The National Institute of Standards and Technology[1] was established by an act of Congress on March 3, 1901. The Institute's overall goal is to strengthen and advance the Nation's science and technology and facilitate their effective application for public benefit. To this end, the Institute conducts research to assure international competitiveness and leadership of U.S. industry, science and technology. NIST work involves development and transfer of measurements, standards and related science and technology, in support of continually improving U.S. productivity, product quality and reliability, innovation and underlying science and engineering. The Institute's technical work is performed by the National Measurement Laboratory, the National Engineering Laboratory, the National Computer Systems Laboratory, and the Institute for Materials Science and Engineering.

The National Measurement Laboratory

Provides the national system of physical and chemical measurement; coordinates the system with measurement systems of other nations and furnishes essential services leading to accurate and uniform physical and chemical measurement throughout the Nation's scientific community, industry, and commerce; provides advisory and research services to other Government agencies; conducts physical and chemical research; develops, produces, and distributes Standard Reference Materials; provides calibration services; and manages the National Standard Reference Data System. The Laboratory consists of the following centers:

- Basic Standards[2]
- Radiation Research
- Chemical Physics
- Analytical Chemistry

The National Engineering Laboratory

Provides technology and technical services to the public and private sectors to address national needs and to solve national problems; conducts research in engineering and applied science in support of these efforts; builds and maintains competence in the necessary disciplines required to carry out this research and technical service; develops engineering data and measurement capabilities; provides engineering measurement traceability services; develops test methods and proposes engineering standards and code changes; develops and proposes new engineering practices; and develops and improves mechanisms to transfer results of its research to the ultimate user. The Laboratory consists of the following centers:

- Computing and Applied Mathematics
- Electronics and Electrical Engineering[2]
- Manufacturing Engineering
- Building Technology
- Fire Research
- Chemical Engineering[3]

The National Computer Systems Laboratory

Conducts research and provides scientific and technical services to aid Federal agencies in the selection, acquisition, application, and use of computer technology to improve effectiveness and economy in Government operations in accordance with Public Law 89-306 (40 U.S.C. 759), relevant Executive Orders, and other directives; carries out this mission by managing the Federal Information Processing Standards Program, developing Federal ADP standards guidelines, and managing Federal participation in ADP voluntary standardization activities; provides scientific and technological advisory services and assistance to Federal agencies; and provides the technical foundation for computer-related policies of the Federal Government. The Laboratory consists of the following divisions:

- Information Systems Engineering
- Systems and Software Technology
- Computer Security
- Systems and Network Architecture
- Advanced Systems

The Institute for Materials Science and Engineering

Conducts research and provides measurements, data, standards, reference materials, quantitative understanding and other technical information fundamental to the processing, structure, properties and performance of materials; addresses the scientific basis for new advanced materials technologies; plans research around cross-cutting scientific themes such as nondestructive evaluation and phase diagram development; oversees Institute-wide technical programs in nuclear reactor radiation research and nondestructive evaluation; and broadly disseminates generic technical information resulting from its programs. The Institute consists of the following divisions:

- Ceramics
- Fracture and Deformation[3]
- Polymers
- Metallurgy
- Reactor Radiation

[1]Headquarters and Laboratories at Gaithersburg, MD, unless otherwise noted; mailing address Gaithersburg, MD 20899.
[2]Some divisions within the center are located at Boulder, CO 80303.
[3] Located at Boulder, CO, with some elements at Gaithersburg, MD.

PROPERTIES OF LENNARD-JONES MIXTURES AT VARIOUS TEMPERATURES AND ENERGY RATIOS WITH A SIZE RATIO OF TWO

M. L. Huber and J. F. Ely

Thermophysics Division
National Institute of Standards and Technology
Boulder, Colorado 80303

In this work we present the results of molecular dynamics computer simulations for binary Lennard-Jones mixtures with a size ratio of two. A total of 84 state points were investigated, at seven compositions ranging from 5 percent to 95 percent of the small molecule, energy ratios from 0.5 to 3.0, and three reduced temperatures. In addition to the thermodynamic results, we present extensive tabular data for the radial distribution functions, local compositions and the direct correlation functions. We also discuss several theories of dense fluid mixtures and give a new approximation for the radial distribution function of a pair in a mixture, which we call the modified mean density approximation. The predictions of various thermodynamic quantities from the different liquid mixture models are compared with simulation results. For mixtures with large size differences, the modified mean density approximation was found to be competitive with first order, Lee-Levesque type statistical mechanical perturbation theory.

Key words: computer simulation; Lennard-Jones mixtures; mean density approximation; molecular dynamics

1. Introduction

The design of chemical process unit operations equipment requires detailed knowledge of the thermophysical properties of fluids and fluid mixtures. In order to meet these design needs, accurate predictive models are necessary, especially for emerging technologies such as enhanced oil recovery, CO_2-rich gas processing, supercritical extraction, biotechnology and coal-based feedstock chemical processing. These technologies typically involve materials which are not well represented in the current experimental data base or which involve a region of fluid behavior which is difficult if not impossible to study in a controlled laboratory environment.

A problem which touches on all of the applications mentioned above is that of predicting the properties of mixtures which contain molecules with large size differences. Previous studies have shown that systems such as these exhibit substantial deviations from most, if not all, theoretically based corresponding states models for fluid thermophysical properties. In this report we present the results of our investigations of the cause of these failures. We have chosen to limit our study to systems whose components obey the Lennard-Jones (LJ) 6-12 potential function. This limitation enables us to focus on the mixture physics rather than on the

form of the intermolecular potential function and related deviations from pure fluid corresponding states. We conjecture that any valid results obtained for these systems will also be applicable to real fluids; that is, if we capture the basic physics of the system, the physics will scale to more complex systems.

There are two main goals of this work. One goal is to extend the composition, size and energy ratio ranges of computer simulation data for Lennard-Jones mixtures. We view this information as being essential if one wishes to develop molecularly based theories of fluid mixtures. Computer simulation studies of LJ 6-12 mixtures have appeared in the literature; however, most previously reported data are for equimolar mixtures of molecules with relatively small size ratios.

The second goal of this work is to develop an improved analytic approximation for mixture radial distribution functions. Once this approximation is in hand, it will be possible to develop new predictive models for the properties of mixtures exhibiting large size differences from rigorous statistical mechanical relations.

A basic outline of the contents of this report is as follows. In section 2 we describe our molecular dynamics computer simulation technique and results for Lennard-Jones mixtures with a size ratio of two. We present extensive tables of the radial distribution functions (RDF), local compositions, and plots of the radial distribution functions obtained from the simulations. In addition, we report how we obtained the direct correlation functions (DCF) for the mixtures from the simulation radial distribution functions and present the DCF's in tabular form. In section 3 we discuss several important theories of dense fluid mixtures including the van der Waals one fluid theory (VDW-1), the mean density approximation (MDA), the hard sphere expansion theory (HSE) and the Lee-Levesque first order statistical mechanical perturbation theory. We also present a new approximation for radial distribution functions in mixtures, the modified mean density approximation (MMDA). In section 4 we compare the predictions of these theories with our own MD simulation results, as well as with computer simulation results found in the technical literature.

2. Computer Simulation Studies

During the past few years, there has been great interest in developing more accurate corresponding states theories for fluid mixtures by using

molecular theory. This is especially true for systems which exhibit large differences in size or polarity among the mixture components. One approach to this problem focuses on the development of local composition models, which combine a microscopic intuitive picture of fluid structure with a semiempirical equation of state. In this type of model the local compositions are obtained theoretically from the particle coordination numbers n_{ij} where

$$n_{ij}(L_{ij}^c) = 4\pi\rho x_i \int_0^{L_{ij}^c} g_{ij}\,(r;\{\rho_k\},T;\{\epsilon_{kl}\},\{\sigma_{kl}\},\ldots)\; r^2 dr. \qquad (1)$$

The definition of the local composition X_{ij} of a particle of type i about a central molecule of type j with a cutoff parameter L_{ij}^c is

$$X_{ij} = \frac{n_{ij}(L_{ij}^c)}{\sum_{k=1}^{M} n_{kj}(L_{kj}^c)} \qquad (2)$$

In eq (1), ρ is the bulk density, x_i is the mole fraction of i in the mixture, and g_{ij} is the radial distribution function for the ij pair. It is proportional to the probability of finding a molecule of type i a distance r from a central molecule of type j in the mixture. Generally, the radial distribution function depends upon the set of component number densities $\{\rho_k\}$, the temperature T, and the complete set of intermolecular potential parameters $\{\epsilon_{kl}\}$ $\{\sigma_{kl}\}$,..., for all of the M components in the mixture. One of the main problems with the local composition approach is the definition of the cutoff parameter L^c_{ij}. The local compositions obtained from eq (2) are a strong function of this parameter.

An alternate microscopic approach which avoids having to define the cutoff parameter was proposed by Leland and coworkers [1-3]. In Leland's approach one makes an approximation which directly relates the radial distribution function of a pair in a mixture to that of a hypothetical pure fluid. This approximate distribution function can then be used to derive mixing rules for use in corresponding states models. An example of this

approach is presented in section 3 of this report.

In both of these approaches, detailed information concerning the radial distributions of mixture pairs is essential. In spite of this need, relatively few distribution functions have been reported in the literature; most of those were for equimolar mixtures at small size ratios (which we define as σ_{22}/σ_{11}), generally less than 1.3. There have been several simulation studies of Lennard-Jones 6-12 systems [4-13], but a systematic study covering a wide range of composition at several energy ratios ($\epsilon_{22}/\epsilon_{11}$) for mixtures with large size ratios has never been done.

One of the initial goals of this study was, therefore, to generate an extensive base of radial distribution function and thermodynamic data which could be used to test and evaluate existing and future molecular theories of fluid mixtures. Since it is essential that the intermolecular potential be known in the development of new theories, the only route to this goal was computer simulation.

There are two simulation methods available by which one can obtain mixture properties and radial distribution functions. The first is the Monte Carlo approach where a system of particles is taken through a series of randomly assigned configurations. A given configuration is accepted or rejected on the basis that the configuration space generated is consistent with the probability density of the ensemble chosen. Thermodynamic properties are calculated from configurational averages of the appropriate functions of the intermolecular potential.

In the second method, molecular dynamics, a system of particles is assigned an initial set of positions and momenta. A series of configurations is generated by solving the equations of motion describing the particles. Properties are obtained from time averages in the system. In this work we have used the molecular dynamics method, primarily because the necessary computer programs were already available for pure fluids [14].

2.1 Description of Simulations

The systems investigated in this study were chosen to overlap some of the results of previous investigators [8,9] and to extend the base of calculations to higher temperatures and lower densities. The components of the mixtures interacted with a pairwise additive Lennard-Jones (12-6) potential

$$u_{ij}(r) = 4\epsilon_{ij}[(\sigma_{ij}/r)^{12} - (\sigma_{ij}/r)^{6}] \quad (3)$$

where i and j denote the components, ϵ_{ij} denotes the value of the intermolecular potential depth at the minimum $r_m = 2^{1/6}\sigma_{ij}$, and σ_{ij} is the collision diameter such that $u_{ij}(\sigma_{ij}) = 0$. In these calculations, the smaller molecule was assigned the potential parameters associated with argon, $\sigma_{11} = 0.3405$ nm and $\epsilon_{11}/k_B = 120$ K, where k_B is Boltzmann's constant. In the calculations presented in this report $\sigma_{22}/\sigma_{11} = 2$, $\epsilon_{22}/\epsilon_{11}$ varies from 0.5 to 3.0, and k_BT/ϵ_{11} ranges from 1.0 to 3.0. This is a fairly large size ratio; methane-decane has a size ratio of about 1.8. The densities were chosen such that $p\sigma_{11}^3/\epsilon_{11} \approx 0.5$ ($p \approx 20.9$ MPa). Nominal compositions studied were 5, 10, 25, 50, 75, 90 and 95 mol percent of the small molecule. The unlike pair parameters were calculated from the Lorentz-Berthelot rules

$$\epsilon_{12} = (\epsilon_{11}\epsilon_{22})^{1/2} \quad (4)$$

and

$$\sigma_{12} = (\sigma_{11} + \sigma_{22})/2. \quad (5)$$

2.1.1 Computational Details

The simulations were performed using system sizes ranging from 864 to 2048 particles, depending upon the composition of the mixture. In all cases the system contained at least 102 particles of each component. Hamilton's equations of motion were solved at constant kinetic temperature by imposing a Gaussian thermostat of the form proposed by Evans and Hoover [15-17]. The basic form of the equations of motion for particle i is

$$q_i = \dot{p}_i/m_i \quad (6)$$

and

$$\dot{p}_i = F_i - \lambda p_i. \quad (7)$$

The isothermal constraint λ is found by requiring that the time derivative of the kinetic temperature be identically zero, namely

$$\frac{\partial}{\partial t}\frac{3}{2}NkT = \frac{\partial}{\partial t}\frac{1}{2}\sum \frac{p_i^2}{m_i} = 0$$

or

$$\sum \mathbf{p}_i \cdot \dot{\mathbf{p}}_i = 0. \tag{8}$$

Substituting eq (7) for $\mathbf{p}_i$ into eq (8) and solving for λ one finds

$$\lambda = \sum \mathbf{p}_i \cdot \mathbf{F}_i \; / \; \sum p_i^2 \tag{9}$$

The details of the Hamiltonian and the Gaussian constraint method are discussed in depth by Evans and Morriss [17].

The equations of motion, eqs (6) and (7) are solved using a fourth order Gear predictor-corrector method [18] with an integration time step of $\delta = 0.005\ \sigma_{11}(m_{11}/\epsilon_{11})^{1/2}$, which for the values given previously and an atomic mass corresponding to argon is approximately 10 fs. The simulations were initiated from a fcc crystal with random assignments to the lattice sites. The systems were typically equilibrated for a minimum of 1000 time steps to remove any history of the initial configuration. The intermolecular potential was truncated at $r^c_{ij} = 2.5\ \sigma_{ij}$ and neighbor lists were maintained at varying distances ranging from $2.8\ \sigma_{ij}$ at $T^*(= k_B T/\epsilon_{11}) = 1.0$, to $3.5\ \sigma_{ij}$ at $T^* = 3$. Anywhere from 20,000 to 100,000 equilibrium time steps were generated for each state point. The primary criterion for stopping the simulations was noise in the radial distribution functions (see below) approaching their theoretical values (1/N).

The pressure p and internal energy U were corrected for the truncated potential by assuming that the radial distribution function was identically unity from the potential cutoff distance r_{ij}^c to infinity. The resulting corrections ΔU^{COR} and Δp^{COR} are

$$\frac{\Delta U^{COR}}{N\epsilon_{11}} = 2\pi\rho \sum_i^M \sum_j^M x_i x_j \int_{r^c_{ij}}^{\infty} (u_{ij}/\epsilon_{11})\, r^2\, dr \tag{10}$$

$$= 8\pi\rho^* \sum_i^M \sum_j^M x_i x_j\, \epsilon^*_{ij} \left[\sigma^*_{ij}\right]^3 \left[\frac{1}{9}(\sigma_{ij}/r^c_{ij})^9 - \frac{1}{3}(\sigma_{ij}/r^c_{ij})^3\right]$$

and

$$\frac{\Delta p^{COR}\sigma_{11}^3}{\epsilon_{11}} = -\frac{2\pi\rho^2}{3}\sum_i^M\sum_j^M x_i x_j \sigma_{11}^3 \int_{r_{ij}^c}^{\infty} (u'_{ij}/\epsilon_{11})\, r^3\, dr \qquad (11)$$

$$= \frac{16}{9}\pi(\rho^*)^2 \sum_i^M\sum_j^M x_i x_j \epsilon_{ij}^* \left[\sigma_{ij}^*\right]^3 \left[2(\sigma_{ij}/r_{ij}^c)^9 - 3(\sigma_{ij}/r_{ij}^c)^3\right]$$

where ρ is the molecular number density, and we define the reduced quantities $\rho^* = \rho\sigma_{11}^3$, $\sigma_{ij}^* = \sigma_{ij}/\sigma_{11}$ and $\epsilon_{ij}^* = \epsilon_{ij}/\epsilon_{11}$. We used the cutoff $r_{ij}^c = 2.5\sigma_{ij}$.

The pair correlation functions were determined by sampling the system at a frequency of approximately once every hundred time steps. The step size ΔR_{ij} of the resulting histograms was chosen to be $0.025\sigma_{ij}$. The distribution functions were generated from the resulting histograms using eq (14). In particular, the number of molecules of type j in a spherical shell of thickness ΔR at a distance R from a central molecule of type i is given by

$$N_{ij}(R + \tfrac{1}{2}\Delta R) - N_{ij}(R - \tfrac{1}{2}\Delta R) = 4\pi\rho x_i \int_{R-\frac{1}{2}\Delta R}^{R+\frac{1}{2}\Delta R} g_{ij}(r;\{\rho_k\},T;\{\epsilon_{kl}\},\{\sigma_{kl}\}) r^2 dr$$

$$\equiv \Delta N_{ij}(R). \qquad (12)$$

If ΔR is small, g_{ij} may be approximated as a constant in the integrand and we find that

$$g_{ij}(R) = \frac{\Delta N_{ij}(R)}{(4\pi/3)\rho x_i \Delta R^3\, [3(R/\Delta R)^2 + 1/4]} \qquad (13)$$

Defining R to be $k\Delta R$ and $R_{ij}^* = R/\sigma_{ij} = k(\Delta R/\sigma_{ij}) = k\delta_{ij}$ we find

$$g_{ij}(R_{ij}^*) = \frac{\Delta N_{ij}^*(R_{ij})}{(4\pi/3)\rho^* x_i(\delta_{ij}\sigma_{ij}^*)^3[3k^2 + 1/4]}. \quad (14)$$

2.1.2 Accuracy

The overall accuracy of the simulations is a strong function of the total number of particles and the concentration. In all cases the total energy of the system with the thermostat off was conserved within 0.1 percent per 10,000 time steps. We estimate that the accuracy of the radial distribution functions is better than 0.5 percent except for the like-like distribution functions for the cases where the concentrations were less than 10 percent of that component. In this case uncertainties are of the order of 2 percent. Increasing the system size would increase the accuracy of the simulated distribution functions at the expense of computational time.

2.2 Simulation Results

The results of the simulations are summarized in tables 1-3, which give the compositions and energy ratios studied, in addition to the relevant thermodynamic state data. The column titled #TS refers to the number of time steps performed in the simulation, and the units for the binary diffusivities D_1 and D_2 are 10^{-5} cm^2/s. The diffusivities were calculated from the generalized Einstein relationship [19].

2.2.1 Radial Distribution Functions

Appendix A contains tables of the radial distribution functions obtained from the simulations as well as the local compositions calculated from eq (2). In addition, Appendix B contains figures which show the radial distribution functions for the state points obtained in this study. These results will be discussed in more detail in sections 3.2.5 and 4.1 of this report.

2.2.2 Direct Correlation Functions

In addition to the radial distribution functions defined above, another correlation function, the direct correlation function, is of great interest in integral-equation fluid theory. Relatively little has been reported for this function for mixtures, so we have attempted to obtain these functions from our simulation results. The direct correlation function, c(r), is defined in terms of the total correlation function, h(r), by the Ornstein-Zernike (OZ) equation [18],

$$h_{ij}(r) = c_{ij}(r) + \sum_k \rho_k \int ds\, c_{ik}(s)\, h_{kj}(|\mathbf{r}-\mathbf{s}|), \tag{15}$$

where

$$r = |\mathbf{r}|, \qquad s = |\mathbf{s}|, \qquad \rho_k = x_k \rho,$$

and

$$h_{ij}(r) = g_{ij}(r) - 1. \tag{16}$$

The integration is carried out over all three dimensional space. Physically, the OZ equation describes the fact that the total correlation between particles one and two, h_{12}, arises not only from a direct contribution, c_{12}, but also from an indirect correlation propogated by intermediate particles.

The direct correlation function generally has much shorter range than the radial distribution function - typically it has the same range as the intermolecular potential function [19]. At large r, $c(r) \approx -u(r)/k_B T$. It is also relatively simple in structure compared to the radial distribution function. Figure 1 presents a typical radial distribution function and the

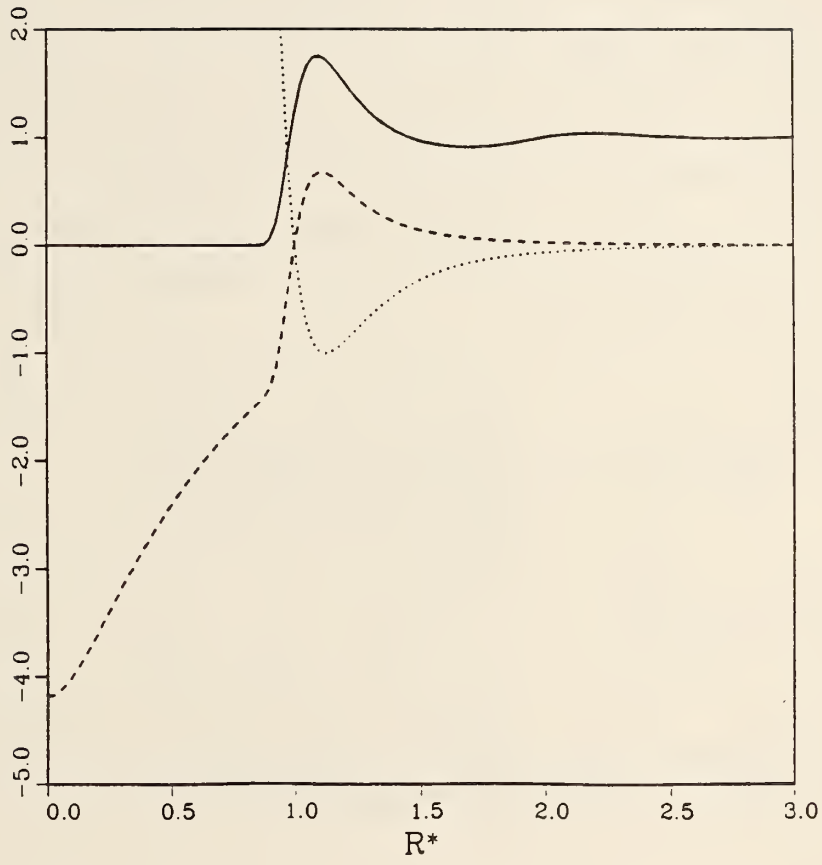

Figure 1. Molecular functions for a Lennard-Jones 6-12 fluid. Radial distribution function, solid line; Direct correlation function, dashed line; Intermolecular potential function, dotted line.

corresponding direct correlation and intermolecular potential functions for a Lennard-Jones 6-12 fluid, giving an idea of typical structure and range for these functions.

In order to obtain the direct correlation functions, the Ornstein-Zernike integral equation must be solved. There are several possible solution methods, as discussed by Watts [20] and Lee [21]. In this work, the objective is to obtain the direct correlation functions from simulation data for the radial distribution functions, which are known only over a finite interval, (typically 0-4 σ_{ij}). Thus it is necessary to use a method which is not sensitive to the nature of the tail of the RDF. Such a method was proposed by Baxter [22,23], whose method is applicable to systems which have direct correlation functions of finite range. It transforms the OZ equation, which involves h(r) over an infinite range, into two integro-differential equations which involve h(r), c(r) and a new function q(r) only over a finite range. Baxter found that

$$rc_{ij}(|r|) = -\frac{dq_{ij}(r)}{dr} + 2\pi \sum_k \rho_k \int_{s_{ki}}^{r_m} dt\, q_{ki}(t) \frac{dq_{kj}(r+t)}{dr} \qquad (17)$$

for $s_{ij} \le r \le r_{ij}$ and

$$rh_{ij}(|r|) = -\frac{dq_{ij}(r)}{dr} + 2\pi \sum_k \rho_k \int_{s_{ik}}^{r_{ik}} dt\, q_{ik}(t)(r-t)h_{kj}(|r-t|) \qquad (18)$$

for $r \ge s_{ij}$.

In these equations $r_{ij} = (r_i+r_j)/2$, $s_{ij} = (r_i-r_j)/2$, and $r_m = \min\{r_{ki}, r_{kj}-r\}$. The r_i are range parameters chosen such that $c_{ij}(r) = 0$ for $r > r_{ij}$, and the q_{ij} satisfy the condition $q_{ij}(r) = 0$ for $r \ge r_{ij}$. The only approximation made in this method is that $c_{ij}(r)$ is exactly zero after the cutoff parameter r_{ij}.

The Baxter method can be used to obtain c(r), or to extend the RDF to larger values of r. Dixon and Hutchinson [24] have used Baxter's method to extend radial distribution functions from computer simulations for single component Lennard-Jones fluids. Jolly et al. [25] have used this procedure

to extend simulation RDF's for binary Lennard-Jones mixtures.

The method may also be used within the context of solving the OZ subject to some particular closure relation. In the Percus-Yevick approximation we assume that

$$c^{PY}(r) = f(r)y(r), \tag{19}$$

where f(r) is the Mayer f-function,

$$f(r) = e^{-u(r)/k_B T} - 1,$$

and

$$y(r) \equiv e^{u(r)/k_B T} g(r).$$

For example, Fischer and Lago [26] used Baxter's method to solve the Percus-Yevick equation for binary, softly-repulsive spherical particles, while Ebner et al. [27] used the Baxter technique to solve the Percus-Yevick equation for a pure Lennard-Jones 6-12 fluid.

We have solved the OZ, eq (15) using Baxter's method in order to obtain direct correlation functions for Lennard-Jones 6-12 mixtures using the simulation data for the radial distribution functions. The calculation begins by assuming a starting set of values for dq(r)/dr; these were taken to be the Percus-Yevick solution for a mixture of hard spheres, as given by Baxter [23]. The $q_{ij}(r)$ functions can be found from $dq_{ij}(r)/dr$ using

$$q_{ij}(r) = -\int_{r}^{r_{ij}} \frac{dq_{ij}(t)}{dt}\, dt. \tag{20}$$

Equation (18) is then solved for the next iterate of $dq_{ij}(r)/dr$, and the procedure repeated until convergence to within some specified tolerance is obtained. In this work, iteration continued until successive iterates of each $dq_{ij}(r)/dr$ at all points in the range of $q_{ij}(r)$ differed by less than 1 part in 10^6, resulting in anywhere from 20-300 iterations. The iteration was stable, and it was not necessary to use a mixing of the successive iterations as suggested by Broyles [28].

Baxter's method requires that the direct correlation functions be exactly zero past the cutoff parameter r_{ij}. In actuality, the direct correlation functions for Lennard-Jones potentials do not go exactly to zero, but only asymptotically approach zero. We chose to use $2.5\sigma_{ij}$ as the cutoff parameter, since the simulations were performed with the Lennard-Jones potential truncated at $2.5\sigma_{ij}$. Integrals were evaluated numerically using Simpson's rule with a grid size of $0.025\sigma_{ij}$. As a test of the method, we compared the direct correlation function obtained from a Percus-Yevick integral equation program by Monson [29] which uses the solution method of Gillan [30] with the direct correlation function computed using the Baxter method. As input to the Baxter program, we used the RDF obtained from the Percus-Yevick integral equation program. In table 4 we compare the resulting direct correlation functions. The agreement is very good; the deviation at the peak of c(r) is on the order of one tenth of one percent.

The direct correlation functions found from the Baxter method using our molecular dynamics simulation data are tabulated in Appendix C. They were found without assuming any type of closure relationship, such as the Percus-Yevick; the only assumption is that c(r) goes to zero at $2.5\sigma_{ij}$. Figures 2-4 show some typical direct correlation functions for three compositions at a reduced temperature of two and equal energy ratios. In these figures the independent variable is r/σ_{ij}.

Figure 5 illustrates the Baxter q functions corresponding to the c(r) given in figure 3. In contrast to c(r) and g(r) which have the symmetry relationships $c_{12}(r) = c_{21}(r)$ and $g_{12}(r) = g_{21}(r)$, the q functions do not have this type of symmetry.

Table 4. Comparison of Direct Correlation Functions for an Equimolar Binary Lennard-Jones 6-12 Mixture Subject to the Percus-Yevick Approximation.

3.0 Theories of Fluids

In the following sections we present a review of conformal solution theory, as it is applied to both pure fluids and mixtures. We describe the most useful mixture theories currently in use, including the mean density approximation, the van der Waals one-fluid theory, hard sphere expansion theory and Weeks-Chandler-Andersen perturbation theory. We then present a new model which is useful for mixtures containing large size differences.

3.1 Conformal Solution Theories for Pure Fluids

A conformal solution is a system in which all the molecules obey the same reduced intermolecular potential energy function which can be represented as the product of a universal function F of reduced distance and other molecular parameters (such as dipole moments) and an energy parameter. For simple spherically symmetric molecules obeying a two parameter force law, we have

$$u_{ii}(r) = \epsilon_{ii} F(r/\sigma_{ii}). \tag{21}$$

The LJ potential of eq (3) is of this type. For two pure fluids obeying this type of force law, simple scaling arguments for the partition function in the canonical ensemble lead to the conclusion that the fluids' residual Helmholtz free energies A_i^r and compressibility factors Z_i^r are related by the expressions [31]

$$A_i^r(V,T) = f_i A_o^r(V/h_i, T/f_i), \tag{22}$$

and

$$Z_i^r(V,T) = Z_o^r(V/h_i, T/f_i), \tag{23}$$

where the subscript "o" denotes the reference fluid, and the factors f_i and h_i are called equivalent substance reducing ratios. These factors are defined by

$$h_i = (\sigma_{ii}/\sigma_{oo})^3 = V_i^c/V_o^c \quad \text{and} \quad f_i = \epsilon_{ii}/\epsilon_{oo} = T_i^c / T_o^c, \tag{24}$$

where the superscript "c" denotes a critical property. This result demonstrates the concept of corresponding states - the macroscopic

properties of one fluid may be calculated from a knowledge of another, by scaling.

The concept of corresponding states may also be used when the fluids are not conformal. For this situation, Leland and coworkers [32-34] developed an extended corresponding states model where shape factors ϕ_i and θ_i were used to account for nonconformality of the potentials. They used

$$h_i = \frac{V_i^c}{V_o^c} \phi_i(T_{ri}, V_{ri}, \omega_i) \tag{25}$$

and

$$f_i = \frac{T_i^c}{T_o^c} \theta_i(T_{ri}, V_{ri}, \omega_i) \tag{26}$$

where

$$T_{ri} = T/T_i^c , \qquad V_{ri} = V/V_i^c$$

where the r denotes a reduced quantity ,the i notation refers to the species and ω_i is the accentric factor. The shape factors are in general functions of both density and temperature. Fisher and Leland [33] fit these shape factors to a generalized mathematical form.

3.2 Mixture Theories

Even though the extended corresponding states theory is essentially exact for pure fluids, the scaling arguments which lead to eqs (22) and (23) are no longer applicable for mixtures - even if the molecules are conformal. One approach to this problem, proposed by Leland and coworkers, involves making direct approximations about the radial distribution functions in mixtures.

The starting equation for Leland's development [32-34] is the rigorous statistical mechanical result for the equation of state of a mixture of pairwise additive, spherically symmetric molecules:

$$Z = 1 - \frac{2\pi\rho}{3k_BT} \sum_i^M \sum_j^M x_i x_j \int_o^\infty \frac{du_{ij}(r)}{dr} g_{ij}(r;\{\rho_k\},T;\{\epsilon_{kl}\},\{\sigma_{kl}\}) r^3 dr. \tag{27}$$

In this equation Z is the compressibility factor pV/RT, u_{ij} is the intermolecular potential whose parameters are σ_{ij} and ϵ_{ij}, and ρ is the number density. In Leland's development, the intermolecular potential is assumed to be a hard sphere term plus a long range attraction F^{LR}, that is,

$$u_{ij}(r) = u_{ij}^{HS}(r) + \epsilon_{ij} F^{LR}(r/\sigma_{ij}) \tag{28}$$

where

$$u_{ij}^{HS} = \infty \qquad r \leq \sigma_{ij}$$

$$= 0 \qquad r > \sigma_{ij}.$$

The form of the long range contribution to the potential is immaterial since contributions of this term to the thermodynamic properties will be evaluated with a corresponding states argument.

The next step in Leland's theory is the mean density approximation [1,3,33] for the radial distribution function appearing in eq (27). In the mean density approximation, one assumes that the radial distribution function of the ij pair is identical to that of a pure fluid evaluated at the reduced conditions of the pair and a mean number density. Mathematically,

$$g_{ij}(r;\rho,T;\{x_k\},\{\sigma_{kl}\},\{\epsilon_{kl}\}) = g_o(r/\sigma_{ij};\eta'_{ij};k_BT/\epsilon_{ij}) \tag{29}$$

$$\eta'_{ij} = \pi\rho'_{ij}\sigma^3_{ij}/6$$

where ρ'_{ij} is the mean density for the ij pair. The subscript o denotes a pure fluid distribution function.

Given the pure fluid distribution function, the expansion techniques developed by Kirkwood et al.[35] can be used to express the distribution function of a real fluid in terms of that of a hard sphere fluid, namely

$$g_o(r/\sigma_{ij};\eta'_{ij};k_BT/\epsilon_{ij}) = g_o^{HS}(r/\sigma_{ij};\eta'_{ij})\left[\sum_{n=o}^{\infty}\left[\frac{\epsilon_{ij}}{k_BT}\right]^n \Psi_n(r/\sigma_{ij};\eta'_{ij})\right] \quad (30)$$

where the Ψ_n are complicated integrals over the hard sphere radial distribution function. Substituting these results into eq (27) and scaling the results by σ_{ij} gives for a mixture

$$Z_{mix} - 1 = \sum_{n=o}^{\infty}\left[\frac{\epsilon_{ij}}{k_BT}\right]^n \left[\sum_i^M \sum_j^M x_i\, x_j\, \epsilon_{ij}^n \sigma_{ij}^3 I_n(\eta'_{ij})\right]. \quad (31)$$

The analogous result for a hypothetical pure fluid is

$$Z_x - 1 = \sum_{n=o}^{\infty}\left[\frac{\epsilon_{ij}}{k_BT}\right]^n I_n(\eta_x)\, \epsilon_x^n\, \sigma_x^3. \quad (32)$$

Setting $\eta_x = \eta'_{ij}$ $(= \pi\rho\sigma_x^3/6)$ and subtracting, results in

$$Z_x - Z_{mix} = \sum_{n=o}^{\infty}\left[\frac{\epsilon_{ij}}{k_BT}\right]^n I_n(\rho\sigma_x^3)\left[\epsilon_x^n\sigma_x^3 - \sum_i^M \sum_j^M x_i x_j\, \epsilon_{ij}^n \sigma_{ij}^3\right]. \quad (33)$$

Thus, upon setting $Z_x - Z_{mix} = 0$, we have at our disposal an infinite set of terms (coefficients of $[\epsilon_{ij}/k_BT]^n$) from which we can choose two for the determination of the potential parameters of the hypothetical pure fluid. The properties of this hypothetical pure fluid can then be evaluated from pure fluid corresponding states theory as described above.

3.2.1 Mean Density Approximation n-Fluid Theory

The mean density approximation for radial distribution functions plays a central role in modern corresponding states theories. In particular, the three most accurate mixture corresponding states theories may be obtained using the development outlined above. The easiest of these theories to derive is obtained by using the MDA directly in eq (27). The van der Waals

mixing rule, eq (35), for the size parameter is usually used which results in the mean reduced density for the pair being given by

$$\rho'_{ij}\sigma^3_{ij} = \rho\left[\frac{\sigma_x}{\sigma_{ij}}\right]^3 \sigma^3_{ij} = \rho\sigma^3_x, \tag{34}$$

where

$$\sigma^3_x = \sum_i^M \sum_j^M x_i x_j \sigma^3_{ij}. \tag{35}$$

The resulting expression for the equation of state of the fluid is of the n-fluid form

$$Z^r_{MDA}(\rho,T) = \sum_i^M \sum_j^M x_i x_j \left[\frac{\sigma_{ij}}{\sigma_x}\right]^3 Z^r_{ij}(\rho\sigma^3_x, k_BT/\epsilon_{ij}), \tag{36}$$

where Z_{ij} denotes a pure fluid compressibility factor evaluated at the indicated reduced state conditions for the ij pair.

3.2.2 Van der Waals one-Fluid Theory

One of the most commonly used forms of conformal solution theory uses the van der Waals one-fluid (VDW-1) approximation. It is called a one-fluid approximation because the configurational properties of the mixture are approximated by those of a single, hypothetical pure fluid as opposed to the MDA theory which has a separate contribution for each molecular pair. It is also possible to develop VDW theories involving more than one fluid.

There are two methods to derive the VDW-1 model. In the first, the distribution function of a pair in a mixture is written in terms of the radial distribution function of a hypothetical pure fluid with potential size parameter σ_x and energy parameter ϵ_x,

$$g_{ij}(r,\rho,T;\{x_k\},\{\sigma_{kl}\},\{\epsilon_{kl}\}) = g_o(r/\sigma_x, \rho\sigma^3_x, k_BT/\epsilon_x), \tag{37}$$

where the subscript o denotes a pure fluid radial distribution function.

Substitution into eq (27) then yields the equation of state

$$Z^r_{VDW1} = Z^r_o(\rho\sigma_x^3, k_BT/\epsilon_x) \left[\frac{1}{\epsilon_x\sigma_x^3} \sum_i^M \sum_j^M x_i x_j \epsilon_{ij}\sigma_{ij}^3 \right]. \quad (38)$$

Setting the term in square brackets equal to one, we obtain the "second" van der Waals mixing rule,

$$\epsilon_x\sigma_x^3 = \sum_i^M \sum_j^M x_i x_j \epsilon_{ij}\sigma_{ij}^3, \quad (39)$$

and the van der Waals one-fluid equation of state is

$$Z^r_{VDW1}(\rho,T) = Z^r_o(\rho\sigma_x^3, k_BT/\epsilon_x). \quad (40)$$

Generally in this derivation the van der Waals mixing rule for the size parameter, eq (35), is *assumed*. This assumption is not required by the theory.

In the second derivation of the VDW-1 theory, the first two terms of the expansion eq (33) are set equal to zero and the remaining terms ignored. This procedure gives the VDW-1 model as described above. This derivation, incidentally, shows that the VDW-1 mixing rules are essentially exact to order 1/T. Thus, if a reference fluid equation of state has only linear dependence on the inverse temperature, the van der Waals one-fluid model should be an excellent approximation for the composition dependence of the equation of state.

3.2.3 Hard Sphere Expansion Theory

The hard sphere expansion theory (HSE) [1] is a conformal solution theory which uses the accurately known properties of hard sphere mixtures to model a mixture with a given potential function. It splits the molecular interactions into a repulsive portion and an attractive portion. The contribution from the attractive terms is evaluated by a one-fluid

corresponding states principle using the second two terms of the series eq (33) for mixing rules. The residual compressibility factor for the HSE model is given by

$$Z^{r}_{HSE} = Z^{HS,r}_{mix} - Z^{HS,r}_{o} + Z^{r}_{o}(\rho d_x^3, k_B T/\epsilon_x). \tag{41}$$

The repulsive contributions $Z^{HS,r}_{mix}$ and $Z^{HS,r}_{o}$ may be found using hard sphere equations of state such as the Mansoori-Carnahan-Starling-Leland (MCSL) [36] which may be written as

$$Z^{HS}_{mix} = \frac{1}{(1-\eta_m)} + \frac{a_1\eta_m}{(1-\eta_m)^2} + \frac{a_2\eta_m^2(3-\eta_m)}{(1-\eta_m)^3} \tag{42}$$

and the Carnahan-Starling (CS) [37],

$$Z^{HS}_{o} = \frac{1 + \eta_o + \eta_o^2 - \eta_o^3}{(1-\eta_0)^3}, \tag{43}$$

where

$$\eta_i = \pi\rho x_i d_{ii}^3/6, \quad \eta_m = \sum_i^M \eta_i, \quad S_n = \sum_i^M x_i d_{ii}^n, \quad \eta_o = \pi\rho d_x^3/6 \tag{44}$$

$a_1 = 3S_1S_2/S_3$ and $a_2 = S_2^3/S_3^2$.

As mentioned above, the term Z_o^r is found using a one-fluid corresponding states model and the HSE mixing rules,

$$\epsilon_x d_x^3 = \sum_i^M \sum_j^M x_i x_j \epsilon_{ij} d_{ij}^3 \tag{45}$$

and

$$\epsilon_x^2 d_x^3 = \sum_i^M \sum_j^M x_i x_j \epsilon_{ij}^2 d_{ij}^3. \tag{46}$$

It is also necessary to specify the hard sphere diameters, d_{ij}, to be used in the model. Several approaches are available in the literature [38-40]. In this work, we chose the diameter as calculated by the perturbation theory of Weeks, Chandler and Andersen [41], as implemented by Lee and Levesque [42], as discussed in the next section.

3.2.4 Statistical Mechanical Perturbation Theory

Hard sphere perturbation theories express the properties of a given system in terms of an equivalent system of hard spheres, whose properties are well known. The intermolecular potential of the system of interest is expressed as a perturbation applied to a hard sphere system. The method is very powerful and has been used with success. Reviews have appeared periodically [43,44]. Two important theories in this class are the perturbation theory of Barker and Henderson [45] and that of Weeks, Chandler and Andersen [41]. We will limit our discussion to WCA theory, especially the extension of the WCA method to mixtures as done by Lee and Levesque [42]. Recently, Shukla [46] has presented an improved form of first order perturbation theory, which appears to be better than the Lee-Levesque form.

The Lee-Levesque theory is based upon WCA theory and begins by splitting the Lennard-Jones intermolecular potential u_{ij}^{LJ} into a purely repulsive reference portion u_{ij}^{o} and an attractive portion w_{ij} according to

$$u_{ij}^{o}(r) = u_{ij}^{LJ}(r) + \epsilon_{ij} \qquad \text{for } r \le 2^{1/6}\sigma_{ij} \tag{47}$$

$$= 0 \qquad \text{otherwise,}$$

$$w_{ij}(r) = -\epsilon_{ij} \qquad \text{for } r \le 2^{1/6}\sigma_{ij} \tag{48}$$

$$= u_{ij}^{LJ}(r) \qquad \text{otherwise,}$$

where $2^{1/6}\ \sigma_{ij}$ is the location of the potential minimum for the Lennard-Jones potential. Expanding the configurational Helmholtz energy about the reference potential gives

$$\frac{A^{LJ}}{Nk_BT} = \frac{A^{o}}{Nk_BT} + \frac{2\pi\rho}{Nk_BT} \sum_{i}^{M}\sum_{j}^{M} x_i x_j \int_{o}^{\infty} r^2\, w_{ij}(r)\, g_{ij}^{o}(r)\, dr, \tag{49}$$

where the superscript o refers to the reference system.

The next step is to represent the free energy of the reference system in terms of that of an equivalent system of hard spheres. If the free energy of the reference system is expanded about that of a system of hard spheres, and if the hard sphere diameter is chosen so that

$$\int_0^\infty r^2 \left[e^{-u_{ij}^o(r)/k_BT} - e^{-u_{ij}^{HS}(r)/k_BT} \right] e^{u_{ij}^{HS}(r)/k_BT} g_{ij}^o(r/d_{11})\, dr = 0, \tag{50}$$

and if only first order terms are retained, then the configurational free energy of the reference system is simply

$$A^o = A^{HS}. \tag{51}$$

This may be evaluated by integrating the hard sphere equation of state developed by Mansoori et al.[36]. The result is

$$\frac{A^o}{Nk_BT} = \frac{A^{HS}}{Nk_BT} = (a_2-1)\,\ell n(1-\eta_m) + \frac{a_1\eta_m}{(1-\eta_m)} + \frac{a_2\eta_m}{(1-\eta_m)^2}, \tag{52}$$

where a_1, a_2 and η_m are given in eq (44).

Rather than solve the integral in eq (50) to obtain the hard sphere diameter, Lee and Levesque developed the following approximate analytic method. The Lee-Levesque effective hard sphere diameters are given by

$$d_{ij}^{LL}(\rho,T) = d_{ij}^{BH} \left[1 + \frac{\gamma_{ij}^{(1)} d_{ij}^{LL}(\rho,T)\delta_{ij}^{BH}}{2\gamma_{ij}^{(o)} d_{11}} \right], \tag{53}$$

where d_{ij}^{BH} and δ_{ij}^{BH} are temperature dependent (but not density dependent) parameters that arise in Barker-Henderson perturbation theory. The parameters $\gamma_{ij}^{(1)}$ and $\gamma_{ij}^{(o)}$ are functions of $d_{ij}^{LL}(\rho,T)$ which makes an iterative solution of eq (53) necessary.

An extension of the Verlet and Weis [47] approximations for the Barker-

Henderson parameters may be used,

$$d_{ij}^{BH} = \left[\frac{0.3837 + 1.068/T_{ij}^{*}}{0.4293 + 1/T_{ij}^{*}} \right] \sigma_{ij}, \qquad T_{ij}^{*} = \frac{k_B T}{\epsilon_{ij}}, \tag{54}$$

$$\delta_{ij}^{BH} = \frac{1.}{210.21 + 404.6/T_{ij}^{*}} \tag{55}$$

where σ_{ij} and ϵ_{ij} are the Lennard-Jones size and energy potential parameters. The composition dependence of d_{ij} in the WCA comes from the coefficients $\gamma_{ij}^{(o)}$ and $\gamma_{ij}^{(1)}$ which are

$$\gamma_{ij}^{(o)} = g_{ij}^{HS} \Big|_{r=d_{ij}} \tag{56}$$

and

$$\gamma_{ij}^{(1)} d_{ij} / d_{11} = \gamma_{ij}^{(o)} + \frac{dg_{ij}^{PY}}{dr} \Big|_{r=d_{ij}}. \tag{57}$$

For the evaluation of these two parameters it is necessary to have both the value of the hard sphere radial distribution function and its first derivative at contact. For the hard sphere contact value, we use the MCSL value. Using η_m as in eq (44), the contact value is

$$g_{ij}^{MCSL}\Big|_{d_{ij}} = \frac{1}{1-\eta_m} + \frac{3S_2 \hat{d}_{ij}}{2(1-\eta_m)^2} + \frac{3S_2^2 \hat{d}_{ij}^2}{4(1-\eta_m)^3} \tag{58}$$

where the S_n have been defined previously in eq (44) and

$$\hat{d}_{ij} \equiv 2\, d_{ii} d_{jj} / (d_{ii} + d_{jj}). \tag{59}$$

For the derivative of the hard sphere RDF at contact, it is possible to use the method developed by Grundke and Henderson [48], which involves

expressing the natural logarithm of y(r) as a cubic polynomial in r. This procedure was used by Shukla et al.[49]. We chose instead to follow the Lee-Levesque procedure which expresses the exact hard sphere RDF in terms of the Percus-Yevick solution for hard spheres. The phase of the Percus-Yevick RDF is corrected, according to Verlet-Weis [47], by using an effective density

$$\eta_e = \eta_m - (\eta_m^2/16). \tag{60}$$

This is equivalent to using effective diameters given by

$$d_{eij} = d_{ij} (\eta_e/\eta_m)^{1/3} . \tag{61}$$

To bring the Percus-Yevick core values into better agreement with the exact hard sphere RDF, a short-range function is added:

$$g_{ij}^{HS}(r,\eta_m) = g_{ij}^{HS,PY}(r,\eta_e) + (\alpha_{ij}/r)e^{-[\beta_{ij}(r-d_{ij})]} \cos [\beta_{ij}(r-d_{ij})]. \tag{62}$$

The coefficient α_{ij} is chosen to reproduce the MCSL contact value

$$\alpha_{ij}/d_{ij} = g_{ij}^{MCSL}(\eta_m)\Big|_{r=d_{ij}} - g_{ij}^{HS,PY}(\eta_e)\Big|_{r=d_{ij}/d_{eij}}. \tag{63}$$

Because $d_{ij} > d_{eij}$, the value of the PY RDF at a point outside the core is required. The coefficient β_{ij} is chosen empirically according to

$$\beta_{ij}d_{ij} = \frac{24\ \alpha_{ij}/d_{ij}}{\eta_e\ g_{ij}^{HS,PY}(\eta_e)\Big|_{r=d_{eij}}}. \tag{64}$$

The use of eqs (58)-(64) in eq (57) leads to

$$\sigma_{ij}^{(1)} d_{ij}/d_{ll} = 2\sigma_{ij}^{(o)} - \alpha_{ij}/d_{ij} - \alpha_{ij}\beta_{ij} + d_{ij} \frac{dg_{ij}^{HS,PY}(\eta_e)}{dr}\Big|_{r=d_{ij}}. \tag{65}$$

In order to obtain the derivative at $r = d_{ij}$, a Taylor series expansion is made about the point $r = d_{eij}$ and yields

$$\left.\frac{dg_{ij}^{HS,PY}(\eta_e)}{dr}\right|_{r=d_{ij}} = \left.\frac{dg_{ij}^{HS,PY}(\eta_e)}{dr}\right|_{r=d_{eij}} + (d_{ij}-d_{eij}) \left.\frac{d^2 g_{ij}^{HS,PY}(\eta_e)}{dr^2}\right|_{r=d_{eij}} \tag{66}$$

where higher order terms have not been retained. The derivatives of the Percus-Yevick RDF at d_{eij} need to be evaluated. The Percus-Yevick g(r) could be evaluated using Perram's [50] algorithm and the derivatives computed numerically; however, we have chosen a different approach. Although c(r) and g(r) for hard spheres are discontinuous at contact, the difference between them is continuous and twice differentiable [51] giving

$$\left.\frac{dg_{ij}^{HS}(r)}{dr}\right|_{r=d_{ij}^-} = \left.\frac{-dc_{ij}^{HS}(r)}{dr}\right|_{r=d_{ij}^+} \tag{67}$$

and

$$\left.\frac{d^2 g_{ij}^{HS}(r)}{dr^2}\right|_{r=d_{ij}^-} = \left.\frac{-d^2 c_{ij}^{HS}(r)}{dr^2}\right|_{r=d_{ij}^+} . \tag{68}$$

In our calculations the derivatives of the Percus-Yevick direct correlation functions are found using the solution for binary hard sphere mixtures found by Lebowitz [52], and extended to a general M component mixture by Hoshino [53]. Hoshino gives the direct correlation functions for Percus-Yevick hard spheres as

$$\begin{aligned} -c_{ii}^{HS,PY}(r) &= a_i + b_i r + \xi r^3 && \text{for } r < d_{ii} \\ -c_{ij}^{HS,PY}(r) &= a_i && \text{for } r < \lambda_{ij} \\ &= a_{ij} + b_{ij} r + \xi r^3 + f_{ij}/r && \text{for } \lambda_{ij} < r < d_{ij} \end{aligned} \tag{69}$$

where

$$c_{ij}^{HS,PY}(r) = c_{ji}^{HS,PY}(r), \quad d_{ij} = (d_{ii}+d_{jj})/2, \quad a_{ij} = (a_i+a_j)/2,$$
$$\lambda_{ij} = (d_{ii}-d_{jj})/2, \quad b_{ij} = (b_i+b_j)/2,$$

and the d_{ii} are the hard sphere diameters. The remaining coefficients are found using

$$a_i = [1/(1-\eta_m)] + ad_{ii} + bd_{ii}^2 + \tfrac{1}{3}\, cd_{ii}^3, \tag{70}$$

$$b_i = -a/2 - bd_{ii} - \tfrac{1}{2}\, cd_{ii}^2,$$

$$\xi = \tfrac{1}{2}\,[\,\zeta_o + 2(3\zeta_1\zeta_2 - \zeta_o\eta_m) + (\zeta_o\eta_m^2 - 6\zeta_1\zeta_2\eta_m + 9\zeta_2^3)\,]\,(1-\eta_m)^{-4},$$

$$f_{ij} = -\tfrac{1}{8}\,(d_{jj} - d_{ii})^2\,[a + b(d_{ii} + d_{jj}) + \tfrac{1}{4}\, c(d_{ii} + d_{jj})^2\,],$$

$$a = \frac{3\zeta_2}{(1-\eta_m)^2},$$

$$b = \frac{3\zeta_1}{(1-\eta_m)^2} + \frac{9\zeta_2^2}{(1-\eta_m)^3},$$

$$c = \frac{3\zeta_o}{(1-\eta_m)^2} + \frac{18\zeta_1\zeta_2}{(1-\eta_m)^3} + \frac{27\zeta_2^3}{(1-\eta_m)^4},$$

and

$$\zeta_n = \pi\rho S_n/6$$

along with eq (44). In our computations, since we want a Verlet-Weis "corrected" Percus-Yevick value, we use the effective η_e as given by eq (60).

The computation of the equivalent hard sphere diameters is an iterative process using eq (53). We used the Barker-Henderson diameter as a first guess. Also, we used the arithmetic mean for d_{12}, rather than solve for it independently. Typically 7-10 iterations were necessary to obtain convergence to one part in 10^6.

Once the proper diameter has been obtained, the configurational

Helmholtz free energy is evaluated using (49) and (52). The radial distribution function of the reference system, $g_{ij}^{o}(r)$, which appears in the integral in eq (49) is approximated by Lee and Levesque as

$$g_{ij}^{o}(r) \approx \left[e^{-u_{ij}^{o}(r)/k_B T} \right] y_{ij}^{HS}(r), \tag{71}$$

where

$$y_{ij}^{HS}(r) = \left[e^{-u_{ij}^{HS}(r)/k_B T} \right] g_{ij}^{HS}(r). \tag{72}$$

With diameters chosen according to eq (50) and using the Verlet-Weis correction for the Percus-Yevick hard sphere g(r), eq (49) becomes

$$\frac{A^{LJ}}{Nk_BT} = \frac{A^{o}}{Nk_BT} + \frac{2\pi\rho}{Nk_BT} \sum_{i}^{M} \sum_{j}^{M} x_i x_j d_{ij}^3 \int_{o}^{\infty} (S^*)^2 \, w_{ij}(S^* d_{ij}/\sigma_{ij}) \, g_{ij}^{PY,HS}(S^*, \eta_e) \, dS^* \tag{73}$$

where $S^* = r/d_{ij}$; w_{ij} is given in eq (48). We computed the Percus-Yevick hard sphere RDF's according to Perram's [50] algorithm. Typically, the two terms on the right hand side of eq (73) are of the same order of magnitude, but of opposing signs.

In order to compute thermodynamic properties, we used the thermodynamic relationships

$$\frac{p}{\rho k_B T} = \rho \frac{\partial (A^{con}/Nk_BT)}{\partial \rho} + 1 \tag{74}$$

and

$$\frac{U^{con}}{Nk_BT} = - T \frac{\partial (A^{con}/Nk_BT)}{\partial T} \tag{75}$$

where the superscipt con denotes a configurational quantity and the derivatives were computed numerically using a five-point Lagrange formula. The results of these computations are given in section 4.

3.3 Modified Mean Density Approximation

The MDA, eqs (34)-(36), works well for systems where the molecules are similar in size, for size ratios up to about 1.1 [49]. At larger size ratios the approximation begins to fail. In simulation studies [54] for model Lennard-Jones 6-12 systems with a size ratio equal to two, two major deficiencies of the MDA were found:

1) The MDA consistently underestimates the height of the first neighbor peak in the RDF for the small molecule pair.

and 2) The MDA fails to predict the proper location of the second neighbor peak.

These results are illustrated in figures 6 and 7, which show the RDF's from simulation data and the RDF's predicted with the MDA for LJ mixtures with a size ratio of two. In these figures, $\rho^* = \rho\sigma_{11}^3$, $T^* = k_B T/\epsilon_{11}$ and $R^*_{ij} = r/\sigma_{ij}$. In figure 6 (which has a concentration of 5 percent of the small molecule), the peak height for the small-small pair is significantly underestimated by the MDA. Also, the MDA predicts the second peak to occur at a reduced distance of two, while the simulations place the peak almost at three. This discepancy occurs because the location of the second peak is related to the size of the molecule most likely to be found in between the pair of molecules under observation. In a pure fluid, the molecules are all of the same size and thus the second neighbor peak will always occur at a reduced distance, r/σ, of approximately two. In a mixture, when the concentration of one of the molecules is small, packing effects occur because the molecules have different sizes. For the case of figure 6, the space between two small molecules is most likely to be filled by a large molecule, because these are in the greatest concentration. The second peak of the small-small distribution function then occurs at a reduced distance of $r/\sigma_{11} = (\sigma_{11}+\sigma_{22})/\sigma_{11} = (1+2)/1 = 3$. In figure 7, there is a very large concentration of small molecules, so that the second peak of the large-large pair actually occurs at approximately $r/\sigma_{22} = (\sigma_{11}+\sigma_{22})/\sigma_{22} = (1+2)/2 = 1.5$. Since the MDA uses only pure fluid radial distribution functions, it cannot predict this type of behavior.

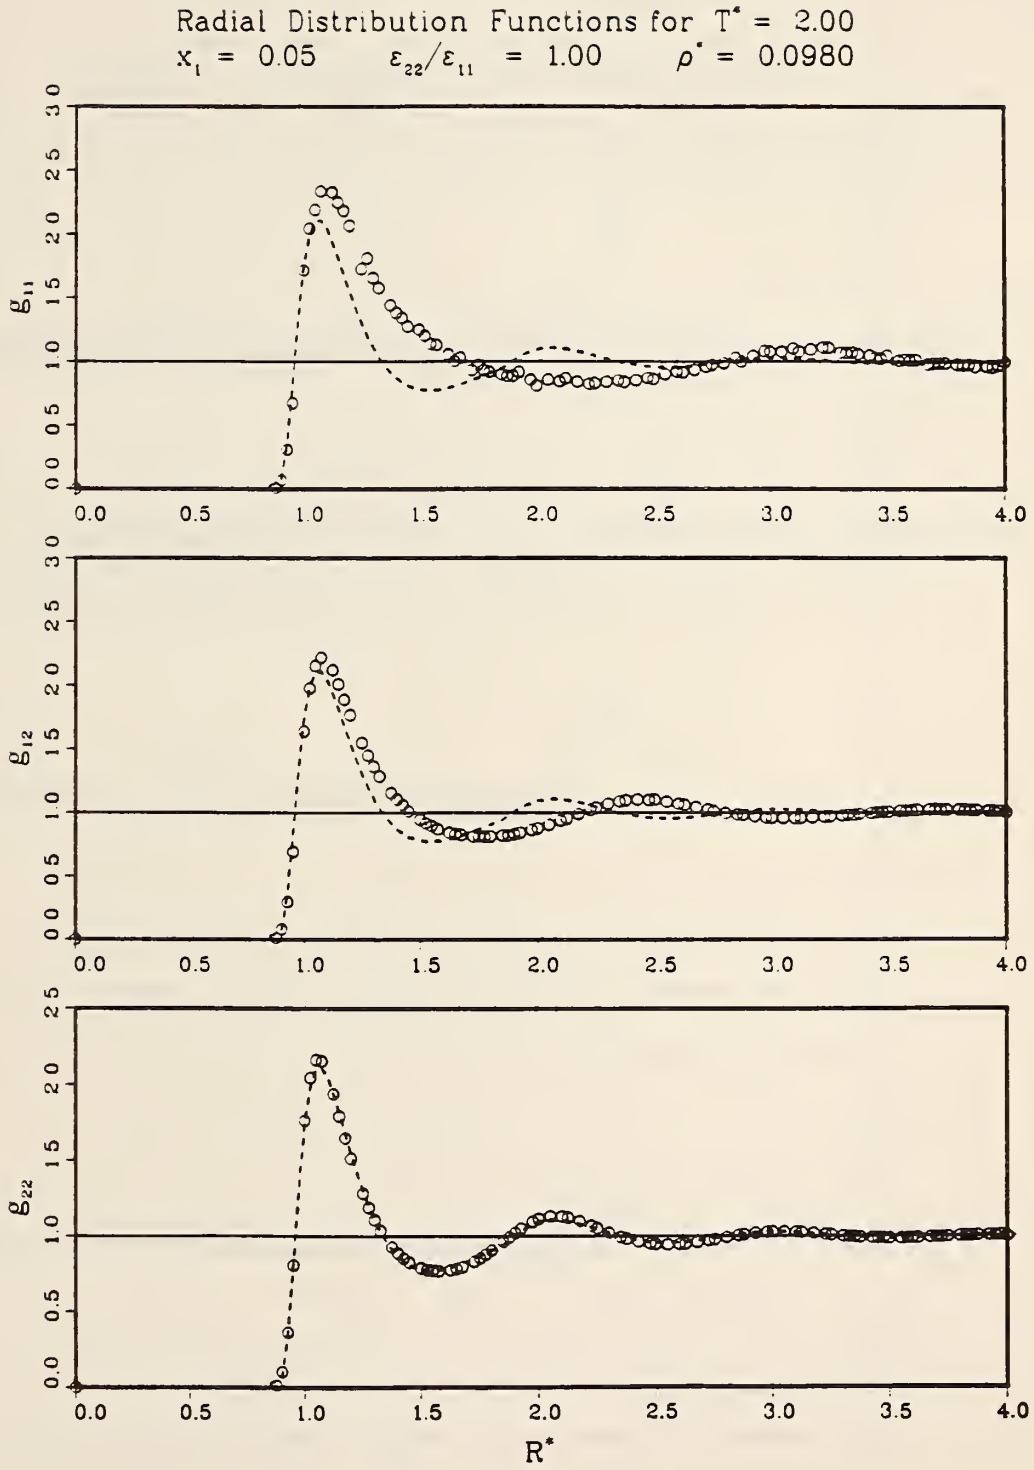

Figure 6. Comparison of simulation and MDA radial distribution functions for x_1 = 0.05. Circles, MD simulation data, this work; Dashed line, MDA.

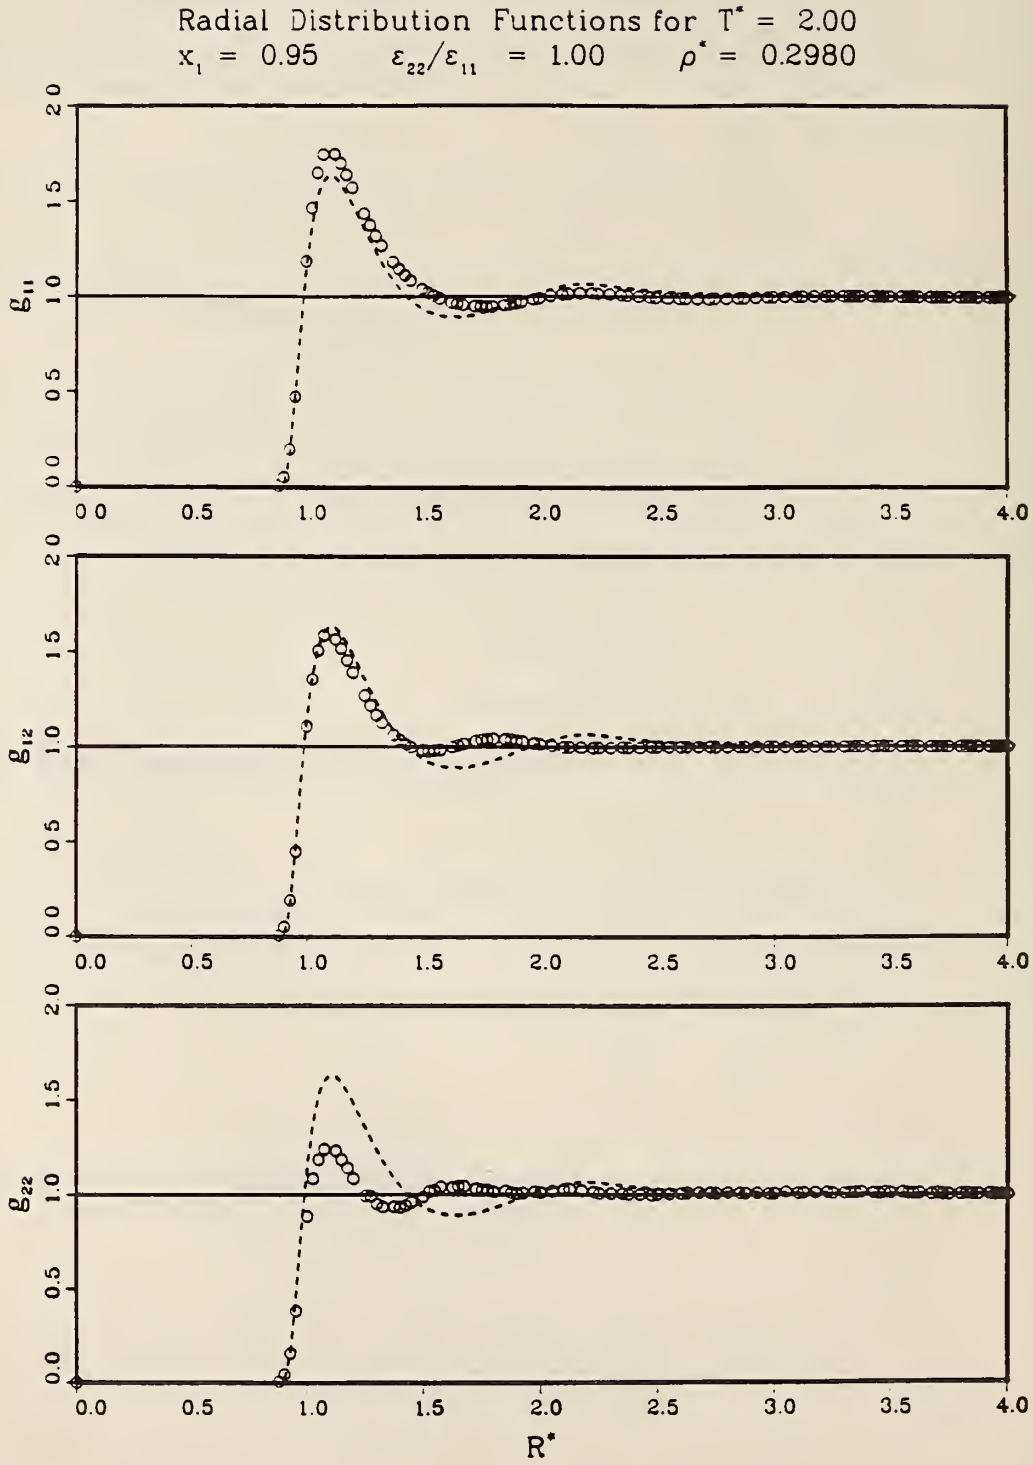

Figure 7. Comparison of simulation and MDA radial distribution functions for x_1 = 0.95. Circles, MD simulation data, this work; Dashed line, MDA.

In our simulation studies, we also observed that the MDA tracks energy effects reasonably well for mixtures possessing differences in energy parameters. This is illustrated in figure 8 which shows the large-large RDF as a function of reduced distance for four different values of the energy ratio. The composition is fixed at $x_1 = 0.75$, the reduced temperature is two, and the size ratio is two for all of the RDF's shown. As illustrated in figure 8, the MDA does a good job of predicting the RDF even when the energy ratio is changed by a factor of four.

Figure 9 shows the deviations between the RDF's of hard sphere mixtures and the RDF's predicted using the MDA for hard spheres. It also shows the deviations between the RDF's of Lennard-Jones mixtures and the RDF's predicted using the MDA for LJ mixtures. The figure demonstrates that hard spheres show essentially the same behavior (excepting the region nearest contact) as Lennard-Jones mixtures. This suggests that the physics of mixtures which are lacking in the MDA are found in a simple mixture of hard spheres. We propose the following correction to the MDA:

$$g_{ij}(r) = g_{ij}^{MDA}(r) + \Delta g_{ij}^{HS}(r), \tag{76}$$

$$\Delta g_{ij}^{HS}(r) = \frac{g_{ij}^{HS}(r) - 1}{g_{ij}^{HS}(\sigma_{ij}) - 1} - \frac{g_o^{HS}(r) - 1}{g_o^{HS}(\sigma_x) - 1} \qquad \text{for } r \geq \sigma_{ij} \tag{77}$$

$$= 0 \qquad \text{for } r < \sigma_{ij}.$$

We scaled the correction term, eq (76), so that it is zero at contact in order to prevent discontinuity in the distribution function at contact. The Percus-Yevick hard sphere contact values, $g_{ij}^{HS}(\sigma_{ij})$ and $g_o^{HS}(\sigma_x)$, are used as the scaling factors. (The Carnahan-Starling [37] and Mansoori-Carnahan-Starling-Leland [36] contact values could also be used). The Percus-Yevick hard sphere contact values were obtained from the Wertheim [55] or Thiele [56] and Lebowitz [52] solutions to the Percus-Yevick equation:

$$g_{ij}^{HS,PY}(\sigma_{ij}) = \frac{1}{(1 - \eta_m)} + \frac{3\chi_m}{(1 - \eta_m)^2} \frac{\sigma_{ii}\sigma_{jj}}{(\sigma_{ii} + \sigma_{jj})} \tag{78}$$

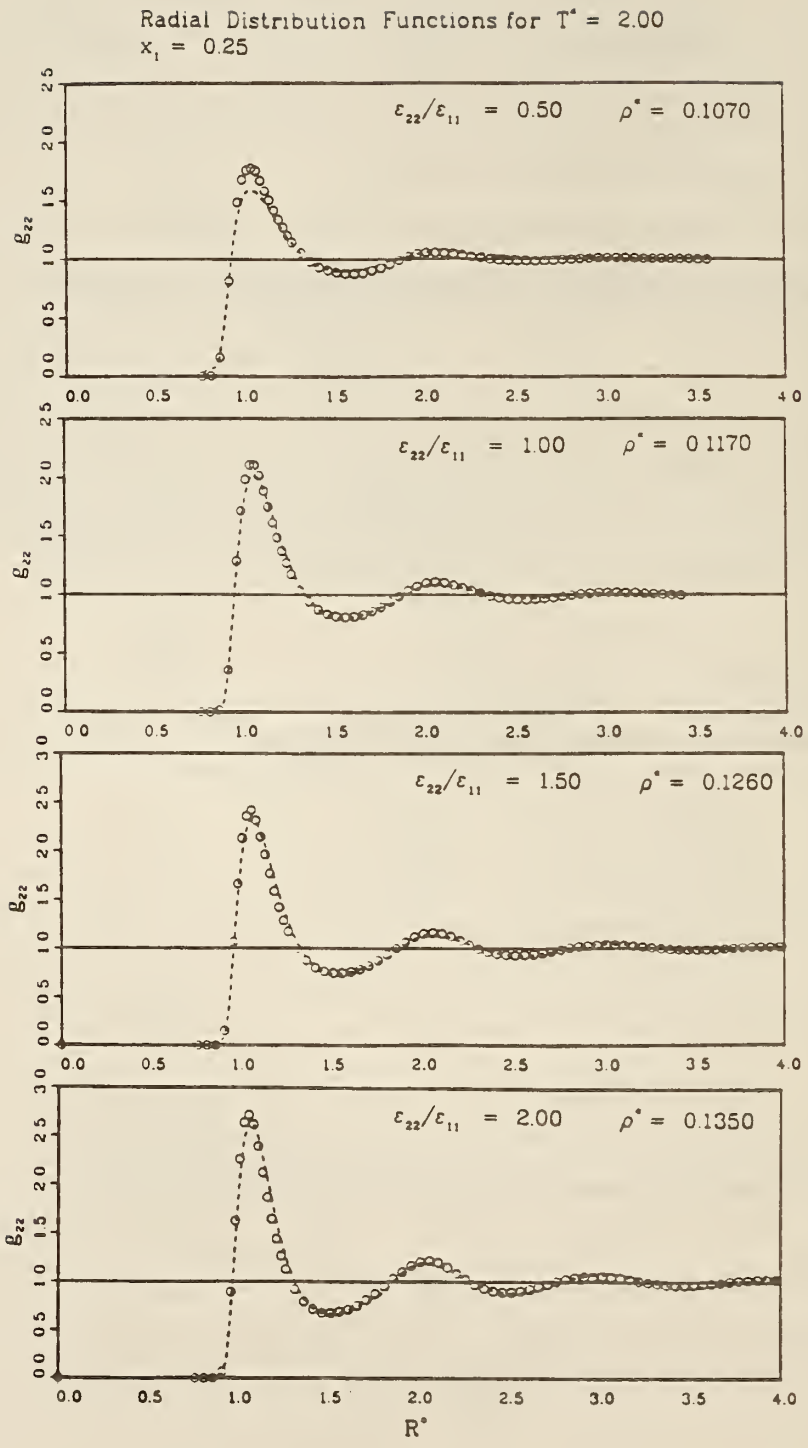

Figure 8. Comparison of 2-2 pair radial distribution function for x_1 = 0.25 at different energy ratios. Circles, MD simulation data, this work; Dashed line, MDA.

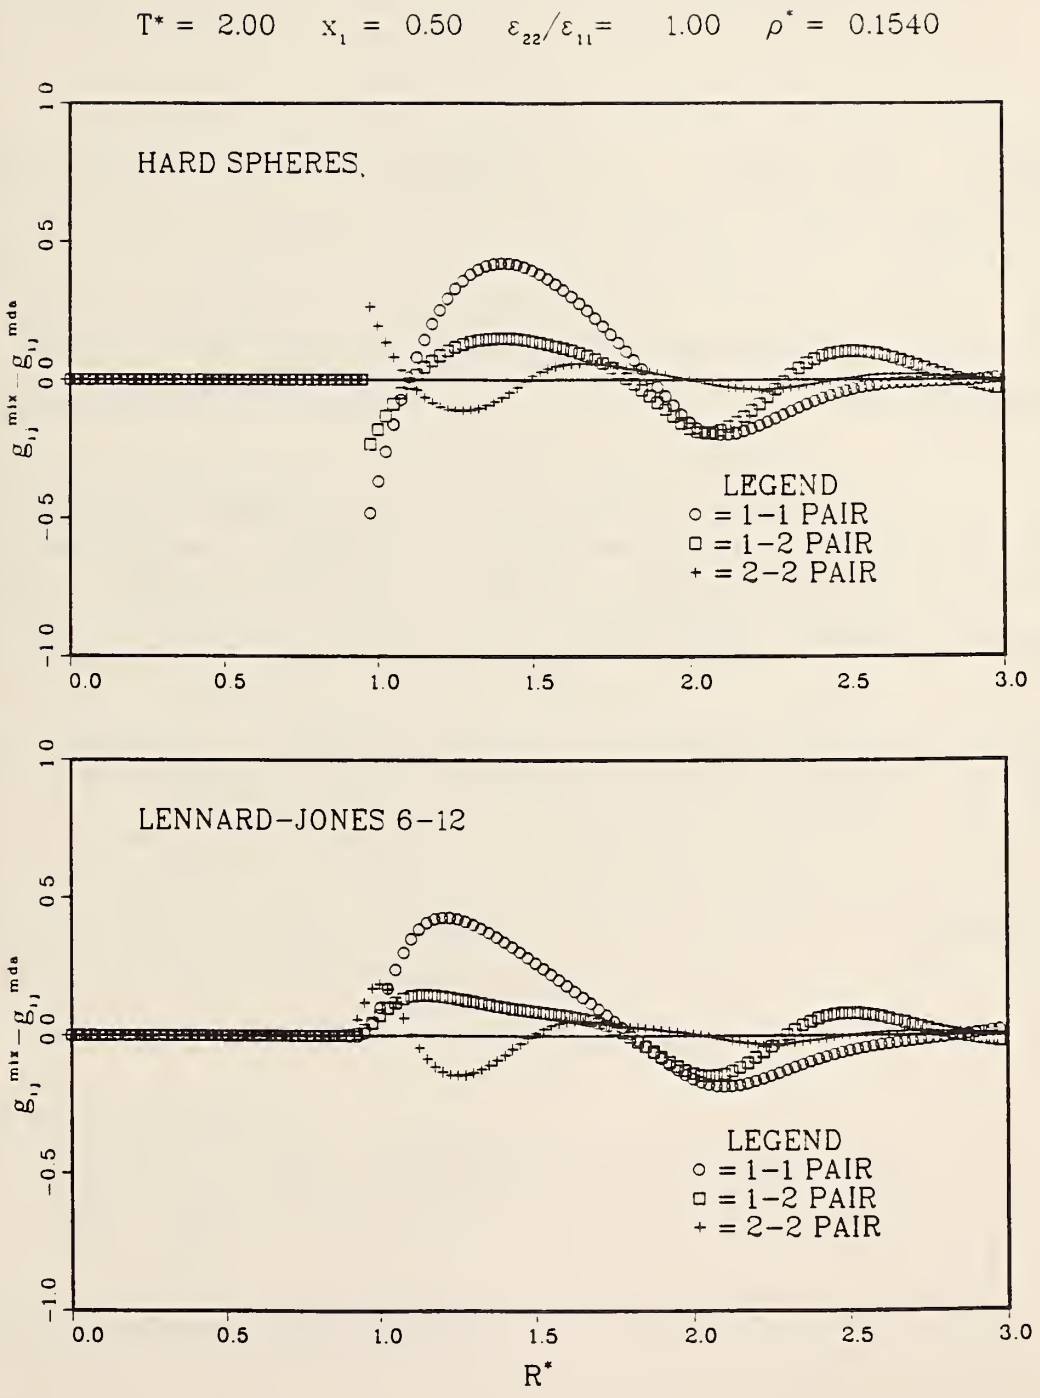

Figure 9. Comparison of $(g^{mix} - g^{mda})$ for Lennard-Jones 6-12 mixtures and hard sphere mixtures.

and

$$g_o^{HS,PY}(\sigma_x) = \frac{1 + \eta_x/2}{(1 - \eta_x)^2} \tag{79}$$

where

$$\eta_m = \pi\rho S_3/6, \qquad \chi_m = \pi\rho S_2/6, \qquad \eta_x = \pi\rho\sigma_x^3/6 \tag{80}$$

and

$$S_n = \sum_i^M x_i \sigma_{ii}^n$$

We also propose an empirical prescription for σ_x, which has the effect of changing the mean density. There are no theoretical reasons that one must use the van der Waals mixing rule, eq (35), for the size parameter. We used the following empirical mixing rule:

$$\sigma_x^3 = \frac{3}{4} \sum_i^M x_i \sigma_{ii}^3 + \frac{1}{4} \sum_i^M \sum_j^M x_i x_j \sigma_{ij}^3 \tag{81}$$

with

$$\sigma_{ij} = (\sigma_{ii} + \sigma_{jj})/2.$$

4.0 Comparisons of the Theories

In this section we compare the results from the modified MDA with simulation results and with the results of the various mixture theories discussed in section 3. First, we examine the radial distribution functions. Then we go on to compare predictions of the pressure, internal energy, and excess properties.

4.1 Radial Distribution Functions

In order to compute the radial distribution function using the MMDA, eqs (76)-(81), we used simulation data for the pure radial distribution functions, (evaluated at the reduced conditions for the ij pair, g_{ij}^{MDA} in eq (76)). An alternative would be to use an explicit equation for the RDF of a Lennard-Jones fluid such as Goldman's [57]. For the hard sphere correction term in eq (76) we used the Percus-Yevick solution for hard sphere RDF's, following the numerical computation scheme of Perram [50].

We computed the RDF's using the MMDA for all of our simulation state points and compare them graphically in Appendix B. The open circles are the results of our MD simulations and the solid line is the MMDA. We found that the radial distribution functions computed with the modified MDA, eqs (76)-(81), agreed well with the simulation data and were in much better agreement with the simulation data than the original MDA. For example, Figures 10 and 11 show the same two mixtures that were presented in figures 6 and 7, but with the modified MDA (MMDA). The modified MDA predicts the first peak height better than the original MDA, and also more correctly represents the "packing " effects of the mixture.

4.2 Equation of State

In order to compute the pressure using the MMDA, we use

$$p = p^{MDA} + \Delta p^{HS} \tag{82}$$

with the pressure equation [58],

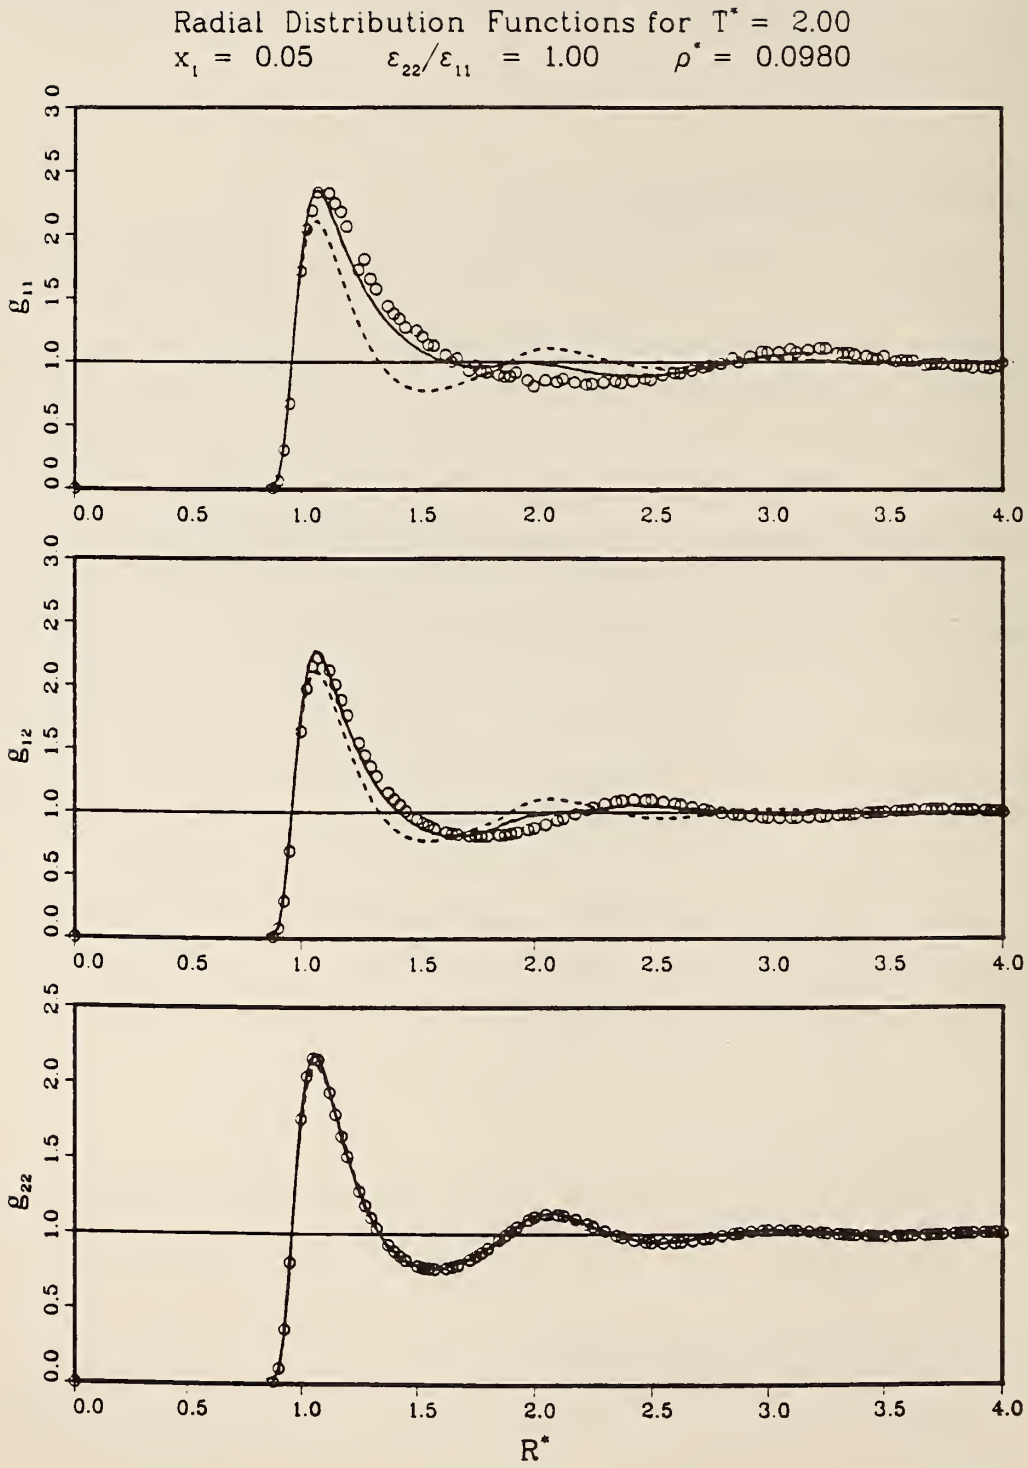

Figure 10. Comparison of simulation and MDA radial distribution functions for $x_1 = 0.05$. Circles, MD simulation data, this work; Dashed line, MDA; solid line, MMDA.

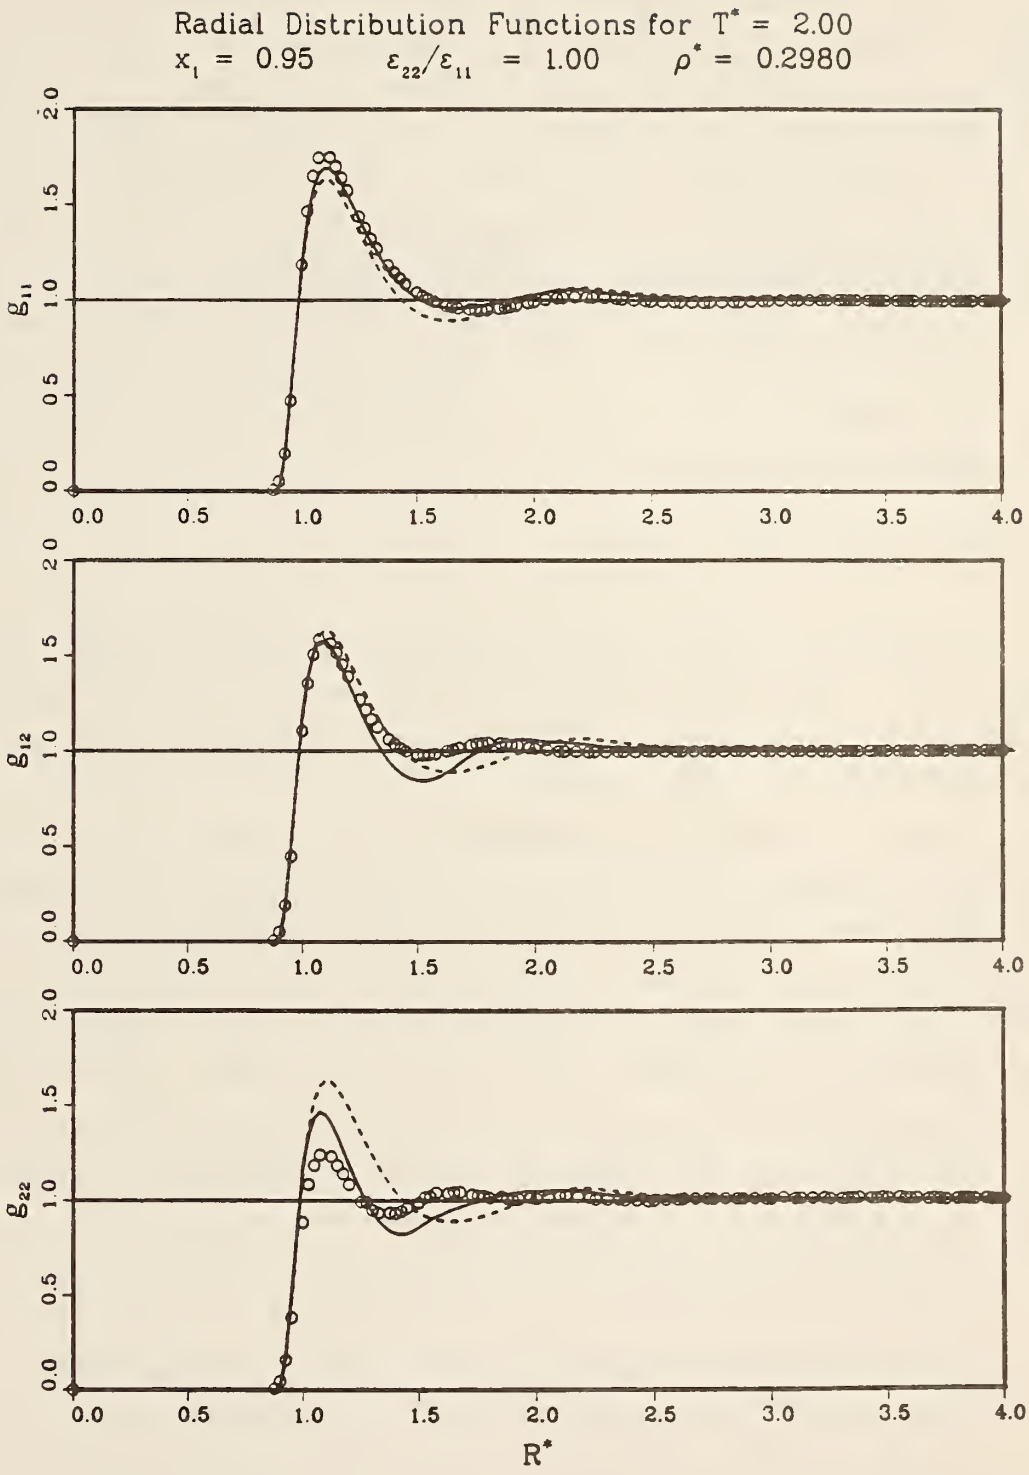

Figure 11. Comparison of simulation and MDA radial distribution functions for x_1 = 0.95. Circles, MD simulation data, this work; Dashed line, MDA; solid line, MMDA.

$$\frac{p}{k_B T} = \rho - \frac{2\pi}{3k_B T} \rho^2 \sum_i^M \sum_j^M x_i x_j \int_o^\infty \frac{du(r)}{dr} g_{ij}(r)\, r^3\, dr \qquad (83)$$

so that

$$\Delta p^{HS} = \frac{-2\pi}{3} \rho^2 \sum_i^M \sum_j^M x_i x_j \sigma_{ij}^3 \epsilon_{ij} \int_o^\infty \frac{du^*(R^*)}{dR^*} \Delta g_{ij}^{HS}(R^*)\, [R^*]^3\, dR^* \,. \qquad (84)$$

In this equation R^* is the dimensionless distance r/σ_{ij} and we are using the Lennard-Jones potential, so

$$u^*(R^*) = 4\, [(R^*)^{-12} - (R^*)^{-6}]. \qquad (85)$$

We used the Percus-Yevick solution for the hard sphere distribution functions, using the algorithm given by Perram [50]. The trapezoidal rule was used for the integrations, and an upper limit on the integrals was taken as $R^* = 4.0$.

Tables 5-7 show the comparisons of calculated pressures with our molecular dynamics simulation data. The models used in the comparisons are the MMDA, VDW-1, MDA and WCA. The Lee-Levesque WCA perturbation theory was implemented as described in section 3.2.4. The size ratio is two for all data, the energy ratios range from 0.5 to 3.0, and three different temperatures were studied. The use of the MMDA improved the results considerably over the van der Waals one-fluid and the original MDA theory; in some cases the improvement was an order of magnitude. The MMDA also gave results comparable to LL-WCA theory. All of the theories have a bias toward underpredicting the pressure. The poor results of both WCA and MMDA at T* = 1 can be attributed in part to the fact that many of the points in the table are either metastable liquids or may even be solid, as can be seen by observing the radial distribution function plots in Appendix B.

Table 8 shows comparisons of the MMDA pressure with simulation data from Hoheisel et al. [8]. The size ratio ranges from 1.05 to 2.0 and the energy ratio ranges from one to 4.5. The temperature is approximately constant at 200 K. The MMDA gave significant improvement over the MDA and VDW-1 theories for this data set, especially when the size ratio is greater than 1.55. The highest deviations are seen at the highest size and energy

ratios.

Table 9 gives further comparisons of the pressure computed with the MMDA with simulation data and theory. In this table, the values for the simulation data are taken from Hoheisel et al. [8] while the model predictions are taken from Shukla et al. [49]. They use a slightly different form of the WCA perturbation theory, in which the Grundke-Henderson [48] procedure is used to compute the derivatives of y at contact. The MMDA results were superior to VDW-1, MDA and HSE theories. The MMDA was slightly better than WCA perturbation theory at the highest size ratio, while for the lower size ratios WCA was slightly better.

4.3 Internal Energy

The energy equation [58],

$$U = \frac{3}{2} Nk_BT + 2\pi N\rho \sum_i^M \sum_j^M x_i x_j \int_o^\infty u_{ij}(r)\, g_{ij}(r)\, r^2 dr \quad . \tag{86}$$

may be used to compute the internal energy using the radial distribution functions. The MMDA hard sphere correction is implemented by

$$U = U^{MDA} + \Delta U^{HS} \tag{87}$$

and

$$\frac{\Delta U^{HS}}{Nk_BT} = \frac{2\pi\rho}{k_BT} \sum_i^M \sum_j^M x_i x_j \epsilon_{ij} \sigma_{ij}^3 \int_o^\infty \Delta g_{ij}^{HS}(R^*)\, u^*(R^*)\, [(R^*)]^2\, dR^*, \tag{88}$$

where the Δg term is given by eq (77), and $u^*(R^*)$ is given in eq (85). The integrations were performed using the trapezoidal rule, with an upper limit chosen as $R^*=4.0$. We again used the Percus-Yevick solution for the hard sphere distribution functions, following the algorithm given by Perram [50].

Tables 10-12 show the residual, dimensionless internal energy, U^r/Nk_BT, computed with the MMDA in comparison to the value found from the molecular dynamics simulation runs and the predictions of VDW-1, MDA and CWA theories. Here the CWA theory is the Lee-Levesque version described in section 3.2.4. Deviations from the simulation values are expressed as percentages, where here we define percent error = 100 (calculated - simulation)/simulation. The MMDA gives slightly better results than the MDA, VDW-1, and CWA. The improvement achieved with the use of MMDA is not as great for the internal energy as it was for the pressure.

4.4 Excess Properties

In order to further test the new MDA model, conformal solution calculations for excess properties were performed. A Lennard-Jones 6-12 reference fluid was used (with the 32 term BWR type equation of state of Nicolas et al.[59]). Calculations were made using the VDW-1, MDA and MMDA models. Unless stated otherwise, the mixing was performed at constant pressure,

$$X^E(T,p,\{x_i\}) = X^{mix}(T,p,\{x_i\}) - \sum_i^M x_i X_i(p,T) \qquad (89)$$

where X^E is any excess property and X_i denotes a pure fluid value of that property. In all computations the Lorentz-Berthelot combining rules, eq (4)-(5) were used for the unlike pair potentials.

Table 13 shows a comparison of the predicted excess volume and excess enthalpy and the Monte Carlo (MC) simulation data from Singer and Singer [5], as well the MDA and VDW-1 predictions. Singer and Singer's data are for equimolar mixtures of relatively small size ratios, 1.00-1.2727, and energy ratios of 0.656-1.235 for two temperatures. For equally sized particles, the MMDA reduces to the MDA. In general, as the size ratio increases the MMDA shows improvements over both VDW-1 and MDA theories for both excess volume and enthalpy, particularly when the energy ratio is also high. It is not clear why the MMDA does not do as well as MDA or VDW-1 for some of the points with energy ratio of 0.656.

Table 14 compares excess volume predictions to the data of Gupta [9], covering a range of size ratios and compositions at equal energy ratios. The excess volumes are quite small. For the largest size ratio, the MMDA offers significant improvement over VDW-1, which tends to give a much too large, negative number for the excess volume. The MDA theory also gives better results than the VDW-1 for these data.

Table 15 compares selected points from simulations of Hoheisel et al. [8] with conformal solution models. Hoheisel et al. estimate the isochoric excess internal energy from the simulation data is accurate to ± 20 J/mol. Although the MMDA does not give results within the experimental error, it does give a better approximation than MDA or VDW-1. For isobaric excess internal energy, excepting the point at p=3551 bar, the MMDA also gives the best predictions. The excess volume comparisons show the MMDA to give the best approximation as well, but not within experimental accuracy (estimated as ± 0.1 cm^3/mol [8]).

[1] ϵ_{11}/k_B = 34 K, σ_{11} = 0.2850 nm, σ_x from eq (35); simulation data from ref [8].

5.0 Conclusions

We have presented the results of an extensive molecular dynamics simulation study of Lennard-Jones 6-12 molecules with a size ratio of two. Energy ratios ranged from 0.5 to 3.0, and seven compositions (5, 10, 25, 50, 75, 90 and 95 mol percent) were investigated. Thermodynamic state data and radial distribution functions were presented. The method of Baxter was used to obtain direct correlation functions from the simulation radial distribution functions.

We also have presented a new conformal solution model, the modified mean density approximation, which is an improvement upon the mean density approximation. Extensive comparisons with simulation data and with other theories were given. The modified mean density approximation was shown to be superior to the VDW-1 fluid, HSE and MDA theories. It gave results comparable to those of the hard sphere perturbation theory of Lee and Levesque.

6.0 Acknowledgements

The authors would like to acknowledge Drs. Jeffery R. Fox and Denis J. Evans for many helpful discussions on computer simulation techniques, and Barry M. Valentine for his help with the graphs. This work was sponsored by the U. S. Department of Energy, Office of Basic Energy Sciences.

Nomenclature

Symbol	Physical Quantity
$c(r)$	direct correlation function
d	hard sphere diameter
$f(r)$	Mayer f function, eq (19)
f_i	equivalent substance reducing ratio, eq (24)
$g(r)$	radial distribution function
$h(r)$	total correlation function, eq (19)
h_i	equivalent substance reducing ratio, eq (24)
k_B	Boltzman constant
n_{ij}	particle coordination number, eq (1)
p	pressure
$q(r)$	Baxter q function, eq (17),(18)
r	distance
$u(r)$	intermolecular potential function
$w_{ij}(r)$	potential function, eq (48)
x_i	mol fraction of component i
$y(r)$	function defined in eq (19)
A	Helmholtz energy
	diffusivity
L_{ij}^c	cutoff parameter in eq (1)
M	number of components in the mixture
N	number of particles
S	sums defined in eq (44)
T	temperature
U	internal energy
X_{ij}	local composition, eq (2)
Z	compressibility factor

Symbol	Physical Quantity
α_{ij}, β_{ij}	parameters defined in eq (63,64)
ϵ_{ij}	Lennard-Jones potential parameter
ϕ, θ	shape factors, eq (25,26)
ρ	density
σ_{ij}	Lennard-Jones potential parameter
η	packing fraction, eq (29,44)
$\gamma_{ij}^{(0)}$, $\gamma_{ij}^{(1)}$	parameters in eq (56, 57)
X_m	quantity defined in eq (80)
ω	acentric factor
R^*	r/σ_{ij}
S^*	r/d_{ij}
T^*	$k_B/T\epsilon_{11}$
P^*	$p\sigma_{11}^3/\epsilon_{11}$
U^*	$(U - U^{ig})/N\epsilon_{11}$
ρ^*	$\rho\sigma_{11}^3$
BH	Barker-Hendersen
CS	Carnahan-Starling
DCF	direct correlation function
HS	hard sphere
HSE	hard sphere expansion
LJ	Lennard-Jones
MC	Monte Carlo
MCSL	Mansoori-Carnahan-Starling-Leland
MD	molecular dynamics
MDA	mean density approximation
MMDA	modified mean density approximation
o	reference fluid value
PY	Percus-Yevick
RDF	radial distribution function
VDW-1	Van der Waals one-fluid
WCA	Weeks-Chandler-Andersen

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

In this work we present the results of molecular dynamics computer simulations for binary Lennard-Jones mixtures with a size ratio of two. A total of 84 state points were investigated, at seven compositions ranging from 5 per cent to 95 per cent of the small molecule, energy ratios from 0.5 to 3.0, and three reduced temperatures. In addition to the thermodynamic results, we present extensive tabular data for the radial distribution functions, local compositions and the direct correlation functions. We also discuss several theories of dense fluid mixtures and give a new approximation for the radial distribution function of a pair in a mixture, which we call the modified mean density approximation. The predictions of various thermodynamic quantities from the different liquid mixture models are compared with simulation results. For mixtures with large size differences, the modified mean density approximation was found to be competitive with first order, Lee-Levesque type statistical mechanical perturbation theory.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

computer simulation; Lennard-Jones mixtures; mean density approximation, molecular dynamics

NIST Technical Publications

Periodical

Journal of Research of the National Institute of Standards and Technology—Reports NIST research and development in those disciplines of the physical and engineering sciences in which the Institute is active. These include physics, chemistry, engineering, mathematics, and computer sciences. Papers cover a broad range of subjects, with major emphasis on measurement methodology and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Institute's technical and scientific programs. Issued six times a year.

Nonperiodicals

Monographs—Major contributions to the technical literature on various subjects related to the Institute's scientific and technical activities.

Handbooks—Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications—Include proceedings of conferences sponsored by NIST, NIST annual reports, and other special publications appropriate to this grouping such as wall charts, pocket cards, and bibliographies.

Applied Mathematics Series—Mathematical tables, manuals, and studies of special interest to physicists, engineers, chemists, biologists, mathematicians, computer programmers, and others engaged in scientific and technical work.

National Standard Reference Data Series—Provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated. Developed under a worldwide program coordinated by NIST under the authority of the National Standard Data Act (Public Law 90-396). NOTE: The Journal of Physical and Chemical Reference Data (JPCRD) is published quarterly for NIST by the American Chemical Society (ACS) and the American Institute of Physics (AIP). Subscriptions, reprints, and supplements are available from ACS, 1155 Sixteenth St., NW., Washington, DC 20056.

Building Science Series—Disseminates technical information developed at the Institute on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

Technical Notes—Studies or reports which are complete in themselves but restrictive in their treatment of a subject. Analogous to monographs but not so comprehensive in scope or definitive in treatment of the subject area. Often serve as a vehicle for final reports of work performed at NIST under the sponsorship of other government agencies.

Voluntary Product Standards—Developed under procedures published by the Department of Commerce in Part 10, Title 15, of the Code of Federal Regulations. The standards establish nationally recognized requirements for products, and provide all concerned interests with a basis for common understanding of the characteristics of the products. NIST administers this program as a supplement to the activities of the private sector standardizing organizations.

Consumer Information Series—Practical information, based on NIST research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

Order the **above** *NIST publications from: Superintendent of Documents, Government Printing Office, Washington, DC 20402.*

Order the **following** *NIST publications—FIPS and NISTIRs—from the National Technical Information Service, Springfield, VA 22161.*

Federal Information Processing Standards Publications (FIPS PUB)—Publications in this series collectively constitute the Federal Information Processing Standards Register. The Register serves as the official source of information in the Federal Government regarding standards issued by NIST pursuant to the Federal Property and Administrative Services Act of 1949 as amended, Public Law 89-306 (79 Stat. 1127), and as implemented by Executive Order 11717 (38 FR 12315, dated May 11, 1973) and Part 6 of Title 15 CFR (Code of Federal Regulations).

NIST Interagency Reports (NISTIR)—A special series of interim or final reports on work performed by NIST for outside sponsors (both government and non-government). In general, initial distribution is handled by the sponsor; public distribution is by the National Technical Information Service, Springfield, VA 22161, in paper copy or microfiche form.
