortíz 1998, p. 211). Two hypotheses have been suggested to explain the lack of seed production of *C. corallicola*. The first hypothesis is that the species is a sterile polyploid (abnormal cell division that results in more than two sets of chromosomes) (Negrón-Ortíz 1998, p. 212). An alternative hypothesis is the dioecious breeding system of *C. corallicola*. All plants in the known populations produce only male flowers, and no female individuals have ever been located. As a result, all existing occurrences of *C. corallicola* appear to be incapable of sexual reproduction at this time (Negrón-Ortíz and Strittmatter 2004, p. 22).

Cariaga *et al.* (2005, pp. 225–230) found no genetic diversity within the two remaining wild populations of *Consolea corallicola* and concluded that all plants within each population are likely derived clonally from a single parent plant. These data support asexual propagation as the reproductive strategy of *C. corallicola*. However, there is a small amount of variation between the two remaining wild populations, suggesting the possibility that they originated from different parent plants (Lewis 2007, p. 3). Likewise, Cariaga *et al.* (2005, p. 225) found that a single plant collected by George Avery in 1963 from Big Pine Key and maintained at Fairchild Tropical Botanical Gardens was a unique genotype, but Lewis (2007, pp. 6–7) found it to be identical to the plants from the other populations. Thus, *C. corallicola* has extremely limited genetic diversity, consisting of just one to three genetic lines.

Demographics

Annual monitoring has provided a perspective on the population structure and dynamics of *Consolea corallicola*. The wild population at BNP was monitored from 2002 to 2005. At the beginning of the study, the population consisted of 655 plants. At the end of the 3-year study in 2005, 594 plants were alive, and 61 had died (9 percent decline). Only 8 percent of plants produced flowers, and plants grew very slowly (about 1.2 cm (0.5 in) per year) (Grahl and Bradley 2005, pp. 4–5). From 2008 to 2010, the population was estimated to number approximately 600 individuals (McDonough 2010a, pers. comm.). Annual fluctuations in the number of plants is largely due to mortality of branches (pads) that fall from the larger plants but fail to...
permanently establish (McDonough 2010a, pers. comm.). Overall, the number of plants comprising this population appears to be stable (Bradley and Koop 2003, p. 2; Grah and Bradley 2005, p. 2; McDonough 2010a, pers. comm.).

Population decline has been shown in a wild population on an island in the Florida Keys, which now consists of 9 to 11 adult plants (defined as plants greater than 91.4 cm (3 ft) tall) and hundreds of small juveniles originating from fallen pads. Overall, the number of adult plants in this population has declined more than 50 percent over the past 10 years, due to crown rot and damage caused by the Cactoblastis moth and hurricanes (Higgins 2007, pers. comm.; Gun 2012, pers. comm.; see Summary of Factors Affecting the Species below).

_Harrisia aboriginum_

Description

_Harrisia aboriginum_ (Family: Cactaceae) is a sprawling cactus, usually with multiple stems arising from a single base. The stems are erect, slender, and cylindrical. They possess 9 to 11 longitudinal ribs, and may reach 6 m (20 ft) in height. Spines are 1.0 cm (0.4 in) long and originate in clusters of seven to nine spines. Flowers are funnel-shaped, white, up to 15 cm (5.9 in) long, and have a slight scent. The inside of the flower is lined with stiff, brown hairs. Fruits are yellow, round in shape, and have a slight scent. The inside of the flower is lined with stiff, brown hairs. Fruits are yellow, round in shape, and have a slight scent. The inside of the flower is lined with stiff, brown hairs. Fruits are yellow, round in shape, and have a slight scent. The inside of the flower is lined with stiff, brown hairs. Fruits are yellow, round in shape, and have a slight scent.

Climate

The climate of south Florida where _Harrisia aboriginum_ occurs is classified as tropical savanna as described above for _Chromolaena frustata_.

Habitat

_Harrisia aboriginum_ occurs on coastal berms, coastal strand, coastal grasslands and maritime hammocks, with a sand substrate. It also occurs on shell mounds with a calcareous shell substrate (Bradley et al. 2004, pp. 4, 14). The coastal berm community is described above for _Chromolaena frustata_. _Harrisia aboriginum_ growing in coastal berm habitat sometimes occur close to the mangrove zone, but never within it.

Coastal Strand

Coastal strand is an evergreen shrub community growing on stabilized coastal dunes. It is usually the first woody plant community inland from the coast. On the southwest Gulf coast of Florida, coastal strand is patchily distributed. It usually develops as a band between dunes dominated by _Uniola paniculata_ (sea oats) along the immediate coast, and maritime hammock, scrub, or mangrove swamp communities farther inland. On broad barrier islands, it may also occur as patches of shrubs within a coastal grassland matrix (FNAI 2010f, p. 2).

On the southwest Gulf coast of Florida, the species composition of coastal strand consists of tropical plant species, including _Coccoloba uvifera_, _Forestiera segregata_ (Florida swampscrub), _Rapean punctata_ (myrsine), _Lantana involucrata_, _Randia aculeata_, _Chiococca alba_ (snowberry), _Eugenia foetida_, _Guapira discolor_, _Zanthoxylum fagara_ (wild lime), _Pithecoclibium keyense_, _Chrysobalanus icaco_ (coco plum), _Dalbergia ecastaphyllum_ (coinvine), _Sophora tomentosa_ var. _truncata_ (yellow necklaccepod), _Caesalpinia bonduc_ (gray nicker), _Sideroxylon celastrinum_, and _Jaucquinia keyensis_ (FNAI 2010f, p. 2).

Storm waves periodically destroy dunes and the coastal strand behind them, with the resulting bare area being recolonized first by pioneer beach species and then by coastal grassland. The resulting coastal grassland is in turn invaded by patches of woody species, which eventually coalesce into a continuous woody community of coastal strand. Natural disturbances, such as strong winds and storm surge associated with hurricanes, or hard freezes, serve to open up coastal strand canopies. There is little information on natural fire frequency in coastal strand (FNAI 2010f, p. 2).

Coastal strand is distinguished from maritime hammock by the absence of distinct tree canopy and understory layers. It is distinguished from coastal berm and shell mound by its occurrence on sand deposits along a high-energy sandy coast, rather than on shell deposits along a low-energy, mangrove-dominated coast. It is distinguished from coastal grassland by the dominance of woody, rather than herbaceous, species.

Coastal Grassland

Coastal grassland is a predominantly herbaceous community occupying the drier portions of the transition zone between beach dunes on the immediate coast and communities dominated by woody species, such as coastal strand or maritime hammock, farther inland. It occurs primarily on the broader barrier islands and capes along the sandy coasts of Florida. The specialized dune building grasses of the beach dune community, _Uniola paniculata_, _Panicum amarum_ (bitter panicgrass), and _Spartina patens_ (saltmeadow cordgrass), are usually present, along with a variety of other herbaceous species typically found on more stable soils, such as _Andropogon_ and _Schizachyrium_ (bluestem grasses), _Heterotheca subaxillaris_ (camphorweed), and _Smilax auriculata_. On the southwest Gulf coast, a distinctive coastal grassland community is found on the broad barrier islands such as Cayo Costa, North Captiva, and...
Coastal grassland is distinguished from the beach dune community by its position inland from the immediate coastline and the presence of a variety of grasses, forbs, and pioneer dune-building grasses. It differs from coastal berm in its position on a sandy coast, rather than on a storm-deposited shell ridge on a mangrove-dominated shoreline. Coastal grassland is distinguished from coastal strand and maritime hammock in being dominated by herbaceous, rather than woody, species (FNAI 2010g, entire).

Maritime Hammock

Maritime hammock is a predominantly evergreen hardwood forest growing on stabilized coastal dunes lying at varying distances from the shore. On the southwest Gulf coast of Florida, most of the barrier islands and peninsulas are long and narrow with correspondingly small, narrow areas of hammock. Maritime hammock is best developed on the few broad islands, including Caladesi, Cayo Costa, North Captiva, and the inner barrier islands at Stump Pass and Keewaydin Island (FNAI 2010h, entire).

Canopy species include Cococarpus erectus, Piscidia piscipula, Bursera simaruba, Sideroxylon foetidissimum, Exothea paniculata, Eugenia axillaris (white stopper), Ficus aurea, Coccoloba uvifera, Eugenia foetida, and Pithecellobium keyense: shrubs include Rapanea punctata, Myrcianthes fragrans (Simpson’s stopper), Ardisia escallonioides, Psychotria nervosa, Chiococca alba, and Randia aculeata. Cacti and other spiny species, such as Agave sisalana (susal) and Acanthocereus tetragonus, may also be present. The herb layer is sparse to absent (FNAI 2010h, entire).

Maritime hammock occurs on deep, well-drained, acid quartz sands, or well-drained, moderately alkaline, quartz sands mixed with shell fragments (FNAI 2010h, entire).

Due to their coastal location with water barriers on at least one, if not two sides, fire was probably naturally rare and very spotty in maritime hammock, especially on the narrower barrier islands. Maritime hammocks are principally influenced by wind-borne salt spray, storm waves, and sand burial. If storm waves destroy the protective dunes seaward of the hammock, sand can blow inland, burying the trees. In addition to physical destruction by storm waves, hammock trees are susceptible to being killed by standing salt water deposited in low areas by storm surge (FNAI 2010h, entire).

Tropical maritime hammock can be distinguished from rockland hammock by their occurrence on sand substrate, rather than limestone. They may be similar in species composition to coastal berm, being distinguished primarily by location along a high wave energy sandy coast, rather than a low-energy, mangrove-dominated coast, and the presence of a distinct canopy layer. They are very similar to shell mounds in species composition, being distinguished by their occurrence on a natural sand deposit rather than on pure shell (FNAI 2010h, entire).

Shell Mound

Shell mounds are small hills, usually in coastal locations, composed entirely of shells (clams, oysters, whelks) discarded by generations of Native Americans. Shell mounds are found along the coast throughout Florida and range westward and northward along the coastlines of the southeastern United States. Originally, there were many such shell mounds along coastal lagoons and at the mouths of rivers, but most were destroyed for road building in the early part of the last century. A rich, calcareous soil develops on the deposited shells, which supports a diverse hardwood forest on undisturbed mounds. Several shell mounds are now surrounded by mangroves, evidence that they were built when sea level was lower than today (FNAI 2010i, entire).

The plant species composition of shell mound forests tends to be more strictly tropical than that of maritime hammocks on sandy substrates in the same region. South Florida shell mounds are often characterized by tropical tree species such as Bursera simaruba, Eugenia axillaris, Amryris elemifera, Zanthoxylum fagara, Sideroxylon foetidissimum, Exothea paniculata, Ficus aurea, and Ocotoe coriacea. Characteristic shrub species include Chiococca alba, Forestiera segregata, and Sideroxylon celastrinum. Shell mounds may have vegetation similar to tropical or temperate types of maritime hammock, but differ in that they grow on pure shells rather than sand or sand mixed with shell fragments (FNAI 2010i, entire).

In the habitats described above, Harrisia aboriginum seems to prefer areas where canopy cover is open to partially closed (Fellows et al. 2001, p. 3; Woodmansee et al. 2007, p. 115). Mortality of plants growing in deep shade under fully closed canopy has been observed (Bradley et al. 2004, p. 11; Bender 2011, p. 5). Plants growing in open to partially closed canopy sites tend to be more robust and produce more flowers and fruits (Bender 2011, p. 17; Conrad 2012, pers. comm.).

Historical Range

Harrisia aboriginum was known historically from coastal areas of southwest Florida along the Gulf coast in Manatee, Charlotte, Sarasota, and Lee Counties. The species was documented on six keys along approximately 125 km (78 mi) of Gulf coastline. Populations reported for Delnor-Wiggins Pass State Park, San Marco Island, Fort Pierce, and ENP are considered unsubstantiated (Bradley et al. 2004, pp. 5–6).

Current Range

A 2004 status survey confirmed 10 extant populations along a 100-km (62-mile) stretch of coast (Bradley et al. 2004, p. 8), one of which has since been extirpated (Nielsen 2009, pers. comm.). The species is extirpated in the northern extent of its historic range in Manatee County (Bradley et al. 2004, pp. 3, 8–9). Currently 12 sites support extant populations. Plants occur on seven public and private conservation areas, four County parcels not managed for conservation, and at least three unprotected private parcels. In total, the species was represented by an estimated 300 to 500 individuals in 2007 (Woodmansee et al. 2007, p. 87). Besides a few anecdotal accounts, population trends were unknown prior to 2004. Extant populations of Harrisia aboriginum are provided in Table 3.
Reproductive Biology and Population Genetics

There has been little research into the reproductive biology of *Harrisia aboriginum*. Flowers are produced May through September. Ripe fruits have been observed from June through October. In some populations, fruits are frequently removed from plants by unknown animals (Fellows et al. 2001, p. 2). Observations suggest that establishment of new plants is likely an infrequent event. Seedlings are rarely observed. Plant fragmentation has been observed, suggesting that this could be a dispersal mechanism. New clonal plants are observed to arise from small stem fragments ranging from 5.1 to 7.6 cm (2 to 3 in) in length (Bender 2011, p. 17). Establishment from plant fragments is probably more frequent than from seed (Fellows et al. 2001, p. 2). There have been no genetic studies of *H. aboriginum*.

Summary of Factors Affecting the Species

Section 4 of the Act (16 U.S.C. 1533) and its implementing regulations at 50 CFR part 424 set forth the procedures for adding species to the Federal Lists of Endangered and Threatened Wildlife and Plants. Under section 4(a)(1) of the Act, we may list a species based on any of the following five factors: (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; and (E) other natural or manmade factors affecting its continued existence. Listing actions may be warranted based on any of the above threat factors, singly or in combination. Each of these factors as applied to these three plants is discussed below.

**A. The Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range**

**Human Population Growth and Development**

Destruction and modification of habitat are a threat to *Chromolaena frustrata*, *Conseola coralicola*, and *Harrisia aboriginum*. Terrestrial ecosystems of south Florida have been heavily impacted by humans, through widespread clearing for agricultural, residential, commercial, and infrastructure development. Extensive areas of rockland hammock, pine rockland, and other ecosystems have been lost (Solecki 2001, p. 350; Hodges and Bradley 2006, p. 6). Because of their proximity to the beach and relatively higher elevations, coastal hammocks, strands, and berms have been heavily impacted by residential and tourism development. As a result, only isolated fragments of these habitats remain (Bradley et al. 2004, pp. 3–4). Loss and modification of coastal habitat due to development is expected to continue and increase in the coming decades in Florida (Zwick and Carr 2006, p. 13). Species populations are more secure on public lands than on private lands, but still face the threats of habitat loss and modification through development of public facilities such as new buildings, parking lots, and other associated facilities and through recreational opportunities to support visitor services. Impacts to each of the species are discussed below.

**Chromolaena frustrata**

Habitat destruction and modification resulting from development are considered a major threat to *Chromolaena frustrata* throughout the species’ range (Gann et al. 2002, p. 387). The populations on Fiesta Key, Knights Key, Key Largo, and Key West were lost due to development. Fiesta Key is completely developed as a Kampgrounds of America (KOA) campground and is devoid of native plant communities. Knights Key is almost completely developed and has no remaining suitable habitat (Bradley and Gann 2004, p. 5). Key Largo has undergone extensive disturbance and development. Although suitable coastal berm and rockland hammock habitat are still located in State and Federal conservation sites on Key Largo (Bradley and Gann 2004, p. 8), despite extensive surveys of the island *C. frustrata* has not been located (Bradley and Gann 2004, p. 5).

**Two Chromolaena frustrata**

populations, including the largest population, are located on privately owned sites, which are vulnerable to further development (Bradley and Gann 2004, p. 7; Table 1). The statewide population of *C. frustrata* was estimated at fewer than 5,000 plants in 2004, but 4,500 plants (90 percent) are located at a single, privately owned, unprotected site (Bradley and Gann 2004, p. 7). The site, Big Munson Island, is owned by the Boy Scouts of America (BSA) and is utilized as a Boy Scout Camp. Scout campsites have been established along the coastal berm (Hodges and Bradley 2006, p. 10), and recreation development (campsites) and possibly recreational activities (trampling) potentially remain a threat to *C. frustrata* at this site. At this time, we do not believe that this site faces threats from residential or commercial development. However, if development pressure and BSA recreational usage increase, this largest population may face threats from habitat loss and modification.

</table>
The population on Long Key at Layton Hammock is vulnerable to commercial or residential development (Bradley and Gann 2004, pp. 3–20). In addition, development remains a threat to any suitable rock barren or rockland hammock habitat on private lands within the species’ historic range. Overall, the human population in Monroe County is expected to increase from 79,589 to more than 92,287 people by 2060 (Zwick and Carr 2006, p. 21). All vacant land in the Florida Keys is projected to be developed by then, including lands not currently accessible by automobile (Zwick and Carr 2006, p. 14).

Chromolaena frustrata populations in conservation areas have been impacted and may continue to be impacted by development with increased public use. Mechanical disturbances such as trail construction in coastal berms may have exacerbated nonnative plant invasions (see Factor E discussion below) (Bradley and Gann 2004, p. 4). C. frustrata has been impacted by park development on State lands, and habitat modifications such as mowing and trail maintenance remain a threat (Gann et al. 2002, p. 391; Bradley and Gann 2004, p. 6; Hodges and Bradley 2006, p. 30).

Conseola coralllica

 Destruction and modification of habitat from development throughout the species’ range continue to be a threat to Conseola coralllica. Unoccupied suitable habitat throughout the species’ former range is under intense development pressure. Development and road building were the causes of this species’ original extirpation on Big Pine Key (Bradley and Gann 1999, p. 77; Bradley and Woodmansee 2002, p. 810). Residential and commercial development and roadway construction continue to occur throughout Miami-Dade County and the Florida Keys. Both remaining wild populations are secure from habitat destruction because they are located within private and Federal conservation areas. However, at one State-owned site where a reintroduction was attempted, all of the plants were accidentally destroyed by the expansion of a trail.

Harrisia aboriginum

 Destruction and modification of habitat from development throughout the species’ range continue to be a threat to Harrisia aboriginum. The coastal habitats of this species have been heavily impacted by development over the past 50 years (Morris and Miller 1981, pp. 1–17; Bradley et al. 2004, p. 3). Shell mounds created by Native Americans were among the first areas colonized by early Western Europeans because of their higher elevation and were later extensively utilized for construction material, in some cases resulting in the complete destruction of the habitat. Coastal hammocks, strands, and berms, because of their proximity to the beach and higher elevations, were also used for coastal residential construction. Only isolated fragments of suitable habitat for H. aboriginum remain (Bradley et al. 2004, p. 3). The species was extirpated from the northern extent of its range in Manatee County by the 1970s, due to urbanization (Morris and Miller 1981, p. 2; Austin 1984, p. 69). Despite the recent downturn in residential construction, coastal development is ongoing in the habitat of H. aboriginum. Populations on private land or non-conservation public land are most vulnerable to habitat loss. Threats include residential development, road widening, and landscape maintenance (Morris and Miller 1981, pp. 2–11; Bradley et al. 2004, pp. 36–37). Suitable habitat within the species’ range was recently destroyed by encroachment from a private development onto State land (FNAI 2011a, pp. 207–208). The threats of habitat loss, modification, and degradation are expected to increase with increased human population, development pressure, and infrastructure needs. Sarasota, Charlotte, and Lee Counties, where this plant currently occurs, are expected to build out before 2060 (Zwick and Carr 2006, p. 13), placing further pressure on remaining natural areas. Populations located on public lands are better protected than those on private land, but still may face the threat of habitat loss through development of park facilities such as new buildings, parking lots, and trails (Morris and Miller 1981, p. 4). Construction of new bathrooms in 2011 at a site owned by Sarasota County eliminated a portion of the coastal berm habitat, and parking lot renovations are planned for 2012 at a second County site where Harrisia aboriginum occurs (Bender 2011, p. 11). Not all land managers are aware of the presence of H. aboriginum at sites under their jurisdiction; for example, managers at one site in Charlotte County were unaware of H. aboriginum on county lands (Bender 2011, p. 13). Nevertheless, the population has persisted, probably due to its anonymity and difficulty of access. The lack of management, however, has allowed a heavy infestation of nonnative plants, which have modified the habitat and are shading out native species (Bender 2011, p. 13). Portions of at least two populations located on public land also extend onto adjacent unprotected, private lands (Bradley et al. 2004, pp. 16, 36).

Populations on privately owned conservation sites may have inadequate protection from habitat loss or modification as well. One such site that was declared a “Preserve” in 1992 as part of a residential community has no formal protection; it was partially bulldozed and landscaped with native species within the past 10 years (Bradley et al. 2004, p. 10). The number of plants observed at this “Preserve” site decreased from 226 plants in 1981 (Morris and Miller 1981, p. 5), to 5 plants in 2006 (Woodmansee et al. 2007, p. 87). Another site is owned by a nonprofit organization and managed for historical preservation. The site is severely disturbed from a long history of human activity and is currently open to public visitation (Woodmansee et al. 2007, p. 103). This population has declined over the past 30 years from 21 stems comprising 7 plants in 1981 (Morris and Miller 1981, p. 4), to only 3 plants of H. aboriginum in 2005 (Bender 2004, p. 13). Development of the site for public visitation likely played a role in the decline (Morris and Miller 1981, p. 4).

Other Conservation Efforts

The National Wildlife Refuge System Improvement Act of 1997 and the Fish and Wildlife Service Manual (601 FW 3, 602 FW 3) require maintaining biological integrity and diversity, comprehensive conservation planning for each refuge, and set standards to ensure that all uses of refuges are compatible with their purposes and the Refuge System’s wildlife conservation mission. The comprehensive conservation plans (CCP) address conservation of fish, wildlife, and plant resources and their related habitats, while providing opportunities for compatible wildlife-dependent recreation uses. An overriding consideration reflected in these plans is that fish and wildlife conservation has first priority in refuge management, and that public use be allowed and encouraged as long as it is compatible with, or does not detract from, the Refuge System mission and refuge purpose(s).

The CCP for the Lower Florida Keys National Wildlife Refuges (National Key Deer Refuge, Key West National Wildlife Refuge, and Great White Heron National Wildlife Refuge) provides a description of the environment and priority resource issues that were considered in developing the objectives and strategies that guide management over the next 15 years. The CCP promotes the enhancement of wildlife populations by
maintaining and enhancing a diversity and abundance of habitats for native plants and animals, especially imperiled species that are only found in the Florida Keys. The CCP also provides for obtaining baseline data and monitoring indicator species to detect changes in ecosystem diversity and integrity related to climate change. In the Lower Key Refuges CCP management objective no. 16 provides specifically for maintaining and expanding populations of candidate plant species including *Chromolaena frustrata* and *Consolea coralllicola*.

Special Use Permits (SUPs) are also issued by the Refuges as authorized by the National Wildlife Refuge System Administration Act (16 U.S.C. 668dd–ee) as amended, and the Refuge Recreation Act (16 U.S.C. 460k–460k–4). The SUPs cover commercial activities (such as guiding hunters, anglers or other outdoor users, commercial filming, agriculture, cabins, and trapping); research and monitoring by students, universities, or other non-Serviceto organizations; and general use (woodcutting, miscellaneous events (fishing tournaments, one-time events, other special events), cabins/subsistence cabins, education activity). The Service has no information concerning the effects of the issuance of SUPs for any of the three species.

Summary of Factor A

In summary, the decline of *Chromolaena frustrata*, *Consolea coralllicola*, and *Harrisia aboriginum* habitat is the result of threats that have operated in the past, are impacting these species now, and will continue to impact these species in the future. It is reasonable to conclude that the changes in the habitats historically and currently occupied by the species are the cause of observed population-level declines. The decline of these species is primarily the result of the long-lasting effects of habitat loss, degradation, and modification from human population growth and associated development. Thus, we believe these changes in the species’ historic or current range will not be ameliorated in the future; therefore, we find it reasonably likely that the effects on the species will continue at current levels or potentially increase.

**B. Overutilization for Commercial, Recreational, Scientific, or Educational Purposes**

Overutilization (collection by hobbyists, also known as poaching) is a major threat to *Consolea coralllicola* (Gann et al. 2002, p. 440) and *Harrisia aboriginum* (Austin et al. 1980, p. 2; Morris and Miller 1981, pp. 1–11; Gann et al. 2002, p. 481; Bradley et al. 2004, p. 6; Bender 2011, p. 5). Cactus poaching is an international phenomenon. Cacti are frequently impacted at sites that are known and easily accessed by poachers (Anderson 2001, pp. 73–78). The rarity of *C. coralllicola* and *H. aboriginum*, coupled with their showy flowers, make these cacti particularly desirable to collectors. Seeds of *H. aboriginum* and *H. fragrans* (the fragrant prickly-apple, a federally listed endangered cactus listed as *Cereus eriophorus var. fragrans*) from Florida’s east coast are currently offered for sale by online plant distributors, demonstrating that a demand exists for these cacti from collectors. The severity of the threat of poaching is exacerbated by the fact that some populations of these cacti are limited to just a few individuals. These smaller populations could easily be extirpated by a single poaching episode.

*Consolea coralllicola*

Collecting by cactus hobbyists is suspected to have played a part in the extirpation of *Consolea coralllicola* from Big Pine Key and Key Largo in the late 1970s, and poaching remains a major threat to this species (Gann et al. 2002, p. 481). Other species of *Consolea* are currently offered for sale by online plant distributors. Probable evidence of poaching activity was observed at a site in Monroe County on multiple occasions, and caused the death of one *C. coralllicola* plant (Slapczinsky et al. 2006, p. 3). Although the remaining populations are somewhat protected due to their location on conservation lands, these plants remain vulnerable to illegal collection because the sites are remote and not patrolled regularly by enforcement personnel.

Collection for scientific and recovery purposes has so far relied on the harvesting of cuttings from plants growing in botanical garden and private collections. We expect that collection for the purposes of recovery will continue and ultimately be beneficial in augmenting and reintroducing *C. coralllicola* at suitable sites. We have no evidence that collection for scientific or recovery purposes is a threat to the species at this time.

*Harrisia aboriginum*

Poaching of *Harrisia aboriginum* is a major threat (Morris and Miller 1981, pp. 1–11; Gann et al. 2002, p. 440; Bradley et al. 2004, p. 6). Damage and evidence of *H. aboriginum* poaching was reported by Morris and Miller (1981, pp. 1–11) at several sites. Evidence of poaching was recently observed at a site in Sarasota County that has high public visitation. At that site, there was evidence that cuttings had been removed from multiple *H. aboriginum* plants at numerous different times (Bender 2011, pp. 5–6).

*Chromolaena frustrata*

We have no evidence suggesting that overutilization for commercial, recreational, scientific, or educational purposes are a threat to *Chromolaena frustrata*. Except for its rarity, the species does not possess any attributes that would make it desirable to collectors, such as showy foliage or flowers, and there are no known medicinal, culinary, or religious uses for this species.

Summary of Factor B

In summary, based on our analysis of the best available scientific and commercial information we find that collecting for commercial or scientific reasons or recreational activities is not a threat to *Chromolaena frustrata* in any portion of its range at this time and is not likely to become so in the future.

We find that overutilization by poachers is a major threat to *Consolea coralllicola* and *Harrisia aboriginum*. There is a current market for these cacti and evidence of ongoing collecting activity such that it is reasonable to conclude that collecting has caused declines and extirpation of populations. All populations of *C. coralllicola* and *H. aboriginum* are vulnerable to this ongoing threat; however, populations at sites that are easily accessible to the public likely face the greatest threat from collectors. The small number of remaining plants at most sites exacerbates this threat; smaller populations could be completely lost to a single collection episode. The areas that support these cacti are somewhat remote, making enforcement extremely difficult. These threats have operated in the past, are impacting these species now, and are expected to continue into the future. Based on our analysis of the best available information, we find that overutilization is a threat to these species throughout their entire range. We believe that overutilization will not be ameliorated in the future; therefore, we find it reasonably likely that the effects on the species will continue at current levels or potentially increase.

**C. Disease or Predation**

*Chromolaena frustrata*

On Big Munson Island, much of the *Chromolaena frustrata* population was...
observed to suffer from severe herbivory in 2004. No insects were observed on any plants, and the endangered Key deer (*Odocoileus virginianus clavium*) was the suspected culprit (Bradley and Gann 2004, p. 4). The significance of herbivory on *C. frustrata* population dynamics is unknown. No diseases have been reported for *C. frustrata*.

**Consolea coralicola**

A fungal pathogen, *Fusarium oxysporum*, can infect *Consolea coralicola*, causing crown rot, a disease in which plants rot near their base (Slapcinsky *et al.* 2006, p. 2; Stiling 2010, p. 191). Cacti in the Florida Keys populations that are affected by this disease have also tested positive for a fungus, *Phomopsis* sp. (Slapcinsky *et al.* 2006, p. 3). This disease was largely responsible for the high mortality rates in some reintroduced populations in the Florida Keys (Stiling 2010, p. 193). At present, crown rot does not appear to be affecting the population at BNP.

Predation by the moth *Cactoblastis cactorum* (Lepidoptera: Pyralidae) is considered a significant threat to *Consolea coralicola* (Stiling *et al.* 2000, pp. 2, 6; Gann *et al.* 2002, p. 481; Wright and Maschinski 2004, p. 4; Grahl and Bradley 2005, pp. 2, 7; Slapcinsky *et al.* 2006, pp. 2–4). Native to South America, *Cactoblastis cactorum* was introduced to Australia in 1925, as a biological control agent for nonnative species of *Opuntia*. Adult moths deposit eggs on the branches of host species. When these eggs hatch, larvae then burrow into the cacti and feed on the inner tissue of the plant’s stems. The larvae then pupate, and the cycle repeats. *Cactoblastis cactorum* was extremely effective as a biological control agent, and credited with reclaiming 6,474,970 ha (16,000,000 ac) of land infested with *Opuntia* species in Australia alone. The moth also has been an effective control agent for *Opuntia* species in Hawaii, India, and South Africa. It was introduced to a few Caribbean islands in the 1960s and 1970s, and rapidly spread throughout the Caribbean. The effectiveness of *C. cactorum* at controlling *Opuntia* populations is described as “rapid and spectacular” (Habeeb and Bennett 1990, p. 1). The moth had spread to Florida by 1989, prompting the Florida Department of Agriculture and Consumer Services (FDACS) to issue an alert that *C. cactorum*, along with another unidentified species of moth, had the potential to adversely impact *Opuntia* populations due to the high rate of mortality, as demonstrated in other localities in the Caribbean and elsewhere (Habeeb and Bennett 1990, p. 1). Among local cactus species in the Florida Keys, *C. coralicola* is a preferred host (Stiling 2010, p. 190). Between 1990 and 2000, the moth infested and damaged multiple *C. coralicola* plants in the Florida Keys’ wild populations, killing one plant and damaging others (Gun 2012 pers.comm. Fortunately, these infestations were detected very early and controlled before *C. cactorum* could kill multiple plants and fully spread throughout the population. Planted *C. coralicola* populations in the Florida Keys fared much worse; at one planting site, 90 individuals (50 percent of those planted) were killed by *C. cactorum* over a 4-year period (Stiling 2010, p. 193). To date, *C. cactorum* has not been observed in BNP (McDonough 2010a, pers. comm.). Even if the moth has not yet reached the Park, it likely will, based on its rapid spread in the Caribbean and Florida. This threat has the potential to cause steep declines in populations of *Consolea coralicola* if they become infested. No satisfactory method of large-scale control is known at this time (Habeck *et al.* 2009, p. 2).

Potential impacts to *C. coralicola* at the population level as a result of predation by *C. cactorum* are severe. As stated above, experts are certain of the potential for the moth to cause massive mortality in populations of *C. coralicola* if they become infested and the infestation is not caught early and aggressively controlled.

Predation by the Cuban garden snail (*Zachrysia provisoria*) has been observed at one *Consolea coralicola* reintroduction site (Duquesnel 2008, pers. comm.). The population-level impact of the Cuban garden snail is not known.

**Harrisia aboriginum**

An as yet unidentified pathogen can attack *Harrisia aboriginum* and cause stems to rot and die within about a week (Austin 1984, p. 2; Bradley 2005, pers. comm.). However, no signs of this disease were observed at several sites visited in 2011 (Bender 2011, p. 19).

Herbivory of flowers by iguanas (Bradley *et al.* 2004, p. 30) and stems by gopher tortoises (Woodmansee *et al.* 2007, p. 108) has been noted. Scale insects have been observed in some *H. aboriginum* populations, occasionally causing severe damage to plants (Bradley 2005, pers. comm.).

Overall, evidence indicates disease and predation are relatively minor stressors to *H. aboriginum* at present, but could become threats in the future if they become more prevalent in the cacti populations.

**Summary of Factor C**

In summary, *Chromolaena frustrata* does not appear to be affected by disease or predation; disease and predation have been reported occasionally for *Harrisia aboriginum*. We have no evidence that the severity of either stressor has affected either species at a population level. Though it is possible the amount of disease or predation may increase in the future, there is no evidence that this stressor is growing in extent. Thus, based on our analysis of the best available scientific and commercial data available, we find that disease or predation is not a significant stressor to the overall status of *C. frustrata* or *H. aboriginum* at current levels, though these stressors could potentially become a threat in the future if these pests become more prevalent.

Disease and predation are severe threats to *Consolea coralicola*. Threats from disease include a pathogen that can cause crown rot and predation by the nonnative moth, *Cactoblastis cactorum*. Both are severe and pervasive threats, and it is reasonable to conclude that disease and predation have caused population declines. We have no reason to believe that diseases or predation will be ameliorated in the future; therefore, we find it reasonably likely that the effects on *C. coralicola* will continue at current levels or potentially increase in the future.

**D. The Inadequacy of Existing Regulatory Mechanisms**

Under this factor, we examine whether existing regulatory mechanisms are inadequate to address the threats to the species discussed under the other factors. Section 4(b)(1)(A) of the Act requires the Service to take into account “those efforts, if any, being made by any State or foreign nation, or any political subdivision of a State or foreign nation, to protect such species * * *.” In relation to Factor D, we interpret this language to require the Service to consider relevant Federal, State, and tribal laws, plans, regulations, and other such mechanisms that may minimize any of the threats we describe in threat analyses under the other four factors, or otherwise enhance conservation of the species. We give strongest weight to statutes and their implementing regulations and to management direction that stems from those laws and regulations. An example would be State governmental actions enforced under a State statute or constitution, or Federal action under statute.
State

Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum are listed on the Regulated Plant Index as endangered under Chapter 5B–40, Florida Administrative Code. The Regulated Plant Index also includes all federally listed endangered and threatened plant species. Florida Statutes 581.185 sections (3)(a) and (b) prohibit any person from willfully destroying or harvesting any species listed as endangered or threatened on the Index, or growing such a plant on the private land of another, or on any public land, without first obtaining the written permission of the landowner and a permit from the Florida Department of Plant Industry (DPI). The statute also requires that collection permits issued for species listed under the Act must be consistent with Federal standards (i.e., only the Service can issue permits to collect plants on Federal lands). The statute further provides that any person willfully destroying or harvesting; transporting, carrying, or conveying on any public road or highway; or selling or offering for sale any plant listed in the Index must have a permit from the State at all times when engaged in any such activities. However, despite these regulations, recent poaching is evident, and threats to the three species (particularly the two cacti) remain. Lack of implementation or compliance with existing regulations may be a result of funding, work priorities, or staffing.

In addition, subsections (8)(a) and (b) of the statute waive State regulation for certain classes of activities for all species on the Regulated Plant Index, including the clearing or removal of regulated plants for agricultural, forestry, mining, construction (residential, commercial, or infrastructure), and fire-control activities by a private landowner or his agent. However, section (10) of the statute provides for consultation similar to section 7 of the Federal Act for listed species by requiring the Department of Transportation to notify the FDACS and the Endangered Plant Advisory Council of planned highway construction at the time bids are first advertised, to facilitate evaluation of the project for listed plants populations, and to “provide for the appropriate disposal of such plants” (i.e., transplanting). The Service has no information concerning the State of Florida’s implementation of the enforcement of these statutes. However, it is clear that illegal collection and vandalism of cacti are both occurring, despite these and other provisions that specifically prohibit these activities. Insufficient implementation or enforcement of these statutes constitutes a threat to both Consolea corallicola and Harrisia aboriginum as they continue to decline in numbers.

Shell mounds on State land, some of which support populations of Harrisia aboriginum, are protected as historical resources under Florida Statute 267.13, sections (1)(a) and (b). Despite these protections, there is a long history of utilization and excavation of shell mounds by artifact hunters in Florida, causing erosion and opening areas for invasion by invasive plants [FNAI 2010i, p.3].

The Florida Division of Forestry (FDOT) administers Florida’s outdoor burning and forest fire laws. Florida Statute 590.08 prohibits any person to willfully or carelessly burn or cause to be burned, or to set fire to or cause fire to be set to, any forest, grass, woods, wildland, or marshes not owned or controlled by such person. Despite this protection, unauthorized bonfires have been documented at sites supporting Harrisia aboriginum (Woodmansee et al. 2007, p. 108; Bender 2011, pp. 5–6).

d Federal

National Park Service (NPS) regulations at 36 CFR 2.1 prohibit visitors from harming or removing plants, listed or otherwise, from ENP or BNP.

The Archaeological Resources Protection Act of 1979 (ARPA) (16 U.S.C. 470aa–470mm) protects archaeological sites, including shell mounds, on Federal lands. Shell mounds are known from the area of ENP where Chromolaena frustrata occurs; however the Service has no specific information regarding illegally excavated or vandalized shell mounds at ENP.

The Service has no information concerning ENP’s or BNP’s implementation or the enforcement of these Federal regulations protecting the plants and their habitats from harm. Insufficient implementation or enforcement could become a threat to the two species in the future if the species continue to decline in numbers.

Summary of Factor D

In summary, there are currently State regulatory mechanisms and NPS regulatory mechanisms that provide for the conservation of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum. Despite the existing regulatory mechanisms, these species continue to decline due to the effects of a wide array of threats, and it is reasonable to conclude that the limitations of current regulatory mechanisms have allowed population declines of Chromolaena frustrata and Consolea corallicola due to habitat loss and modification and declines of Consolea corallicola and Harrisia aboriginum due to poaching, vandalism, and illegal bonfires.

Based on our analysis of the best available information, we find that existing regulatory mechanisms, due to their inherent limitations and constraints, are inadequate to address threats to these species throughout their ranges. We have no information to indicate that poaching, unauthorized fires, or habitat loss will be ameliorated in the future by enforcement of existing regulatory mechanisms. Therefore, we find it reasonably likely that the effects of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum will continue at current levels or potentially increase in the future.

E. Other Natural or Manmade Factors Affecting Their Continued Existence

Wildfire

Wildfire, whether naturally ignited or caused by unauthorized burning, such as bonfires, is a threat to Consolea corallicola and Harrisia aboriginum. In general these plants do not survive fires, making this a severe threat to remaining populations and occupied sites. At a site in Sarasota County, a large illegal bonfire pit is located within the habitat that supports one of the larger populations of H. aboriginum. The bonfires occur just a few yards from the plants (Bender 2011, pp. 5–6). At least one plant was killed by an escaped fire that affected part of this site in 2006 (Woodmansee et al. 2007, p. 108) and should another fire escape into occupied habitat in the future, it is reasonable to conclude this could result in the loss of individuals or extirpation of populations.

Nonnative Plant Species

Nonnative, invasive plant species are a threat to all three species (Morris and Miller 1981, pp. 1–11; Bradley et al. 2004, pp. 6, 25; Woodmansee et al. 2007, p. 91; Bradley and Gann 2004, p. 8; Bradley 2007, pers. comm.; Sadle 2010, pers. comm.; McDonough 2010b, pers. comm.). They compete with native plants for space, light, water, and nutrients, and they have caused population declines in all three species. Schinus terebinthifolius (Brazilian pepper), a nonnative, invasive tree, occurs in all of the habitats of the three species. Schinus terebinthifolius forms dense thickets of tangled, woody stems that completely shade out and displace
native vegetation (Loflin 1991, p. 19; Langeland and Craddock-Burks 1998, p. 54). Schinus terebinthifolius can dramatically change the structure of rockland hammocks, coastal berms, and shell mounds, making habitat conditions unsuitable for Chromolaena frustrata, Consoelea corralicola, and Harrisia aboriginum, which prefer moderate to full sun exposure. For example, at more than one site, numerous H. aboriginum plants occurring in the shade of S. terebinthifolius were observed to have died (Bradley et al. 2004, p. 10; Bender 2011, pp. 5, 13). By the mid-1990s, S. terebinthifolius had spread dramatically and had become a dominant woody species at sites known to support H. aboriginum (Morris and Miller 1981, pp. 5, 10; Loflin 1991, p. 19; Herwitz et al. 1996, pp. 705–715; Bradley et al. 2004, p. 7). Schinus terebinthifolius is a threat to populations of Chromolaena frustrata along the Coastal Prairie Trail in ENP (Sadle 2010, pers. comm.) and is invading the habitat of Consoelea corralicola (McDonough 2010b, pers. comm.).

Colubrina asiatica (lather leaf), a nonnative shrub, has invaded large areas of coastal berm and coastal berm edges (Bradley and Gann 2004, p. 4). Colubrina asiatica also forms dense thicketts and mats, and is of particular concern in coastal hammocks (Langeland and Craddock-Burks 1998, p. 122). Colubrina asiatica is invading large areas of hammocks within ENP along the edge of Florida Bay (Bradley and Gann 2004, p. 37). Populations of Chromolaena frustrata along the Coastal Prairie Trail and habitat within ENP face threats from Colubrina asiatica (Sadle pers. comm. 2010). Colubrina asiatica is also present in BNP in areas supporting Consoelea corralicola (McDonough 2010b, pers. comm.).

Casuarina equisetifolia (Australian pine) invades coastal berm and is a threat to suitable habitat at most sites that could support all three species (FINA 2010a, p. 2). Casuarina equisetifolia forms dense stands that exclude all other species through dense shade and a thick layer of needles that contain substances that leach out and suppress the growth of other plants. Coastal strand habitat that once supported Harrisia aboriginum has experienced dramatic increases in C. equisetifolia over the past 30 years (Loflin 1991, p. 19; Herwitz et al. 1996, pp. 705–715).

Other invasive plant species that are a threat to Chromolaena frustrata, Consoelea corralicola, and Harrisia aboriginum include Scaevola taccada (beach naupaka), Nevraudia reynaudiana (Burma reed), Cupaniopsis anacardioides (carrotwood), Thespesia populnea (Portia tree), Mannikara zapota (sapodilla), Hibiscus tilicaceus (hau), and Hylocereus undatus (night blooming cactus) (FINA 2010f, p. 4; Bradley et al. 2004, p. 13; McDonough 2010b, pers. comm.).

Vandalism

Vandalism is a threat to Consoelea corralicola and Harrisia aboriginum, and has caused population declines in both species. For Consoelea corralicola, vandalism has been documented twice. In 1990, branches were cut off plants at one site, but instead of being taken (as would be the case for poaching), the cut stems were left at the base of plants. In 2003, vegetation recruits and pads were damaged by unauthorized removal of protective cages from plants (Slapcinsky et al. 2006, p. 3). At a Sarasota County site, the Service has documented numerous H. aboriginum plants that have been uprooted, trampled, and harvested (Bender 2011, p. 5).

Due to their historic significance and possible presence of artifacts, shell mounds are susceptible to vandalism by artifact hunters. Despite regulations that protect these sites on State lands (Florida Statute 267. 13), there is a long history of artifact hunters conducting unauthorized excavation of shell mounds in Florida, including some mounds where Harrisia aboriginum has been found, causing erosion and opening areas for invasion by nonnative plants (FINA 2010b, p. 3).

Recreation

Recreational activities may inadvertently impact some populations of Chromolaena frustrata. These activities may affect some individual plants in some populations but have not likely caused significant population declines in the species. Foot traffic and campsites at Big Munson Island may be a threat to Chromolaena frustrata. Recreation is a threat to some populations of Harrisia aboriginum. Coastal berms and dunes are impacted by recreational activities that cause trampling of plants, exacerbate erosion, and facilitate invasion by nonnative plants. As noted above, in 2011, numerous bonfire sites in BNP were observed to be intentionally uprooted, hacked, and trampled, and there was a large amount of trash deposited nearby. At the same site, there is an ongoing problem with recreational bonfires in the coastal berm habitat just a few yards from H. aboriginum plants (Bradley et al. 2004, p. 16; Woodmansee et al. 2007, p.108; Bender 2011, pp. 5–6). One escaped bonfire has the potential to destroy this entire population.

Hurricanes, Storm Surge, and Extreme High Tide Events

Hurricanes, storm surge, and extreme high tide events are natural events that can pose a threat to all three species. Hurricanes and tropical storms can modify habitat (e.g., through storm surge) and have the potential to destroy entire populations. Climate change may lead to increased frequency and duration of severe storms (Golladay et al. 2004, p. 504; McLaughlin et al. 2002, p. 6074; Cook et al. 2004, p. 1015). All three species experienced these disturbances historically, but had the benefit of more abundant and contiguous habitat to buffer them from extirpations. With most of the historical habitat having been destroyed or modified, the few remaining populations of these species could face local extirpations due to stochastic events.

The Florida Keys were impacted by three hurricanes in 2005: Katrina on August 26th, Rita on September 20th, and Wilma on October 24th. Hurricane Wilma had the largest impact, with storm surges flooding much of the landmass of the Keys. The vegetation in many areas was top-killed due to salt water inundation (Hodges and Bradley 2006, p. 9).

Chromolaena frustrata

The ecology of coastal rock barrens is poorly understood. Periodic storm events may be responsible for maintaining the community (Bradley and Gann 1999, p. 37). There is some evidence that, over the long term, hurricanes can be beneficial to the species by opening up tree canopies allowing more light to penetrate, thereby creating the necessary conditions for growth (Woodmansee et al. 2007, p. 115). The large population of Chromolaena frustrata observed at Big Munson Island in 2004 suggests that this species may respond positively to occasional hurricanes or tropical storms that thin hammock canopies, providing more light (Bradley and Gann 2004, p. 8). Populations of C. frustrata in ENP initially appeared to have been eliminated by storm surge during Hurricane Wilma in 2005 (Bradley 2007, pers. comm.; Duquesnel 2005, pers. comm.)
significant impact to these species; however, the small size of some populations makes impacts from freezing more significant.

Effects of Small Population Size and Isolation

Endemic species whose populations exhibit a high degree of isolation are extremely susceptible to extinction from both random and nonrandom catastrophic natural or human-caused events. Species that are restricted to geographically limited areas are inherently more vulnerable to extinction than widespread species because of the increased risk of genetic bottlenecks, random demographic fluctuations, climate change, and localized catastrophes such as hurricanes and disease outbreaks (Mangel and Tier 1994, p. 607; Pimm et al. 1988, p. 757). These problems are further magnified when populations are few and restricted to a very small geographic area, and when the number of individuals is very small. Populations with these characteristics face an increased likelihood of stochastic extinction due to changes in demography, the environment, genetics, or other factors (Gilpin and Soule 1986, pp. 24–34).

Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species’ capacity to adapt and respond to environmental changes, thereby decreasing the probability of long-term persistence (e.g., Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361). Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression. Isolated individuals have difficulty achieving natural pollen exchange, which limits the production of viable seed. The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as those discussed above (Factors A, B, and C).

Chromolaena frustrata

The current range of Chromolaena frustrata includes eight populations spread across 209 km (130 mi) between ENP and Boca Grande Key; four of eight adult plants (see Table 2). Threats exacerbated by small population size include hurricanes, storm surges, and poaching. Populations can also be impacted by demographic stochasticity, where populations are skewed toward either male or female individuals by chance. This may be the case with C. corallicola, in which the two remaining populations do not contain any female plants. While the species may continue to reproduce indefinitely by clonal means, populations may not be viable over the long term due to a lack of genetic mixing and thus the potential to adapt to environmental changes.

Harrisia aboriginum

Climatic changes, including sea level rise, are major threats to south Florida and Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum. Our analyses under the Act include consideration of ongoing and projected changes in climate. The terms “climate” and “climate change” are defined by the Intergovernmental Panel on Climate Change (IPCC). “Climate” refers to the mean and variability of different types of weather conditions over time, with 30 years being a typical period for such
measurements, although shorter or longer periods also may be used (IPCC 2007, p. 78). The term “climate change” thus refers to a change in the mean or variability of one or more measures of climate (e.g., temperature or precipitation) that persists for an extended period, typically decades or longer, whether the change is due to natural variability, human activity, or both (IPCC 2007, p. 78). Various types of changes in climate can have direct or indirect effects on species. These effects may be positive, neutral, or negative, and they may change over time, depending on the species and other relevant considerations, such as the effects of interactions of climate with other variables (e.g., habitat fragmentation) (IPCC 2007, pp. 8–14, 18–19). In our analyses, we use our expert judgment to weigh relevant information, including uncertainty, in our consideration of various aspects of climate change.

Projected changes in climate and related effects can vary substantially across and within different regions of the world (e.g., IPCC 2007a, pp. 8–12). Thus, although global climate projections are informative and in some cases are the only or the best scientific information available, to the extent possible we use “downscaled” climate projections, which provide higher resolution information that is more relevant to the spatial scales used to assess effects to a given species (see Glick et al. 2011, pp. 58–61 for a discussion of downscaling).

With regard to our analysis for Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum, downscaled projections suggest that sea-level rise is the largest climate-driven challenge to low-lying coastal areas and refuges in the subtropical ecoregion of southern Florida (U.S. Climate Change Science Program (CCSP) 2008, pp. 5–31, 5–32). The long-term record at Key West shows that sea level rose on average 0.224 cm (0.088 in) annually between 1913 and 2006 (National Oceanographic and Atmospheric Administration (NOAA) 2008, p. 1). This equates to approximately 22.3 cm (8.76 in) over the last 100 years (NOAA 2008, p. 1). IPCC (2008, p. 28) emphasized it is very likely that the average rate of sea level rise during the 21st century will exceed that rate, although it was projected to have substantial geographical variability.

Other processes expected to be affected by climate change include temperatures, rainfall (amount, seasonal timing, and distribution), and storms (frequency, intensity, or duration). Temperatures are projected to rise from 2 °C to 5 °C (35.6 °F to 41.5 °F) for North America by the end of this century (IPCC 2007, pp. 7–9, 13).

The Nature Conservancy (TNC) modeled several scenarios for the Florida Keys, and predicted that sea level rise will first result in the conversion of habitat, and eventually the complete inundation of habitat. In the best-case scenario, by the year 2100, a rise of 18 cm (7 in) would result in the inundation of 745 ha (1.840 acres) (34 percent) of Big Pine Key and the loss of 11 percent of the island’s upland habitat (TNC 2010, p. 1). In the worst-case scenario, a rise of 140 cm (4.6 ft) would result in the inundation of about 2,409 ha (5.950 acres) (96 percent) and the loss of all upland habitat on the Key (TNC 2010, p. 1).

Hydrology has a strong influence on plant distribution in these and other coastal areas (IPCC 2008, p. 57). Such communities typically grade from salt to brackish to freshwater species. From the 1930s to 1950s, increased salinity of coastal waters contributed to the decline of cabbage palm forests in southwest Florida (Williams et al. 1999, pp. 2056–2059), expansion of mangroves into adjacent marshes in the Everglades (Ross et al. 2000, pp. 9, 12–13), and loss of pine rockland in the Keys (Ross et al. 1994, pp. 144, 151–155). The possible effects of sea level rise were noted in the 1980s, at a site supporting Harrisia aboriginum (Morris and Miller 1981, p. 10), and recent deaths of cabbage palms at this location suggest that this is a continuing threat (Bradley et al. 2004, p. 7). Furthermore, Ross et al. (2000, pp. 109–111) suggested that interactions between sea level rise and pulse disturbances (e.g., storm surges) can cause vegetation to change sooner than projected based on sea level alone. Patterns of development will also likely be significant factors influencing whether natural communities can move and persist (IPCC 2008, p. 57; CCSP 2008, p. 7–6).

Most populations of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum are located just slightly above mean sea level, and the effects of sea level rise are expected to be a continual problem for coastal species and habitats (Gann et al. 2002, pp. 391, 481; Bradley et al. 2004, p. 7; Sadle 2007, pers. comm.; Higgins 2007, pers. comm.; Duquesnel 2008, pers. comm.). Research on C. corallicola (Stiling 2010, p. 2) and other Florida cacti suggests that increased soil salinity levels can cause mortality of these plants (Goodman et al. 2012, pp. 9–11). Natural populations of Harrisia aboriginum and Consolea corallicola do not occur on saturated soils (fresh or saline) and would likely be extirpated at sites affected by sea level rise.

Similarly, the extant populations of Consolea corallicola occur near sea level in a transitional zone between mangrove and hardwood hammock habitats. Populations at two sites have been declining for years, and this may be partially attributed to rising sea level, as most of the cacti are on the edge of the hammock and buttonwood transition zone or directly in the transition zone (Higgins 2007, pers. comm.; Duquesnel 2008, 2009, pers. comm.).

Summary of Factor E

In summary, Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum are vulnerable to a wide array of threats from human activities; invasive, nonnative plant species; small population sizes; weather events, and climate change, which have operated in the past, are impacting these species now, and have caused population declines in all three species. Based on our analysis of the best available information, these threats are likely to continue in the future at current levels or potentially increasing.

Cumulative Effects of Threats

The limited distributions and small population sizes of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum make them extremely susceptible to further habitat loss and competition from nonnative species. Poaching, vandalism, and wildfires are additional threats to C. corallicola and H. aboriginum. Mechanisms leading to the decline of these species as discussed above, range from local (e.g., poaching, vandalism, wildfire), to regional (e.g., development, nonnative species), to global (e.g., climate change, sea level rise). The synergistic (interaction of two or more components) effects of threats (such as hurricane effects on a species with a limited distribution consisting of just a few small populations) make it difficult to predict population viability. While these stressors may act in isolation, it is more probable that many stressors are acting simultaneously (or in combination) on populations of Chromolaena frustrata, Consolea corallicola, and H. aboriginum.

Proposed Determination

We have carefully assessed the best scientific and commercial information available regarding the past, present, and future threats to Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum. Section 6 of the Act defines an endangered species as “any species that is in danger of
extinction throughout all or a significant portion of its range,” and section 3(20) of the Act defines a threatened species as “any species that is likely to become endangered throughout all or a significant portion of its range within the foreseeable future.”

As described in detail above, these three species are currently at risk throughout all of their respective ranges due to the immediacy, severity, and scope of threats from habitat destruction and modification (Factor A), inadequacy of existing regulatory mechanisms (Factor D), and other natural or manmade factors affecting their continued existence (Factor E).

Consolea corallicola and Harrisia aboriginum are currently at risk throughout all of their respective ranges due to the immediacy, severity, and scope of threats from overutilization (Factor B), and C. corallicola is immediately threatened by disease or predation (Factor C). Although there are ongoing actions to alleviate some threats, there appear to be no populations without current significant threats. Current State and Federal regulatory mechanisms (Factor D) are inadequate to protect Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum from taking and habitat loss. Despite the existing regulatory mechanisms, Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum continue to decline. In particular, poaching remains a concern for Consolea corallicola, and H. aboriginum. Habitat loss or modification from development (Factor A) and sea level rise, competition from nonnative plants, small population sizes, and restricted range (Factor E) are threats to all three species. Hurricanes, storm surge, and future sea level rise are threats to all three species through direct mortality of individuals and modification of habitat. The majority of the remaining C. frustrata, C. corallicola, and H. aboriginum populations are generally small and geographically isolated. The narrow distribution of their populations in hurricane-prone south Florida makes them more susceptible to extirpation from a single catastrophic event. Furthermore, this level of isolation makes natural recolonization of extirpated populations virtually impossible without human intervention.

Chromolaena frustrata

Chromolaena frustrata has been extirpated (no longer in existence) from half of the islands in the Florida Keys where it historically occurred. Threats of poaching and vandalism (Factor B), predation by a nonnative moth, disease (Factor C), competition from nonnative, invasive plant species and wildfire (Factor E), and habitat loss (Factor A) still exist in the remaining populations. Additionally, low genetic diversity and lack of sexual reproduction are threats to C. corallicola. Because there are only a few small populations of this cactus, and the remoteness of occupied habitat that makes enforcement difficult, collection has and continues to be a significant threat to the species. Existing regulatory mechanisms (Factor D) at the State level are inadequate to protect the species from poaching or vandalism. Because populations are isolated and the species has a limited ability to recolonize suitable habitats, it continues to be vulnerable to natural or human-caused changes in its habitats. As a result, impacts from increasing threats, singly or in combination, are likely to result in the extinction of the species. Significant threats are occurring now and are likely to continue in the foreseeable future, at a high intensity.

and across the species’ entire range; therefore, we have determined the species is currently on the brink of extinction. Because these threats are placing the species in danger of extinction now and not only at some point in the foreseeable future, we find this species meets the definition of an endangered species, versus a threatened species. Therefore, we are proposing to list it as an endangered species. We are not proposing threatened status for C. corallicola due to the severity of the threats described above. These threats described above are currently active, and will continue to affect the populations of C. corallicola into the foreseeable future, and these threats will individually and collectively contribute to the species’ local extirpation and potential extinction.

Harrisia aboriginum

Harrisia aboriginum has been extirpated from the northern extent of its range in Manatee County, and threats of poaching (Factor B), predation from nonnative, invasive plant species, wildfire (Factor E), disease, predation (Factor C), vandalism (Factor B), and habitat loss (Factor A) still exist in the remaining populations. Because there are only a few small populations of this cactus, and the remoteness of occupied habitat that makes enforcement difficult, collection has and continues to be a significant threat to this species. Existing regulatory mechanisms (Factor D) at the State level are inadequate to protect this species from poaching or vandalism. Because populations are isolated and the species has a limited ability to recolonize historically occupied habitats, it is vulnerable to natural or human-caused changes in its habitats. As a result, impacts from increasing threats, singly or in combination, are likely to result in the extinction of the species. Significant threats are occurring now and are likely to continue in the foreseeable future, at a high intensity, and across the species’ entire range; therefore, we have determined the species is currently on the brink of extinction. Because these threats are placing the species in danger of extinction now and not only at some point in the foreseeable future, we find this species meets the definition of an endangered species, versus a threatened species. Therefore, we are proposing to list it as an endangered species. We are not proposing threatened status for H. aboriginum due to the severity of the threats described above. These threats described above are currently active, and will continue to affect the populations of H. aboriginum into the foreseeable future, and these threats will...
individually and collectively contribute to the species’ local extirpation and potential extinction.

Significant Portion of Its Range

We evaluated the current range of the Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum to determine if there is any apparent geographic concentration of potential threats for either species. All three species are highly restricted in their ranges, and the threats occur throughout their ranges. We considered the potential threats due to habitat loss or modification from development and sea level rise, competition from nonnative plants, hurricanes, storm surge, small populations, and restricted range. We found no concentration of threats because of the species’ limited and curtailed ranges, and uniformity of the threats throughout their entire ranges. Having determined that Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum are endangered throughout their ranges, it is not necessary to evaluate whether there are any significant portions of their ranges.

Available Conservation Measures

Conservation measures provided to species listed as endangered or threatened under the Act include recognition, recovery actions, requirements for Federal protection, and prohibitions against certain practices. Recognition through listing encourages and results in public awareness and conservation by Federal, State, and local agencies; private organizations; and individuals. The Act encourages cooperation with the States and requires that recovery actions be carried out for all listed species. The protection required of Federal agencies and the prohibitions against take and harm are discussed, in part, below.

The primary purpose of the Act is the conservation of endangered and threatened species and the ecosystems upon which they depend. The ultimate goal of such conservation efforts is the recovery of these listed species, so that they no longer need the protective measures of the Act. Subsection 4(f) of the Act requires the Service to develop and implement recovery plans for the conservation of endangered and threatened species. The recovery planning process involves the identification of actions that are necessary to halt or reverse the species’ decline by addressing the threats to its survival and recovery. The goal of this process is to restore listed species to a point where they are secure, self-sustaining, and functioning components of their ecosystems.

Recovery planning includes the development of a recovery outline shortly after a species is listed and after preparation of a draft and final recovery plan. The recovery outline guides the immediate implementation of urgent recovery actions and describes the process to be used to develop a recovery plan. Revisions of the plan may be done to address continuing or new threats to the species, as new substantive information becomes available. The recovery plan identifies site-specific management actions that set a trigger for review of the five factors that control whether a species remains endangered or may be down listed or delisted, and methods for monitoring recovery progress. Recovery plans also establish a framework for agencies to coordinate their recovery efforts and provide estimates of the cost of implementing recovery tasks. Recovery teams (comprising species experts, Federal and State agencies, nongovernmental organizations, and stakeholders) are often established to develop recovery plans. When completed, the recovery outline, draft recovery plan, and the final recovery plan will be available on our Web site (http://www.fws.gov/endangered), or from our South Florida Ecological Services Office (see FOR FURTHER INFORMATION CONTACT).

Implementation of recovery actions generally requires the participation of a broad range of partners, including other Federal agencies, States, Tribal, nongovernmental organizations, businesses, and private landowners. Examples of actions include habitat restoration (e.g., restoration of native vegetation), research, captive propagation and reintroduction, and outreach and education. The recovery of many listed species cannot be accomplished solely on Federal lands because their range may occur primarily or solely on non-Federal lands. Achieving recovery of these species requires cooperative conservation efforts on private, State, and Tribal lands.

If these species are listed, funding for recovery actions will be available from a variety of sources, including Federal budgets, State programs, and cost share grants for non-Federal landowners, the academic community, and nongovernmental organizations. In addition, under section 6 of the Act, the State of Florida would be eligible for Federal funds to implement management actions that promote the protection and recovery of Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum. Information on our grant programs that are available to aid species recovery can be found at: http://www.fws.gov/grants.

Although Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum are only being proposed for listing under the Act at this time, please let us know if you are interested in participating in recovery efforts for this species. Additionally, we invite you to submit any new information on this species whenever it becomes available and any information you may have for recovery planning purposes (see FOR FURTHER INFORMATION CONTACT).

Federal agencies are required to confer with us informally on any action that is likely to jeopardize the continued existence of a species proposed for listing or result in destruction or adverse modification of proposed critical habitat. If a species is listed subsequently, section 7(a)(4) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of the species or destroy or adversely modify its critical habitat. If a Federal action may adversely affect a listed species or its critical habitat, the responsible Federal agency must enter into formal consultation with the Service.

Federal agency actions within these species’ habitats that may require conference or consultation or both as described in the preceding paragraph include, but are not limited to, the funding of, carrying out or issuance of permits for resource management activities, development of facilities, road and trail construction, recreational programs, and any other any landscape-altering activities on Federal lands administered by the Department of Defense, NPS, Fish and Wildlife Service, and U.S. Forest Service; or the issuance of Federal permits under section 404 of the Clean Water Act (33 U.S.C. 1251 et seq.) by the U.S. Army Corps of Engineers; construction and management of gas pipeline and power line rights-of-way by the Federal Energy Regulatory Commission; and construction and maintenance of roads or highways by the Federal Highway Administration.

The Act and its implementing regulations set forth a series of general prohibitions and exceptions that apply to endangered plants. All prohibitions of section 9(a)(2) of the Act, implemented by 50 CFR 17.61, apply. These prohibitions, in part, make it illegal for any person subject to the jurisdiction of the United States to import or export, transport in interstate or foreign commerce in the course of a
commercial activity, sell or offer for sale in interstate or foreign commerce, or remove and reduce the species to possession from areas under Federal jurisdiction. In addition, for plants listed as an endangered species, the Act prohibits the malicious damage or destruction on areas under Federal jurisdiction and the removal, cutting, digging up, or damaging or destroying of such plants in knowing violation of any State law or regulation, including State criminal trespass law. Certain exceptions to the prohibitions apply to agents of the Service and State conservation agencies.

Preservation of native flora of Florida (Florida Statutes 581.185) sections (3)(a) and (b) provide limited protection to species listed in the State of Florida Regulated Plant Index including Chromolaena frustrata, Consola
corallicola, and Harrisia aboriginum, as described under Factor D. The Inadequacy of Existing Regulatory Mechanisms.

Federal listing increases protection by for these species by making violations of Section 3 of the Florida Statute punishable as a Federal offense under section 9 of the Act. This provides increased protection from unauthorized collecting and vandalism for the plants on State and private lands, where they might not otherwise be protected by the Act, and increases the severity of the penalty for unauthorized collection, vandalism, or trade in these species.

We may issue permits to carry out otherwise prohibited activities involving endangered and threatened plant species under certain circumstances. Regulations governing permits are codified at 50 CFR 17.62 for endangered plants, and at 50 CFR 17.72 for threatened plants. With regard to endangered plants, a permit must be issued for the following purposes: For scientific purposes or to enhance the propagation or survival of the species.

The Service acknowledges that it cannot fully address some of the natural threats facing Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum (e.g., hurricanes, tropical storms) or even some of the other significant, long-term threats (e.g., climatic changes, sea level rise). However, through listing, we provide protection to the known population(s) and any new population of the species that may be discovered (see discussion below). With listing, we can also influence Federal actions that may potentially impact the species (see discussion below); this is especially valuable if it is found at additional locations. With this action, we are also better able to deter illicit collection and trade.

It is our policy, as published in the Federal Register on July 1, 1994 (59 FR 34272), to identify to the maximum extent practicable at the time a species is listed, those activities that would or would not constitute a violation of section 9 of the Act. The intent of this policy is to increase public awareness of the effect of a proposed listing on proposed and ongoing activities within the range of species proposed for listing. The following activities could potentially result in a violation of section 9 of the Act; this list is not comprehensive:

1. Import any such species into, or export any such species from the United States;
2. Remove and reduce to possession any such species from areas under Federal jurisdiction; maliciously damage or destroy any such species on any such area; or remove, cut, dig up, or damage or destroy any such species on any other area in knowing violation of any law or regulation of any State or in the course of any violation of a State criminal trespass law;
3. Deliver, receive, carry, transport, or ship in interstate or foreign commerce, by any means whatsoever and in the course of a commercial activity, any such species;
4. Sell or offer for sale in interstate or foreign commerce any such species;
5. Introduce any nonnative wildlife or plant species to the State of Florida that compete with or prey upon Chromolaena frustrata, Consolea corallicola, or Harrisia aboriginum;
6. Release any unauthorized biological control agents that attack any life stage of Chromolaena frustrata, Consolea corallicola, or Harrisia aboriginum;
7. Modify the habitat of Chromolaena frustrata, Consolea corallicola, or Harrisia aboriginum on Federal lands that are authorized or not covered under the Act for impacts to these species.

Questions regarding whether specific activities would constitute a violation of section 9 of the Act should be directed to the Field Supervisor of the Service’s South Florida Ecological Services Office (see FOR FURTHER INFORMATION CONTACT). Requests for copies of regulations regarding listed species and inquiries about prohibitions and permits should be addressed to the U.S. Fish and Wildlife Service, Ecological Services Division, Endangered Species Permits, 1875 Century Boulevard, Atlanta, GA 30345 (Phone 404–679–7140; Fax 404–679–7081).

If Chromolaena frustrata, Consola
corallicola, and Harrisia aboriginum are listed under the Act, the State of Florida’s Endangered Species Act (Florida Statutes 581.185) is automatically invoked, which would also prohibit take of these species and encourage conservation by State government agencies. Further, the State may enter into agreements with Federal agencies to administer and manage any area required for the conservation, management, enhancement, or protection of endangered species (Florida Statutes 581.185). Funds for these activities could be made available under section 6 of the Act (Cooperation with the States). Thus, the Federal protection afforded to these species by listing them as endangered species would be reinforced and supplemented by protection under State law.

Critical Habitat Designation for Chromolaena frustrata, Consolea corallicola, and Harrisia aboriginum

Background

It is our intent to discuss below only those topics directly relevant to the designation of critical habitat for Chromolaena frustrata, Consola
corallicola, and Harrisia aboriginum in this section of the proposed rule.

Critical habitat is defined in section 3 of the Act as:

1. The specific areas within the geographical area occupied by the species, at the time it is listed in accordance with the Act, on which are found those physical or biological features

(a) Essential to the conservation of the species and
(b) Which may require special management considerations or protection; and

2. Specific areas outside the geographical area occupied by the species at the time it is listed, upon a determination that such areas are essential for the conservation of the species.

Conservation, as defined under section 3 of the Act, means to use and the use of all methods and procedures that are necessary to bring an endangered or threatened species to the point at which the measures provided pursuant to the Act are no longer necessary. Such methods and procedures include, but are not limited to, all activities associated with scientific resources management such as research, census, law enforcement, habitat acquisition and maintenance, propagation, live trapping, and transplantation, and, in the
extraordinary case where population pressures within a given ecosystem cannot be otherwise relieved, may include regulated taking.

Critical habitat receives protection under section 7 of the Act through the requirements that Federal agencies, in consultation with the Service, that any action they authorize, fund, or carry out is not likely to result in the destruction or adverse modification of critical habitat. The designation of critical habitat does not affect land ownership or establish a refuge, wilderness, reserve, preserve, or other conservation area. Such designation does not allow the government or public to access private lands. Such designation does not require implementation of restoration, recovery, or enhancement measures by non-Federal landowners. Where a landowner requests Federal agency funding or authorization for an action that may affect a listed species or critical habitat, the consultation requirements of section 7(a)(2) of the Act would apply, but even in the event of a destruction or adverse modification finding, the obligation of the Federal action agency and the landowner is not to restore or recover the species, but to implement reasonable and prudent alternatives to avoid destruction or adverse modification of critical habitat.

Prudency Determination

Section 4(a)(3) of the Act, as amended, and implementing regulations (50 CFR 424.12), require that, to the maximum extent prudent and determinable, the Secretary designate critical habitat at the time we determine that a species is endangered or threatened. Our regulations (50 CFR 424.12(a)(1)) state that the designation of critical habitat is not prudent when one or both of the following situations exist: (1) The species is threatened by taking or other human activity, and identification of critical habitat can be expected to increase the degree of threat to the species; or (2) such designation of critical habitat would not be beneficial to the species. This determination involves a weighing of the expected increase in threats associated with a critical habitat designation against the benefits gained by such designation. We have determined that for Consolea corallicola and Harrisia aboriginum, identification of critical habitat can be expected to increase the degree of threat to the species from over utilization by collectors and poachers and that the benefits of designating critical habitat are minimal.

Increased Threat to the Consolea corallicola and Harrisia aboriginum by Designating Critical Habitat

Rare cacti are highly desirable to collectors and often targeted for collection in the wild (Anderson 2001, pp. 73–78). The Service has documented unauthorized collection of both Consolea corallicola and Harrisia aboriginum on public lands in Florida. Collection appears to be ongoing, prevalent, and damaging (see Factor B analysis above for specific cases). In addition, we are aware that a market exists for trade in rare, imperiled, and federally-listed cacti, including those in south Florida (see Factor B analysis above). For example, there is currently a demand for Harrisia fragrans, a rare cactus from south Florida that is listed (under the scientific name Cereus eriophorus var. fragrans) as an endangered species under the Act, and that closely resembles H. aboriginum. Websites currently offer for sale seeds of C. corallicola and H. aboriginum. It is clear that a demand currently exists for specimens of both cacti.

Due to the low number of populations, small population sizes, restricted range, and remoteness of occupied habitat (which makes enforcement difficult), we believe that collection is a significant and continuing threat to Consolea corallicola and Harrisia aboriginum. Even limited collection from the remaining populations (or other populations, if discovered) could have significant and long-lasting deleterious effects on reproductive and genetic viability and thus could contribute to the extinction of these cacti. Identification of critical habitat units would increase the severity of this threat by describing the exact locations where the species may be found and more widely publicizing this information, exposing small, isolated populations and habitat to greater risks of collection and vandalism.

Designation of critical habitat requires the publication of maps and a narrative description of specific critical habitat units in the Federal Register. The degree of detail in those maps and boundary descriptions would be greater than what is currently available to the public. Thus, designation of critical habitat could more widely announce the exact location of the two cacti to collectors and poachers, and further encourage and facilitate unauthorized collection and trade. Due to their extreme rarity (a low number of individuals, combined with small areas inhabited by the remaining populations), these cacti are highly vulnerable to collection. We believe that these threats would be exacerbated by the publication of maps and descriptions outlining the specific locations of these cacti in the Federal Register, on Service Web sites, and in local newspapers.

Identification and publication of critical habitat for Consolea corallicola and Harrisia aboriginum would also likely increase enforcement problems. Although take prohibitions exist, effective enforcement is difficult. As discussed under Factors B, D, and E and elsewhere above, the threats of collection and inadvertent impacts from human activities exist and areas where the species currently exist are already difficult to patrol due to the remoteness of those areas. Many of the areas supporting the cacti are remote and accessible mainly by boat, making them difficult for law enforcement personnel to patrol and monitor, and more desirable for illegal activities. Limited patrolling is available for resource protection on the lands supporting Consolea corallicola and Harrisia aboriginum. We believe that designation of critical habitat would facilitate further use and misuse of sensitive habitats and resources, creating additional difficulty for law enforcement personnel in an already challenging environment. Overall, we believe that designation of critical habitat would increase the likelihood and severity of the threats of illegal collection of C. corallicola and H. aboriginum, as well as exacerbate enforcement issues.

Benefits to Consolea corallicola and Harrisia aboriginum From Critical Habitat Designation

The principal benefit of including an area in critical habitat is the requirement for agencies to ensure actions they fund, authorize, or carry out are not likely to result in the destruction or adverse modification of any designated critical habitat. The regulatory standard of section 7(a)(2) of the Act under which consultation is completed. Critical habitat provides protections only where there is a Federal nexus, that is, those actions that come under the purview of section 7 of the Act. Critical habitat designation has no application to actions that do not have a Federal nexus. Section 7(a)(2) of the Act mandates that Federal agencies, in consultation with the Service, evaluate the effects of their proposed actions on any designated critical habitat. Similar to the Act’s requirement that a Federal agency action not jeopardize the continued existence of listed species, Federal agencies have the
absence of a critical habitat designation. Federal lands that support _C. corallicola_ would continue to be subject to conservation actions implemented under section 7(a)(1) of the Act and to the regulatory protections by the section 7(a)(2) jeopardy standard consultation requirements and may still result in jeopardy findings. Therefore, designation of specific areas as critical habitat that are currently occupied is unlikely to provide a measurable benefit to the species while designation of unoccupied areas as critical habitat could provide a measurable benefit to the species.

**Harrisia aboriginum**

All _Harrisia aboriginum_ populations are at least in part on protected Federal, State, County, and private conservation lands. A few plants are located on private non-conservation parcels adjacent to larger populations on protected conservation sites. Most, but not all, of the protected sites are currently being managed at some level for the species. Management efforts are limited to nonnative species control at this time. These efforts are expected to continue in the future. The Federal listing of the species regardless of critical habitat designation, could result in increased enforcement efforts and population augmentation, although to what extent is unknown. One of the 12 sites where _H. aboriginum_ occurs is on Federal lands and represents approximately one third of all existing individuals and would be subject to section 7(a)(2) consultation requirements of the Act. However, _Harrisia aboriginum_ has been extirpated from the northern extent of its range in Manatee County. There are a few small County-owned and private land parcels that are occupied and not currently being managed for the species; and these lands would not be subject the requirements of section 7 consultation without a Federal nexus. Designation of these small parcels as occupied critical habitat would provide limited additional protection because a Federal nexus would still be needed to trigger consultation and it is unlikely the loss of the habitat would have an adverse effect on the conservation of the species. If unoccupied critical habitat were designated for _H. aboriginum_, additional habitat could be protected from adverse habitat modification or destruction on State, county, or private land if a Federal nexus were present and the action rose to the level of adversely modifying the critical habitat. Additional unoccupied habitat may be necessary for the recovery of _C. corallicola_ and _H. aboriginum_, as areas targeted for reintroduction would likely be on existing State, Federal, or county conservation lands. However, the identification of these lands would increase the risk of poaching in the future at these reintroduced sites.

In summary, for both _Consolea corallicola_ and _Harrisia aboriginum_, consultation with respect to critical habitat would provide additional protection to a species if the agency action would result in the destruction or adverse modification of the critical habitat but would not jeopardize the continued existence of the species. In the absence of a critical habitat designation, areas that support _C. corallicola_ and _H. aboriginum_ would continue to be subject to conservation actions implemented under section 7(a)(1) of the Act. Also, Federal actions affecting _C. corallicola_ and _H. aboriginum_ in the absence of designated critical habitat areas would still benefit from consultation pursuant under to section 7(a)(2) of the Act and may still result in jeopardy findings. Therefore, although designation of specific areas as critical habitat that is currently occupied, recently occupied, or unoccupied would provide some additional protections under the Act, that protection is likely to be minimal.

Another potential benefit to _Consolea corallicola_ and _Harrisia aboriginum_ from designating critical habitat is that it could serve to educate private landowners, and Federal, State, and local government agencies, Refuge, or Park visitors, and the general public regarding the potential conservation value of the area for the species. Through the processes of listing the cacti under the State of Florida’s endangered species statute and the recognition of the _C. corallicola_ and _H. aboriginum_ as a Federal candidate species in 2005 and 2006, respectively, much of this educational component is already in effect. Agencies, organizations, and stakeholders are actively engaged in efforts to raise awareness for these cacti and their conservation needs, including the need to deter poaching of wild specimens, designation of critical habitat would help in increasing the awareness. In addition, designation of critical habitat could inform State agencies and local governments about areas that could be conserved under State laws, local ordinances, or land management initiatives by State, local, and Federal agencies. However, nearly all land managers responsible for sites supporting _Consolea corallicola_ and _Harrisia aboriginum_ are now aware the presence of these species. Designation of critical habitat that is occupied would
likely provide benefits concerning awareness by private entities where management for the species could be enhanced or initiated.

Increased Threat to Consolea coralicola and Harrisia aboriginum Outweighs the Benefits of Critical Habitat Designation

Upon reviewing the available information, we have determined that the designation of critical habitat would increase the threat to Consolea coralicola and Harrisia aboriginum from unauthorized collection and trade, and may further facilitate inadvertent or purposeful disturbance and vandalism to the cacti’s habitat. We believe that designation of occupied critical habitat is likely to confer only an educational benefit to these cacti beyond that provided by listing. Alternatively, the designation of unoccupied critical habitat for either species could provide an educational and at least some regulatory benefit for each species. However, we believe that the risk of increased significant threats to the species by publishing more specific location information in a critical habitat designation greatly outweighs the benefits of designating critical habitat.

In conclusion, we find that the designation of critical habitat is not prudent, in accordance with 50 CFR 424.12(a)(1), because Consolea coralicola and Harrisia aboriginum are threatened by collection and habitat destruction, and designation can reasonably be expected to increase the degree of these threats to these species and their habitats. Critical habitat designation could provide some benefit to these species, but these benefits are significantly outweighed by the increased risk of collection pressure and enforcement problems that could result from depicting, through publicly available maps and descriptions, exactly where these extremely rare cacti and their habitat can be found.

Determination of Prudency for Chromolaena frustrata

In contrast to Consolea coralicola and Harrisia aboriginum, Chromolaena frustrata is not sought after by collectors and there is no evidence that the designation of critical habitat would result in an increased threat from taking (particularly poaching) or other human activity for this species. On the other hand, as for these other species, we find that the designation of critical habitat for C. frustrata, as for the other two species, is likely to provide at least some benefit to the species by serving to focus conservation efforts on the restoration and maintenance of ecosystem functions that are essential for attaining its recovery and long-term viability. Similarly, the designation of critical habitat could serve to inform management and conservation decisions by identifying any additional physical and biological features of the ecosystem that may be essential for the conservation of the species. We therefore find that designation of critical habitat for C. frustrata is prudent.

Critical Habitat Determinability

Having determined that designation of critical habitat is prudent for Chromolaena frustrata, under section 4(a)(3) of the Act, we must find whether critical habitat is determinable for the species. Our regulations at 50 CFR 424.12(a)(2) state that critical habitat is not determinable when one or both of the following situations exist:

(i) Information sufficient to perform required analyses of the impacts of the designation is lacking; or
(ii) The biological needs of the species are not sufficiently well known to permit identification of an area as critical habitat.

We reviewed the available information pertaining to the biological needs of Chromolaena frustrata and habitat characteristics where the species is located. This and other information represent the best scientific data available and have led us to conclude that the designation of critical habitat is determinable for C. frustrata.

Designation of Critical Habitat

Under the first prong of the Act’s definition of critical habitat, areas within the geographical area occupied by the species at the time it was listed are included in a critical habitat designation if they contain physical or biological features (1) which are essential to the conservation of the species and (2) which may require special management considerations or protection. For these areas, critical habitat designations identify, to the extent known using the best scientific and commercial data available, those physical or biological features that are essential to the conservation of the species (such as space, food, cover, and protected habitat). In identifying those physical and biological features within an area, we focus on the principal biological or physical constituent elements (primary constituent elements such as roost sites, nesting grounds, seasonal wetlands, water quality, tide, soil type) that are essential to the conservation of the species. Primary constituent elements are the specific elements of physical or biological features that provide for a species’ life-history processes, are essential to the conservation of the species.

Under the second prong of the Act’s definition of critical habitat, we can designate critical habitat in areas outside the geographical area occupied by the species at the time it is listed, upon a determination that such areas are essential for the conservation of the species. We designate critical habitat in areas outside the geographical area occupied by a species only when a designation limited to its range would be inadequate to ensure the conservation of the species.

Section 4 of the Act requires that we designate critical habitat on the basis of the best scientific data available. Further, our Policy on Information Standards Under the Endangered Species Act (published in the Federal Register on July 1, 1994 (59 FR 34271)), the Information Quality Act (section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001 (Pub. L. 106–554; H.R. 5658)) and our agency’s Information Quality Guidelines, provide criteria, establish procedures, and provide guidance to ensure that our decisions are based on the best scientific data available. They require our biologists, to the extent consistent with the Act and with the use of the best scientific data available, to use primary and original sources of information as the basis for recommendations to designate critical habitat.

When we are determining which areas should be designated as critical habitat, our primary source of information is generally the information developed during the listing process for the species. Additional information sources may include the recovery plan for the species, articles in peer-reviewed journals, conservation plans developed by States and counties, scientific status surveys and studies, biological assessments, other unpublished materials, or experts’ opinions or personal knowledge.

Habitat is dynamic, and species may move from one area to another over time. We recognize that critical habitat designated at a particular point in time may not include all of the habitat areas that we may later determine are necessary for the recovery of the species. For these reasons, a critical habitat designation does not signal that habitat outside the designated area is unimportant or may not be needed for recovery of the species. Areas that are important to the conservation of the species, both inside and outside the critical habitat designation, would continue to be subject to: (1) Conservation actions implemented
under section 7(a)(1) of the Act, (2) regulatory protections afforded by the requirement in section 7(a)(2) of the Act for Federal agencies to ensure their actions are not likely to jeopardize the continued existence of any endangered or threatened species, and (3) section 9 of the Act’s prohibitions on taking any individual of the species, including taking caused by actions that affect habitat. Federally funded or permitted projects affecting listed species outside their designated critical habitat areas may still result in jeopardy findings in some cases. These protections and conservation tools would continue to contribute to recovery of this species if we list *Chromolaena frustrata*.

Similarly, critical habitat designations made on the basis of the best available information at the time of designation will not control the direction and substance of future recovery plans, habitat conservation plans (HCPs), or other species conservation planning efforts if new information available at the time of these planning efforts calls for a different outcome.

**Physical or Biological Features**

In accordance with section 3(5)(A)(i) and 4(b)(i)(A) of the Act and regulations at 50 CFR 424.12, in determining which areas within the geographical area occupied by the species at the time of listing to designate as critical habitat, we consider the physical or biological features (PBFs) that are essential to the conservation of the species and which may require special management considerations or protection. These include, but are not limited to:

1. Space for individual and population growth and for normal behavior;
2. Food, water, air, light, minerals, or other nutritional or physiological requirements;
3. Cover or shelter;
4. Sites for breeding, reproduction, or rearing (or development) of offspring; and
5. Habitats that are protected from disturbance or are representative of the historical, geographical, and ecological distributions of a species.

We derive the specific PBFs for *Chromolaena frustrata* from observations of this species’ habitat, ecology, and life history as described below. The PBFs for *C. frustrata* were defined on the basis of the habitat features of the areas actually occupied by the plants, which included climate, substrate types, hydrologic regimes, plant community structure, associated plant species, and locale information.

**Space for Individual and Population Growth**

**Plant Community and Competitive Ability.** *Chromolaena frustrata* occurs in communities classified as coastal berms, coastal rock barrens, buttonwood forests, and rockland hammocks restricted to tropical South Florida and the Florida Keys. These communities and their associated native plant species are provided in the Status Assessment for *Chromolaena frustrata*, *Consolea corallicola*, and *Harrisia aboriginum* section above.

**Food, Water, Air, Light, Minerals, or Other Nutritional or Physiological Requirements**

**Climate (temperature and precipitation).** The climate of south Florida where *Chromolaena frustrata* occurs is characterized by distinct wet and dry seasons, a monthly mean temperature above 18 °C (64.4 °F) in every month of the year, and annual rainfall averaging 75 to 150 cm (30 to 60 in) (Gable et al. 1994, p. 211). Freezes can occur in the winter months, but are very infrequent at this latitude in Florida.

**Soils.** Substrates supporting *Chromolaena frustrata* for anchoring or nutrient absorption vary depending on the habitat and location and include marl (an unconsolidated sedimentary rock or soil consisting of clay and lime) (Sadle, 2008 and 2012, pers. comm.); soils consisting of covering limestone; exposed bare limestone rock or with a thin layer of leaf litter or highly organic soil (Bradley and Gann 1999, p. 37; FNAI 2010d, p. 1); or loose sediment formed by a mixture of coarse sand, shell fragments, pieces of coralline algae, and other coastal debris (FNAI 2010a, p. 1).

**Hydrology.** The species requires coastal berms and coastal rock barrens that occur above the daily tidal range, but are subject to flooding by seawater during extreme tides and storm surge. Rockland hammock occurs on high ground that does not regularly flood, but it is often dependent upon a high water table to keep humidity levels high, and they can be inundated during storm surges (FNAI 2010d, p. 1).

**Sites for Breeding, Reproduction, or Rearing (or Development) of Offspring**

The reproductive biology and needs of *Chromolaena frustrata* have not been studied (Bradley and Gann 1999, p. 37). We have no other information available beyond the habitat preferences and demographic trends and life-history cycles. Thus, except habitat requirements discussed above we have no other information regarding the ecology of the species related to reproduction needs.

**Habitats Protected From Disturbance or Representative of the Historical, Geographic, and Ecological Distributions of the Species**

*Chromolaena frustrata* continues to occur in habitats that are protected from human-generated disturbances and are representative of the species’ historical, geographical, and ecological distribution although its range has been reduced. The species still is found in all of its representative plant communities: Rock barrens, coastal berms, buttonwood forest, and rockland hammocks. In addition, representative communities are located on Federal, State, local, and private conservation lands that implement conservation measures benefitting the species.

**Disturbance Regime.** All of the habitats that support *Chromolaena frustrata* depend on some degree of natural disturbance. Damage from hurricanes or tidal inundation to reduce the canopy in order to provide light levels sufficient to support the species. The historical frequency and magnitude of hurricanes and tidal inundation has allowed for the persistence of *C. frustrata* by occasionally creating areas of open canopy that support the species. In the absence of disturbance, some of these habitats may have closed canopies, resulting in areas lacking enough available sunlight to support *Chromolaena frustrata*. However, too frequent or severe disturbance that transitions the habitat toward more saline conditions could result in the decline of the species in the area.

The natural process giving rise to coastal rock barren is not known, but as it occurs on sites where the thin layer of organic soil over limestone bedrock is missing, coastal rock barren may have formed by soil erosion following destruction of the plant cover by fire or storm surge (FNAI 2010c, p. 2). Fires are rare to nonexistent in coastal rock barren coastal berm, and buttonwood forest communities (FNAI 2010a, b, c, entire). Historically, rockland hammocks in south Florida evolved with fire in the landscape; fire most often extinguished near the edges when it encountered the hammock’s moist microclimate and litter layer. However, rockland hammocks are susceptible to damage from fire during extreme drought or when the water table is lowered (FNAI 2010d, p. 2).

**Cover or Shelter**

*Chromolaena frustrata* occurs in open canopy and semi-open to closed canopy
hhabitats and thrives in areas of moderate sun exposure (Bradley and Gann 1999, p. 37). The amount and frequency of such microsites varies by habitat type and time, and since the last disturbance. In rockland hammocks, suitable microsites will often be found near the hammock edge where the canopy is most open. However, the species has been observed to spread into the hammocks when canopy cover is reduced by hurricane damage to canopy trees. More open communities (e.g., coastal berm, buttonwood and salt marsh ecotone) provide more abundant and temporally consistent suitable habitat than communities capable of establishing a dense canopy (e.g., hardwood hammock).

Accordingly, we have determined that Chromolaena frustrata requires the following PBFs:

(1) Upland habitats consisting of coastal berm, coastal rock barren, rockland hammocks, and buttonwood forest;

(2) Habitats inundated by storm surge or tidal events at a frequency needed to limit plant species competition while not creating too saline conditions;

(3) Substrate derived from calcareous sand, limestone, or marl to provide anchoring and nutritional requirements;

(4) Vegetation composition and structure that allows for adequate sunlight, and space for individual growth and population expansion;

(5) Habitat connectivity of sufficient size and suitability, or habitat that can be restored to these conditions that supports species growth, distribution and population expansion; and

(6) Disturbance regimes, including hurricanes, and infrequent inundation events that saturate the substrate, to maintain suitable sites for Chromolaena frustrata within these habitats.

Primary Constituent Elements for Chromolaena frustrata

Under the Act and its implementing regulations, we are required to identify the PBFs essential to the conservation of Chromolaena frustrata in areas occupied at the time of listing, focusing on the features’ primary constituent elements (PCEs). Primary constituent elements are those specific elements of the physical or biological features that provide for a species’ life-history processes and are essential to the conservation of the species.

We derive the PCEs for Chromolaena frustrata primarily based on those PBFs that support the successful functioning of the habitat upon which the species depends. C. frustrata is dependent upon functioning habitats to provide its fundamental life requirements, such as substrate, hydrology, disturbance regime, and the species composition and structure of vegetation. The PCEs collectively provide the suite of PBFs essential to meeting the requirements of C. frustrata.

Based on our current knowledge of the PBFs and habitat characteristics required to sustain the species’ life-history processes, we determine that the PCEs for C. frustrata are:

(1) Areas of upland habitats consisting of coastal berm, coastal rock barren, rockland hammocks, and buttonwood forest. (A) Coastal berm habitat contains:

(1) Open to semi-open canopy, subcanopy, and understory;

(2) Substrate of coarse, calcareous, storm-deposited sediment; and

(3) A plant community of predominately native vegetation and either no competitive nonnative, invasive plant species or such species in quantities low enough to have minimal effect on the survival of Chromolaena frustrata. Coastal berm habitat has a canopy vegetated by Bursera, Coccoloba, Coccothrinax, Guapia, Drypetes, Genipa, and Metopium; a subcanopy vegetated by Eugenia, Ximenia, Randia, Piscidia, Swietenia, Sideroxylon, Conocarpus, Guapira, and Pisonia; and an understory vegetated by Eugenia, Thrinax, Amyris, Ardisia, Psychotria, Chrysophyllum, Sabal, Guaiacum, Ximenia, and Colubrina; and an understory vegetated by Zamia, Acanthocereus, and Oplismenus.

(B) Coastal rock barren (Keys cactus barren, Keys tidal rock barren) habitat contains:

(1) Open to semi-open canopy and understory;

(2) Substrate with calcareous marl muds, calcareous sands, or limestone rock; and

(3) A plant community of predominately native vegetation and either no competitive nonnative, invasive plant species or such species in quantities low enough to have minimal effect on the survival of Chromolaena frustrata. Buttonwood forest has a canopy vegetated by Conocarpus, and an understory vegetated by Borrichia, Lycium, and Limonium.

(2) A disturbance regime, due to the effects of strong winds or salt-water inundation from storm surge or infrequent tidal inundation, that creates canopy disruption in coastal berm, coastal rock barren, rockland hammocks, and buttonwood forest habitats listed above.

(3) Habitats that are connected and of sufficient area to sustain viable populations in in coastal berm, coastal rock barren, rockland hammocks, and buttonwood forest habitats listed above.

Special Management Considerations or Protection

When designating critical habitat, we assess whether the specific areas within the geographic area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. Management considerations or protection are necessary throughout the critical habitat areas proposed here to avoid further degradation or destruction of the habitat that provides those features essential to the species’
Conservation. The primary threats to the PBFs that *Chromolaena frustrata* depends on include: (1) Habitat destruction and modification by development; (2) competition with nonnative, invasive plant species; (3) wildfire; (4) hurricanes and storm surge; and (5) sea level rise. Some of these threats can be addressed by special management considerations or protection while others (e.g., sea level rise, hurricanes) are beyond the control of land owners and managers. However, while land owners or land managers may not be able to control all the threats, they may be able to address the results of these threats.

Management activities that could ameliorate these threats include monitoring and minimization of recreational activities impacts, nonnative species control, and protection from development. Precautions are needed to avoid the inadvertent trampling of *Chromolaena frustrata* in the course of management activities and public use. Development of recreation facilities or programs should avoid impacting these habitats directly or indirectly. Ditching should be avoided because it alters the hydrology and species composition of these habitats. Sites that have shown increasing encroachment of woody species over time may require efforts to maintain the open nature of the habitat, which favors these species. Nonnative species control programs are needed to reduce competition and prevent habitat degradation. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this proposed rule. All proposed critical habitat requires active management to address the ongoing threats listed above (and those presented in Factors A through E).

In summary, we find that each of the areas we are proposing as critical habitat that are occupied by *Chromolaena frustrata* contain features essential to the conservation of the species that may require special management considerations for protection to ensure conservation of the species. These special management considerations and protection are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of these threats is presented above in “Summary of Factors Affecting the Species.”

**Criteria Used To Identify Critical Habitat**

As required by section 4(b)(2) of the Act, we use the best scientific data available to designate critical habitat. We reviewed available information pertaining to the habitat requirements of this species. We are proposing to designate critical habitat in areas within the geographical area occupied by *Chromolaena frustrata* at the time of listing. All of these units are designated based on sufficient elements of physical and biological features being present to support known *Chromolaena frustrata* life-history processes.

In accordance with the Act and its implementing regulation at 50 CFR 424.12(e), we considered whether designating additional areas—outside those currently occupied as well as those occupied at the time of listing—are necessary to ensure the conservation of the species. For the reasons described below, we also are proposing to designate specific areas outside the geographical area currently occupied by the species (that would mean occupied at the time of listing), but which were historically occupied, because we have determined that such areas are essential for the conservation of species. Small populations and plant species with limited distributions, like those of *Chromolaena frustrata*, are vulnerable to relatively minor environmental disturbances (Frankham 2005, pp. 135–136), and are subject to the loss of genetic diversity from genetic drift, the random loss of genes, and inbreeding (Ellstrand and Elam 1993, pp. 217–237; Leimu et al. 2006, pp. 942–952). Plant populations with lowered genetic diversity are more prone to local extinction (Barrett and Kohn 1991, pp. 4, 28). Smaller plant populations generally have lower genetic diversity, and lower genetic diversity may in turn lead to even smaller populations by decreasing the species’ ability to adapt, thereby increasing the probability of population extinction (Newman and Pilsen 1997, p. 360; Palstra and Ruzzante 2008, pp. 3428–3447). Because of the dangers associated with small populations or limited distributions, the recovery of many rare plant species includes the creation of new sites or reintroductions to ameliorate these effects.

When designating critical habitat, we consider future recovery efforts and conservation of the species. Realizing that the current occupied habitat is not enough for the conservation and recovery of *Chromolaena frustrata*, we used habitat and historical occurrence data to identify unoccupied habitat essential for the conservation of the species. The justification for why unoccupied habitat is essential to the conservation of these species and the methodology we used to identify the best unoccupied areas for consideration of inclusion are described below.

Habitat fragmentation can have negative effects on biological populations, especially rare plants, and can affect survival and recovery (Aguilar et al. 2006, pp. 968–980; Aguilar et al. 2008, pp. 5177–5188; Potts et al. 2010, pp. 345–352). Fragments are often not of sufficient size to support the natural diversity prevalent in an area, and thus exhibit a decline in biodiversity (Fahrig 2003, pp. 487–515). Fragmentation effects are especially prevalent in systems where multiple generations have elapsed since the fragmentation occurred (Aguilar et al. 2008b, p. 5177).

Habitat fragmentation has been shown to disrupt plant-pollinator interactions and predator-prey interactions (Steffan-Dewenter and Tscharntke 1999, pp. 432–440; Aguilar et al. 2006, pp. 968–980; Eckert et al. 2010, pp. 35–43), alter seed germination percentages (Menges 1991, pp. 158–164), affect recruitment (Santos and Telleria 1997, pp. 181–187; Quesada et al. 2003, pp. 400–406), and result in lowered fruit set (Burk 1994, pp. 83–139; Cunningham 2000, pp. 1149–1152; Eckert et al. 2010, p. 38).

In general, habitat fragmentation causes habitat loss, habitat degradation, habitat isolation, changes in species composition, changes in species interactions, increased edge effects, and reduced habitat connectivity (Fahrig 2003, pp. 487–515; Fisher and Lindenmayer 2007, pp. 265–280). Habitat fragments are often functionally smaller than they appear because edge effects (such as increased nonnative, invasive species or wind speeds) impact the available habitat within the fragment (Liénert and Fischer 2003, p. 597).

Shaffer and Stein (2000) identify a methodology for conserving imperiled species known as the “three Rs”: Representation, resiliency, and redundancy. Representation, or preserving some of everything, means conserving not just a species but its associated plant communities. Resiliency and redundancy ensure there is enough of a species so it can survive into the future. Resiliency means ensuring that the habitat is adequate for a species and its representative components. Redundancy ensures an adequate number of sites and individuals. This methodology has been widely accepted as a reasonable conservation strategy (Tear et al. 2005, p. 841).

We have addressed representation through our PCEs (as discussed above) and by providing habitat for *Chromolaena frustrata*. There are only approximately 6,000 to 8,000 known individuals and only 8 populations, four
of which have fewer than 100
individuals (low redundancy). Seven of
eight populations occur on small islands
where the amount of suitable and
remaining habitat is limited (low
resiliency). For adequate redundancy
and resiliency, we believe it is necessary
for conservation and recovery that
additional populations of C. frustrata be
established. Therefore, we have
proposed two unoccupied areas for
designation as critical habitat units on
islands of the Florida Keys where C.
frustrata was historically recorded, but
has since been extirpated.

To determine the location and
boundaries of critical habitat, the
Service used the following sources of
information:
(1) FNAl population records and
ArcGIS geographic information system
(GIS) software to spatially depict the
location and extent of documented
populations of Chromolaena frustrata
(FNAI 2011b, pp. 1–17);
(2) Reports prepared by botanists with
the Institute for Regional Conservation
(IRC), NPS, and Florida Department of
Environmental Protection (FDEP). Some
of these were funded by the Service,
others were requested or volunteered by
biologists with the NPS or FDEP;
(3) Historical records found in reports
and associated voucher specimens
housed at herbaria, all of which are also
referenced in the above mentioned
reports from the IRC and FNAI;
(4) Digitally produced habitat maps
provided by NPS and Monroe County;
and
(5) Aerial images of Miami-Dade and
Monroe Counties. The presence of PCEs
was determined through the use of GIS
spatial data depicting the current habitat
status. This habitat data for the Keys
were developed by Monroe County from
2006 aerial images, and ground
conditions for many areas were checked
in 2009. Habitat data for ENP were
provided by the NPS. The areas that
contain PCEs follow predictable
landscape patterns and have a
recognizable signature in the aerial
photographs.

We have identified areas to include in
this proposed designation by applying
the following considerations.

The amount and distribution of
critical habitat being proposed for
designated would allow populations of
Chromolaena frustrata to:
(1) Maintain their existing
distribution;
(2) Expand their distribution into
previously occupied areas (needed to
offset habitat loss and fragmentation);
(3) Use habitat depending on habitat
availability (response to changing nature
of coastal habitat including occurring
sea level rise) and support genetic
diversity;
(4) Increase the size of each
collection to a level where the threats
of genetic, demographic, and normal
environmental uncertainties are
diminished; and
(5) Maintain their ability to withstand
local or unit level environmental
fluctuations or catastrophes.

We utilized the following process to
select appropriate critical habitat units for
Chromolaena frustrata:
Areas Occupied at Time of Listing
(1) For the purpose of designating
critical habitat for Chromolaena
frustrata, we defined the geographical
area currently occupied by the species
as required by section 3(5)(A)(i) of the
Act. Proposed occupied critical habitat
units were delineated around extant
populations. These units include the
mapped extent of the population and
adjacent areas that contain the elements
of the PBFs that allow for population
growth and expansion and to account
for dynamic habitat processes (i.e., gain
and loss of areas with sufficient light
availability due to disturbance of
canopy by natural events such as
inundation and hurricanes), and habitat
transition or loss due to sea level rise.

In the ENP, the distribution of
Chromolaena frustrata is across a larger
area than at any other single location. In
the Keys, the same criteria were used,
but the size of the proposed units is
limited by the size of individual islands.

(2) Areas to maintain connectivity of
habitat. Some areas that may contain
only some of the elements of the PBFs
were included if they were contiguous
with areas containing one or more of
those elements and if they contribute to
the hydrologic processes and
disturbance regime essential to the
ecological function of the system. These
areas maintain connectivity within
populations and allow for population
expansion.

(3) Areas for restoration. We have
selected some areas within occupied
units that, once restored, would be able
to support expansion and a larger
number of the species. These areas
generally are habitats within or adjacent
to coastal berms, coastal barrens,
rockland hammocks, or buttonwood
forest that retain some of the elements
of the PBFs although some PBFs have
been lost through natural or
anthropogenic causes. These areas
would provide habitat to offset the
anticipated loss and degradation of
habitat occurring from the
effects of climate change (such as sea
level rise) or due to development.

(4) Areas to allow the dynamic nature
of coastal berm, buttonwood forest,
rockland hammock, and coastal rock
barren habitats to respond to hurricane
and salt-water inundation. Areas with
an open canopy which are suitable for
C. frustrata are patchy within rockland
hammock and coastal rock barrens. At
any one time, not all the elements of the
PBFs are found in these habitats and
affect the suitability for C. frustrata. The
size and location of these areas are
dynamic over time, being largely driven
by disturbance by hurricanes in
hammocks and storm surge in coastal
rock barrens. After hurricanes, canopy
gaps created by the storm begin to close
over time, limiting light availability and
suitability of the gap to C. frustrata.
Thus, these areas could be transitory in
providing all the elements of the PBFs
as canopy regrows and closes. To
address the dynamic nature of these
habitats, we included all contiguous
habitat associated with a current
population record that retains at least
one element of the PBFs.

(5) Areas to ensure the persistence of
Chromolaena frustrata in the face of
imminent effects on habitats as a result
of sea level rise.

Areas Not Occupied at Time of Listing
(1) Areas where Chromolaena
frustrata occurred historically but has
since been extirpated. Chromolaena
frustrata has been extirpated from
several locations where it was
previously recorded. Of those areas
found in reports, we are proposing
critical habitat only for those that are
well-documented and still retain some
or all the elements of the PBFs (i.e., Big
Pine Key, Key Largo (Bradley and Gann
2004, pp. 4–6)). Areas such as Fiesta
Key and Knight’s Key, which once
supported populations of C. frustrata
but no longer contain any PCEs and
cannot be restored, are not included.
As it is not always possible to identify that
exact location where a specimen was
collected, we used available
descriptions to speculate upon likely
locations, but ultimately were guided by
the location of remaining habitats on
islands where little of these habitats
remain.

(2) Areas of sufficient size to support
ecosystem processes for occupied
populations of Chromolaena frustrata.
Large contiguous parcels of habitat are
more likely to be resilient to ecological
processes of disturbance and
succession, and support viable
populations of Chromolaena frustrata.

When determining proposed critical
habitat boundaries, we made every effort to avoid including developed
areas such as lands covered by
buildings, pavement, and other structures because such lands lack physical or biological features for *Chromolaena frustrata*. The scale of the maps we prepared under the parameters for publication within the Code of Federal Regulations may not reflect the exclusion of such developed lands. Any such lands inadvertently left inside critical habitat boundaries shown on the maps of this proposed rule have been excluded by text in the proposed rule and are not proposed for designation as critical habitat. Therefore, if the critical habitat is finalized as proposed, a Federal action involving these lands would not trigger section 7 consultation with respect to critical habitat and the requirement of no adverse modification unless the specific action would affect the physical or biological features in the adjacent critical habitat.

The critical habitat designation is defined by the map or maps, as modified by any accompanying regulatory text, presented at the end of this document in the rule portion. We include more detailed information on the boundaries of the critical habitat designation in the preamble of this document. We will make the coordinates or plot points or both on which each map is based available to the public on [http://www.regulations.gov](http://www.regulations.gov) at Docket No. FWS–R4–ES–2012–0076, on our Internet sites ([http://www.fws.gov/verobeach/](http://www.fws.gov/verobeach/)), and at the field office responsible for the designation (see FOR FURTHER INFORMATION CONTACT above).

### Proposed Critical Habitat Designation

We are proposing nine units as critical habitat for *Chromolaena frustrata*. The critical habitat areas we describe below constitute our current best assessment of areas that meet the definition of critical habitat for *C. frustrata*. The nine areas we propose as critical habitat are: (1) Everglades National Park; (2) Key Largo; (3) Upper Matecumbe Key; (4) Lignumvitae Key; (5) Lower Matecumbe Key; (6) Long Key; (7) Big Pine Key; (8) Big Munson Island; and (9) Boca Grande Key. Landownership within the proposed critical habitat consists of Federal (62 percent), State (30 percent), and private and other (8 percent). Table 4 summarizes these units.

**Note:** Area sizes may not sum due to rounding.

Seven of the nine critical habitat units proposed for *Chromolaena frustrata* are also currently designated under the Act for the wintering piping plover (*Charadrius melodus*) and the American crocodile (*Crocodylus acutus*). The specific units, and the species for which they are designated are shown in Table 4.

</table>

We present brief descriptions of all units and reasons why they meet the definition of critical habitat for *Chromolaena frustrata*, below.

**Unit 1: Everglades National Park, Monroe County and Miami-Dade County**

Unit 1 consists of 1,525 ha (3,768 ac) in Monroe County and Miami-Dade County. This unit is comprised entirely of lands in Federal ownership, 100 percent of which are located within the ENP along the southern coast of Florida from Cape Sable to Trout Cove, located between the mean high water line to approximately 4.02 km (2.5 miles) inland. This unit is currently occupied...
and contains the features essential to the conservation of the species. The unit contains coastal berm, rockland hammock, and buttonwood forest PCEs. This unit contains all the PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative plant species and sea level rise.

**Unit 2: Key Largo, Monroe County**

Unit 2 consists of 1,388 ha (3,430 ac) in Monroe County. This unit is comprised of Federal lands within Crocodile Lake National Wildlife Refuge (NWR) (325 ha [803 ac]); State lands within Dagny Johnson Botanical State Park, John Pennekamp Coral Reef State Park, and the Florida Keys Wildlife and Environmental Area (878 ha [2,170 ac]); and parcels in private ownership (185 ha [457 ac]).

This unit extends from near the northern tip of Key Largo, along the length of Key Largo, beginning at the south shore of Ocean Reef Harbor near South Marina Drive and the intersection of County Road (CR) 905 and Clubhouse Road on the west side of CR 905, and between CR 905 and Old State Road 905, then extending to the shoreline south of South Harbor Drive. The unit then continues on both sides of CR 905 through the Crocodile Lake NWR, Dagny Johnson Key Largo Hammock Botanical State Park, and John Pennekamp Coral Reef State Park. The unit then terminates near the junction of U.S. 1 and CR 905 and Garden Cove Drive. The unit resumes on the east side of U.S. 1 from South Andros Road to Key Largo Elementary; then from intersection of Taylor Drive and Pamela Street to Avenue A; then from Sound Drive to the intersection of Old Road and Valencia Road; then resumes on the east side of U.S. 1 from Hibiscus Lane and Ocean Drive. The unit continues south near the Port Largo Airport from Poisonwood Road to Bo Peep Boulevard. The unit resumes on the west side of U.S. 1 from the intersection of South Drive and Meridian Avenue to Casa Court Drive. The unit then continues on the west side of U.S. 1 from the point on the coast directly west of Peace Avenue south to Caribbean Avenue. The unit also includes a portion of the barrier island in Largo Sound located directly east of Avenue A, extending south to a point directly east of Mahogany Drive. This unit is currently occupied but contains habitat essential to the conservation of the species because it serves to protect habitat needed to recover the species, reestablish wild populations within the historical range of the species, and maintain populations throughout the historic distribution of the species in the Florida Keys, and provides area for recovery in the case of stochastic events that otherwise would eliminate the species from the one or more locations it is presently found.

**Unit 3: Upper Matecumbe Key, Monroe County**

Unit 3 consists of 27 ha (66 ac) in Monroe County. This unit is comprised of State lands within Lignumvitae Key State Botanical Park, Indian Key Historical State Park (9 ha [22 ac]); City of Islamorada lands within the Key Tree Cactus Preserve and Green Turtle Hammock Park and parcels in private ownership (18 ha [44 ac]). This unit extends from Matecumbe Avenue south to Seashore Avenue along either side of U.S. 1. The unit then continues along the west side of U.S. 1, including the Green Turtle Hammock Park and a nature preserve owned by the City of Islamorada; straddles U.S. 1 in the vicinity of Indian Key Historical Park; and continues for 0.8 km (0.5 mi) to near the southern tip of Key Largo on the west side of U.S. 1.

This unit is currently occupied and contains the features essential to the conservation of the species. It contains the PCEs of coastal berm, coastal rock barren, and rockland hammock. This unit contains all PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative species and sea level rise.

**Unit 4: Lignumvitae Key, Monroe County**

Unit 4 consists of 73 ha (180 ac) in Monroe County. This unit is comprised entirely of lands in State ownership, 100 percent of which are located within the Lignumvitae Key Botanical State Park (LK BSP).

This unit is currently occupied and contains the features essential to the conservation of the species. This unit includes all PCEs of rockland hammock and buttonwood forest habitat that occur within LK BSP on Lignumvitae Key. This unit contains all PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative species and sea level rise.

**Unit 5: Lower Matecumbe Key, Monroe County**

Unit 5 consists of 18 ha (44 ac) in Monroe County. The unit is comprised of State lands within Lignumvitae Key State Botanical Park, parcels owned by the Florida Department of Transportation (9 ha [22 ac]); and parcels in private ownership (9 ha [22 ac]). This unit extends from the east side of U.S. 1 from 0.2 km (0.14 mi) from the north edge of Lower Matecumbe Key, situated across U.S. 1 from Davis Lane and Tiki Lane. The unit continues on either side of U.S. 1 approximately 0.4 mi (0.6 km) from the north edge of Lower Matecumbe Key for approximately 0.9 km (0.6 mi).

This unit is currently occupied and contains the features essential to the conservation of the species. It contains all PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative species and sea level rise.

**Unit 6: Long Key, Monroe County**

Unit 6 consists of 84 ha (208 ac) in Monroe County. This unit is comprised of State lands within Long Key State Park (61 ha [151 ac]) and parcels in private ownership (23 ha [57 ac]). The unit extends from the southwestern tip of Long Key along the island’s west and south shores.

The unit is currently occupied and contains the features essential to the conservation of the species. It contains the PCEs of coastal berm, coastal rock barren, rockland hammock, and buttonwood forest. This unit contains all PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative species and sea level rise.

**Unit 7: Big Pine Key, Monroe County**

Unit 7 consists of 315 ha (778 ac) in Monroe County. Unit 7 consists of 315 ha (778 ac) in Monroe County. This unit is comprised of Federal land within the National Key Deer Refuge (NKDR) (277 ha [684 ac]) and parcels in private ownership (38 ha [94 ac]). This unit extends from near the northern tip of Big Pine Key along the eastern shore to the vicinity of Hellenga Drive and
Watson Road; from Gulf Boulevard south to West Shore Drive; from the southwest tip of Big Pine Key, bordered by Big Pine Avenue and Elma Avenues on the east, Coral and Yacht Club Road, and U.S. 1 on the north, and Industrial Avenue on the east; extending along the undeveloped portion of Long Beach Drive; and from the southeastern tip of Big Pine Key to Avenue A.

This unit is not currently occupied but is essential to the conservation of the species because it serves to protect habitat needed to recover the species, reestablish wild populations within the historical range of the species, and maintain populations throughout the historic distribution of the species in the Florida Keys, and it provides area for recovery in the case of stochastic events that otherwise hold the potential to eliminate the species from the one or more locations where it is presently found.

Unit 8: Big Munson Island, Monroe County

Unit 8 consists of 11 ha (27 ac) in Monroe County. This unit is comprised entirely of lands in private ownership, owned by the Boy Scouts of America. This unit is occupied and contains the features essential to the conservation of the species. It includes all the PCEs of coastal berm, rockland hammock, and buttonwood forest habitat that occur on Big Munson Island. This unit contains all PBFs, including suitable climate, hydrology, substrate, associated native plant species, and disturbance regimes, required by the species. The PBFs in this unit may require special management considerations or protection to address threats of nonnative species and sea level rise.

Effects of Critical Habitat Designation

Section 7 Consultation

Section 7(a)(2) of the Act requires Federal agencies, including the Service, to ensure that any action they fund, authorize, or carry out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat of such species. In addition, section 7(a)(4) of the Act requires Federal agencies to confer with the Service on any agency action which is likely to jeopardize the continued existence of any species proposed to be listed under the Act or result in the destruction or adverse modification of proposed critical habitat.

Decisions by the United States Court of Appeals for the Fifth and Ninth Circuits have invalidated our regulatory definition of “destruction or adverse modification” (50 CFR 402.02) (see Gifford Pinchot Task Force v. U.S. Fish and Wildlife Service, 378 F. 3d 1059 (9th Cir. 2004) and Sierra Club v. U.S. Fish and Wildlife Service et al., 245 F.3d 434, 442 (5th Cir. 2001)), and we do not rely on this regulatory definition when analyzing whether an action is likely to destroy or adversely modify critical habitat. Under the provisions of the Act, we determine destruction or adverse modification on the basis of whether, with implementation of the proposed Federal action, the affected critical habitat would continue to serve its intended conservation role for the species.

If a Federal action may affect a listed species or its critical habitat, the responsible Federal agency (action agency) must enter into consultation with us. Examples of actions that are subject to the section 7 consultation process are actions on State, tribal, local, or private lands that require a Federal permit (such as a permit from the U.S. Army Corps of Engineers under section 404 of the Clean Water Act or a permit from the Service under section 10 of the Act) or that involve some other Federal action (such as funding from the Federal Highway Administration, Federal Aviation Administration, or the Federal Emergency Management Agency). Federal actions not affecting listed species or critical habitat, and actions on State, tribal, local, or private lands that are not federally funded or authorized, do not require section 7 consultation.

As a result of section 7 consultation, we document compliance with the requirements of section 7(a)(2) through our issuance of:

(1) A concurrence letter for Federal actions that may affect, but are not likely to adversely affect, listed species or critical habitat; or

(2) A biological opinion for Federal actions that may affect, or are likely to adversely affect, listed species or critical habitat.

When we issue a biological opinion concluding that a project is likely to jeopardize the continued existence of a listed species and/or destroy or adversely modify critical habitat, we provide reasonable and prudent alternatives to the project, if any are identifiable, that would avoid the likelihood of jeopardy and/or destruction or adverse modification of critical habitat. We define “reasonable and prudent alternatives” (at 50 CFR 402.02) as alternative actions identified during consultation that:

(1) Can be implemented in a manner consistent with the intended purpose of the action,

(2) Can be implemented consistent with the scope of the Federal agency’s legal authority and jurisdiction,

(3) Are economically and technologically feasible, and

(4) Would, in the Director’s opinion, avoid the likelihood of jeopardizing the continued existence of the listed species and/or avoid the likelihood of destroying or adversely modifying critical habitat.

Reasonable and prudent alternatives can vary from slight project modifications to extensive redesign or relocation of the project. Costs associated with implementing a reasonable and prudent alternative are similarly variable.

Regulations at 50 CFR 402.16 require Federal agencies to reinitiate consultation on previously reviewed actions in instances where we have listed a new species or subsequently designated critical habitat that may be affected and the Federal agency has retained discretionary involvement or control over the action (or the agency’s discretionary involvement or control is authorized by law). Consequently, Federal agencies sometimes may need to request reinitiation of consultation with us on actions for which formal consultation has been completed, if those actions with discretionary involvement or control may affect subsequently listed species or designated critical habitat.

Application of the “Adverse Modification” Standard

The key factor related to the adverse modification determination is whether,
with implementation of the proposed Federal action, the affected critical habitat would continue to serve its intended conservation role for the species. Activities that may destroy or adversely modify critical habitat are those that alter the physical or biological features to an extent that appreciably reduces the conservation value of critical habitat for *Chromolaena frustrata*. As discussed above, the role of critical habitat is to support life-history needs of the species and provide for the conservation of the species.

Section 4(b)(8) of the Act requires us to briefly evaluate and describe, in any proposed or final regulation that designates critical habitat, activities involving a Federal action that may destroy or adversely modify such habitat, or that may be affected by such designation.

Activities that may affect critical habitat, when carried out, funded, or authorized by a Federal agency, should result in consultation for *Chromolaena frustrata*. These activities include, but are not limited to:

1. Actions that would significantly alter the hydrology or substrate, such as ditching or filling. Such activities may include, but are not limited to, road construction or maintenance, and residential, commercial, or recreational development.
2. Actions that would significantly alter vegetation structure or composition, such as clearing vegetation for construction of residences, facilities, trails, and roads.
3. Actions that would introduce nonnative species that would significantly alter vegetation structure or composition. Such activities may include, but are not limited to, residential and commercial development, and road construction.

Exclusions

Application of Section 4(a)(3) of the Act

The Sikes Act Improvement Act of 1997 (Sikes Act) (16 U.S.C. 670a) required each military installation that includes land and water suitable for the conservation and management of natural resources to complete an integrated natural resources management plan (INRMP) by November 17, 2001. An INRMP integrates implementation of the military mission of the installation with stewardship of the natural resources found on the base. Each INRMP includes:

1. An assessment of the ecological needs of the installation, including the need to provide for the conservation of listed species;
2. A statement of goals and priorities;
3. A detailed description of management actions to be implemented to provide for these ecological needs; and

Among other things, each INRMP must, to the extent appropriate and applicable, provide for fish and wildlife management; fish and wildlife habitat enhancement or modification; wetland protection, enhancement, and restoration where necessary to support fish and wildlife; and enforcement of applicable natural resource laws.

The National Defense Authorization Act for Fiscal Year 2004 (Pub. L. 108–136) amended the Act to limit areas eligible for designation as critical habitat. Specifically, section 4(a)(3)(B)(i) of the Act (16 U.S.C. 1533(a)(3)(B)(i)) now provides: “The Secretary shall not designate as critical habitat any lands or other geographic areas owned or controlled by the Department of Defense, or designated for its use, that are subject to an integrated natural resources management plan prepared under section 101 of the Sikes Act (16 U.S.C. 670a), if the Secretary determines in writing that such plan provides a benefit to the species for which critical habitat is proposed for designation.”

There are no Department of Defense lands with a completed INRMP within the proposed critical habitat designation for *Chromolaena frustrata*.

Exclusions

Application of Section 4(b)(2) of the Act

Section 4(b)(2) of the Act states that the Secretary must designate and make revisions to critical habitat on the basis of the best available scientific data after taking into consideration the economic impact, national security impact, and any other relevant impact of specifying any particular area as critical habitat. The Secretary may exclude an area from critical habitat if he determines that the benefits of such exclusion outweigh the benefits of specifying such area as part of the critical habitat, unless he determines, based on the best scientific data available, that the failure to designate such area as critical habitat will result in the extinction of the species. In making that determination, the statute on its face, as well as the legislative history, are clear that the Secretary has broad discretion regarding which factor(s) to use and how much weight to give to any factor.

Under section 4(b)(2) of the Act, we may exclude an area from designated critical habitat based on economic impacts, impacts on national security, or any other relevant impacts. In considering whether to exclude a particular area from the designation, we identify the benefits of including the area in the designation, identify the benefits of excluding the area from the designation, and evaluate whether the benefits of exclusion outweigh the benefits of inclusion. If the analysis indicates that the benefits of exclusion outweigh the benefits of inclusion, the Secretary may exercise his discretion to exclude the area only if such exclusion would not result in the extinction of the species.

Economic Impacts

Under section 4(b)(2) of the Act, we consider the economic impacts of designating any particular area as critical habitat. In order to consider economic impacts, we are preparing an economic analysis of the proposed critical habitat designation and related factors.

We will announce the availability of our draft economic analysis as soon as it is completed. During the development of a final designation, we will consider the draft economic analysis, public comments, and other new information related to economic impacts, and as a result areas that were proposed for critical habitat may be excluded from the final critical habitat designation under section 4(b)(2) of the Act and our implementing regulations at 50 CFR 424.19.

National Security Impacts

Under section 4(b)(2) of the Act, we consider whether there are lands where a national security impact might exist. In preparing this proposal, we have determined that none of the lands within the proposed designation of critical habitat for *Chromolaena frustrata* are owned or managed by the Department of Defense, or designated for its use, and, therefore, we anticipate no impact on national security.

Consequently, the Secretary does not intend to exercise his discretion to exclude any areas from the final designation based on impacts on national security.

Other Relevant Impacts

Under section 4(b)(2) of the Act, we consider any other relevant impacts, in addition to economic impacts and impacts on national security. We consider a number of factors, including whether the landowners have developed any HCPs or other management plans for the area, or whether there are conservation partnerships that would be encouraged by designation of, or exclusion of lands from, critical habitat.
In addition, we look at any tribal issues, and consider the government-to-government relationship of the United States with tribal entities. We also consider any social impacts that might occur because of the designation.

In preparing this proposed rule, we have determined that there are currently no HCPs or other management plans that affect *Chromolaena frustrata* or its proposed critical habitat. Furthermore, we are not aware of any potential social impacts that might occur because of the designation. Accordingly, the Secretary does not intend to exercise his discretion to exclude any areas from the final designation based on other relevant impacts.

**Peer Review**

In accordance with our joint policy on peer review published in the *Federal Register* on July 1, 1994 (59 FR 34270), we will seek the expert opinions of at least three appropriate and independent specialists regarding this proposed rule. The purpose of peer review is to ensure that our proposed listing and critical habitat designation are based on scientifically sound data, assumptions, and analyses. We have invited these peer reviewers to comment during this public comment period on our specific proposed rule.

We will consider all comments and information we receive during this comment period on this proposed rule during our preparation of a final determination. Accordingly, the final decision may differ from this proposal.

**Public Hearings**

Section 4(b)(5) of the Act provides for one or more public hearings on this proposal, if requested. Requests must be received within 45 days after the date of publication of this proposed rule in the *Federal Register*. Such requests must be sent to the address shown in the FURTHER INFORMATION CONTACT section. We will schedule public hearings on this proposal, if any are requested, and announce the dates, times, and places of those hearings, as well as how to obtain reasonable accommodations, in the *Federal Register* and local newspapers at least 15 days before the hearing.

**Required Determinations**

*Regulatory Planning and Review (Executive Orders 12866 and 13563)*

Executive Order 12866 provides that the Office of Information and Regulatory Affairs (OIRA) will review all significant rules. The Office of Information and Regulatory Affairs has determined that this rule is not significant.

Executive Order 13563 reaffirms the principles of E.O. 12866 while calling for improvements in the nation’s regulatory system to promote predictability, to reduce uncertainty, and to use the best, most innovative, and least burdensome tools for achieving regulatory ends. The executive order directs agencies to consider regulatory approaches that reduce burdens and maintain flexibility and freedom of choice for the public where these approaches are relevant, feasible, and consistent with regulatory objectives. E.O. 13563 emphasizes further that regulations must be based on the best available science and that the rulemaking process must allow for public participation and an open exchange of ideas. We have developed this rule in a manner consistent with these requirements.

*Regulatory Flexibility Act (5 U.S.C. 601 et seq.)*

Under the Regulatory Flexibility Act (RFA; 5 U.S.C. 601 et seq.) as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA; 5 U.S.C. 801 et seq.), whenever an agency is required to publish a notice of rulemaking for any proposed or final rule, it must prepare and make available for public comment a regulatory flexibility analysis that describes the effects of the rule on small entities (small businesses, small organizations, and small government jurisdictions). However, no regulatory flexibility analysis is required if the head of the agency certifies the rule will not have a significant economic impact on a substantial number of small entities. The SBREFA amended the RFA to require Federal agencies to provide a certification statement of the factual basis for certifying that the rule will not have a significant economic impact on a substantial number of small entities. According to the Small Business Administration, small entities include small organizations such as independent nonprofit organizations; small governmental jurisdictions, including school boards and city and town governments that serve fewer than 50,000 residents; and small businesses (13 CFR 121.201). Small businesses include such businesses as manufacturing and mining concerns with fewer than 500 employees, wholesale trade entities with fewer than 100 employees, retail and service businesses with less than $5 million in annual sales, general and heavy construction businesses with less than $27.5 million in annual business, special trade contractors doing less than $11.5 million in business, and forestry and logging operations with fewer than 500 employees and annual business less than $7 million. To determine whether small entities may be affected, we will consider the types of activities that might trigger regulatory impacts under this designation as well as types of project modifications that may result. In general, the term “significant economic impact” is meant to apply to a typical small business firm’s business operations.

Importantly, the incremental impacts of a rule must be both significant and substantial to prevent certification of the rule under the RFA and to require the preparation of an initial regulatory flexibility analysis. If a substantial number of small entities are affected by the proposed critical habitat designation, but the per-entity economic impact is not significant, the Service may certify. Likewise, if the per-entity economic impact is likely to be significant, but the number of affected entities is not substantial, the Service may also certify.

Under the RFA, as amended, and following recent court decisions, Federal agencies are only required to evaluate the potential incremental impacts of rulemaking on those entities directly regulated by the rulemaking itself, and not the potential impacts to indirectly affected entities. The regulatory mechanism through which critical habitat protections are realized is section 7 of the Act, which requires Federal agencies, in consultation with the Service, to ensure that any action authorized, funded, or carried by the Agency is not likely to adversely modify critical habitat. Therefore, only Federal action agencies are directly subject to the specific regulatory requirement (avoiding destruction and adverse modification) imposed by critical habitat designation. Under these circumstances, it is our position that only Federal action agencies will be directly regulated by this designation. Therefore, because Federal agencies are not small entities, the Service certifies that the proposed critical habitat rule will not have a significant economic impact on a substantial number of small entities.

We acknowledge, however, that in some cases, third-party proponents of the action subject to permitting or funding may participate in a section 7 consultation, and thus may be indirectly affected. We believe it is good policy to assess these impacts if we have sufficient data before us to complete the necessary analysis, whether or not this analysis is strictly required by the RFA. While this regulation would not directly regulate these entities in our draft economic analysis we will conduct a brief evaluation of the potential number...
of third parties participating in consultations on an annual basis in order to ensure a more complete examination of the incremental effects of this proposed rule in the context of the RFA.

In conclusion, we believe that, based on our interpretation of directly regulated entities under the RFA and relevant case law, this designation of critical habitat would only directly regulate Federal agencies, which are not by definition small business entities. Accordingly, we certify that, if promulgated, this designation of critical habitat would not have a significant economic impact on a substantial number of small business entities. Therefore, an initial regulatory flexibility analysis is not required. However, though not necessarily required by the RFA, in our draft economic analysis for this proposal we will consider and evaluate the potential effects to third parties that may be involved with consultations with Federal action agencies related to this action.

Energy Supply, Distribution, or Use—Executive Order 13211

Executive Order 13211 (Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use) requires agencies to prepare Statements of Energy Effects when undertaking certain actions. All proposed units are remote from energy supply, distribution, or use activities. We do not expect that if made final, this designation of critical habitat would significantly affect energy supplies, distribution, or use. Therefore, this action is not a significant energy action, and no Statement of Energy Effects is required. However, we will further evaluate this issue as we conduct our economic analysis, and review and revise this assessment as warranted.

Unfunded Mandates Reform Act (2 U.S.C. 1501 et seq.)

In accordance with the Unfunded Mandates Reform Act (2 U.S.C. 1501 et seq.), we make the following findings:

(1) This rule would not produce a Federal mandate. In general, a Federal mandate is a provision in legislation, statute, or regulation that would impose an enforceable duty upon State, local, or tribal governments with two exceptions. It excludes “a condition of Federal assistance.” It also excludes “a duty arising from participation in a voluntary Federal program,” unless the regulation “relates to a then–existing Federal program under which $500,000,000 or more is provided annually to State, local, and tribal governments under entitlement authority,” if the provision would “increase the stringency of conditions of assistance” or “place caps upon, or otherwise decrease, the Federal Government’s responsibility to provide funding,” and the State, local, or tribal governments “lack authority” to adjust accordingly. At the time of enactment, these entitlement programs were: Medicaid; Aid to Families with Dependent Children work programs; Child Nutrition; Food Stamps; Social Services Block Grants; Vocational Rehabilitation State Grants; Foster Care, Adoption Assistance, and Independent Living; Family Support Welfare Services; and Child Support Enforcement. “Federal private sector mandate” includes a regulation that “would impose an enforceable duty upon the private sector, except (i) a condition of Federal assistance or (ii) a duty arising from participation in a voluntary Federal program.”

The designation of critical habitat does not impose a legally binding duty on non-Federal Government entities or private parties. Under the Act, the only regulatory effect is that Federal agencies must ensure that their actions do not destroy or adversely modify critical habitat under section 7. While non-Federal entities that receive Federal funding, assistance, or permits, or that otherwise require approval or authorization from a Federal agency for an action, may be indirectly impacted by the designation of critical habitat, the legally binding duty to avoid destruction or adverse modification of critical habitat rests squarely on the Federal agency. Furthermore, to the extent that non-Federal entities are indirectly impacted because they receive Federal funding or participate in a voluntary Federal aid program, the Unfunded Mandates Reform Act would not apply, nor would critical habitat shift the costs of the large entitlement programs listed above onto State governments.

(2) We do not believe that this rule would significantly or uniquely affect small governments because the areas proposed for critical habitat designation are not owned by one Federal, State, or City government. None of the government entities fit the definition of “small governmental jurisdiction.” Therefore, a Small Government Agency Plan is not required. However, we will further evaluate this issue as we conduct our economic analysis, and review and revise this assessment if appropriate.

Takings—Executive Order 12630

In accordance with Executive Order 12630 (Government Actions and Interference with Constitutionally Protected Private Property Rights), we have analyzed the potential takings implications of designating critical habitat for Chromolaena frustrata in a takings implications assessment. Critical habitat designation does not affect landowner actions that do not require Federal funding or permits, nor does it preclude development of habitat conservation programs or issuance of incidental take permits to permit actions that do require Federal funding or permits to go forward. The takings implications assessment concludes that this designation of critical habitat for Chromolaena frustrata would not pose significant takings implications for lands within or affected by the designation.

Federalism—Executive Order 13132

In accordance with Executive Order 13132 (Federalism), this proposed rule does not have significant Federalism effects. A federalism impact summary statement is not required. In keeping with Department of the Interior and Department of Commerce policy, we requested information from, and coordinated development of, this proposed critical habitat designation with appropriate State resource agencies in Florida. If finalized, the designation of critical habitat in areas occupied by Chromolaena frustrata may impose nominal additional regulatory restrictions to those currently in place and, therefore, may have little incremental impact on State and local governments and their activities. The designation may have some benefit to these governments because the areas that contain the physical or biological features essential to the conservation of the species are more clearly defined, and the elements of the features of the habitat necessary to the conservation of the species are specifically identified. This information does not alter where and what federally sponsored activities may occur. However, it may assist local governments in long-range planning (rather than having them wait for case—by—case section 7 consultations to occur).

Where State and local governments require approval or authorization from a Federal agency for actions that may
affect critical habitat, consultation under section 7(a)(2) would be required. While non-Federal entities that receive Federal funding, assistance, or permits, or that otherwise require approval or authorization from a Federal agency for an action, may be indirectly impacted by the designation of critical habitat, the legally binding duty to avoid destruction or adverse modification of critical habitat rests squarely on the Federal agency.

**Civil Justice Reform—Executive Order 12988**

In accordance with Executive Order 12988 (Civil Justice Reform), the Office of the Solicitor has determined that the rule does not unduly burden the judicial system and that it meets the requirements of sections 3(a) and 3(b)(2) of the Order. We have proposed designating critical habitat in accordance with the provisions of the Act. This proposed rule uses standard property descriptions and identifies the elements of physical or biological features essential to the conservation of *Chromolaena frustrata* within the designated areas to assist the public in understanding the habitat needs of the species.

**Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.)**

This rule does not contain any new collections of information that require approval by OMB under the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.). This rule will not impose recordkeeping or reporting requirements on State or local governments, individuals, businesses, or organizations. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number.

**National Environmental Policy Act (42 U.S.C. 4321 et seq.)**

We have determined that environmental assessments and environmental impact statements, as defined under the authority of the National Environmental Policy Act (NEPA; 42 U.S.C. 4321 et seq.), need not be prepared in connection with listing a species as endangered or threatened under the Act. We published a notice outlining our reasons for this determination in the Federal Register on October 25, 1983 (48 FR 49244).

It is also our position that, outside the jurisdiction of the U.S. Court of Appeals for the Tenth Circuit, we do not need to prepare environmental analyses pursuant to NEPA in connection with designating critical habitat under the Act. We published a notice outlining our reasons for this determination in the Federal Register on October 25, 1983 (48 FR 49244). This position was upheld by the U.S. Court of Appeals for the Ninth Circuit (Douglas County v. Babbitt, 46 F.3d 1495 (9th Cir. 1995), cert. denied 516 U.S. 1042 (1996)).

**Clarity of the Rule**

We are required by Executive Orders 12866 and 12988 and by the Presidential Memorandum of June 1, 1998, to write all rules in plain language. This means that each rule we publish must:

1. Be logically organized;
2. Use the active voice to address readers directly;
3. Use clear language rather than jargon;
4. Be divided into short sections and sentences; and
5. Use lists and tables wherever possible.

If you feel that we have not met these requirements, send us comments by one of the methods listed in the ADDRESSES section. To better help us revise the rule, your comments should be as specific as possible. For example, you should tell us the numbers of the sections or paragraphs that are unclearly written, which sections or sentences are too long, the sections where you feel lists or tables would be useful, etc.

**Government-to-Government Relationship With Tribes**

In accordance with the President’s memorandum of April 29, 1994 (Government-to-Government Relations with Native American Tribal Governments; 59 FR 22951), Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments), and the Department of the Interior’s manual at 512 DM 2, we readily acknowledge our responsibility to communicate meaningfully with recognized Federal Tribes on a government-to-government basis. In accordance with Secretarial Order 3206 of June 5, 1997 (American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act), we readily acknowledge our responsibilities to work directly with tribes in developing programs for healthy ecosystems, to acknowledge that tribal lands are not subject to the same controls as Federal public lands, to remain sensitive to Indian culture, and to make information available to tribes.

We determined that there are no tribal lands that are currently occupied by *Chromolaena frustrata* that contain the features essential for conservation of the species, and no tribal lands unoccupied by *C. frustrata* that are essential for the conservation of the species. Therefore, we are not proposing to designate critical habitat for *C. frustrata* on tribal lands.

Endangered and threatened species, Exports, Imports, Reporting and recordkeeping requirements, Transportation.

**Proposed Regulation Promulgation**

Accordingly, we propose to amend part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations, as set forth below:

**PART 17—[AMENDED]**

1. The authority citation for part 17 continues to read as follows:

2. Amend §17.12 (h) by adding entries for *Chromolaena frustrata, Consoloea coralicola,* and *Harrisia aboriginum,* in alphabetical order under FLOWERING PLANTS, to the List of Endangered and Threatened Plants, to read as follows:

   **§17.12 Endangered and threatened plants.**

   *(h) * *

   *(h) * * *
3. Amend §17.96(a) by adding an entry for “Chromolaena frustrata (Cape Sable Thoroughwort)” in alphabetical order under the family Asteraceae, to read as follows:

§17.96 Critical habitat—plants.

(a) Flowering plants.

Family Asteraceae: Chromolaena frustrata (Cape Sable Thoroughwort)

(1) Critical habitat units for Chromolaena frustrata are depicted for Miami-Dade and Monroe Counties, Florida, on the maps below.

(2) Within these areas, the primary constituent elements of the physical or biological features essential to the conservation of Chromolaena frustrata are:

(i) Areas of upland habitats consisting of coastal berm, coastal rock barren, rockland hammocks, and buttonwood forest.

(A) Coastal berm habitat contains:

(1) Open to semi-open canopy, subcanopy, and understory;

(2) Substrate of coarse, calcareous, storm-deposited sediment; and

(3) A plant community of predominately native vegetation and either no competitive nonnative, invasive plant species or such species in quantities low enough to have minimal effect on survival of Chromolaena frustrata. Coastal berm habitat has a subcanopy vegetated by Conocarpus, Lycium, Gossypium, Sideroxylon, Pinheccellobium, Suriana, Randia, Metopium, Acanthocereus, Maytenus, Opuntia, Agave, Bursera, and Eugenia; and an understory vegetated by Evolvulus, Cienfuegosia, Indigofera, Borrichia, Sarcocornia, Batis, Leptochloa, Paspalidium, Monanthochloa, Distichlis, Sporobolus, and Fimbristylis.

(B) Rockland hammock habitat contains:

(1) Canopy gaps and edges with an open to semi-open canopy, subcanopy, and understory;

(2) Substrate with a thin layer of highly organic matter that accumulates on top of the underlying limestone; and

(3) A plant community of predominately native vegetation and either no competitive nonnative, invasive plant species or such species in quantities low enough to have minimal effect on survival of Chromolaena frustrata. Rockland hammock has a canopy vegetated by Bursera, Lysiloma, Simarouba, Krugiodendron, Ocotea, Piscidia, Swietenia, Sideroxylon, Exothea, Ficus, Cocclobola, Metopium, Conocarpus, Guapira, and Pisonia; a subcanopy vegetated by Eugenia, Thrinax, Amyris, Ardisia, Psychotria, Chrysophyllum, Sabal, Guaiacum, Ximenia, and Colubrina; and an understory vegetated by Zamia, Acanthocereus, and Opisulusmenes.

(D) Buttonwood forest habitat contains:

(1) Open to semi-open canopy and understory;

(2) Substrate with calcareous marl muds, calcareous sands, or limestone rock; and

(3) A plant community of predominately native vegetation and either no competitive nonnative, invasive plant species or such species in quantities low enough to have minimal effect on survival of Chromolaena frustrata. Buttonwood forest has a canopy vegetated by Conocarpus, and an understory vegetated by Borrichia, Lycium, and Limonium.

(ii) A disturbance regime, due to the effects of strong winds or salt-water inundation from storm surge or intermittent tidal inundation, that creates canopy disruption in all habitats listed above in (1).

(iii) Habitats that are connected and of sufficient area to sustain viable populations in all habitats listed above in (1).

(3) Critical habitat does not include manmade structures (such as buildings, aqueducts, runways, roads, and other paved areas) and the land on which they are located exists within the legal boundaries on the effective date of this rule.

(4) Critical habitat map units. Unit maps were developed using ESRI ArcGIS mapping software along with various spatial data layers. ArcGIS was also used to calculate the projection used in mapping and calculating distances and locations within the units was North American Albers Equal Area Conic, NAD 83. The maps in this entry, as modified by any accompanying regulatory text, establish the boundaries of the critical habitat designation. The coordinates or plot points or both on
which each map is based are available to the public at the Service’s internet site, (http://www.fws.gov/verobeach/), the Federal eRulemaking Portal (http://www.regulations.gov at Docket No. FWS–R4–ES–2012–0076) and at the field office responsible for this designation. You may obtain field office location information by contacting one of the Service regional offices, the addresses of which are listed at 50 CFR 2.2.
