Table of Wavenumbers

Charles DeWitt Coleman, William R. Bozman, and William F. Meggers

A two-volume table for converting wavelengths in standard air to wavenumbers in vacuum was computed by using the equation $\sigma_{vac} = 1/(n\lambda_{air})$, where n was computed from Edlén's 1953 equation for the refractive index of air. Wavenumbers are given to the nearest 0.001 K (cm^{-1}) for wavelengths from 2000 to 7000 Å in volume I, and 7000 Å to 1000 μ in volume II. Proportional tables are given for linear interpolation between entries of λ . Also included are the vacuum increase in wavelength, $(n-1)$; and the refractivity of standard air in the form $(n-1) \times 1000$.

1. Introduction

In 1883, W. N. Hartley [1]¹ discovered empirically that constant differences occurred between spectral lines if the latter were mapped according to their *inverse wavelengths*, or their *oscillation frequencies*, instead of in the usual manner on wavelength scales. Oscillation frequencies, $\nu = c/\lambda$, (c is the velocity of light, and λ the wavelength) are ungainly numbers (of the order of 10^{14}), so inverse wavelengths, that is the number of waves per centimeter, have been preferred. It was recognized that wavelengths measured in air were variously affected by atmospheric refractivity, and real numerical relations between wavenumbers could be found only if the measured wavelengths were corrected to vacuum values by multiplying each wavelength, λ , by the refractive index of air, n , appropriate for that wavelength. During three decades a considerable number of regularities were thus found in relatively simple atomic spectra; it was shown that in a particular spectrum the wavenumbers of a large number of lines could be represented as differences between a smaller number of derived quantities called spectral terms, but the physical meaning of this remained obscure.

In 1913 Niels Bohr suggested that the derived spectral terms represented stationary atomic energy states, and that a spectral line originated in a transition between two such states according to $E_1 - E_2 = h\nu$, in which E_1 and E_2 are the initial and final atomic energies involved and h is Planck's constant. In little more than a decade this suggestion developed into the quantum theory of spectra as it is known today. All atomic spectra became amenable to interpretation, and during the past 35 years, thousands of scientific papers have been published on atomic energy levels derived from analyses of optical spectra. The quantum interpretation of spectra led to deductions of the electronic structure of

atoms and ions, and its extension to spectral hyperfine structure disclosed many properties of atomic nuclei, thus speeding the arrival of this atomic-nuclear age.

Since the observational data consisted mainly of wavelengths measured in standard air, all required conversion to vacuum. For this purpose, W. F. Meggers and C. G. Peters [2] provided a dispersion formula based upon index of refraction measurements for wavelengths between 2200 and 9000 Å. But the calculation of the refractive index, n , for each wavelength, λ , the multiplication of these two quantities, $n\lambda$, and the computation of the reciprocal of this product to obtain wavenumbers, $\sigma = 1/n\lambda$, cost much time and labor. In order to save most of this cost, H. Kayser, in 1925, produced his *Tabelle der Schwingungszahlen* [3] based on the above-mentioned dispersion formula. That table was computed with an 8-place desk calculator and gave 8-figure reciprocals of wavelengths (converted to vacuum) at intervals of 0.1 Å between 2000 and 7000 Å, and intervals of 1 Å between 7000 and 10000 Å. Proportional tables enabled the user to take account of hundredths and thousandths of an angstrom. This table was revised by W. F. Meggers and reprinted in 1944 [3]. These two editions of Kayser's table of wavenumbers have served spectroscopic sciences over a third of a century, minimizing the labor of converting wavelengths in air to wavenumbers in vacuum, essential for all work dealing with the energy levels of atoms and molecules.

In 1950, W. F. Meggers and K. G. Kessler [4] accurately measured relative values of ^{198}Hg wavelengths to eight figures and showed that the Meggers and Peters dispersion formula was slightly in error when rigidly tested by the combination principle of spectroscopy.

2. Edlén's Formula

In 1952 the Joint Commission for Spectroscopy recommended [5] the use of a dispersion formula synthesized by B. Edlén [6] who combined the index measurements of three independent observers (H. Barrell and J. E. Sears [7]; J. Koch [8]; W. Traub [9]) and thus derived a new formula which satisfied the combination principle when tested with ^{198}Hg wavelengths. According to Edlén's formula, the Kayser *Tabelle der Schwingungszahlen* gives wavenumbers accurately at 2500 Å, but requires corrections of +8 units in the seventh figure of wavenumbers for 2000 Å, -3 units for 3500 Å, and -0.2 units for 10000 Å.

Because of recent improvements in spectroscopic light sources, standard wavelengths, and spectrographic dispersions, wavelengths now can be measured more accurately and it was decided to produce from Edlén's formula a new, expanded, and extended table for obtaining the wavenumber σ from the wavelength λ . Since a table of this size and precision would be nearly impossible to compute by desk calculator, the computations were performed by an electronic computer.

A multiphase electronic computer program had been used for the automatic reduction of spectroscopic data (description of the program in preparation). This program had been written to search for new atomic energy levels utilizing measured spectrum lines and previously identified atomic energy levels. The program included the use of Edlén's formula to compute the wavenumbers of the given lines; this portion of the program code was modified to set up the wavelengths in chosen increments and compute their wavenumbers. The index of refraction of air, and the difference $(\lambda_{vac} - \lambda_{air})$ were computed for each wavelength given in the left-hand column of the present table. The wavenumbers were computed by an iterative method by using the equation $\sigma_{vac} = 1/(n\lambda_{air})$ where n , the index of refraction of air, is a function of σ_{vac} . Iterations continued until successive values of the wavenumber (for that wavelength) differed by less than one part in a hundred million. When the complete page of the table was computed and set up in page format, it was written on a magnetic tape for subsequent listing on a tape-controlled printer. Printing plates were photographically produced from these master pages.

¹ Figures in brackets indicate the literature references on page V.

Edlén's formula for the refractive index of standard (dry) air at 15° C and 760 mm Hg pressure, upon which this table is based, is:

$$n=1+6432.8 \times 10^{-8} + \frac{2,949,810}{146 \times 10^8 - \sigma^2} + \frac{25,540}{41 \times 10^8 - \sigma^2}$$

in which σ is the vacuum wavenumber in kaysers (K), that is, waves per centimeter in a vacuum, ($K = \text{cm}^{-1}$). This formula appears to give relative values of the index of refraction with an accuracy of $\pm 1 \times 10^{-8}$ for any wavelength greater than 2000 Å.

Since this formula was derived from measurements of n for λ shorter than 6439 Å, it was somewhat doubtful if it could be extrapolated reliably to 10000 Å and beyond. Fortunately, n has

3. Extension of Tables

Although the present limit of spectral observation by photography is only slightly above 10000 Å, recent improvements in infrared detectors and infrared spectrographs have greatly extended the range in which accurate measurements of longer waves can be made. The infrared is very important in atomic spectroscopy and even more so in molecular spectroscopy. There are, therefore, four good reasons for publishing this new table of wavenumbers: (1) It is based on a new formula that satisfies the combination principle; (2) increased accuracy in wavelength measurements justifies a 10-fold expansion of this table over Kayser's; (3) improvements in observing infrared radiation requires its extension beyond 10000 Å; and (4) the human labor of preparing this table can be largely circumvented by programming an electronic computer to carry out the calculations and write the table on magnetic tape.

This table is designed to give wavenumbers directly for all wavelengths between 2000 Å and 10000000 Å = 1000 μ = 1 mm. The left-hand column of the table contains the wavelengths, λ , in standard air, given in angstroms from 2000 Å to 10000 Å, and in microns from 10000 Å = 1 μ to 1000 μ = 1 mm. The main body of the table contains the corresponding wavenumbers, $\sigma = 1/n\lambda$, in vacuum. Proportional tables at the bottom of each page are to be used for linear interpolation between successive entries of σ .

The extreme right-hand column gives $\lambda (n-1)$ which is the amount to be added to λ_{air} to obtain λ_{vac} , and the second column from the right shows $(n-1) \times 1,000$, where n is the refractive index of standard air for the wavelength appearing in the left-hand column of the table.

Because of its range and size, this table of wavenumbers is in two volumes, Volume I presenting wavenumbers for all wavelengths between 2000 and 7000 Å, and Volume II giving wavenumbers for all wavelengths from 7000 Å to 10000000 Å = 1 mm. In some cases Volume I may suffice for ionic spectra, and in others Volume II may be adequate for molecular spectra, but in general both volumes will be needed to cover the entire range of spectral wavelengths measured in standard air.

The present table for obtaining vacuum wavenumbers from wavelengths in air applies to all optical wavelengths that are determined by interpolation between internationally adopted standard wavelengths with values valid for standard air at a temperature of 15° C and a pressure of 760 mm Hg. If the prism or grating spectrograms are made under other atmospheric conditions this procedure is still permissible provided the spectrum containing standards is simultaneously superposed on the unknown spectrum (in the same grating order). However, the effect of the temperature and pressure of the air must be taken into account in all accurate comparisons of wavelengths made either by the overlapping-orders coincidence method with diffraction gratings, or with interferometers. The wavelength correction required on account of nonstandard air density is $\lambda_0 - \lambda_{\text{meas}} = \lambda_0 (n_0 - n'_0) [(d - d_0)/d_0]$, where d represents air density, n refractive index, the subscript 0 indicates normal air, and the prime an index for a standard wavelength. W. F. Meggers and C. G. Peters [13] provided two tables to obviate the calculation of this

recently been measured for λ greater than 10000 Å; in all cases these measurements confirm Edlén's formula. Thus, measurements of the dispersion of air from 3651 to 15300 Å by D. H. Rank et al. [10] "show that within experimental error, which is very small, the Edlén formula is completely correct over the wavelength region investigated". Also new measurements of the refractivity of air in the near infrared by D. J. Schuster and E. R. Peck [11] lead to the conclusion "that these separate absolute measurements show no evidence of failure of Edlén's formula up to a wavelength of 2 μ ". Finally, L. Essen [12] pointed out that "the Edlén formula fits present measurements in the microwave region within the errors of observation".

correction, one for the density factor $(d - d_0)/d_0$, and another to give the appropriate wavelength correction for any density factor and the wavelength interval between the standard and measured line. These tables have been recalculated and extended over a greater range with an electronic computer; they are presented here as tables 1 and 2. Table 1 gives air-density factors for temperatures from 9° C to 35° C, and pressures from 780 to 485 mm Hg (to serve spectroscopists working on high mountains). Table 2 has been recomputed and is based on the green radiation from ^{198}Hg with a wavelength of 5460.7529 Å in standard air; it provides the proper correction for any wavelength relative to 5460 Å on account of air-density departures from standard.

For wavelengths measured relative to standards other than 5460 Å, the following formula still applies: $\lambda_0 - \lambda_{\text{meas}} = \lambda_0 (n_0 - n'_0) [(d - d_0)/d_0]$. $(d - d_0)/d_0$ is taken from table 1 and n_0 and n'_0 are now taken from table 3.

The above tables and formulas pertain to the calculation of the wavelength shift due to a density change from standard air, where a wavelength λ_m is measured relative to a standard line. If direct calculation is desired, the following formula from Edlén can be used, relative to any desired standard line:

$$\lambda - \lambda_m = (\Delta\lambda_m - \Delta\lambda_s \cdot \lambda_m / \lambda_s) \left(\frac{0.0013882p}{1 + 0.00367t} - 1 \right),$$

where λ is the value of the measured line at standard temperature and pressure, λ_m is the wavelength as measured in nonstandard air, $\Delta\lambda_m$ is the vacuum correction: $\Delta\lambda_m = \lambda_v - \lambda$, which is the wavelength difference of the measured line in a vacuum and in normal air, as given in the right-hand column of table 1; λ_s is the vacuum correction for the standard wavelength (e.g., the vacuum correction for the green Hg 5460 Å line is 1.5175 Å); p is the atmospheric pressure in millimeters of Hg; and t is the temperature in ° C.

For high-precision work, an additional correction must be made for water vapor:

$$\lambda - \lambda_m = [+0.63(1 + \lambda_m / \lambda_s)(\sigma_m - \sigma_s)f] \times 10^{-9},$$

where λ is in angstroms, f is in millimeters (Hg) of water vapor, and σ is in cm^{-1} . This formula, based on the measurements of Barrell and Sears [7] is the same as that given by Edlén [6] except that σ is given here in cm^{-1} instead of μ^{-1} .

To obtain the actual wavelength of any line, including any standard line, at conditions other than standard air, for applications such as metrology, the following equation adapted from Barrell and Sears may be used:

$$(n_{t,p,f} - 1)10^6 = \left[\frac{(n-1)10^6}{720.8826} \right] \times \left[\frac{p\{1 + (1.049 - 0.0157t)p \times 10^{-6}\}}{1 + 0.003661t} \right] - \left[0.0624 - \frac{0.0680}{\lambda^2} \right] \frac{f}{1 + 0.003661t}$$

Where $n_{t,p,f}$ is the index at nonstandard temperature, pressure and water vapor, and n is the index in standard air as given in table 1. Barrell and Sears state that this equation is applicable for the

ranges $t=10-30^\circ\text{C}$ and $p=720-800\text{ mm}$. Their measurements for water vapor covered the range from 4358 to 6438 Å. The water vapor f is measured in millimeters (Hg) pressure, and the wavelength λ is in angstroms. T. Masui [14] also gives a general formula for calculating the corrections to Edlén's formula at nonstandard conditions:

$$(n_{t,p,f,k}-1)=(n-1)+C/[1+0.00348(t-15)]$$

$$\text{where } C=(0.9845+5.75\sigma^2\times 10^{-11})(t-15)$$

$$+(0.3588+2.17\sigma^2\times 10^{-11})(p-760)$$

$$-(0.052-4.5\sigma^2\times 10^{-12})f$$

$$+(0.0145+1.1\sigma^2\times 10^{-12})(k-3)$$

where the temperature, t , is in $^\circ\text{C}$; the pressure, p is in millimeters (Hg); the water vapor, f , is in millimeters (Hg); and, k , the CO_2 content is in hundredths of a percent. Masui states that this formula is applicable to the visible spectrum near standard conditions.

Also included, in appendix, section 5, are tested formulas for interpolating wavelengths in prismatic spectrograms and in grating spectrograms. The direct evaluation of three constants in the Hartmann dispersion formula is especially convenient because it avoids struggles with the solution of simultaneous equations.

We wish to acknowledge the assistance given by all concerned with this publication, and especially to K. G. Kessler for many helpful suggestions from the very beginning; to J. L. Tech, who encouraged us to start the project; to P. J. O'Hara, G. M. Galler, and V. Dantzler who operated the electric computer; to B. F. Scribner for assistance and advice especially during preparation of the manuscript; to E. K. Plyler for suggestions concerning the infrared portion of the table. We are especially indebted to Bengt Edlén for advice, and for a copy of his mimeographed (October 1958) "Vacuum Corrections for Wavelengths from 2000 Å to 50000 Å," which in this range served as a check on our machine calculations. The cooperation and careful work of the Publications Section concerning many details of publication are also gratefully acknowledged.
