Foreword

The National Standard Reference Data System provides effective access to the quantitative data of physical science, critically evaluated and compiled for convenience, and readily accessible through a variety of distribution channels. The System was established in 1963 by action of the President's Office of Science and Technology and the Federal Council for Science and Technology, with responsibility to administer it assigned to the National Bureau of Standards.

The System now comprises a complex of data centers and other activities, carried on in academic institutions and other laboratories both in and out of government. The independent operational status of existing critical data projects is maintained and encouraged. Data centers that are components of the NSRDS produce compilations of critically evaluated data, critical reviews of the state of quantitative knowledge in specialized areas, and computations of useful functions derived from standard reference data. In addition, the centers and projects establish criteria for evaluation and compilation of data and make recommendations on needed improvements in experimental techniques. They are normally closely associated with active research in the relevant field.

The technical scope of the NSRDS is indicated by the principal categories of data compilation projects now active or being planned: nuclear properties, atomic and molecular properties, solid state properties, thermodynamic and transport properties, chemical kinetics, and colloid and surface properties.

The NSDRS receives advice and planning assistance from the National Research Council of the National Academy of Sciences-National Academy of Engineering. An overall Review Committee considers the program as a whole and makes recommendations on policy, long-term planning, and international collaboration. Advisory Panels, each concerned with a single technical area, meet regularly to examine major portions of the program, assign relative priorities, and identify specific key problems in need of further attention. For selected specific topics, the Advisory Panels sponsor subpanels which make detailed studies of users' needs, the present state of knowledge, and existing data resources as a basis for recommending one or more data compilation activities. This assembly of advisory services contributes greatly to the guidance of NSRDS activities.

The NSRDS-NBS series of publications is intended primarily to include evaluated reference data and critical reviews of long-term interest to the scientific and technical community.

The JANAF Thermochemical Tables Project, sponsored and monitored by agencies of the Defense Department, has been considered an important part of the National Standard Reference Data System. The tables have found wide utility in technical areas far removed from those for which the work was initiated. Consequently, when plans for a Second Edition of the JANAF Thermochemical Tables were under discussion, a suggestion was made that they be incorporated into the NSRDS-NBS publication series. This suggestion was accepted, and the present volume, NSRDS-NBS 37, is the outcome. It is hoped that this publication channel will lead to even wider distribution and greater use of these very valuable tables.

LEWIS M. BRANSCOMB, *Director*

PREFACE TO THE FIRST EDITION

Beginning in the mid-1950's, when elements other than the conventional carbon, hydrogen, oxygen, nitrogen, chlorine, and fluorine came into consideration as rocket propellant ingredients, formidable difficulties were encountered in conducting rigorous theoretical performance calculations for these new propellants. The first major problem was calculational techniques. The second was the lack of accurate thermodynamic data.

By the end of 1959, the calculational technique problem had been substantially resolved by applying the method of minimization of free energy to large, high-speed digital computers. At this point the calculations became as accurate as the thermodynamic data upon which they were based. However, serious gaps were present in the available data. For propellant ingredients, only the standard heat of formation is required to conduct a performance calculation. However, this must be known to a high degree of accuracy. For combustion products, the enthalpy and entropy must be known, as a function of temperature, in addition to the standard heat of formation.

In order to resolve the problem, a substantial experimental thermodynamic research program was initiated under the sponsorship and technical direction of Project PRINCIPIA of the Advanced Research Projects Agency. Simultaneously, a project was initiated to critically evaluate and compile consistent tables of thermodynamic properties of propellant combustion products for use by the aerospace industry. This project, known as the "JANAF Thermochemical Tables," was undertaken by the Dow Chemical Company. Since the objective of the project was to have one single source of "best available data" prepared for use by the entire industry, the JANAF Thermochemical Panel undertook the task of furnishing a critical review of the Tables prior to their publication and distribution. This approach was designed to insure that the Tables be of the highest possible quality.

PREFACE TO THE SECOND EDITION

It is appropriate to call attention to some of the reasons for the phenomenal success of the JANAF Thermochemical Tables in achieving, first, the initial limited objective of providing the standard data for the chemical rocket propulsion industry, and later, upon publication, world-wide recognition as thermodynamic reference data of the highest quality and timeliness.

First, and most obvious, there was the selection and continued support of a highly competent evaluation team, themselves engaged in a broad spectrum of thermodynamic research. The personnel of the Thermal Research Laboratory of the Dow Chemical Company, under the direction of Dr. D. R. Stull and Dr. H. Prophet, have filled this role to a degree of excellence not likely to be exceeded anywhere. Moreover, the group has heroically remained productive in spite of many battles to retain continuing support, and the actual sharp reduction of funding over the past two years to a less-than-viable level.

A second important factor is the unusual approach to format, evaluation, and distribution of the Tables, as it has been followed since their inception. The primary distribution is in frequently issued loose-leaf supplements. Each previously issued table may thus be revised as often as necessary to take account of improved data. Each loose-leaf table is accompanied on its reverse side by a complete explanation of the selection of the key data, together with all references.

The third vital distinction of these Tables has been the existence of a continuing cognizant working group composed of technological users of data, thermodynamicists, and government sponsors of both research and development. Independent prepublication review of the Tables has been an important contribution of some of the members of this group; but its annual technical meetings have resulted in even more far-reaching benefits. Together, the users and generators of data have been able to establish realistic priorities for the species to be included in the Tables; at the same time the course of experimental research has been guided by the demonstration of absence or inadequacy of needed data. Although the working group no longer enjoys official recognition, the members and participants have enthusiastically volunteered to continue meeting in this important work.

Special words of appreciation are due to Dr. Charles W. Beckett, who has lined up all the technical presentations at the last six annual meetings of the working group; and to Mr. Curtis C. Selph who has served with wisdom and insight as the Air Force project monitor for the JANAF Thermochemical Tables contracts.

JOSEPH F. MASI
Air Force Office of Scientific Research

Arlington, Virginia
October, 1970

Members of the JANAF Thermochemical Panel (1959-1961) and the JANAF Thermochemical Working Group (1961-1964) were:

T. O. Dobbins, Advanced Research Projects Agency (Past Chairman)
W. H. Jones, Institute for Defense Analysis; Aerospace Corporation (Past Chairman)
W. G. May, Institute for Defense Analyses; Esso Research and Engineering Company
(Past Chairman)
C. W. Beckett, National Bureau of Standards (Vice Chairman)
G. W. Avery, Chemical Propulsion Information Agency (Past Secretary)
B. K. Farris, Chemical Propulsion Information Agency (Past Secretary)
T. L. Reedy, Chemical Propulsion Information Agency (Secretary)
B. J. Alley, Army Materiel Command
P. W. Bender, University of Wisconsin
W. A. Bennett, Bureau of Naval Weapons
B. Brown, Hercules Powder Company
C. L. Funk, Jet Propulsion Laboratory
J. S. Gordon, Thiokol Chemical Corporation
L. J. Gordon, Aerojet-General Corporation
S. A. Greene, North American Aviation, Incorporated
C. B. Henderson, Atlantic Research Corporation
D. L. Hildenbrand, Philco Corporation
J. L. Margrave, University of Wisconsin
J. P. McCullough, U.S. Bureau of Mines
P. L. Nichols, Jr., Jet Propulsion Laboratory
C. C. Selph, Air Force Systems Command
D. R. Stull, Dow Chemical Company

The Thermochemical Working Group of the Interagency Chemical Rocket Propulsion Group (ICRPG) has consisted of the following at various times during its existence (1964-1969).

Members

J. F. Masi, Air Force Office of Scientific Research (Chairman)
C. W. Beckett, National Bureau of Standards (Vice Chairman)
T. O. Dobbins, Advanced Research Projects Agency
S. Gordon, National Aeronautics and Space Administration
R. Jackel, Office of Naval Research
J. Murrin, Naval Ordnance Systems Command
R. Odom, Army Materiel Command
C. E. Selph, Air Force Rocket Propulsion Laboratory
D. Squire, Army Research Office

Participants

G. S. Bahn, Marquardt Corporation
B. Brown, Hercules, Incorporated
H. F. Calcote, AeroChem Research Laboratories
J. P. Coughlin, Aerojet-General Corporation
J. S. Gordon, Atlantic Research Corporation
D. R. Douslin, U.S. Bureau of Mines
M. Farber, Space Sciences, Incorporated
R. M. Fristrom, Applied Physics Laboratory
C. B. Henderson, Atlantic Research Corporation
D. L. Hildenbrand, Douglas Aircraft Company
J. L. Margrave, Rice University

W. G. May, Esso Research and Engineering Company
W. Mitchell, Thiokol Chemical Corporation
C. F. Robillard, Jet Propulsion Laboratory
L. Schieler, Aerospace Corporation
C. H. Shomate, Naval Weapons Center
D. R. Stull, Dow Chemical Company
M. Zimmer, Naval Ordnance Station

Secretariat (Chemical Propulsion Information Agency)

T. Gilliland
M. McCormack
T. L. Reedy

Project Personnel

The Tables began under the direction of Daniel R. Stull in 1959. Major contributions in the first two years were made by Thomas E. Dergazarian, Samuel Levine and Louis A. DuPlessis. In the years from 1961 to 1969 the major contributors were Jing Chao, Harold Prophet, Alan N. Syverud and Andrew T. Hu. In 1969 Harold Prophet succeeded Daniel R. Stull as project director. At present Alan N. Syverud, Andrew T. Hu and Jerry L. Curnutt are the principal contributors.

Special mention must be made of Alan N. Syverud for his help in the technical editing of the Tables. Also G. C. Sinke has aided the project on numerous occasions with criticism, advice and tables.

We also wish to acknowledge the valuable assistance of Norma Dumont 1959-64, Viola E. Harrington 1964-66, Carol S. Scheffler 1966-67, Wildene B. Harris 1967-68 and Mary J. Walter since 1968 in the typing of these Tables. Isabel Carr has provided valuable services to the group in abstracting, searching and ordering documents, and proof reading the Tables.

We also wish to thank the staff of the Computation Research Laboratory for their assistance in the many facets of the production of these Tables.

DANIEL R. STULL
HAROLD PROPHET

The fundamental constants are those recommended by the International Union of Pure and Applied Chemistry as reported by F. D. Rossini, Pure and Applied Chemistry, 9, 453 (1964). The physical scale based on the atomic mass of $^{12}\text{C} = 12$ reported by A. E. Cameron and E. Wichers, J. Am. Chem. Soc. 84, 4175 (1962) is employed. The temperature scale is nominally the 1948 International Practical Temperature Scale for measured quantities and nominally the thermodynamic temperature scale for calculated gaseous quantities. The probable errors between these scales and the 1968 International Practical Temperature Scale are given by T. B. Douglas, J. Research Natl. Bur. Std. 73A, 451 (1969).

Fundamental Constants

<u>Name</u>	<u>Symbol</u>	<u>Value</u>	<u>Units</u>
Velocity of Light	c	2.997925×10^{10}	cm s ⁻¹
Planck Constant	h	6.6256×10^{-27}	erg s
Avogadro Constant	N	6.02252×10^{23}	mol ⁻¹
Faraday Constant	$\mathcal{F}$	96,487.0	C mol ⁻¹
Absolute temperature of the "ice point", 0°C	T ₀ °C	273.1500	K
Molar volume of ideal gas (1 atm)	V ₀ °C	22,413.6	cm ³ mol ⁻¹
Pressure-Volume product for a mole of gas at 0°C and zero pressure	$\begin{matrix} P=0 \\ (PV) \\ T_0^\circ\text{C} \end{matrix}$	2271.06	J mol ⁻¹
Electronic Charge	e	1.60210×10^{-19}	C
Gas constant	R	8.3143	J deg ⁻¹ mol ⁻¹
		1.987165	cal deg ⁻¹ mol ⁻¹
Boltzmann Constant	k	1.38054×10^{-16}	erg deg ⁻¹ molecule ⁻¹
Second radiation constant	c ₂	1.43879	cm deg
Constant relating wave number and energy per mole E, in the relation $(\Delta E) = Nhc(\Delta\nu) = Z(\Delta\nu)$	Z	11.96255	J cm mol ⁻¹

Defined Constants

<u>Name</u>	<u>Symbol</u>	<u>Value</u>	<u>Units</u>
Standard gravity	g	980.665	cm s ⁻²
Standard atmosphere	atm	101 325	N m ⁻²
Standard millimeter of mercury pressure	mmHg	1/760	atm
Thermochemical calorie	cal	4.1840	J

SYMBOLS AND TERMINOLOGY

Throughout these tables, the symbols used are defined as follows:

amorph.	Amorphous state	S	Entropy
B	The rotational constant for diatomic or linear molecules	T	Temperature in degrees Kelvin ($T^\circ = t^\circ + 273.15^\circ$)
C_p	Molar heat capacity at constant pressure	t	Temperature in degrees Celsius
c	Crystalline state	V	Volume
D	Centrifugal distortion constant	V_0	Potential barrier
D_0	Dissociation energy required to break a bond at 0°K	x	First order vibrational anharmonicity constant
E	Internal or intrinsic energy	y	Second order vibrational anharmonicity constant
G or F	Gibbs energy = $E + PV - TS = H - TS$	α	Vibrational-rotational interaction constant
g_i	Quantum weight of electronic states	ϵ	Electronic energy level
()	Parentheses following a vibrational frequency are used to indicate the degeneracy	μ	Reduced mass of the molecule
g	Gaseous state, or statistical weight	ρ	Density
GFW	Gram Formula Mass	σ	Symmetry number
gls	Glassy state	ω	Vibrational frequency
H	Enthalpy (or heat content) = $E + PV$	[]	Square brackets enclose estimated quantities
I_A, I_B, I_C	Principal moments of inertia of a molecule	<u>Subscripts</u>	
$I_A I_B I_C$	Product of the principal moments of inertia of a molecule	a	Atomization
K	Equilibrium constant	b	Boiling point at one atmosphere pressure
k	Hooke's Law force constant	c	Combustion, or critical state
liq. or l	Liquid state	d	Dissociation
ln	Logarithm to the base e ($e = 2.7182818$)	e	Equilibrium position
log	Logarithm to the base 10	f	Formation from elements in their standard states
n	Number of potential maxima in an internal rotation	i	The i th quantity
P	Pressure in atmospheres	m	Melting
r	Internuclear distance	p	Constant pressure
		r	Reaction
		s	Sublimation
		t	Transition
		v	Vaporization

In addition to the above symbols, the spectroscopic symbols and terminology employed by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., and "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., New York, are adopted.

Circular superscript, °, indicates the thermodynamic standard state.

Numerical subscript, as $_{298.15}$, denotes temperature in Kelvins.

Δ indicates the increment in a given property for a given process or reaction, taken as the value for the final state (or sum for the products) less that for the initial state (or sum for reactants).

ΔH , ΔG , ΔS , ΔC_p equal the increment in enthalpy, Gibbs energy, entropy and heat capacity, respectively, for a process or reaction.

ΔH_f° represents the standard enthalpy of formation, which is the increment in enthalpy associated with the reaction of forming the given compound from its elements, with each substance in its thermodynamic standard state at the given temperature.

$\Delta H_c^\circ_{298.15}$ symbolizes the enthalpy of combustion of a given substance, in gaseous oxygen to completely oxidized products at 25°C. and constant pressure, with all reactants and products in their appropriate standard states.

SYMBOLS AND TERMINOLOGY

$\Delta H_{298.15}^\circ$ represents the enthalpy change in a given reaction at 25°C and constant pressure with all the reactants and products in their appropriate standard states.

When the reaction or process evolves heat, the sign of the change in enthalpy is negative. Conversely, when the reaction or process absorbs heat, the sign of the change in enthalpy is positive.

ΔG_f° or ΔF_f° denotes the standard Gibbs energy of formation, which is the increment in Gibbs energy associated with the reaction of forming the given compound from its elements, with each substance in its thermodynamic standard state at the given temperature.

$\log_{10} K_p$ stands for the logarithm (to the base 10) of the thermodynamic equilibrium constant of formation for the reaction of forming the given compound from its elements at the indicated temperature.

$(H_T^\circ - H_{298.15}^\circ)$ indicates the enthalpy (or heat content) in the standard state at the temperature T less the enthalpy in the standard state at 298.15 K.

$(G_T^\circ - H_{298.15}^\circ)/T$ or $(F_T^\circ - H_{298.15}^\circ)/T$ denotes the Gibbs energy function in the standard state at temperature T, and is defined as $-S_T^\circ + (H_T^\circ - H_{298.15}^\circ)/T$.

S_T° represents the absolute entropy of the thermodynamic standard state at the absolute temperature T, omitting contributions from nuclear spins.

The Standard State is taken as the state at one atmosphere pressure and the temperature under consideration for the solid, liquid, and ideal gas. Only homogeneous substances are considered here.

The Reference State applies to elements in their stable standard state. Consequently the Reference State tables presented here are either single phase or polyphase tables.

CHANGES IN SYMBOLS ON TABLES DATED 6-30-66 OR LATER

The following symbols are used, without periods, to indicate units as follows:

<u>Symbol</u>	<u>Unit</u>	<u>Symbol</u>	<u>Unit</u>
Å	angstrom	eu	calories per degree-mole
atm	atmosphere	g	gram
cal	calorie	J	joule
deg	degree (temperature)	kcal	kilocalorie
°C	degree Celsius	mm	millimeter
°K	degree Kelvin	mol	mole
eV	electron volt	gibbs	calories per degree

Subscripts as defined earlier are used as symbol modifiers but are placed on the same line, thus, heat capacity is abbreviated as C_p° , enthalpy of formation as ΔH_f° , etc.

RELATIONSHIP TO SI UNITS

The symbols cal. mole⁻¹ deg⁻¹ and gibbs/mol are identical and refer to units of calories per degree-mole. These units can be converted to SI units of joules per degree-mole by multiplying the tabulated values by 4.184. Similarly values in kilocalories per mole can be converted to joules per mole by multiplying with the factor 4184. For further discussions of the SI system and for conversions from other units the reader should consult Pure and Applied Chemistry, 21, 1 (1970).

EVALUATION OF THERMODYNAMIC DATA

A. Interconsistency

The basic aim of these thermodynamic property tables is to provide a related and consistent set of enthalpies and Gibbs energies of formation. This allows the prediction of the enthalpy and Gibbs energy changes of any reaction among the constituents of the tables. Since the enthalpy and Gibbs energy of formation are related to each other by the entropy of formation we may choose to make consistent any two of these quantities. The entropy, which is an absolute quantity in thermochemical calculations, is ideal for this purpose. Since the enthalpy of reaction is the most common link between different materials, we adopt it as the other consistent quantity. Unfortunately enthalpies are not absolute quantities and in order to achieve consistency it is necessary to provide a consistent base. This is done by referring all enthalpies of formation to the elements in their reference states. By convention the enthalpy of formation of an element in its reference state is zero at all temperatures.

The reference state may be single phase or multiphase and examples of both kinds are found in this compilation. In these tables we have generally chosen the ideal diatomic gas for the reference state of permanent gases such as O_2 , N_2 , Cl_2 etc. For elements which are solid at room temperature we adopt the solid state up to the melting point, then the liquid up to the boiling point, and then the gas phase. These choices are arbitrary and vary in different compilations. Enthalpies or Gibbs energies of formation taken from different sources should be checked to ensure that the reference states are the same.

The choice of reference states is the first step in any scheme for interconsistency, and is the relation of all quantities to comparable bases. The next step in obtaining an interconsistent set of values, ideally, would be to take all the measured values of enthalpies, Gibbs energies and entropies of reaction and, after adjustment to the proper reference states, to solve the whole set simultaneously. This would provide values for enthalpies, Gibbs energies and entropies which when combined would yield the minimum overall deviations from the measured values. We have already taken this approach in a limited sense by treating groups of interrelated fluorides simultaneously. Hopefully with even larger memories in computers we shall be able to move towards the ultimate goal. As an interim solution it is necessary to fix, simultaneously when possible, certain key values for common reactants such as water, hydrochloric acid, etc., these can then be used to help fix smaller groups of interrelated compounds.

Because of the several revisions of these tables we do not claim to maintain perfect interconsistency. However, the consistency of the tables is a prime concern and a cause for revision if the effects are of the same order of magnitude as the stated uncertainties. As an example, over 100 fluoride tables have been revised since a new HF gas table was adopted in December 1968.

Another type of consistency is involved in systems where properties must be estimated. For example the estimation of certain properties of a series of halides must be done so that the proper graduation in properties occurs from fluoride to iodide and from polyhalide to monohalide. Similarly the evaluation of experimental data must be done in a consistent manner, and this is discussed in the next section.

B. General Evaluation Techniques

1. The Second-Law Method

Starting from the equation $\Delta G^\circ = -T\ln K$, by differentiation with respect to T and substitution of $d(\Delta G^\circ)/dT = -\Delta S^\circ$, we obtain $\Delta H^\circ = RT^2 d(\ln K)/dT$, the well known van't Hoff equation. By substituting $dT = -T^2 d(1/T)$ one obtains $\Delta H^\circ = -Rd(\ln K)/d(1/T)$, thus, the slope of a $\ln K$ versus $1/T$ plot is $-\Delta H^\circ/R$. If ΔH° is constant then the slope is constant and the plot is a straight line. Since the variation of ΔH° with temperature is often quite small it is customary to assume a straight line relationship. This method of obtaining heats of reaction from equilibrium measurements is known as a "second-law" calculation. However, it should be noted that for greatest accuracy the equilibrium measurements should extend over a wide range of temperature, and in this case ΔH° is probably not constant. Curvature corrections can be applied by assuming a specific form for the variation of ΔH° with temperature, however, the effects of such corrections are of significance only with very precise measurements. It should be noted that the second law cannot be applied to a single observation, but the third-law method, which is described below, can be used. The second-law method can be applied when only relative values of the equilibrium constant are available, for example, from mass-spectroscopic intensity measurements.

2. The Third-Law Method

The third-law method is based on a knowledge of the absolute entropy of the reactants and products. It allows the calculation of a reaction enthalpy from each data point when the change in the Gibbs-energy function for the reaction is known. The Gibbs-energy function is defined as $gef_T = (G_T^\circ - H_{ref}^\circ)/T$ and is easily calculated from the relation

$$S_T^\circ = -(G_T^\circ - H_{ref}^\circ)/T = (H_T^\circ - H_{ref}^\circ)/T - (G_T^\circ - H_{ref}^\circ)/T$$

thus,

$$gef_T = -S_T^\circ + (H_T^\circ - H_{ref}^\circ)/T.$$

From the definition we can write for the change in a reaction

$$\Delta G^\circ/T = \Delta gef_T + \Delta H_{ref}^\circ/T = -R\ln K_p$$

thus,

$$\Delta H_{ref}^\circ/T = -R\ln K_p - \Delta gef_T$$

where Δ signifies Σ products $-\Sigma$ reactants.

In the JANAF Thermochemical Tables, Gibbs-energy functions are based on 298 K and, thus, yield enthalpies at 298 K regardless of the temperature of the reaction. It should be noted that, since most of these tables are single phase tables, the Gibbs-energy functions of liquids are based on liquid at 298 K even though it may not exist at 298 K. This differs from the usual convention of combining all condensed phases into one table; in this case the enthalpy of reaction refers to the state stable at the base temperature. In these tables the functions always refer to the state of the table at 298 K regardless of its stability. For

example, if the vapor pressure over liquid copper is analysed using $\text{Cu}(l)$ Gibbs-energy functions the enthalpy of vaporization at 298 K will result. To calculate the enthalpy of sublimation of Cu it is necessary to add the heat of melting at 298 K, which is the difference in the heat of formation of $\text{Cu}(l)$ and $\text{Cu}(c)$ at 298 K. It should also be noted that Gibbs-energy functions are always negative, thus the function $-(G_T^\circ - H_T^\circ)/T$ is usually tabulated and the proper sign must be remembered when using these functions.

The analysis of data by the third law is generally considered superior to the second-law analysis. It is definitely superior if the Gibbs-energy functions are measured, because each data point is independent of the others. Thus, third-law analysis will often reveal trends in the equilibrium constants of a set of data that indicate nonequilibrium or erroneous values. We have found a combination of the two methods to be so valuable that a third-law calculation is always accompanied by a second-law treatment of the same data. The calculation is done in ascending temperature order to give ΔH_{298} and its deviation from the mean, δ , and the calculated $\log K_p$ and its deviation from the least-squares line. Third-law analyses enables bad points to be seen as deviations from the general trend of the differences; thus the method can be used even when the Gibbs-energy functions are estimated. If these bad points are located on the ends of the data set, the second-law line often fits quite well through them and by itself does not arouse suspicion. Moreover, the dropping of such points can bring widely discordant slopes into agreement with each other and often with the third-law values. The data sets given in Table 1 illustrate these comments. The first set of data contains all the reported points and is in disagreement with earlier values around 54 kcal/mole. The third-law analysis indicates the first two points are poor, and the effect of dropping these two is shown in the second set of data. This latter second-law slope has changed considerably; the heat is in good agreement with the earlier data and with the third law. The size of the third-law deviations in the second set indicates that the data are not very reproducible. A deviation of 0.5 kcal at 1000°K represents an uncertainty of 30% in the measured equilibrium constants.

If measured Gibbs-energy functions are available, third-law analysis is preferred; however, if the data are good, the second-law value should agree. When the Gibbs-energy functions are estimated, the third-law values derived from them must be handled carefully. Values that are constant and that agree with the second-law enthalpy indicate that the Gibbs-energy functions and equilibrium data are mutually consistent. A drift with temperature of the third-law values indicates errors in either the data or the functions. The magnitude of such drifts is often given in the table write-up and represents the entropy change required to bring the second- and third-law values into agreement. If the drift is within the experimental entropy uncertainty then the data are acceptable. Drifts which are much larger than reasonable entropy errors generally indicate failure to attain equilibrium.

Table 1. Analysis of Equilibrium Data
 $\text{PbF}_2(c) \rightarrow \text{PbF}_2(g)$, data of Nesmeyanov and Iofa, Russ. J. Inorg. Chem. 4, 219 (1959)

$\Delta H_{298} = 55.38$			$\Delta H_{298} = 47.29$								

3. Heat Capacities

The evaluation of reported values is a relatively subjective procedure, but the analysis should be as objective as possible and therefore certain ground rules must be laid. The first step is the fitting by orthogonal polynomials and the computer-generated plotting of all information so that a general idea of the agreement can be visually obtained. If certain data sets differ from the majority, they are examined for possible causes of the difference. Calibration data, sample purity, and experimental scatter are checked. If the source of error can be located, the data are given appropriately less weight. Otherwise all data of equal reliability are considered equal, even if they disagree. Such data are then smoothed by a weighted orthogonal polynomial curvefit. Enthalpy data are smoothed similarly and heat capacities are derived directly from the differentiated polynomial. The smoothing of enthalpy data requires constraining the fit so that it passes through zero at the reference temperature. Additional constraints are often used to fix the heat capacity at 298 K, or to join enthalpy data smoothly with low-temperature heat capacities.

4. Transitions

The evaluation of solid state transitions involves first the recognition of the type of transition, which may not always be obvious. A first-order transition such as fusion involves a change of enthalpy and entropy at the transition point, whereas second-order transitions involve only discontinuities in heat capacity. Because of impurities and other factors, all first-order transitions do not occur at one temperature; rather, they spread a little on either side and are sometimes difficult to distinguish from λ -type second-order transitions. In order to evaluate the enthalpy of a first-order transition from heat-capacity data, an enthalpy change $(H_{T_2} - H_{T_1})$ from T_1 to T_2 °K must be reported on either side of the transition. The normal heat-capacity curve is extended forward and backward to the temperature of the transition-heat-capacity maximum to form a base line. If T_1' and T_2' are the temperatures at which the transitional heat capacity curve leaves and rejoins the base line, and ubl and obl designate under and over the base line, the heat of transition given by

$$\Delta H_t = (H_{T_2} - H_{T_1}) - (H_{T_2} - H_{T_1})_{ubl} + (H_{T_1'} - H_{T_1})_{obl} + (H_{T_2'} - H_{T_2})_{obl}$$

Figures 1 and 2 show two possible cases. The shaded areas represent the enthalpy over the base line and cross-hatched areas the enthalpy under the base line.

EVALUATION OF TRANSITIONAL ENTHALPIES

FIGURE 1

EVALUATION OF TRANSITIONAL ENTHALPIES

FIGURE 2

Many enthalpies of fusion and enthalpies of solid-state transitions are obtained from enthalpy measurements and therefore require different treatment. Here the heats are given directly by the difference in enthalpy at the transition temperature. Normally, the enthalpy above and below can be smoothly extended to the temperature of transition, although the transition temperature may not be clearly obtainable from the enthalpy data.

The heats of the remaining transitions, vaporization and sublimation, are evaluated from equilibrium data by the second- and third-law methods just described except when calorimetric measurements are available.

5. Equilibrium

Perhaps the most significant factors to be established in evaluating equilibrium data are that equilibrium was attained and that the process was properly described. For example, in a sublimation process the most accurate measurements are valueless if the vapor phase is not uniquely defined. If polymerization or breakdown might have occurred, the first order of business is to establish the exact reaction. Because mass spectroscopy has shown that vapor phases are often extremely complex, it is almost a requirement that before equilibrium data can be accepted the vapor phases must be examined by a mass spectrometer to ensure their composition. Some methods of measurement are less accurate than others and should be given less weight. For example, equilibria determined in a mass spectrometer are usually quite rough because many approximations and uncertainties are involved in obtaining an absolute pressure measurement. On the other hand, measurements of the electromotive force of reversible cells can have great accuracy. Once the system is defined and equilibrium data are available, the data are analyzed by the second- and third-law methods.

CONSTRUCTION OF THE TABLES

1. Solid Phase

To produce a final table after all of the data have been evaluated or estimated, the enthalpy of formation, the entropy at 298 K, and the heat capacity at reasonable intervals through the temperature range of interest are needed. The enthalpy is obtained from the heat capacity by evaluating $\int_{298}^T C_p dT$. The entropy is similarly obtained from the heat capacity by evaluating $\int_{298}^T (C_p/T) dT$. The Gibbs energy function is then obtained from the relation $(G_T^\circ - H_{ref}^\circ)/T = -S_T^\circ + (H_T^\circ - H_{ref}^\circ)/T$. Enthalpies of

formation at temperatures other than 298 K require a knowledge of the enthalpies of the reference elements:

$$\Delta H_f^\circ = \Delta H_f^\circ_{298} + (H_T - H_{298})_{\text{compd}} - \sum (H_T - H_{298})_{\text{elements}}$$

The Gibbs energy of formation is readily calculated from the heat of formation when the entropies of the elements are known. Thus

$$\Delta G_f^\circ = \Delta H_f^\circ - T[S_T(\text{compd}) - \sum S_T(\text{elements})]$$

The logarithm of the equilibrium constant of formation is then found from the relation $\Delta G_f^\circ = -4.5756T \log K_p$.

Until now, we have only considered the calculation of values above 298 K; however, it is desirable to have data all the way to absolute zero. The temperature 0 K is a natural base for measurements involving gases in their lowest energy state, and values are needed in order to convert to the thermochemical reference temperature of 298 K. There is no basic difference in evaluating low-temperature data, but many more heat-capacity points are needed because of the large curvature. It is also necessary to evaluate the starting entropy at some temperature above 0 K because data rarely extend to below 5 K. In order to evaluate enthalpy it is necessary to start with a value above zero and integrate up to 298 K; then the value at 298 K is subtracted from the intermediate values, giving negative values below 298 K.

The tables extend to well above the normal melting point to facilitate the use of the tables by computers which can then interpolate values accurately right at the melting point. Dotted and solid lines indicate the end of the phase stability and solid-state transitions respectively.

2. Liquid Phase

The construction is identical with that used for the solid phase; however, the required data at 298 K are not usually readily available. The data are obtained by calculating a preliminary table using the chosen heat capacities with zero values for $\Delta H_f^\circ_{298}$ and S°_{298} . The correct starting values are then determined by comparing the values from the tables of crystal and liquid, using the following equations:

$$\Delta H_m^\circ = \Delta H_f^\circ(\ell) - \Delta H_f^\circ(c)$$

$$\Delta S_m^\circ = \frac{\Delta H_m^\circ}{T_m} = S^\circ_{T_m}(\ell) - S^\circ_{T_m}(c)$$

The correct values at 298 K may be obtained from the above relations. A typical liquid table is extrapolated both below the melting point and above the boiling point to facilitate interpolation near the phase boundaries.

3. Gas Phase

The data required for the various types of molecules are summarized below. The equations used are given in the section on Computational Methods. All molecules require the gram formula mass and enthalpy of formation at 298 K.

Additionally, monatomic species require: $\epsilon_0, \epsilon_1 \dots \epsilon_n$ and $g_0, g_1 \dots g_n$

Diatomic species require: $B_e, \sigma, x_e, \omega_e, \alpha_e, \epsilon_i, g_i$ ($i = 0, \dots, n$)

Linear polyatomic species require: B_e, σ, ω_i ($i = 1, \dots, 3N-5$), ϵ_i, g_i ($i = 0, \dots, n$)

Nonlinear polyatomic species require: $\sigma, \log I_A I_B I_C, \omega_i$ ($i = 1, \dots, 3N-6$), ϵ_i, g_i ($i = 0, \dots, n$)

ϵ_i is the energy of the i th electronic level

g_i is the statistical weight of the i th electronic level

B_e is the rotational constant

σ is the symmetry number

x_e is the anharmonicity correction = $\omega_e x_e / \omega_e$

ω_e is the fundamental frequency of a diatomic molecule

ω_i is a fundamental frequency of a polyatomic molecule

α_e is the rotational vibrational interaction constant

N is the number of atoms in the molecule

$I_A I_B I_C$ is the product of the moments of inertia

Monatomic species often have a large number of electronic levels; it is usual to average the higher levels taking account of the individual multiplicities. Diatomic and polyatomic species sometimes have several excited states which are low enough to make appreciable contributions. These states are treated by direct summation over the individual partition functions using anharmonic-oscillator approximations for each state. If vibrational and rotational constants for the higher states are not available the calculations are simplified by assuming the ground state values for each state.

4. Multiphase Tables

Tables which show only values for the real phases at one atmosphere pressure are multiphase tables. In this compilation they are generally reference state tables, though some solid phase tables include more than one phase. Multiphase tables can always be recognized by the presence of solid lines, indicating phase transitions, on the table. They are prepared in a manner similar to tables for condensed phases. The functions are evaluated in the same manner as for a solid up to the first transition point; then the heat and entropy of transition are added and the integration is continued using the second-phase heat capacities. At each phase boundary the above process is repeated.

USE OF TABLES

The rapid proliferation of thermodynamic tabulations in recent years brings with it the possibility of serious abuse of the information in them. First, as we explained earlier, not all tabulations are based on the same reference states. To avoid this pitfall it is helpful to write down the reaction and check the value and state of each component. It is even better to utilize only a single compilation whenever possible, because values from different compilations may not be consistent or compatible. Second, the base temperatures of compilations differ between 0 and 298 K. Only enthalpies and Gibbs-energy functions are affected, but they can result in serious errors if used indiscriminately.

A different type of error is caused by misunderstanding the significance of negative Gibbs-energy changes. For example, many species in the JANAF Thermochemical Tables have large negative Gibbs energies of formation at 6000 K. This does not necessarily imply that the species are stable, but only that the Gibbs-energy change from the elemental reference state is negative. In fact, nearly all the elements are monatomic gases at 6000 K, and the reference states are generally unstable with respect to the atoms. Similarly, a negative Gibbs-energy change does not mean a reaction will occur, but means only that the reaction is favorable as written. For example, at 298 K

However, at normal pressures this reaction would generally be recognized as unlikely in view of

Similarly, in combining free energies of reaction, one should be careful not to combine impossible reactions with possible ones to obtain an over-all favorability:

This equation is impossible because we cannot combine the reactions

and

by simple addition. Both reactions must be written so that they are possible. They then become

Then by simple addition

Although these tables have been continuously revised it is not possible to keep all the tables fully revised with the latest data. Thus, each table indicates the dates of each revision at the foot of the tabular values. The latest date is most important since information generated after that date has not been incorporated. The frequency of revisions often indicates the level of research activity on the compound and may indicate further changes in the future.

CALCULATIONAL METHODS

The presentation of Mayer and Mayer "Statistical Mechanics", John Wiley & Sons, Inc., New York, (1940) forms the basis for the expressions given below for the ideal gas state. The calculations have been carried out by a Burroughs B5500 electronic computer.

I. Ideal Monatomic gas

(a) Translation

$$\begin{aligned} (H^\circ - H_0^\circ)/T &= C_p^\circ = 4.967913 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ -(G^\circ - H_0^\circ)/T &= 6.863426 \log M + 11.439043 \log T - 7.282868 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ S^\circ &= 6.863426 \log M + 11.439043 \log T - 2.314954 \text{ cal deg}^{-1} \text{ mol}^{-1}. \end{aligned}$$

(b) Electronic

$$\begin{aligned} C_p^\circ &= \frac{4.113664}{T^2} \left[\frac{\sum \epsilon_i^2 g_i e^{-\frac{1.438790 \epsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790 \epsilon_i}{T}}} - \left(\frac{\sum \epsilon_i g_i e^{-\frac{1.438790 \epsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790 \epsilon_i}{T}}} \right)^2 \right] \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ (H^\circ - H_0^\circ)/T &= \frac{2.859114}{T} \frac{\sum \epsilon_i g_i e^{-\frac{1.438790 \epsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790 \epsilon_i}{T}}} \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ -(G^\circ - H_0^\circ)/T &= 4.575617 \log \sum g_i e^{-\frac{1.438790 \epsilon_i}{T}} \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ S^\circ &= \frac{2.859114}{T} \frac{\sum \epsilon_i g_i e^{-\frac{1.438790 \epsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790 \epsilon_i}{T}}} + 4.575617 \log \sum g_i e^{-\frac{1.438790 \epsilon_i}{T}} \text{ cal deg}^{-1} \text{ mol}^{-1}. \end{aligned}$$

II. Ideal Diatomic Gas

(a) Translation and Rotation

$$\begin{aligned} C_p^\circ &= 6.955079 + 0.0914148 (B/T)^2 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ (H^\circ - H_0^\circ)/T &= 6.955079 - 0.953038 (B/T) - 0.0914148 (B/T)^2 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ -(G^\circ - H_0^\circ)/T &= 6.863426 \log M + 11.439043 \log T - 4.575617 \log (B\sigma/T) + 0.953038 (B/T) \\ &\quad + 0.0457074 (B/T)^2 - 8.005804 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ S^\circ &= 6.863426 \log M + 11.439043 \log T - 4.575617 \log (B\sigma/T) - 0.0457074 (B/T)^2 - 1.050725 \\ &\quad \text{cal deg}^{-1} \text{ mol}^{-1}. \end{aligned}$$

where $B = (B_e - \alpha_e/2)$ when spectroscopic constants are available.

$$B = \frac{2.799076 \times 10^{-39}}{I} \text{ when calculated from a molecular model, (I in g cm}^2\text{)}$$

(b) Vibration

$$\begin{aligned} C_p^\circ &= 1.987165 u^2 e^{-u}/(1-e^{-u})^2 \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ (H^\circ - H_0^\circ)/T &= 1.987165 u e^{-u}/(1-e^{-u}) \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ -(G^\circ - H_0^\circ)/T &= -4.575617 \log (1-e^{-u}) \text{ cal deg}^{-1} \text{ mol}^{-1}. \\ S^\circ &= 1.987165 u e^{-u}/(1-e^{-u}) - 4.575617 \log (1-e^{-u}) \text{ cal deg}^{-1} \text{ mol}^{-1}. \end{aligned}$$

where $u = (1.438790/T) \cdot (\omega_e - 2\omega_e x_e)$ when spectroscopic constants are available.

$u = (1.438790/T)\omega$ where ω is the fundamental wave number of a harmonic oscillator.

(c) Electronic

Same as I(b) when the i th-state vibrational partition function, Q_v^i and the i th-state rotational partition function, Q_r^i , are equal to the respective ground state partition functions. In this case the partition function $Q = Q_t Q_v Q_r \sum_i Q_e^i$, otherwise all the thermodynamic functions are derived from $Q = Q_t \sum_i Q_e^i Q_v^i Q_r^i$, where Q_t is the translational partition function and $Q_e^i = g_i \exp(\epsilon_i/kT)$.

(d) Anharmonicity Corrections

$$C_p^\circ = 1.987615 \left[\frac{16\gamma}{u} - \frac{\delta u^2 e^u}{(e^u - 1)^2} + \frac{u^2 e^u (2\delta e^u - 4Xu - 8X)}{(e^u - 1)^3} + \frac{12Xu^3 e^{2u}}{(e^u - 1)^4} \right] \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$(H^\circ - H_0^\circ)/T = 1.987165 \left[\frac{8\gamma}{u} + \frac{u(\delta e^u - 2X)}{(e^u - 1)^2} + \frac{4Xu^2 e^u}{(e^u - 1)^3} \right] \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$-(G^\circ - H_0^\circ)/T = 1.987165 \left[\frac{8\gamma}{u} + \frac{\delta}{(e^u - 1)} + \frac{2Xu}{(e^u - 1)^2} \right] \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$S^\circ = 1.987165 \left[\frac{16\gamma}{u} + \frac{\delta}{(e^u - 1)} + \frac{\delta u e^u}{(e^u - 1)^2} + \frac{4Xu^2 e^u}{(e^u - 1)^3} \right] \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

where u is $(\omega_e - 2\omega_e x_e) \cdot 1.438790/T$

$$X = (\omega_e x_e)/\omega_e; \quad \delta = \alpha_e/B_e; \quad \gamma = B_e/\omega_e.$$

III. Linear Polyatomic Molecule

- (a) Translation and rotation same as for II (a).
- (b) Vibration same as II (b) for 3N-5 vibrational degrees of freedom.
- (c) Electronic same as II (c) where levels and quantum weight are known.
- (d) Anharmonic corrections neglected.

IV. Nonlinear Polyatomic Molecule (Rigid Rotator, Harmonic Oscillator).

(a) Translation and Rotation

$$C_p^\circ = 7.948662 \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$(H^\circ - H_0^\circ)/T = 7.948662 \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$-(G^\circ - H_0^\circ)/T = 6.863426 \log M + 18.302469 \log T - 4.575617 \log \sigma + 2.287809 \log I_A I_B I_C \times 10^{117} - 10.297926 \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$S^\circ = 6.863426 \log M + 18.302469 \log T - 4.575617 \log \sigma + 2.287809 \log I_A I_B I_C \times 10^{117} - 2.349265 \text{ cal deg}^{-1} \text{ mol}^{-1}$$

- (b) Vibration same as II (b) for 3N-6 vibrational degrees of freedom.
- (c) Electronic same as II (c) where levels and quantum weight are known.
- (d) Anharmonic corrections neglected.

V. Condensed States

Evaluation of thermodynamic data for condensed states rests upon either measured or estimated information. Heat-capacity data are plotted, smoothed, and data for calculations read back at regular temperature intervals. Integration of this smoothed heat capacity data is carried out with the relations

$$H_T^\circ - H_{298.15}^\circ = \int_{298.15}^T C_p^\circ dT \quad S_T^\circ = \int_0^T \frac{C_p^\circ}{T} dT$$

by machine, three points at a time. The computer calculates the constants for a parabolic equation through the three points, and employs the constants to integrate the first temperature interval. The lowest point is discarded; the next higher point is combined with the two retained points; and a new set of parabolic constants calculated and used for integrating the next higher temperature interval. This recurrent procedure is well suited to this type of calculation. At the appropriate temperatures, transition enthalpies are added to the enthalpy total, while the quotient of the transition enthalpy divided by the absolute temperature is added to the entropy total.

NOTES

1. Indexing

The modified Hill indexing system, J. Am. Chem. Soc. **22**, 478-94 (1900), for Chemical Compounds as used by Chemical Abstracts and the Classification Division of the U. S. Patent Office is used to index the chemical compounds in this data collection. The arrangement of atomic symbols in chemical formulas is alphabetical except for carbon compounds. Thus, the indexing of chemical compounds is as follows: Ac (actinium compounds), Ag (silver compounds), Al (aluminum compounds), Am (americium compounds), Ar (argon), As (arsenic compounds), Au (gold compounds), B (boron compounds), Ba (barium compounds), Be (beryllium compounds), and so on throughout the alphabet. Once the correct order of the elements in the formula is deduced, the location of a compound within the group is easily accomplished. This obviates the need for pagination, and the index page indicates the correct order.

Organic (carbon) compounds represent a gigantic group, so that for convenience this one class of compounds presents the exceptions to the alphabetical rule. In carbon compounds the C always comes first, followed immediately by H if hydrogen is present, and then followed by any other elements present in their normal alphabetical order. The number of atoms of the element indexed first also influences the order of indexing the compound; e.g., all formulas with C (one carbon atom only) come before those with C₂ (two carbon atoms), followed by C₃ compounds, and so on. Thus: CHBF₄O (formyl fluoride, compound with BF₃), CHCl₃ (chloroform), CH₂F₃P (trifluoromethylphosphine), CH₃NO₃ (methyl nitrate), CH₄Cl₂Si (dichloromethylsilane), CH₁₀N₄O₃ (hydrazine carbonate), CO (carbon monoxide), CO₂ (carbon dioxide), CO₃Zn (zinc carbonate), CZr (zirconium carbide), C₂Ba (barium acetylide), C₂BrClF₂ (bromochlorodifluoroethylene), C₂Ca (calcium carbide), and so on. See any formula index of Chemical Abstracts for further details and examples.

2. Selection of Enthalpy Reference Temperature

Since no enthalpy measurements can be made in the sense of an absolute quantity, and since all enthalpy measurements are made as a difference between an initial and a final state, it is necessary to select the thermodynamic state to which all other thermodynamic states will be referred. For these tables, the thermodynamic state selected is chosen as the state at one atmosphere total pressure tabulated at 298.15 K. Note that the temperature 298 K listed in the table actually refers to 298.15 K, but decimals have been omitted in the temperature column. Usage in theoretical work indicates the selection of the state existing at absolute zero, which is a hypothetical state that is even approached by relatively few measurements. Values of the difference in heat between 298.15 and 0 K will permit theoretical workers to use these tables, so it was decided to tabulate values at 0 K. Modern usage of thermodynamic data sometimes requires application to conditions below ambient, so the decision was made to tabulate values at 0, 100, and 200 K where the information is available.

3. Limitations of Calculated Quantities

Calculation of the contributions of rotation and translation involves the use of quantum statistics, but to obtain a numerical solution the quantum statistics are usually replaced by classical statistics at temperatures above about 100 K. Attempts to employ these methods below 100 K lead into a temperature range where the approximation afforded by classical statistics no longer holds. For this reason the equations presented under "Calculational Methods" fail in the vicinity of 0 K. In agreement with the third law concept, C_p^o and S^o are zero at 0 K. For a reference element, log K_p is zero at 0 K, while for compounds the absolute values of the free energy function and log K_p become infinite at 0 K.

4. Reference State of an Element

A related set of thermodynamic property tables requires that there be a reference table of the thermodynamic properties for each element to which all other forms of that element or any compound involving that element may be referred. If the temperature range of interest (6000 K here) can be represented by a single phase for that material (say hydrogen) the tabulated values in the reference table will be smooth and regular. If the temperature range of interest includes more than one phase (say magnesium) there will be a solid phase (from 0 to 922 K, the melting point), a liquid phase (922 to 1378 K, where the vapor pressure reaches one atmosphere), and a gas phase (1378 to 6000 K), the tabulated values in the reference table will be discontinuous at these phase boundaries. Practical usage dictates that in so far as possible the phase most stable at one atmosphere pressure (that is, the form most easily worked with) be selected. This practice is followed in these tables, and does lead to discontinuities in the thermodynamic functions. Attention is called to these discontinuities in the polyphase reference-state tables by insertion of a solid line at the temperature of a phase transition. The phase transitions considered are: first-order solid-state transformations from one crystal type to some other, solid to liquid, and solid or liquid to gas at one atmosphere.

5. Single-Phase Table

It is expected that these tables will be employed on various problems solved by automatic machine computation. Such calculations are carried out in numerous ways, and vary from one installation to another. Programs to perform these calculations are simplified if the thermodynamic functions are smooth and extend beyond the actual range of use permitting a wide latitude in iterative procedures. For this reason, most tables other than elemental reference states are tabulated as single-phase tables. Thus, tables for the solid state are extrapolated well past the melting point; those for the liquid state are extrapolated below the melting point (into the supercooled-liquid range to 298.15 K) and well above the atmospheric boiling point, while gas tables are tabulated from 0 K to 6000 K. Care has been taken to preserve the correct free energy relationships between the extrapolated-phase functions and the functions of the real phase. Attention is called to these extrapolations by insertion of a dotted line at the temperature where the indicated phase meets an adjacent more stable phase, but for reasons mentioned above the indicated phase is extrapolated into a temperature range where it is thermodynamically unstable.

N O T E S

6. Mole

With each table and text there is listed either the atomic, molecular, or gram formula mass. It is generally understood that this mass in grams refers to Avogadro's number of atoms or molecules, and will be referred to simply as a "mole".

7. Point Groups and Ground-State Configurations

Throughout these tables the nomenclature and definition of the ground-state configurations and point groups are those in use by C. E. Moore, U. S. National Bureau of Standards Circular 467, (1949), and G. Herzberg, "Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, (1950), and "Molecular Spectra and Molecular Structure, II. Infrared and Raman Spectra", D. Van Nostrand Co., New York, (1945).

8. Decimal Places

Three decimal places have been arbitrarily carried in the tables even though in numerous cases the data do not warrant this accuracy. This has been done to preserve the proper relationship of the thermodynamic functions, and to facilitate machine interpolation of these values.

9. Higher Electronic Terms

A single electronic term of $30,000\text{ cm}^{-1}$ and above contributes a negligible amount to the thermodynamic functions at temperatures of 8000 K and below. On the other hand, a number of such terms cannot be neglected. In these cases, the number of terms and their values have been summed and their contribution included.

10. Estimated Vibrational Frequencies

Some vibrational frequencies have been estimated by analogy with related molecules. Occasionally, more than one frequency has been averaged at the same value. This is not to be confused with a true degeneracy which is indicated by placing the degeneracy value in parentheses following the frequency. However, when the information has been taken from another compilation, the degeneracies indicated by the compiler have been retained.

11. Quantum Weight

The term quantum weight is also referred to as statistical weight by many authors. The quantity is the product of the spin multiplicity and state degeneracy of the electronic level under consideration.

12. Isotope Effects

The functions calculated for gases from molecular constants are, in general, obtained from constants which have been corrected to the natural isotopic abundance.

INDEX TO TABLES

Filing Order	Table Title	Filing Order	Table Title
Al	Aluminum (ref. st.)	AlI ₃	Aluminum Triiodide (l)
Al	Aluminum (c)	AlI ₃	Aluminum Triiodide (g)

(CRYSTAL)

AT. WT. = 26.9815

$$\Delta H^\circ_f 0 = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H^\circ_f 298.15 = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H^\circ_m = 2.56 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H^\circ_m 298.15 = 78.0 \text{ kcal. mole}^{-1}$$

$$S^\circ_{298.15} = 6.769 \pm 0.02 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T^\circ_m = 933^\circ\text{K.}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The low temperature heat capacity curve is based on the work of N. E. Phillips, *Phys. Rev.* **114**, 676 (1959) in the range 0.1 to 4°K; J. A. Cox and M. H. Reesom, *Physica* **4**, 835 (1937) from 1-20°K. and M. G. Glaue and P. F. Meads, *J. Am. Chem. Soc.* **63**, 1897 (1941). The high temperature enthalpy adopted here is that of R. A. McDonald, private communication, Dow Thermal Research Laboratory, Oct. 1965. This data is in general agreement with the measurements of J. H. Averbury and E. Griffiths, *Proc. Phys. Soc. (London)* **38**, 378 (1926); E. D. Eastman, A. M. Williams and T. F. Young, *J. Am. Chem. Soc.* **45**, 1178 (1924); M. B. Kandel and R. Hultgren, private communication to D. R. Stull from R. L. Orr Mar. 29, 1960; S. Satoh, *Sci. Papers, Inst. Phys. Chem. Res. (Tokyo)* **29**, 19 (1936); P. Wust, A. Mauthen and R. Durrer, *Forsch. Arb. Ver. deut. Ing. No. 204 (1918). Other investigations have been discussed by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley "Selected Value of Thermodynamic Properties of Metals and Alloys", John Wiley and Sons, Inc., New York, (1963). These other determinations generally lay below the adopted values.*

Melting Data.

The heat of melting was reported by McDonald, loc. cit.. It is in good agreement with the selected value of Hultgren et al, loc. cit. The chosen value also has eliminated uncertainty due to reaction of the liquid aluminum and its vessel by use of BN and TiB₂ containers. The melting point of 933°K. was chosen at the limit of the "well established" 932 ± 1°K., as more likely representing pure aluminum. This choice was based mainly on the work of M. F. Roess and H. T. Wensei, *J. Res. Natl. Bur. Std.* **44**, 247 (1935).

Sublimation Data.

See Al(g) for details.

$$\Delta H_f^{298.15} = 8.42 \text{ gibbs/mol}$$

$$\Delta H_m^\circ = 2.56 \pm 0.05 \text{ kcal/mol}$$

$$\Delta H_v^\circ = 69.497 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 8.42 \text{ gibbs/mol}$$

$$T_m^\circ = 933^\circ \text{K}$$

$$T_b^\circ = 2766.8^\circ \text{K}$$

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between $H_{298}^\circ - H_{298}^\circ$ for (c) and (l).

Heat Capacity and Entropy

The heat capacity is adopted from the enthalpy measurements of R. A. McDonald, private communication, Thermal Research Laboratory, The Dow Chemical Company, Midland, Michigan, Oct. 1965. The liquid enthalpies were determined in crucibles of BN and Ti_2 sealed in a platinum-rhodium capsule. The liquid enthalpies are in agreement with the determination of J. W. Auberry and E. Griffiths, Proc. Phys. Soc. (London) 38, 378 (1976) and higher, by as much as 12 percent, than those of F. Wust, A. Meuthen and R. Dorrer, Forsch. Arb. Deut. Ing. No 204 (1918) and S. Umino, Sci. Repts. Tohoku. Imp. Univ. Ser 1, 15, 597 (1926). The enthalpy data is adequately represented by a constant heat capacity. The entropy is calculated from that of the crystal in a manner analogous to the heat of formation.

Melting Data

See Al(c) for details.

Vaporization Data

The temperature of boiling and the heat of vaporization are derived from the adopted functions and the heat of sublimation in order to maintain thermodynamic consistency.

Heat of Formation.

The heat of sublimation of aluminum has been derived from a second and third law analysis of the vapor pressure data of several investigators; the results are tabulated below.

Ref.	Range °K.	Method	Points	ΔH°_{298} subli. kcal. mole ⁻¹	Drift cal. deg. ⁻¹ mole ⁻¹
1	1273-1473	Knudsen	10*	76.3 ± 2.3	75.32 ± 0.7
2	1734-2237	Boiling	4	83.1 ± 0.3	74.58 ± 1.8
3	1393-1468	Knudsen	10	89.8 ± 32.9	77.29 ± 3.7
4	1410-1468	Knudsen	6	71.9 ± 19.2	78.4 ± 1.3
5	1511-1723	Mass Spec	11	77.2 ± 2	70.5
6	2473	Boiling	1		77.35
7	1476	Knudsen	1		
8	1400-1611	Torsion	104	80.3 ± 1.2	79.5 ± 0.3

*1 point rejected due to failure of statistical test.

It is apparent that there is little real agreement in the data; in Ref. 3 some of this is due to diffusion of liquid Al through the TaC crucibles, while Ref. 8 reports surface oxidation of the sample. The data for Ref. 5 have been reworked since they corrected their data using ΔC_p between (1) and (g) of -2 cal. deg.⁻¹ mole⁻¹, where our tables give a value of -2.62 cal. deg.⁻¹ mole⁻¹. Ref. 8 has obtained by far the largest number of data points all of which are in good agreement, show no trend and little scatter. Ref. 1 has gone to a great deal of trouble to ensure uniform heating, total collection of effluents and good Knudsen conditions and also has no trend. It is difficult to imagine why these two series differ by a factor of 3 in the pressure. An intermediate value of the heat of sublimation has been adopted at 78 ± 2 kcal. mole⁻¹. This choice is also indicated by the decomposition of AlN(c) to Al(g) and 1/2 N₂(g), which has been well established as 163.7 ± 0.8 kcal. mole⁻¹, combined with the heat of formation of AlN(c) = -78 ± 0.3 kcal. mole⁻¹, to yield $\Delta H^{\circ}_{sub} \text{ Al} = 77.7 \pm 0.9 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The electronic ground state configuration and the higher electronic levels are taken from C. E. Moore, Natl. Bur. Stds. Circular 467, "Atomic Energy Levels" Washington 1949.

Aluminum Unipositive Ion (Al⁺)
(Ideal Gas) Mol. Wt. = 26.98095

ALUMINUM UNIPOSITIVE ION (Al⁺) (IDEAL GAS) MOL. WT. = 26.98095

Ground State Configuration 1s² 2s² 2p⁶ 3s¹
ΔH_f⁰ = 215.4 ± .5 kcal/mole
ΔH_f^{298.15} = 217.3 ± .5 kcal/mole
S_{298.15}⁰ = 35.813 cal. deg.⁻¹ mole⁻¹

Heat of Formation.
The heat of formation was calculated from the equation: Al(g) - e⁻ → Al⁺(g) with the JANAP auxiliary value for Al(g) using an I.P. = 4.627916 X 10⁴ cm.⁻¹ (136.047 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.
The electronic levels and quantum weights were obtained from C. E. Moore loc. cit. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H⁺-H₂₉₈²⁹⁸ value at 0°K. is -1.481 kcal/mole.

ALUMINUM BORON DIOXIDE (AlBO₂)

(IDEAL GAS)

Point Group [C_{2v}]
 $\Delta H_f^\circ = -128.8 \pm 4$ kcal/mol
 $S_{298.15}^\circ = [64.4]$ gibbs/mol
 $\Delta H_f^\circ = -129.4 \pm 4$ kcal/mol
 $\Delta H_{298.15}^\circ = -129.4 \pm 4$ kcal/mol
 Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω , cm ⁻¹	ω , cm ⁻¹

[600](1)	[800](1)

Bond Distances: Al-O = [1.66] Å O-B = [1.36] Å B-O = [1.20] Å
 Bond Angle: Al-O-B = [145]° O-B-O = [180]°
 Product of the Moments of Inertia: $I_A I_B I_C = [6.65357] \times 10^{-115}$ g³ cm⁶

$\sigma = 1$

Heat of Formation

The heat of formation, ΔH_f° (AlBO₂, g) = -129.4 ± 4 kcal/mol, was calculated from the heat of reaction, $\Delta H_{1500}^\circ = -14.7 \pm 3.2$ kcal/mol for $1/2 \text{ Al}_2\text{O}_3(\text{g}) + 1/2 \text{ B}_2\text{O}_3(\text{g}) = \text{AlBO}_2(\text{g})$ with all JANAF auxiliary data. The value of ΔH_{1500}° was obtained from the mass spectrometric determination of ion intensity ratios by A. Buchler, P. E. Blackburn and J. L. Stauffer, "Thermodynamics of Vaporization in the Aluminum Oxide-Boron Oxide System," ARPA Order No 315-62, Arthur D. Little, Inc., Cambridge, Mass.

Heat Capacity and Entropy

The bent molecular structure, the bond distances O-B and B-O, and the bond angle O-B-O were assumed to be the same as those in LiBO₂(g). The bond distance Al-O and the bond angle Al-O-B were estimated to be the same as those in Al₂O(g). The three principal moments of inertia are $I_A = 0.7255 \times 10^{-39}$, $I_B = 29.9238 \times 10^{-39}$, and $I_C = 30.6495 \times 10^{-39}$ g cm². The vibrational frequencies were estimated by comparison with those in LiBO₂(g), Al₂O(g), B₂O₃(g), and AlCl(g).

$$\frac{G_i}{\sigma_i}, \text{ cm.}^{-1} \frac{g_i}{1}$$

$$\omega_e x_e = 1.276 \text{ cm.}^{-1} \quad \sigma = 1$$

$$\omega_e = 0.1586 \text{ cm.}^{-1} \quad r_e = 2.295 \text{ \AA}$$

$$\omega_e = 377.40 \text{ cm.}^{-1}$$

$$B_e = 0.1586 \text{ cm.}^{-1}$$

Heat of Formation.

S. A. Semakovich, Zh. Fizik, Khim. 50, 933 (1957) measured the vapor pressure of the reaction $\text{Al(l)} + \text{NaBr(l)} \rightarrow \text{Na(g)} + \text{AlBr(g)}$ at 1175°K. By the third law method the heat of reaction (ΔH_f° , 298.15) was evaluated to be 108.31 kcal. mole⁻¹. The value of ΔH_f° 298.15 for AlBr(g) was calculated as 3.6 ± 5.0 kcal. mole⁻¹. Based on this value the dissociation energy (D_0°) was derived to be 4.3 ± 0.2 e.v. which is in excellent agreement with the value, $D_0^\circ = 4.3 \pm 0.2$ e.v., reported by A. G. Daydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The dissociation energy (D_0°) of AlBr(g) was reported to be 2.4 e.v. and 105 kcal. mole⁻¹ (4.55 e.v.) by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950 and R. P. Barrow, Trans. Faraday Soc. 56, 952 (1960), respectively. However, using these D_0° values, the corresponding values of ΔH_f° 298.15 for AlBr(g) were found to be 48.55 and -1.11 kcal. mole⁻¹. The adopted value was calculated from the vapor pressure data reported by S. A. Semakovich, loc. cit.

Heat Capacity and Entropy.

The spectroscopic constants were taken from G. Herzberg, loc. cit. and corrected to the average isotopic species.

Bond Distances: Al-O = [1.66] Å O-B = [1.36] Å B-O = [1.20] Å
Bond Angle: Al-O-B = [145]° O-B-O = [180]°
Product of the Moments of Inertia: I_AI_BI_C = [6.65357] X 10⁻¹¹⁵ g³ cm⁶

G = 1

Heat of Formation.

The heat of formation, ΔHf°₂₉₈ (AlBO₂, g) = -129.4 ± 4 kcal/mol, was calculated from the heat of reaction, ΔHf°₁₅₀₀ = -14.7 ± 3.2 kcal/mol for 1/2 Al₂O₃(g) + 1/2 B₂O₃(g) = AlBO₂(g) with all JANAP auxiliary data. The value of ΔHf°₁₅₀₀ was obtained from the mass spectrometric determination of ion intensity ratios by A. Büchler, P. E. Blackburn and J. L. Stauffer, "Thermodynamics of Vaporization in the Aluminum Oxide-Boron Oxide System," ARPA Order No 315-62, Arthur D. Little, Inc., Cambridge, Mass.

Heat Capacity and Entropy.

The bent molecular structure, the bond distances O-B and B-O, and the bond angle O-B-O were assumed to be the same as those in LiBO₂(g). The bond distance Al-O and the bond angle Al-O-(BO) were estimated to be the same as those in Al₂O(g). The three principal moments of inertia are I_A = 0.7255 X 10⁻³⁵, I_B = 29.9238 X 10⁻³⁵, and I_C = 30.6493 X 10⁻³⁵ g cm².

The vibrational frequencies were estimated by comparison with those in LiBO₂(g), Al₂O(g), B₂O₃(g), and AlCl(g).

Heat of Formation.

S. A. Semenkovich, Zh. Prikl. Khim. 50, 933 (1957) measured the vapor pressure of the reaction $Al(1) + HgBr(1) \rightarrow Na(g) + AlBr(g)$ at 1175°K. By the third law method the heat of reaction (ΔH_f^0 298.15) was evaluated to be 108.31 kcal. mole⁻¹. The value of ΔH_f^0 298.15 for AlBr(g) was calculated as 3.6 ± 5.0 kcal. mole⁻¹. Based on this value the dissociation energy (D_0^0) was derived to be 4.3 ± 0.2 e.v. which is in excellent agreement with the value, $D_0 = 4.3 \pm 0.2$ e.v., reported by A. O. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The dissociation energy (D_0^0) of AlBr(g) was reported to be 2.4 e.v. and 105 kcal. mole⁻¹ (4.55 e.v.) by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950 and R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960), respectively. However, using these D_0^0 values, the corresponding values of ΔH_f^0 298.15 for AlBr(g) were found to be 48.55 and -1.11 kcal. mole⁻¹. The adopted value was calculated from the vapor pressure data reported by S. A. Semenkovich, loc. cit.

Heat Capacity and Entropy.

The spectroscopic constants were taken from O. Herzberg, loc. cit. and corrected to the average isotopic species.

Aluminum Tribromide (AlBr₃)
(Crystal) GFW = 266.7085

AlBr₃

GFW = 266.7085

(CRYSTAL)

ALUMINUM TRIBROMIDE (AlBr₃)

$\Delta H_f^\circ = -121.4 \pm 3 \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = -126.0 \pm 3 \text{ kcal/mol}$
 $\Delta H_m^\circ = 2.69 \text{ kcal/mol}$

$S_{298.15}^\circ = 43.08 \pm 0.25 \text{ gibbs/mol}$

$T_m = 370.6^\circ\text{K}$

Heat of Formation

The value of ΔH_f° for AlBr₃(c) is that selected by the National Bureau of Standards (1). The methods and auxiliary data used to obtain their value are not given. Their result is apparently based on the heats of reaction of aqueous solutions of AlBr₃ measured by Berthelot (2).

Heat Capacity and Entropy

The heat capacity of AlBr₃(c) has been measured from 11.6° to 308.1°K by Justice (3) and the enthalpy from 337° to 367°K by Fischer (4). The heat capacities used are derived from curve fits of these data. The Cp values above 370.6°K are obtained by graphical extrapolation. Justice (3) reported the value of $S_{298}^\circ = 0.951 \text{ eu}$.

Melting Data

Fischer (4) determined the melting temperature (T_m) of AlBr₃(c). The heat of melting (ΔH_m°) is calculated from the enthalpies of AlBr₃(c) and AlBr₃(l) at the melting temperature. The enthalpy of the crystal at the melting point was determined from the curve used for the heat capacity calculations. The enthalpy of the liquid at the melting point was determined from a linear least squares fit to the enthalpy data for AlBr₃(l) reported by Fischer (4).

ALUMINUM TRIBROMIDE (AlBr₃)

(LIQUID)

GFW = 266.7085

$$S_{298.16}^{\circ} = 49.352 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -123.633 \pm 3 \text{ kcal/mol}$$

$$T_m = 370.6^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 2.69 \text{ kcal/mol}$$

$$T_b = 529^{\circ}\text{K (to dimer gas)}$$

$$\Delta H_v^{\circ} = 5.92 \text{ kcal/mol (to dimer gas)}$$

Heat of Formation

The heat of formation (ΔH_{298}°) of $\text{AlBr}_3(\ell)$ is calculated from ΔH_{298}° of $\text{AlBr}_3(\text{c})$ plus the heat of melting (ΔH_m°) and the enthalpy differences ($H_{370.6}^{\circ} - H_{298}^{\circ}$) of the crystal and liquid.

Heat Capacity and Entropy

Fischer (1) has measured the enthalpy of $\text{AlBr}_3(\ell)$ from 371° to 406°K. The heat capacity used is derived from a linear least squares fit to his data. The resulting constant value for the heat capacity is adopted for temperatures above 406°K. The entropy (S_{298}°) of $\text{AlBr}_3(\ell)$ was determined in a manner analogous to that for the heat of formation.

Melting Data

See $\text{AlBr}_3(\text{c})$ table for details.

Vaporization Data

The heat of vaporization (ΔH_v°) of $\text{AlBr}_3(\ell)$ is determined from the work of Fischer et al. (2). The boiling temperature (T_b) was calculated from their vapor pressure data. See $\text{Al}_2\text{Br}_6(\text{g})$ table for details.

Dec. 31, 1961; June 30, 1964; June 30, 1967

ALUMINUM TRIBROMIDE (AlBr₃) (IDEAL GAS)

GFW = 266.7085

ΔH₀⁰ = -95.7 ± 4 kcal/mol

ΔH_{298.15}⁰ = -101.1 ± 4 kcal/mol

Point Group {D_{3h}}

S_{298.15}⁰ = 84.5 gibbs/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	ω, cm ⁻¹
[215] (1)	[100] (2)
[109] (1)	[418] (2)

σ = {6}

Bond Distance: Al-Br = [2.27] Å

Bond Angle: Br-Al-Br = [120]°

Product of the Moments of Inertia: I_{AlBr₃}⁰ = 2.16 × 10⁻¹¹¹ g² cm⁶

Heat of Formation

Fischer et al. (1) have determined the equilibrium constants for the reaction 2AlBr₃(g) = Al₂Br₆(g) from vapor density measurements. The heats of reaction are calculated from these data using both second law and third law methods. The adopted value of ΔH₂₉₈⁰ is -101.1 ± 4 kcal/mol. The results of the calculations are as follows:

Range	No. Pts.	ΔH ₂₉₈ ⁰ kcal/mol	ΔH ₂₉₈ ⁰ kcal/mol	Drift, Δu	H ₂₉₈ ⁰ kcal/mol
605-854	4	Second Law	Third Law	0.16 ± 1.33	-98.4
	7			-0.20 ± 0.67	-98.5

*Calculation based on the third law value of ΔH₂₉₈⁰

Heat Capacity and Entropy

The molecular structure of AlBr₃(g) is assumed to be the same as that of AlF₃(g). The bond distance was estimated by Heise and Wieland (2). The vibrational frequencies are estimated from the force constants of BBr₃(g) (3) and then adjusted so that the values of ΔH₂₉₈⁰ obtained by the second and third law methods are in good agreement. The principal moments of inertia are: I_A = I_B = 1.03 × 10⁻³⁷, and I_C = 2.05 × 10⁻³⁷ g cm².

Heat of Formation

Equilibrium constants as a function of temperature for the reaction $2\text{Al}(t) + \text{AlCl}_3(g) \rightarrow 3\text{AlCl}(g)$ have been reported by many investigators. The data were subjected to second and third law analyses with results as follows (Alr at 298.15°K refers to $2\text{Al}(c) + \text{AlCl}_3(g) \rightarrow 3\text{AlCl}(g)$):

Investigator(s)	Temp. Range °K	Number of Data Points	ΔH_f° , kcal/mol AlCl ₃	Drift eu
Rao and Dadage (1)	1125-1475	11	102.3±1.6	102.8±0.8
Frisch et al. (2)	931-1034	9	99.7±1.1	106.7±0.5
Gross et al. (3)	1225-1278	7	a	109.7±2.8
Ginsberg et al. (4)	1423-1500	8	91.4±1.8	104.7±0.8
Semenkovich (5)	1223-1473	6	89.2±0.4	98.5±1.3
Heimgartner (6)	978-1383	13	58.8±2.5	100.0±9.5
Weiss (7)	1273-1473	3	93.1±3.4	86.3±1.2
Pinchuk et al. (8)	1173-1373	3	86.0±7.5	95.0±1.9
Mitani et al. (9)	1273-1473	b	88.9	99.1±2.1
Kikuchi et al. (10)	1273-1523	b	78.7	98.7±5.0
Tanabe et al. (11)	1173-1573	b	93.3	94.6±0.5
Russell et al. (12)	1388	1	103.8	0.9

a. Temperature range too small for significant second law calculation.

b. These data available only as equations as given in Chemical Abstracts.

Unfortunately, most of the data are very discordant and of no help in defining $\Delta H_f^\circ(\text{AlCl}, g)$. The results of Rao and Dadage (1) cover a temperature range of 300°K, show good compatibility with the thermodynamic functions, are near an average of all the data, and are judged most acceptable. The third-law heat of reaction derived from their data is adopted and combined with the heat of formation of $\text{AlCl}_3(g)$ to give $\Delta H_f^\circ(298.15)(\text{AlCl}, g) = -12.30 \pm 1.0 \text{ kcal/mol}$.

Gross et al. (3) reported equilibrium constants for the reaction of aluminum with sodium chloride and potassium chloride and Pinchuk et al. (8) determined equilibrium constants for reaction of aluminum with sodium chloride and magnesium chloride. The results of Pinchuk et al. (8) are suspect in that the partial pressures of sodium and magnesium chlorides they calculate from their data exceed the saturation pressures calculated from JANAF data. The data of Gross et al. (3) were recalculated to allow for effects of dimer in sodium chloride and potassium chloride vapors (JANAF data):

Reaction	T, °K	Kp(atm) ²	$\Delta H_f^\circ(298.15)(\text{AlCl}, g)$, kcal/mol
$\text{NaCl}(g) + \text{Al}(t) \rightarrow \text{AlCl}(g) + \text{Na}(g)$	1043	4.178x10 ⁻¹⁰	109.24
$\text{NaCl}(g) + \text{Al}(t) \rightarrow \text{AlCl}(g) + \text{Na}(g)$	1243	1.138x10 ⁻⁶	102.31
$\text{KCl}(g) + \text{Al}(t) \rightarrow \text{AlCl}(g) + \text{K}(g)$	1023	5.14x10 ⁻¹¹	110.47

The result for $\text{NaCl}(s)$ is the average of 12 experiments whereas the $\text{NaCl}(t)$ and $\text{KCl}(s)$ are based on 5 and 3 experiments, respectively, and the $\text{NaCl}(s)$ value is considered the most reliable. The derived heat of formation is in good agreement with the value selected on the basis of the Rao and Dadage data.

Barrow (13) has compared thermochemical and spectroscopic dissociation energies for monohalides of B, Al, Ga, In, and Tl. A short extrapolation of vibrational levels gives $D_0 = 124.1 \text{ kcal/mol}$ for AlCl while predissociation indicates $D_0 \leq 120.1 \text{ kcal/mol}$. The maximum predissociation value gives $\Delta H_f^\circ(298.15)(\text{AlCl}, g) = -14.1 \text{ kcal/mol}$, in reasonable agreement with the selected value. Barrow (13) speculates that a potential maximum occurs in the A'' state of Alr and AlCl which causes extrapolation of vibrational levels to give erroneous heats of dissociation.

Heat Capacity and Entropy

The vibrational frequency and anharmonicity constants were taken from Herzberg (14) and the structural constants are based on microwave spectroscopy by Lide (15). The electronic levels were reported by Sharma (16).

Heat of Formation

D. L. Hildenbrand, E. Murad, L. P. Theard and F. Ju, Aeronutronic Report No. U-3197, July 30, 1965, under contract AF 04(611)-10743, reported an appearance potential of 9.4 ± 0.4eV for AlCl⁺. They suggested that the magnitude of the value indicated formation by direct ionization of AlCl(g).

R. F. Porter and E. E. Zeller, J. Chem. Phys. 33, 858 (1960), obtained an appearance potential of 19.7 ± 0.5eV for AlCl⁺ which they attributed to formation from AlCl(g). Assuming the process to be AlCl₃(g) + e⁻ → AlCl⁺(g) + 2Cl(g) + 2e⁻ ΔH = 454 kcal, one obtains ΔHf²⁹⁸(AlCl⁺) = 257 kcal/mol, or an ionization potential of 11.6eV. This would almost certainly represent an upper limit, since the fragments could easily contain excess kinetic energy.

We adopt the ionization potential of 9.4 ± 0.4eV obtained by Hildenbrand et al., which yields ΔHf²⁹⁸(AlCl⁺, g) = 205 ± 10 kcal/mol.

Heat Capacity and Entropy

AlCl⁺ is isoelectronic with MgCl, and the electronic configuration of the ground state and first excited state are estimated to be those for MgCl. The vibrational frequency, anharmonicity constant and bond length are estimated by comparison with those for MgCl and AlCl. The rotational constant is calculated from the bond length and atomic masses, and ω_e is calculated from the other constants assuming a Morse potential function. The enthalpy at 0°K is -2.236 kcal/mol.

AlCl⁺

Point Group C_{2v} $\Delta H_f^\circ = [-120 \pm 20] \text{ kcal. mole}^{-1}$ $\Delta H_f^\circ = [87.388] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^\circ = [-120 \pm 20] \text{ kcal. mole}^{-1}$

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

 $\omega, \text{ cm}^{-1}$

[590] (1)

[730] (1)

Bond Distances: Al-F = [1.63] Å

Bond Angle: Cl-Al-F = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.48427 \times 10^{-114}] \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The value of ΔH_f° 298.15 for AlClF(g) was calculated based on an assumption that $\Delta H_f^\circ = 0$ for the reaction $\text{AlF}_2(\text{g}) + \text{AlCl}_2(\text{g}) = 2\text{AlClF}(\text{g})$. The ΔH_f° 298.15 values for $\text{AlF}_2(\text{g})$ and $\text{AlCl}_2(\text{g})$ used for calculation are -185.0 and -75.0 kcal. mole⁻¹, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated to be consistent with those for $\text{AlF}_2(\text{g})$ and $\text{AlCl}_2(\text{g})$. The bond distances of Al-F and Al-Cl were estimated to be the same as those in $\text{AlF}_3(\text{g})$ and $\text{AlCl}_3(\text{g})$, respectively. The bond angle and ground state quantum weight were estimated to be consistent with those for $\text{AlF}_2(\text{g})$ molecule. The three principal moments of inertia are: $I_A = 2.41078 \times 10^{-39}$, $I_B = 2.3289 \times 10^{-39}$ and $I_C = 2.64387 \times 10^{-38} \text{ g. cm.}^2$.

Aluminum Chloride Difluoride (AlClF₂)

(Ideal Gas) Mol Wt. = 100.437

AlClF₂

MOL. WT. = 100.437

ALUMINUM CHLORIDE DIFLUORIDE (AlClF₂) (IDEAL GAS)

Point Group C_{2v}
 $\Delta H_f^\circ = [-235.8 \pm 20] \text{ kcal. mole}^{-1}$
 $S^\circ_{298.15} = [71.242] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^\circ = [-237.6 \pm 20] \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ_{298.15} = [-237.6 \pm 20] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω , cm. ⁻¹	ω , cm. ⁻¹	ω , cm. ⁻¹
[500] (1)	[250] (1)	
[280] (1)	[800] (1)	
[200] (1)	[900] (1)	
Bond Distances: Al-P = [1.65]Å Al-Cl = [2.14]Å		
Bond Angle: Cl-Al-P = [120]° P-Al-P = [120]°		
Product of the Moments of Inertia: I _A I _B I _C = 1.47245 X 10 ⁻¹¹³ g. ³ cm. ⁶		
Heat of Formation: $\Delta H_f^\circ = 0$ for the reaction AlCl ₃ (g) + 2AlF ₃ (g) = 3AlClF ₂ (g). The values of ΔH_f° 298.15 for AlF ₃ (g) and AlCl ₃ (g) used for calculation are -286.5 and -139.7 kcal. mole ⁻¹ , respectively.		

$\sigma^\circ = 2$

Heat Capacity and Entropy

The vibrational frequencies were estimated by comparison with those for AlF₃(g) and AlCl₃(g). The bond distances of Al-P and Al-Cl atoms were assumed to be the same as those in AlF₃(g) and AlCl₃(g), respectively. The bond angles and ground state quantum weight were estimated by comparison with those for AlF₃(g). The three principal moments of inertia are 1.28827 X 10⁻³⁸, 2.79746 X 10⁻³⁸ and 4.08573 X 10⁻³⁸ g.² cm.²

Mar. 31, 1964

ΔH_f^o = Unknown

ΔH_f^o 298.15 = -189.6 ± 0.3 kcal. mole⁻¹

ΔH_m^o = Unknown

S_{298.15} = [13 ± 1] cal. deg⁻¹ mole⁻¹

T_m = Unknown

T_d = [500]°K.

Heat of Formation.

The heat of formation (ΔH_f^o 298.15) for AlOCl(c) was calculated from ΔH_f^o 298 = 21.05 kcal. mole⁻¹ for the reaction AlOCl(c) + Cl₂(g) = AlCl₃(c) + 1/2 O₂(g) reported by H. Schafer, F. E. Wittig, and W. Wilborn, Z. anorg. allgem. Chem. 297, 48 (1958). This reaction is the overall reaction of the following four separate reactions.

Chemical Reaction	ΔH _f ^o 298, kcal. mole ⁻¹
AlOCl(c) + 2(HCl·299.5 H ₂ O) = AlCl ₃ ·600 H ₂ O(l)	-46.9
AlCl ₃ ·600 H ₂ O(l) = AlCl ₃ (c) + 600 H ₂ O(l)	+79.3
H ₂ (g) + Cl ₂ (g) = 2(HCl·299.5 H ₂ O)	-79.67
H ₂ O(l) = H ₂ (g) + 1/2 O ₂ (g)	+68.32
AlOCl(c) + Cl ₂ (g) = AlCl ₃ (c) + 1/2 O ₂ (g)	+21.05

Heat Capacity and Entropy.

The heat capacities for AlOCl(c) were estimated based on the assumption that ΔC_p = 0 for the reaction AlCl₃(c) + Al₂O₃(c) = 3AlOCl(c). S_{298.15} was estimated by H. Schafer, F. E. Wittig, and W. Wilborn, loc. cit.

Temperature of Decomposition.

T_d is estimated as the temperature at which the free energy change of the reaction 6AlOCl(c) → 3Al₂O₃(c) + Al₂Cl₆(g) approaches zero.

Bond Distance: O-Al = [1.62] Å Al-Cl = [2.14] Å
 Bond Angle: O-Al-Cl = 180°
 Rotational Constant: B₀ = [0.097703] cm.⁻¹
 $\sigma^- = 1$

Heat of Formation.

The free energy change of the reaction $1/3 \text{ Al}_2\text{O}_3(\text{s}) + 1/3 \text{ AlCl}_3(\text{g}) = \text{AlOCl}(\text{g})$, $\Delta G^\circ_{2400^\circ\text{K.}} = 28 \pm 3 \text{ kcal. mole}^{-1}$, has been determined by M. A. Greenbaum, et al., Marenton Corporation, California, private communication, August 26, 1984. Incorporating appropriate auxiliary data the heat of reaction was derived to be 82.9 kcal. mole⁻¹, yielding $\Delta H_f^{298.15} = -83.2 \pm 5 \text{ kcal. mole}^{-1}$ for AlOCl(g).

Heat Capacity and Entropy.

Point group, ground state quantum weight and vibrational frequencies were obtained from J. Hilsenrath, W. H. Evans and H. M. Woolley, National Bureau of Standards Report 8484, "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum and Their Compounds with Hydrogen, Oxygen, Nitrogen, Fluorine and Chlorine", July 1, 1959. The bond distances of $\text{F}_2\text{O-Al}$ and $\text{F}_2\text{O-Cl}$ were assumed to be the same as those in $\text{AlO}(\text{g})$ and $\text{AlCl}(\text{g})$ molecules, respectively. The three principal moments of inertia are: $I_A = 0$ and $I_B = I_C = 2.86467 \times 10^{-38} \text{ g. cm}^2$.

June 30, 1961/ Sept. 30, 1964

Point Group C_{2v}

ΔH_f⁰ = [-75 ± 20] kcal. mole⁻¹

ΔH_f⁰ 298.15 = [-75 ± 20] kcal. mole⁻¹

S_{298.15} = [68.815] cal. deg⁻¹ mole⁻¹

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	[430] (1)	[210] (1)	[540] (1)
298.15			

Bond Distance: Al-Cl = [2.14] Å

Bond Angle: Cl-Al-Cl = [120]°

Product of the Moments of Inertia: I_AI_BI_C = [6.62845 X 10⁻¹¹⁴] g.³ cm.⁶

Heat of Formation.

The value of ΔH_f⁰ 298.15 for AlCl₂(g) was calculated based on an assumption that ΔH_f⁰ = 0 for the reaction AlCl(g) + AlCl₃(g) = 2AlCl₂(g). The values of ΔH_f⁰ 298.15 for AlCl(g) and AlCl₃(g) used for calculation are -11.2 and -139.7 kcal. mole⁻¹, respectively.

Heat Capacity and Entropies.

The vibrational frequencies were calculated by valence force field method described by O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950, using force constants, k₁ = 2.05 X 10⁵ and k_f/12 = 0.25 X 10⁵ dynes/cm., estimated from those for AlCl(g) and other similar compounds. The bond distance was assumed to be the same as that for AlCl(g). The bond angle and ground state quantum weight were estimated to be consistent with those for AlF₂(g). The three principal moments of inertia are I_A = 4.04243 X 10⁻³⁶, I_B = 3.7149 X 10⁻³⁹ and I_C = 4.41392 X 10⁻³⁸ g. cm.²

[180] (2)
[380] (1)

Bond Distance: Al-Cl = [2.17] Å

Bond Angle: Cl-Al-Cl = [180°]

Rotational Constant: B₀ = [0.0505] cm⁻¹

Heat of Formation

R. F. Porter and E. E. Zeller, J. Chem. Phys. 33, 858 (1960), reported an appearance potential of 13.4 ± 0.5eV (309 ± 12 kcal) for AlCl₂⁺; they indicated that AlCl₂(g) was the probable parent molecule. Assuming the formation reaction to be AlCl₃ + e⁻ → AlCl₂⁺ + Cl + 2 e⁻, we obtain ΔH_f^o(AlCl₂⁺, g) = 140 kcal/mol or an ionization potential of 215 kcal or 9.3eV.

Since there is a possibility of the fragments containing excess kinetic energy, the ionization potential represents an upper limit to the true value. A comparison of the ionization potentials of BF₂ and BCl₂ indicates that the chloride is lower by 1eV per atom; on this basis we would obtain an ionization potential of 7eV using the value for AlF₂ of 9eV.

The National Bureau of Standards Report No. 6628, Jan. 1, 1965, gives an estimate of 8 ± 1eV (185 ± 25 kcal); we adopt this value as being representative of the probable range of values. The adopted ionization potential yields ΔH_f^o(AlCl₂⁺, g) = 110 ± 40 kcal/mol in conjunction with ΔH_f^o(AlCl₃, g) = -75 ± 20 kcal/mol.

Heat Capacity and Entropy

AlCl₂⁺ is isoelectronic with MgCl₂ and on this basis we assume the ground state to be singlet and linear in accordance with the predictions of A. D. Walsh, J. Chem. Soc. 2768 (1953). The vibrational frequencies are estimated to lie between those for AlCl₂ and MgCl₂. The bond length is estimated as the sum of the covalent radii of the atoms.

The enthalpy at 0°K is -3.128 kcal/mol.

ALUMINUM DICHLORIDE UNINEGATIVE ION (AlCl₂⁻)

(IDEAL GAS)

GFW = 97.888

Point Group [C_{2v}]

ΔH_f^o = [-80 ± 40] kcal/mol

S_{298,15}^o = [67.4 ± 0.5] gibbs/mol

ΔH_f_{298,15}^o = [-80 ± 40] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

$\frac{\omega}{\text{cm}^{-1}}$	
[550] (1)	
[200] (1)	
[450] (1)	

Bond Distance: Al-Cl = [2.14] Å

Bond Angle: Cl-Al-Cl = [120°] σ = 2

Product of the Moments of Inertia: I_AI_BI_C = [6.634 × 10⁻⁴⁴] g³ cm⁶

Heat of Formation

AlCl₂⁻ is isoelectronic with SiCl₂ and an estimate of its heat of formation may be obtained by assuming the binding energy to be the same in the two molecules. This leads to ΔH_f^o₂₉₈(AlCl₂⁻, g) = -80 kcal/mol or an electron affinity of 5 kcal. An alternative route assumes that the heat of reaction is identical for the processes AlCl₃(g) + AlCl₂⁻(g) + Cl⁺(g) and AlCl(g) + Al⁺(g) + Cl⁺(g). Using the electron affinity of Al(g) given in National Bureau of Standards Report No. 8628, Jan. 1, 1965, we obtain ΔH_f^o₂₉₈(AlCl₂⁻, g) = -63 kcal/mol or an electron affinity of -12 kcal. In addition, using the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2266 (1953), the electron must go into a non-bonding orbital; thus the binding energy should be close to that of AlCl₂. The dissociation energy of AlCl₂ is 211 kcal which leads to ΔH_f^o₂₉₈(AlCl₂⁻, g) = -87 kcal/mol or an electron affinity of 12 kcal. We adopt an intermediate value for the electron affinity of 5 ± 20 kcal/mol, or ΔH_f^o₂₉₈(AlCl₂⁻, g) = -80 ± 40 kcal/mol using ΔH_f₂₉₈(AlCl₂, g) = -75 ± 20 kcal/mol.

Heat Capacity and Entropy

As noted earlier, AlCl₂⁻ is isoelectronic with SiCl₂ and with 18 valence electrons, should be definitely bent according to the correlation scheme of A. D. Walsh, loc. cit. The vibrational frequencies are estimated to lie between those of SiCl₂ and AlCl₂. The bond length and angle are estimated as equal to those for AlCl₂(g). By analogy with SiF₂ (see G. Herzberg "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Company Inc., New York, 1966) we do not expect any low lying electronic levels. The enthalpy at 0°K is -3.006 kcal/mol. The three principal moments of inertia are: I_A = 3.7155 × 10⁻⁴⁹, I_B = 4.0430 × 10⁻⁴⁹, and I_C = 4.4154 × 10⁻⁴⁸ g cm².

σ⁻ = 2

Heat of Formation.

The value of ΔH_f^o 298.15 was calculated based on an assumption the ΔH_f^o = 0 for the reaction AlP₃(g) + 2AlCl₃(g) = 3AlCl₂F(g). The values of ΔH_f^o 298.15 for AlP₃(g) and AlCl₃(g) used for calculation are -286.5 and -139.7 kcal. mole⁻¹, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for AlP₃(g) and AlCl₃(g). The bond distances of Al-F and Al-Cl atoms were assumed to be the same as those in AlP₃(g) and AlCl₃(g), respectively. The bond angles and ground state quantum weight were estimated by comparison with those for AlP₃(g). The three principal moments of inertia are 4.04374 X 10⁻³⁶, 1.92508 X 10⁻³⁶, and 5.96882 X 10⁻³⁶ g.³ cm.⁶.

Heat of Formation

Gross and Hayman (1) measured the enthalpy of direct combination of "spectrographically pure" aluminum and carefully purified chlorine and derived ΔH_f° 298.15 = -168.80 $\pm$ 0.16 kcal/mol. Siemsen (2) also reported the enthalpy of direct combination and is in agreement at -167.5 kcal/mol within his relatively large uncertainty interval of ± 1.1 kcal/mol.

Coughlin (3) determined the enthalpy of solution of 99.99+ pure Al in 4.360 M HCl and also (4) the enthalpy of solution of anhydrous AlCl₃ in the same solvent. Enthalpies of mixing were measured to close a thermochemical cycle at 303.15°K (adjusted to 1961 at. wts.):

Reaction	ΔH° , 303.15 cal.
(1) Al(c) + 3H ⁺ (sol) = Al ³⁺ (sol) + 3/2 H ₂ (g)	-127,057 $\pm$ 120
(2) 3(HCl·12.731 H ₂ O)(l) = 3H ⁺ (sol) + 3Cl ⁻ (sol) + 38.193 H ₂ O(sol)	0 $\pm$ 10
(3) AlCl ₃ (c) = Al ³⁺ (sol) + 3Cl ⁻ (sol)	-72,504 $\pm$ 50
(4) 38.193 H ₂ O(l) = 38.193 H ₂ O(sol)	-3,050 $\pm$ 20
(5) Al(c) + 3(HCl·12.731 H ₂ O)(l) = AlCl ₃ (c) + 38.193 H ₂ O(l) + 3/2 H ₂ (g)	-51,503 $\pm$ 140

With heat capacity data for Al, AlCl₃, and H₂ from the JANAF tables and for HCl(12.731 H₂O) from Parker et al. (5) reaction 5 at 298.15°K is -51,910 $\pm$ 140 cal/mol AlCl₃. Interpolation of data for ΔH_f° 298.15(HCl, aq) selected by Wagman et al. (6) yields ΔH_f° 298.15(AlCl₃, c) = -168.37 kcal/mol. The overall uncertainty is estimated as 300 cal/mol.

Earlier investigations on the enthalpies of solution of Al were adjusted to the conditions of Coughlin's experiments by means of the data of Smith and Bass (7) for the effects of HCl concentration and H₂O dilution on ΔH_f° (AlCl₃, aq) and estimates of ΔC_p of solution of Al of +20 gibbs/mol.

Investigator(s)	ΔH° (soln) as reported kcal/mol Al	ΔH° (soln) adjusted kcal/mol Al
Young (8)	-126.83	-126.79
Roth and Wolf (9)	-124.01	-127.29
Conneri and Rossi (10)	-125.40	-126.80
Sommerer (11)	-128.36	-126.42
Richards and Burgess (12)	-126.00	-124.06

Only Richards and Burgess deviate more than expected; they report a value for Mg in good agreement with modern values and it seems likely their sample of Al was impure.

Several values for the enthalpy of solution of AlCl₃(c) in water have also been published and are listed here along with Coughlin's value recalculated to solution in pure water at 20°K.

Investigator(s)	ΔH° (soln) in H ₂ O at 20°K (kcal/mol AlCl ₃)
Coughlin (3)	-78.22 (adjusted)
Thomsen (13)	-76.85
Berthelot (14)	-76.3
Saunders (15)	-77.6
Stoll (16)	-77.9
Roth and Böhner (14)	-79.3
Roth and Böger (15)	-77.7 (adjusted)
Klemm and Tanke (16)	-77.7 (adjusted)

Klemm and Tanke (16) measured the enthalpy of solution of AlCl₃ in HCl·20 H₂O at 0°K. A weighted average of this value of Gross and Hayman (1) and of Coughlin (3) is adopted for ΔH_f° 298.15(AlCl₃, c) = -168.65 $\pm$ 0.20 kcal/mol.

Heat Capacity and Entropy

Justice (17) reported low temperature heat capacity data (13° to 310°K) and presented smoothed thermodynamic functions, including $S_{298.15}^\circ$ = 26.12 gibbs/mol, of which 0.086 gibbs/mol is extrapolation below 13°K. Heat content relative to 273.15°K was measured by Fischer (18) from 298°K to 504°K and heat content relative to 298.15°K was measured by Holsen (19) from 310° to 493°K. The heat content data for the crystal can be fit within about 2% by integration of $C_p(c)$ (gibbs/mol) = 15.52 + 0.021T, which is an extrapolation of C_p data reported by Justice (17).

Melting Data

See table for AlCl₃(t).

Sublimation Data

See table for Al₂Cl₆(g).

Aluminum Trichloride (AlCl₃)

(Liquid) GFW = 133.341

AlCl₃

GFW = 133.341

(LIQUID)

ALUMINUM TRICHLORIDE (AlCl₃)

S^{298.15} = 41.326 ± 0.5 gibbs/mol

ΔHf^{298.15} = -161.28 ± 0.40 kcal/mol

Tm = 465.7 ± 0.2°K

ΔHm = 8.45 ± 0.20 kcal/mol

Heat of Formation

ΔHf^{298.15}(l) was obtained from ΔHf^{298.15}(c) by adding ΔHm and the difference between (H_{465.7-298.15}) for crystal and liquid.

Melting Point

Kendall et al. (1) observed AlCl₃ to melt "sharply" at 463.4°K, Foster (2) noted that AlCl₃ began melting and melted completely in the range 465.7 ± 0.2°K, Nisei'son et al. (3) reported Tm = 467.2°K, and Ostriкова et al. (4) reported Tm = 466°K. Smits and Meijering (5) and Treadwell and Terebesi (6) derived triple point temperatures of 465.8°K and 466.5°K, respectively, from intersection of vapor pressure curves for crystal and liquid. The value of Foster is adopted as most accurate. The vapor pressure at the triple point is 2.3 atm.

Heat of Fusion and Heat Capacity

Fischer (7) and McDonald (8) measured heat content data for the liquid over a short range (473°-504°K) of temperature. Their data can be represented within 21 by the heat capacity equation derived for the crystal [see AlCl₃(c) table], a heat of fusion of 8.45 kcal/mol, and a liquid heat capacity of 30.0 gibbs/mol. Fischer's data are high, while McDonald's points lie below the selected values.

Vibrational Frequencies and Degeneracies

ω_e , cm ⁻¹	ω_e , cm ⁻¹	ω_e , cm ⁻¹
371 (1)	148 (2)	148 (2)
[106] (1)	810 (2)	810 (2)

Bond Distances: Al-Cl = 2.06 Å
Bond Angle: Cl-Al-Cl = 120°

Product of the Moments of Inertia: $I_A I_B I_C = 1.0618 \times 10^{-112}$ g cm⁶
 $\sigma = 8$

Heat of Formation

The heat of formation is calculated from the value adopted for Al₂Cl₆(g) and the heat of dissociation of Al₂Cl₆, derived from equilibrium P-V-T data on aluminum chloride vapor as listed below.

$\Delta H_{298.15}^\circ$, kcal/mol	2nd Law	3rd Law
29.28	30.12	30.12
30.82	30.82	30.82
30.22	30.22	30.40

Number of Data Points

6

16^a

16^b

30.40

Twenty six points reported, points at 838, 881, 944, 734, 605, and 688°K rejected by statistical test.
The three investigations are in reasonable agreement. Giving consideration also to equilibrium data on the reaction of AlCl₃(g) and Al(l) to form AlCl(g) [see AlCl(g) table], there is selected as a best value $\Delta H_{298.15}^\circ = 30.24$ kcal/mol AlCl₃(g), which yields $\Delta H_{298.15}^\circ(\text{AlCl}_3, g) = -139.70$ kcal/mol.

Heat Capacity and Entropy

Zaorin and Rambidi (4) carried out electron diffraction experiments on aluminum chloride vapor at 800°K where the monomer should predominate. They found a planar symmetrical structure with Al-Cl = 2.06 ± 0.01 Å and Cl-Al-Cl angles of 120°. The individual moments of inertia are $I_A = I_B = 3.7468 \times 10^{-38}$ g cm² and $I_C = 7.4932 \times 10^{-38}$ g cm². For aluminum chloride vapor at high temperatures (monomer predominant), Klemperer (5) observed a band at 610 cm⁻¹ in the infrared spectrum and Beattie and Hordner (6) reported Raman bands at 371 cm⁻¹ and 146 cm⁻¹. The remaining frequency should be infrared active but presumably was beyond the range of Klemperer's measurements. Zaorin and Rambidi (7) give 96 ± 15 cm⁻¹ based on amplitudes of vibration observed in electron diffraction measurements. However, this frequency gives thermodynamic functions clearly not compatible with the equilibrium P-V-T data. Force constant ratios in the boron halides also suggest a higher wavenumber. An estimate of 185 cm⁻¹ was therefore adopted as an optimum value for fitting both the Al₂Cl₆ dissociation data and the equilibrium data for AlCl₃(g) + 2Al(l) + 3AlCl(g) [see AlCl(g) table].

AlCl₄K

MOL. WT. = 207.908

(CRYSTAL)

POTASSIUM TETRACHLOROALUMINATE (KAlCl₄)

ΔH_f^o 0 = Unknown

ΔH_f^o 298.15 = -286.0 ± 2.5 kcal. mole⁻¹

ΔH_m^o = Unknown

S_{298.15} = [47 ± 2] cal. deg.⁻¹ mole⁻¹

T_m = 529°K.

Heat of Formation.

The heat of reaction of aluminum chloride and potassium chloride was measured by E. Baud, Ann. Chim. Phys. 1, 8 (1904). From ΔH_f^o = -26.38 kcal. mole⁻¹ for the reaction: Al₂Cl₆(c) + 2KCl(c) = 2KAlCl₄(c), the value of ΔH_f^o 298.15 for KAlCl₄(c) was calculated to be -286 kcal. mole⁻¹.

Heat Capacity and Entropy.

Heat capacities were estimated by comparison with those for K₂SO₄(c), reported by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). S_{298.15} was estimated according to the method suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, 1958 and K. K. Kelley, private communication, June, 1960.

Temperature of Melting.

T_m was reported by W. Flacher and A.-L. Simon, Z. anorg. allgem. Chem. 306, 1 (1960).

ΔH_f^o = Unknown

ΔH_f^o 298.15 = -500 ± 1 kcal. mole⁻¹

ΔH_m^o = Unknown

S_{298.15} = [90 ± 2] cal. deg. ⁻¹ mole⁻¹

T_m = [800]°K.

Heat of Formation.

The heat of formation at 298.15°K. was recalculated from the same quantity given in National Bureau of Standards (U. S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952. The latter value was derived from the enthalpy change for the reaction $\text{Al}_2\text{Cl}_6(\text{c}) + 6\text{KCl}(\text{c}) = 2\text{K}_3\text{AlCl}_6(\text{c})$ measured by E. Baud, Ann. chim. phys. 1, 8 (1904).

Heat Capacity and Entropy.

Both C_p and S_{298.15} were estimated by comparison with the corresponding values of the sum of the constituent halides for $\text{Na}_3\text{AlF}_6(\text{c})$.

Temperature of Melting.

T_m was estimated by comparison with that for $\text{K}_2\text{AlF}_6(\text{c})$.

Ground State Configuration $1s^2$ $S_{298.15}^\circ = 51.40 \pm 0.01$ gibbs/mol $\Delta H_f^\circ = -63.4 \pm 0.8$ kcal/mol $\Delta H_f^\circ = -63.4 \pm 0.8$ kcal/mol

Heat of Formation

T. C. Ehlert, G. D. Blue, J. W. Green, and J. L. Margrave, J. Chem. Phys. 41, 2250 (1964) reported the ionization potential of AlF as 9.7 ± 0.5 eV (224 ± 12 kcal). The magnitude of the value has been confirmed by R. F. Porter, J. Chem. Phys. 33, 951 (1960) who found it between 9 and 10 eV. Using the above value in conjunction with $\Delta H_f^\circ(\text{AlF}, g) = -62.5$ kcal/mol, and the equation $\text{AlF}(g) \rightarrow \text{AlF}^+(g) + e^-$ yields $\Delta H_f^\circ(\text{AlF}^+, g) = 161 \pm 12$ kcal/mol.

Heat Capacity and Entropy

AlF⁺ is isoelectronic with MgF, and the electronic configuration of the ground and excited states we estimate to be those for MgF(g). The vibrational frequency, anharmonicity constant and bond length we estimate by comparison with those for MgF and AlF. The rotational constant is calculated from the bond length and atomic masses, and α_e is calculated from the other constants assuming a Morse potential function.

The enthalpy at 0°K is -2.139 kcal.

Aluminum Oxide Fluoride (AlOF)

(Ideal Gas) Mol. Wt. = 61.98

ALUMINUM OXIDE FLUORIDE (AlOF) (IDEAL GAS)

MOL. WT. = 61.98

Point Group $C_{\infty v}$ $\Delta H_f^0 = -139.5 \pm 2.6 \text{ kcal. mole}^{-1}$
 $S^0_{298.15} = [55.986] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^0_{298.15} = -140.2 \pm 2.6 \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω , cm.^{-1}
 [900](1)
 [500](2)
 [750](1)

Bond Distance: O-Al = $[1.62] \text{ \AA}$ Al-F = $[1.65] \text{ \AA}$
 Bond Angle: O-Al-F = $[180]^\circ$ $\sigma^- = 1$
 Rotational Constant: $B_0 = [0.180806] \text{ cm.}^{-1}$

Heat of Formation.

The equilibrium constants (2200-2225°K.) of the chemical reaction $\text{Al}_2\text{O}_3 (c) + \text{AlF}_3 (g) = 3\text{AlOF} (g)$ were measured by M. Farber and H. L. Petersen, Trans. Faraday Soc. 59, 836 (1963). Using this data, the heat of reaction at 298.15°K. was calculated by the third law method to be $266.2 \pm 1.7 \text{ kcal. mole}^{-1}$. The value of ΔH_f^0 298.15 for AlOF (g) was then derived.

Heat Capacity and Entropy.

The bond distances of Al-O and Al-F were estimated to be the same as those for AlO (g) and AlF (g), respectively. The point group, ground state quantum weight and vibrational frequencies were obtained from W. H. Evans, J. Hilsenrath and H. W. Woolley, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element Compounds," National Bureau of Standards Report 6926, July 1, 1960. The moment of inertia is $1.54800 \times 10^{-38} \text{ g. cm.}^2$

Heat of Formation.

The selected heat of formation, -165 ± 20 kcal. mole⁻¹ is the weighted average of two estimates (a) [-163 ± 20 kcal. mole⁻¹] and (b) [-175 ± 30 kcal. mole⁻¹]. The first estimate (a) is based upon appearance potentials reported by T. C. Ehlert and J. L. Margrave, J. Am. Chem. Soc. 86, 3901 (1964).

- (1) AlF₃(g) → AlF₂(ion) + F(g) 15.2 ± 0.3 e.v.
(2) AlF₃(ion) → AlF₂(g) -9 ± 1.8 e.v.
(3) (1) + (2) or AlF₃(g) → AlF₂(g) + F(g) 6.2 ± 1.3 e.v.

The second estimate (b) is based upon the average Al-F bond strength of AlF₃(g) and AlF(g), i.e.

$$(4) \text{AlF}_3(\text{g}) + \text{AlF}(\text{g}) \rightarrow 2 \text{AlF}_2(\text{g}) \quad \Delta H_{\text{r}}^{\circ} = 0$$

Heat Capacity and Entropy.

The bond distance, 1.65 Å, was estimated from a consideration of the Al-F distance 1.63 and 1.65 Å in AlF₃(g) and AlF(g). The bond configuration and bond angle estimates were based on the correlations of A. D. Walsh, J. Chem. Soc., 2266, (1953). From the molecular constants the principal moments of inertia were found to be I_A = 1.7829 X 10⁻³⁹, I_B = 12.8817 X 10⁻³⁹ g. cm.². The vibrational frequencies were calculated assuming valence forces, [G. Herzberg, "Molecular Spectra and Molecular Structure II", D. Van Nostrand Co., 1945] and using force constants calculated from AlF₃(g).

σ = 2

Heat of Formation

T. C. Ehlert, G. D. Blue, J. W. Green and J. L. Margrave, J. Chem. Phys. 41, 2250 (1964) report the appearance potential of AlF₂⁺ from AlF₃ as 15.2 ± 0.3 eV. Assuming the reaction to be AlF₃(g) + e⁻ → AlF₂⁺ + F + 2e⁻ ΔH = 350.5 ± 7 kcal we calculate ΔH_f^o (AlF₂⁺, g) = 42 ± 10 kcal/mol, or an ionization potential for AlF₂ of 9 eV. Due to the neglect of any kinetic energy of the fragments this probably is an upper limit.

Heat Capacity and Entropy

The linear configuration is estimated from the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2268 (1953), however, it should be noted that the isoelectronic MgF₂ is considered to be bent. The vibrational frequencies are estimated to lie between those for AlF₂ and MgF₂. The bond distance is estimated by comparison with AlF and AlF₃.

The enthalpy at 0°K is -2.883 kcal/mol.

AlF₂⁺

Aluminum Difluoride Uninegative Ion (AlF₂⁻)

Heat of Formation

AlF₂⁻ is isoelectronic with SiF₂ and an estimate of its heat of formation may be obtained by assuming the binding energy to be the same; this yields ΔH_f⁰₂₉₈(AlF₂⁻, g) = -191 kcal/mol, or an electron affinity for AlF₂ of 28 kcal/mol.

The binding energy should be close to that of AlF₂ since the extra electron should go into a non-bonding orbital according to the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2266 (1953); using this approach yields ΔH_f⁰₂₉₈(AlF₂⁻, g) = -177 kcal/mol or an electron affinity for AlF₂ of 12 kcal. Another method of estimation assumes that the heats are identical for the two reactions AlF₃ + AlF₂⁻ + F⁺ and AlF₂⁻ + F⁺ which yields ΔH_f⁰₂₉₈(AlF₂⁻, g) = -161 kcal/mol or an electron affinity for AlF₂ of -4 kcal.

We adopt a median value for the electron affinity for AlF₂ of 10 ± 20 kcal, which leads to ΔH_f⁰₂₉₈(AlF₂⁻, g) = -175 ± 40 kcal/mol when combined with ΔH_f⁰₂₉₈(AlF₂, g) = -165 ± 20 kcal/mol.

Heat Capacity and Entropy

According to the predictions of A. D. Walsh, loc. cit., there is no doubt that the molecule is bent; the bond length is assumed to lie between those of AlF and AlF₃, the angle is that in AlF₃. The vibrational frequencies are estimated between those for SiF₂ and AlF₂. By analogy with SiF₂ no low electronic levels are expected (G. Herzberg, "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Co., Inc., New York 1966).

The enthalpy at 0°K is -2.698 kcal/mol.

The individual principal moments of inertia are I_A = 1.783 × 10⁻³⁹ g cm², I_B = 12.882 × 10⁻³⁹ g cm² and I_C = 14.565 × 10⁻³⁹ g cm².

AlF₂⁻

Aluminum Trifluoride (AlF₃)

(Crystal)

GFW = 83.9767

AlF₃ALUMINUM TRIFLUORIDE (AlF₃)

(CRYSTAL)

GFW = 83.9767

$\Delta H_f^\circ = -359.5 \pm 0.3 \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = -361.0 \pm 0.3 \text{ kcal/mol}$
 $\Delta H_t^\circ = 0.1346 \text{ kcal/mol}$
 $\Delta H_s^\circ_{298.15} = 71.865 \pm 0.5 \text{ kcal/mol monomer}$
 $\Delta H_s^\circ_{298.15} = 92.55 \pm 4 \text{ kcal/mol dimer}$

$S^\circ_{298.15} = 15.89 \pm 0.1 \text{ gibbs/mol}$
 $T_t = 728^\circ\text{K}$
 $T_s = [1549]^\circ\text{K}$

Heat of Formation

The adopted value is from separate calorimetric studies of combustion in fluorine of aluminum (1) and aluminum-Teflon mixtures (2). More extensive auxiliary data (2) for Teflon bring the aluminum-Teflon study into exact agreement with the aluminum study (1). Calorimetric data relating AlF₃ to PbF₂ (1, 2) tend to confirm this value, but PbF₂ is probably more uncertain than is AlF₃.

Solid-state emf data (4) relating AlF₃ to HgF₂ via ThF₄ gave $\Delta G_f^\circ = -305.7 \text{ kcal/mol}$ for AlF₃(c) at 600°C. The adopted negative value indicated by entrainment data (3) for 2/3 AlF₃(c) + 1/3 Al₂O₃(c) + 2HF(g) in the range from 849° to 1312°K. Analysis of the equilibrium constants yields $\Delta H^\circ_{298.15} = 33.11 \pm 0.2 \text{ kcal/mol}$ (3rd law) and $33.33 \pm 0.22 \text{ kcal/mol}$ (2nd law) with an insignificant entropy difference, $\Delta S^\circ(2\text{nd law}) - \Delta S^\circ(3\text{rd law}) = 0.2 \pm 0.2 \text{ gibbs/mol}$. It has been suggested (1) that interaction of the condensed phases caused the equilibria to deviate from the standard-state reaction assumed above. An alternative may be that the reaction with water vapor produced Al₂O₃ in a metastable form; such forms require ignition temperatures greater than 1400°K for complete conversion to $\alpha\text{-Al}_2\text{O}_3$ (g).

Heat Capacity and Entropy

C_p° and S°_{298} are taken from Douglas and Dittmars (7), whose tables are based on heat capacity measurements from 54° to 298°K (g) and relative enthalpy measurements from 323° to 1173°K (7). The enthalpy data confirm earlier data (401°-1401°K) of O'Brien and Kelley (8) rather than the adjusted values proposed by Frank (10). Douglas and Dittmars (7) gave a detailed comparison with other data. The entropy is derived from C_p° using the extrapolation $S^\circ_{50} = 0.53 \pm 0.06 \text{ gibbs/mol}$.

Transition Data

T_t and ΔH_t° are from Douglas and Dittmars (7). The values were obtained from extensive enthalpy data for the transition region assuming the presence of a very small amount of impurity in solid solution.

Sublimation Data

T_s is the temperature at which the calculated total pressure (monomer plus dimer) reaches one atm; the mole fraction of dimer is calculated as 0.109 at T_s . Sublimation temperatures of 1533° and 1566°K were obtained in two sublimation-pressure studies (11, 22) at the Technische Hochschule, Breslau. The selected enthalpies of sublimation to AlF₃(g) and Al₂F₆(g) reproduce closely the entrainment data of Krause and Douglas (13). Selection of these values of ΔH_s° and comparisons with other vapor-pressure data are discussed on the gas-phase tables.

Heat of Formation

ΔH_f° is calculated from that of the crystal by use of $\Delta H_{298.15}^\circ = 71.965 \pm 0.5$ kcal/mol. Sublimation studies by mass-spectrometric and entrainment techniques suggest the presence of a small amount of dimer in the saturated vapor. These studies are reviewed on the table for Al₂F₆(g). $\Delta H_{298.15}^\circ$ and $\Delta H_{298.15}^\circ$ are calculated by adopting (a) the JANAF entropies for crystal, monomer and dimer, (b) the mass spectrometric value of 2 $\Delta H_{298.15}^\circ$ (monomer) and $\Delta H_{298.15}^\circ$ (dimer), and (c) the entrainment data of Krause and Douglas (1). The resulting calculated pressures deviate by <0.5% from the entrainment data (1), by <0.1% from the mass-spectrometric equation (3) and by <3% from the mass-effusion equation (4).

Further comparisons with experimental data are given below. The adopted values favor the later (11) of two sublimation-point studies (11, 12); both show considerable scatter and smaller deviations from the calculated dP/dT . Torsion-effusion data suggest the possibility of more serious discrepancy. Although data of Witt and Barrow (3) are consistent with the JANAF pressures, Hildenbrand et al. (2, g) noted a trend toward increasing pressure with decreasing orifice area. They concluded (2) that the condensation coefficient <0.06, based on eightfold variation in the product of Clausius factor $\times$ orifice area. JANAF predictions for the pressure are 60 to 80% of the adjusted torsion values (2) and the discrepancy corresponds roughly to the ratios used in the adjustment. In contrast, the JANAF predictions agree closely with mass-effusion data of Ko et al. (4), who reported no significant effect from a twelvefold variation in orifice area.

Comparison of Calculated and Observed Total Pressures over AlF₃(c)

	T, °K	Method	Range	Calc. Range	Calc./Pobs	Difference ^a in dP/dT
(1) Krause (1968)		Entrainment	1194-1258	0.019-0.029	1.004-0.986	Very small (-)

^a Magnitude and sign of the difference, calculated minus observed, in dP/dT . ^b Absolute pressures of monomer were obtained by integration of the ion intensity during total sublimation. ^c Based on P calculated from the torsion pressure Pt by the equation given.

Heat Capacity and Entropy

The molecular structure is that derived from electron-diffraction data by Akishin et al. (13). Observed vibrational frequencies are those reported by Büchler et al. (14) from infrared spectra of the vapor at 1000-1200°K. These frequencies are confirmed by infrared spectra of AlF₃ isolated in matrices of neon, argon and krypton (15). The Raman-active fundamental ν_1 is estimated as 650 ± 50 cm⁻¹ by three methods: (a) calculation of the force constant k_1 from ν_3 and ν_4 ; (b) comparison of $k_1(XY)/k(XY)$ for X = B, Al and Y = F, Cl and Br; and (c) extrapolation of ν_1 (BY₃) to Y = F from Y = Cl, Br and I, using recent gas-phase Raman data (16) for AlY₃. Principal moments of inertia are $I_A = 12.572 \times 10^{-39}$ and $I_C = 25.14 \times 10^{-39}$ g cm².

Heat of Formation

Mass spectrometric studies (1) of the two-phase systems LiF + Li₃AlF₆ and Li₃AlF₆ + AlF₃ suggested that the vapor contains small amounts of Li₂AlF₅ and Li₂(AlF₄)₂, but that LiAlF₄(g) constitutes of the order of 90%. Hildenbrand et al. (2) reported torsion effusion pressures for the compositions 3LiF·AlF₃ and LiF·AlF₃, as a first approximation, these total pressures should correspond to the reactions (A) Li₃AlF₆(g) = LiAlF₄(g) + 2LiF(g), and (B) 1/3 Li₃AlF₆(g) + 2/3 AlF₃(g) = LiAlF₄(g). Porter and Zeller (3) reported mass spectrometric equilibrium constants for the reaction (C) Li₂F₂ + AlF₃(g) = LiF(g) + LiAlF₄(g). Second-order and third-law analyses of these data are summarized below. Kumann and Tillessen (4) reported total vapor pressures over molten LiAlF₄·3H₂O (0.81 ≤ n ≤ 3), but we have made no attempt to establish the liquid phase activities necessary for use of these data.

The adopted ΔH_f is derived from reaction (B) which exhibits entropy deviations (68) and on the other area effects which are relatively minor. Data for reaction (A) yield a ΔH_f that is more negative by 1.5 kcal/mol, but the very large entropy deviation suggests the presence of systematic uncertainties. Combination of (B) and (A) into the reaction 3LiF(g) + AlF₃(g) + Li₃AlF₆(g) gives ΔH_f = -3.3 kcal/mol, which is fairly consistent with the calorimetric value (5) of ΔH_f = -5.4 ± 0.5 kcal/mol. Sidorov and Kolosov (6) suggested that the equilibrium constants for reaction (C) should be considered as lower limits since AlF₃ and LiAlF₄ are probably both precursors of AlF₂.

Product of the Moments of Inertia: I_AI_BI_C = 4.79396 × 10⁻¹¹³ g³ cm⁶ σ = [2]

Heat of Formation

ΔH_f⁰ is based on ΔH_f⁰_{298.15} = 69.36 kcal/mol for the reaction Na₃AlF₆(c) + NaAlF₄(g) + 2NaF(c). ΔH_f⁰ is calculated by third law analysis of the pressure equation reported for this reaction by Sidorov and Kolosov (1). The second law ΔH_f⁰ = 70.5 kcal/mol and the entropy deviation is 1.1 gibbs/mol. Sidorov and Kolosov obtained their pressure equation by combination of the temperature variation of ion intensities with integration of intensities during total sublimation at 931°K (2).

Sidorov et al. (2) concluded that the pressure of the dimer (NaAlF₄)₂ at 931°K is almost half of the monomer pressure over the two-phase system Na₃AlF₆·1/2NaAlF₄. In contrast, Büchler et al. (3) reported the approximate vapor composition of 97% monomer, 1% dimer, 1% NaAlF₄, and 1% AlF₃ over the same condensed phases at 931°K. The latter composition was obtained from a mass spectrometric study by the twin crucible method.

Vapor pressures over melts in the NaF-AlF₃ system have been measured by the entrainment and boiling point techniques (4-7). We have made no attempt to establish the liquid phase activities necessary for use of these data.

Heat Capacity and Entropy

The adopted structure (C_{2v} symmetry) consists of tetrahedral AlF₄ combined with Na to form a planar ring, AlF₂Na, through coordination with two fluorines. Experimental evidence available for NaAlF₄ and LiAlF₄ does not distinguish conclusively between this structure and the alternatives which have been seriously considered. Alternatives include a C_s structure, in which the ring is non-planar, and two C_{2v} structures, in which Na (or Li) is coordinated to one or three fluorines instead of two.

Electron diffraction data (8) for the vapor gave the adopted bond distances and showed that the AlF₄ group is essentially tetrahedral. Wave error at small scattering angles precluded the calculation of accurate non-bonded distances for Na.

Shelson (9) observed the infrared spectra of LiAlF₄ and NaAlF₄ isolated in matrices of neon and argon. Eight fundamentals were found above 200 cm⁻¹ for LiAlF₄ and six for NaAlF₄. Shelson chose a C_{2v} structure for LiAlF₄ on the basis of Redlich-Teller product-rule calculations for isotopic shifts due to Li.

Neither the infrared data nor the electron-diffraction data are conclusive so we apply these qualitative arguments. Coordination of Na to three fluorines seems less likely, since there are no known examples of this behavior. The C_{2v} structure, as suggested by Büchler and Berkowitz-Mattuck (3), is likely because it is a hybrid between the accepted structures of Na₂F₂ and Al₂F₆. C_{2v} symmetry (σ = 2) is a compromise which has an entropy effect intermediate between the other alternatives. The principal moments of inertia of the C_{2v} structure are I_A = 24.026 × 10⁻³⁹ and I_B = I_C = 44.559 × 10⁻³⁹ g cm².

The fundamental vibrations of 800 and 890 cm⁻¹ are average values from gas phase (10) and matrix (9) spectra. Four other observed values are from the matrix data. Six fundamentals are estimated by comparisons similar to those used for LiAlF₄(g).

 T_m = 1233°K.

Heat of Formation.

The value of ΔH°_f 298.15 adopted was calculated based upon ΔH°_f = -30.2 kcal. mole⁻¹ for the reaction, $AlF_3(c) + 3KF(c) = K_3AlF_6(c)$, which was estimated by comparison with the values of ΔH°_f of the similar reactions for $Na_3AlF_6(c)$, $Na_3AlCl_6(c)$ and $K_3AlCl_6(c)$.

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by the addition of a correction term, $3(M_{KF} - M_{NaF})$, to the corresponding values for $Na_3AlF_6(c)$, where M denotes either C_p or $S^\circ_{298.15}$.

Temperature of Melting.

T_m was obtained from P. F. Hall and H. Inaley, J. Am. Ceram. Soc. 21, 113 (1938).

Heat of Formation

ΔH_f° is derived from $\Delta H_r^\circ = -5.4 \pm 0.5$ kcal/mol at 298.15 K for the reaction $3 \text{LiF}(c) + \text{AlF}_3(c) + \text{Li}_2\text{AlF}_6(c, \beta \text{ mixture})$. Greena et al. (1) obtained this result by heating the fluorides under standardized conditions in a small electrical furnace contained in their calorimeter at 25°C. ΔH_r° includes a small endothermic effect observed during heating of the reaction product. The authors suggest that the enthalpy of conversion between the α - and β -forms is small and thus their result should apply to both forms.

Heat Capacity and Entropy

Furukawa et al. (2) measured C_p° (15-370 K) using a sample prepared by fusion of stoichiometric proportions of LiF and AlF_3 in graphite. X-ray diffraction and petrographic examination of separate portions of the sample indicated a single phase identified as $\beta\text{-Li}_3\text{AlF}_6$. The authors tabulated values of C_p° and S° based on their data and the extrapolation $S_{15}^\circ = 0.042$ gibbs/mol. These values are adopted.

Douglas and Neuffer (3) reported relative enthalpy data (323-973 K) for part of the same sample used in measurement of C_p° (2). Their study was made prior to discovery of the five crystalline phases, and their drop-calorimetric data reveal only the transition near 748 K. Reinterpretation of the data above 748 K is complicated by the proximity of the furnace temperatures to the transition temperatures and by the tendency of high-temperature forms to revert to both α - and β -forms under different conditions of cooling. Björge and Jensen (4) and Rolin et al. (5) also reported crystalline enthalpy data, but these are relatively imprecise and include similar uncertainties in the final state after the drop. These difficulties preclude the derivation of accurate heat capacities for the high-temperature forms.

C_p° for the β -form is adopted from (2, 3), since the two methods are in good agreement. The curve is extrapolated linearly above 748 K to obtain C_p° for the high-temperature forms. Obvious differences in C_p° are not apparent in the observed data for the different forms, so this should be an adequate approximation.

Transition Data

Existence of five polymorphic forms was shown by high-temperature X-ray diffraction (1, 2, 3) and differential thermal analysis (2, 3). Both α - and β -forms persisted at room temperature, but the α -form appeared only on quenching of high-temperature forms (1). The α -form transformed to β near 430 K (1, 2), but the reverse transformation was not observed. Single-crystal X-ray diffraction showed the α -form to be orthorhombic (3).

The adopted values of T_t are the lowest temperatures at which the high-temperature form was observed growing at the expense of the low-temperature form (1). DTA data (2, 3) were higher by roughly 30° for T_{t1} and 25° for T_{t2} . Combination of the observed enthalpies (3) with the adopted C_p° yields $\Delta H_{t1}^\circ = 0.76$ and $\Delta H_{t2}^\circ = 0.03$ or 0.15 kcal/mol; however, we prefer to adopt ΔH_{t1}° values (0.5 and 0.3 kcal/mol) which are more consistent with the areas of peaks in the DTA curve (2). Evidence suggests that ΔH_{t2}° is small, so we estimate 0.1 kcal/mol.

Melting Data

See the table for the liquid.

AlF_6Li_3

TRILITHIUM HEXAFLUOROALUMINATE (Li_3AlF_6) (LIQUID)

$\text{GF}_W = 161.7889$

$\Delta H_{298.15}^0 = -792.935 \text{ kcal/mol}$

$\Delta H_m^0 = 20.6 \pm 1.0 \text{ kcal/mol}$

Heat of Formation

$\Delta H_{298.15}^0$ is calculated from that of the crystal by addition of ΔH_m^0 and the difference of ($H_{1058}^0 - H_{298.15}^0$) for the crystal and liquid.

Heat Capacity and Entropy

Relative enthalpy data were measured by Björge and Jensen (1) from 1065 to 1088 K and by Rolin et al. (2) from about 1075 to 1145 K. The data are consistent with liquid heat capacities in the range from roughly 82 to 92 gibbs/mol. We adopt the mean value of 86 gibbs/mol and extrapolate this to higher and lower temperatures. A glass transition is assumed at 700 K and C_p^0 at lower temperatures is taken to be the same as that of $\beta\text{-Li}_3\text{AlF}_6$. S_{298}^0 is calculated in a manner analogous to that of the heat of formation.

Melting Data

T_m was observed at 780°C (3), 782°C (2, 4), 783°C (5, 8) and 785°C (1). The last and highest value is adopted for this table. Combination of the observed liquid enthalpies with the adopted crystal enthalpies yields values for ΔH_m^0 of 19.7 kcal/mol (1), authors gave 20.2 ± 1.0 and 21.5 ± 0.3 kcal/mol (2, authors gave 21.5). We adopt the mean value of 20.6 kcal/mol which is confirmed by values of 20.7 (8), 20.8 (4), 22.2 (4), 20.1 (4) and 22.0 (2) derived from crystal-liquid phase data for binary systems. The agreement among values for ΔH_m^0 seemingly excludes the possibility of large discrepancies in the enthalpies due to formation of the α -phase instead of β during drop-calorimetry from high temperatures.

Vaporization Data

Li_3AlF_6 vaporizes mainly to $\text{LiAlF}_4(\text{g})$ with small contributions from species such as $\text{Li}_2\text{AlF}_5(\text{g})$, $\text{Li}_2\text{F}_2(\text{g})$ and $\text{LiF}(\text{g})$ (5, 7).

Heat of Formation

The heats of solution of Al(c), NaCl(c), and Na₃AlF₆(c) in 4.36 M HCl acid solution were determined at 303.15°K by Coughlin (1). The enthalpy change for the reaction Al(c) + 2.96 NaCl(c) + 5.96 (HF·5.716 H₂O) + 3.617 H₂O(l) = Na₂96AlF₅96(c) + 2.96 (HCl·12.731 H₂O) + 3/2 H₂(g) was derived as ΔH_{298.15}° = -153.22 ± 0.14 kcal/mol. Using the ΔH₂₉₈° data on H₂O(l), HCl and HF solution from (2, 3) and NaCl from JANAF Table (4), we calculate the value ΔH₂₉₈° = -791.2 ± 0.7 kcal/mol for Na₃AlF₆(c). Baud (5) reported ΔH₂₉₈° = -40.7 kcal/mol for the reaction 2AlF₃(c) + 6NaF(c) = 2Na₃AlF₆(c). Based on JANAF ΔH₂₉₈° values for AlF₃(c) and NaF(c), we obtain ΔH₂₉₈°(Na₃AlF₆, c) = -793.7 ± 2 kcal/mol. Hashovets and Yudin (6) determined the equilibrium constants in the temperature range 1101-1239°K for the reaction 2/3 Na₃AlF₆(c) + H₂O(g) = 1/3 Al₂O₃(c) + 2HF(g) + 2NaF(c), using the transpiration method. Based on the reported K_p values, we evaluate ΔH₂₉₈° = 48.1 ± 0.8 and 46.6 kcal/mol by the second and third law methods, respectively. From the third law ΔH₂₉₈° value, we calculate ΔH₂₉₈°(Na₃AlF₆, c) = -791.3 kcal/mol. The equilibrium pressures of sodium vapor in the reaction 2NaF(c) + 1/3 Al(c) = Na(g) + 1/3 Na₃AlF₆(c) at temperatures 1020 - 1150°K were determined by Ono et al. (7), employing differential thermal analysis and X-ray analysis. Since the reported vapor pressures are the total pressures of Na(g) and Na₂(g), we calculate the partial pressures of Na(g) by use of the equilibrium constants for the reaction Na₂(g) = 2Na(g) derived from JANAF functions for Na₂(g) and Na(g). Based on the calculated Na(g) pressures we evaluate the enthalpy change of the above reaction by the third law method to be 109.2 kcal/mol, yielding ΔH₂₉₈°(Na₃AlF₆, c) = -791.1 kcal/mol.

The amounts of sodium over the mixtures of cryolite and aluminum were measured in the temperature range 1023 - 1373°K by the ultraviolet absorption method by Stokes and Frank (8). The enthalpy change for the reaction 6NaF(t) + Al(t) = 3Na(g) + Na₃AlF₆(t) is not evaluated due to lack of appropriate data on the activities of NaF(t) and Na₃AlF₆(t). The heat of formation (298°K) for cryolite(c) is adopted as -791 ± 1 kcal/mol. The heat capacity and entropy

The low temperature heat capacities, 53.66 - 296.00°K, were measured by King (9). The values of Cp below 53.66°K are extrapolated using the Cp equation given by King. S₂₉₈° is derived based on the adopted low temperature heat capacities. The high temperature enthalpies, 401.3 - 1370.5°K, determined by O'Brien and Kelley (10), are adopted to derive the heat capacities which join smoothly at 298°K with the low temperature Cp's. The heat capacity of Na₃AlF₆(γ) is estimated such that the calculated enthalpy at 1200.5°K is consistent with the measured value reported by O'Brien and Kelley. The heat capacity above the melting point is obtained by linear extrapolation.

Frank (21) commented that the enthalpies reported by O'Brien and Kelley were incorrect due to an apparent error in temperature measurement. However, his reported corrected enthalpy values are not used here (see NaF(c) table for details). The high temperature enthalpies have also been measured by the following investigators: July, 284.5 - 373.3°K (11); Baud, 289 - 328°K (12); Roth and Bertram, 369 - 1371°K (13); Krestovnikov and Karetnikov, 573 - 1773°K (14); Lyshenko, 290 - 1217°K (15); and Albright, 350.0 - 1311.8°K (16). Their data are not used for evaluation due to inconsistencies among the reported values.

Transition Data

Landon and Ubbelohde (17) determined the electrical conductance (σ) of crystals and melt of cryolite, and observed two transition temperatures from a plot of log σ vs 1/T, i.e. Tt(α + β) = 838°K and Tt(β + γ) = 1153°K, which are adopted here. Other values of Tt(α + β) reported are (°K): 823 (18), 833 (18), 834 (19), 835 (20), and 838 (13).

The values of ΔH^{*}(α + β) and ΔH^{*}(β + γ) are calculated as the difference between the adopted enthalpies for α and β at 838°K and β and γ at 1153°K, respectively. The value of ΔH^{*}(α + β) has also been reported as (kcal/mol): 1.24 (13), 2.16 (10), 2.24 (20), and 2.38 (16). Landon and Ubbelohde (17) estimated that ΔH^{*}(β + γ) = 0.01 x ΔH = 0.2 kcal/mol.

The cause of the discrepancies among the reported values for Tt, ΔH^{*} and the high temperature enthalpies may be due to differences in the sample composition.

Melting Data

See the Na₃AlF₆(t) table for details.

Heat of Formation

The $\Delta H_f^{\circ} 298(\ell)$ is obtained from $\Delta H_f^{\circ} 298(c)$ by adding ΔH_m° and the difference between $H_{298}^{\circ} - H_{298}^{\circ}$ for crystal and liquid. Yudin and Mashovets (1) studied the dissociation of cryolite and reported $K_{1300} = 2.33 \times 10^{-5}$ for the reaction $\text{Na}_3\text{AlF}_6(\ell) = 3\text{NaF}(\ell) + \text{AlF}_3(\ell)$. Based on this K_{1300} value, we evaluated the enthalpy change by the third law method as 24.3 kcal/mol. Using $\Delta H_f^{\circ} 298 = -360.8$ and -130.6 kcal/mol for $\text{AlF}_3(\ell)$ and $\text{NaF}(\ell)$, respectively, we obtain $\Delta H_f^{\circ} 298 = -776.7 \pm 3$ kcal/mol for $\text{Na}_3\text{AlF}_6(\ell)$.

Heat Capacity and Entropy

The high temperature enthalpies, $1285.5 - 1370.5^\circ\text{K}$, were measured by O'Brien and Kelley (2). Using their data we derive a constant Cp, 94.7 gibbs/mol. For $\text{Na}_3\text{AlF}_6(\ell)$. A glass transition temperature is assumed at 800°K , and the heat capacities below 800°K are taken to be the same as those of the $\text{Na}_3\text{AlF}_6(c)$. The Cp values above 1370.5°K are obtained by linear extrapolation. The entropy, S_{298}° , is calculated in a manner analogous to that of the heat of formation.

Albright (3) measured the high temperature enthalpies of $\text{Na}_3\text{AlF}_6(\ell)$ in the temperature range $1298.1 - 1311.8^\circ\text{K}$. However, his data are systematically higher (about 4.91) than the values determined by O'Brien and Kelley (2), which is also true for the other sets of enthalpy data measured using this calorimeter. Therefore Albright's enthalpy data is not used for evaluation.

Melting Data

The melting point of cryolite has been reported as ($^\circ\text{K}$): 1273 (4), 1279 (3), 1281 (5), 1282 (6, 7), 1293 (9), and 1300 (2). The value of Tm adopted is that determined by Landon and Ubbelohde (9). This value is corrected from the original measured value 1286°K , due to the thermocouple standardization against the freezing points of assay gold giving a gold point of $1064.2 \pm 0.15^\circ\text{C}$ compared with the fixed value of 1063.0°C .

The value of ΔH_m° is calculated as the difference between the enthalpies at Tm for crystal and liquid. Other reported values of ΔH_m° are (in kcal/mol): 16.64 (4), 26.6 (10), 27.64 (2), and 27.91 (3).

Heat of Formation

A. G. Gaydon, "Dissociation Energies", 2nd Ed., Chapman Hall, Ltd., London (1953), extrapolated the available $X^2\Sigma$ vibrational levels and also considered predissociation in the $A^1\Pi$ state and concluded that the best value of D_0^0 was 2.9 ± 0.2 e.v. The linear Birge-Sponer extrapolation gave a value of 3.05 e.v. while the predissociation limit was 3.07 e.v. Gaydon's recommended value is adopted here and leads to a value of ΔH_f^0 298.15 = 62.16 ± 5.0 kcal mole⁻¹ using JANAF auxiliary data.

Heat Capacity and Entropy

P. B. Zeeman and G. J. Ritter, Can. J. Phys. **32**, 555 (1954) examined the UV band system of AIH under high resolution and reported the molecular constants adopted above.

σ = 1

Heat of Formation.

The heat of formation was estimated by summing the constituent bond energies. The Al-O was taken as that in AlO(g) and the Al-H bond was taken as that in AlH(g), this gave a heat of atomization of 182 kcal.

Heat Capacity and Entropy.

Vibrational frequencies, bond lengths and angles and point group were taken from National Bureau of Standards Report 6297, Jan. 1, 1959, "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum, and Their Compounds with Oxygen, Hydrogen, Fluorine, and Chlorine".

Heat of Formation

From a mass-spectrometric investigation of the equilibrium

$1/3\text{Al}_2\text{O}_3(\text{g}) + 1/3\text{Al}(\text{g}) + 1/2\text{H}_2(\text{g}) = \text{AlOH}(\text{g})$

M. Farber et al. (1) report second law heats of reaction of 56.7 ± 0.6 kcal at 1800°K, 57.1 ± 2.8 kcal at 2060°K and 62.7 ± 1.4 kcal at 2000°K. Using JANAF auxiliary data, assuming AlOH to be AlOH, we obtain $\Delta H_f^\circ(298, \text{g}) = -44.6 \pm 1, -44.0 \pm 3.2$ and $-38.6 \pm 1.8 \text{ kcal/mol}$. A second equilibrium in the same investigation was

$\text{Al}_2\text{O}(\text{g}) + \text{D}_2\text{O}(\text{g}) = 2\text{AlOD}(\text{g})$

for which second law heats of reaction of 6.3 ± 2.1 kcal at 2060°K and 5.7 ± 0.8 kcal at 2000°K were reported. Farber et al. also measured the heat of reaction.

$1/3\text{Al}_2\text{O}_3(\text{g}) + 4/3 \text{Al}(\text{g}) = \text{Al}_2\text{O}(\text{g})$

at the same temperatures as $-10.7 \pm 2.8 \text{ kcal}$ at 2060° and $-10.3 \pm 10.2 \text{ kcal}$ at 2000°K. Combining these reactions and eliminating $\text{Al}_2\text{O}(\text{g})$ yields $\Delta H_f^\circ(2060) = -4.4 \pm 5.0 \text{ kcal}$ and $\Delta H_f^\circ(2000) = -5 \pm 11 \text{ kcal}$ for the reaction

$1/3\text{Al}_2\text{O}_3(\text{g}) + 4/3\text{Al}(\text{g}) + \text{D}_2\text{O}(\text{g}) = 2\text{AlOD}(\text{g})$.

Using auxiliary JANAF values for $\text{Al}_2\text{O}_3(\text{g})$ and $\text{Al}(\text{g})$, $\Delta H_f^\circ(298, \text{D}_2\text{O}, \text{g}) = -69.56 \text{ kcal/mol}$ (2), and functions for $\text{D}_2\text{O}(\text{g})$ from Friedman and Haar (3) we obtain $\Delta H_f^\circ(298, \text{AlOD}, \text{g}) = -43.9 \pm 6 \text{ kcal/mol}$ and $-43.4 \pm 3 \text{ kcal/mol}$. From all the above results we adopt a value of $\Delta H_f^\circ(298, \text{AlOD}, \text{g}) = -44 \pm 3 \text{ kcal/mol}$, assuming that AlOH is less stable than AlOD by 1 kcal/mol as is the case for H_2O , HDO and D_2O . We obtain $\Delta H_f^\circ(298, \text{AlOH}, \text{g}) = -43 \pm 3 \text{ kcal/mol}$.

Farber et al. (1) also performed weight loss experiments under molecular flow conditions by allowing hydrogen to flow over $\text{Al}_2\text{O}_3(\text{c})$. The products assumed were $\text{AlOH}(\text{g})$, $\text{Al}(\text{g})$, $\text{Al}_2\text{O}(\text{g})$, $\text{H}(\text{g})$ and $\text{H}_2\text{O}(\text{g})$ and the equilibrium amounts of $\text{H}(\text{g})$, $\text{Al}(\text{g})$ and $\text{Al}_2\text{O}(\text{g})$ were assumed to be those predicted by the free energies from the JANAF tables. A 3rd law analysis of the equilibrium constants given by Farber for the reaction $2\text{H}_2(\text{g}) + \text{Al}_2\text{O}_3(\text{c}) = 2\text{AlOH}(\text{g}) + \text{H}_2\text{O}(\text{g})$ yields $\Delta H_f^\circ(298, \text{g}) = 238 \pm 12 \text{ kcal/mol}$ and $\Delta H_f^\circ(298, \text{AlOH}, \text{g}) = -52 \pm 6 \text{ kcal/mol}$. However, the assumed equilibria involving $\text{Al}_2\text{O}(\text{g})$ and $\text{Al}(\text{g})$ may be significantly in error and thus the $\Delta H_f^\circ(298)$ should be considered as simply confirming the magnitude determined mass-spectrometrically.

Heat Capacity and Entropy

The vibrational frequencies are estimated by using the $\text{AlO}(\text{g})$ fundamental as approximately the Al-O stretch; the O-H stretch is that in $\text{H}_2\text{O}(\text{g})$; and the bending frequency is approximately the OH bend in $\text{ODOH}(\text{g})$ reported by T. Shimanouchi, U. S. Natl. Bur. Std. NBS-RS-NBS 6, 1967.

The AlO bond length was taken from U. S. Natl. Bur. Std. Report No. 6297, Jan. 1, 1959, and the OH bond length is assumed to be that in $\text{H}_2\text{O}(\text{g})$. The bond angle is assumed to be 180° using the prediction of A. D. Walsh, J. Chem. Soc. 1953, 2788 (1953), for "HAB" molecules with less than 11 valence electrons. Confirmation of this prediction is scanty for molecules having a more electronegative than B; however, R. L. Kuczkowski, D. R. Lide, Jr., and L. C. Krishner, J. Chem. Phys. 44, 3131 (1966), have confirmed the linearity of KOH and CsOH which have 8 valence electrons.

O-H = [0.96] Å

σ = 1

Heat of Formation

The heat of formation is obtained from $\Delta H^\circ_{f, \text{AlOH(g)}}$ and its ionization potential, which is estimated to be $7.5 \pm 1 \text{ eV}$ (173 ± 23 kcal). The ionization potential is estimated from a reported value of 7.5 eV for the appearance potential of AlOH⁺, presumably from the parent AlOH, by M. Farber, M. A. Frisch, G. Grenier, and H. C. Ko, Space Sciences, Inc., Final Report under USAF contract F04611-67-C-0010, AFRL-TR-67-244, November, 1967.

Heat Capacity and Entropy

According to the correlation diagram given by A. D. Walsh, J. Chem. Soc. 1953, 2286 (1953), for "HAg" molecules, a compound with 9 valence electrons would have the three outermost electrons in an unfilled π orbital. Thus, it would be a π state since the molecule ought to be linear if it has less than 11 valence electrons. The outermost orbital is a bonding orbital and thus the loss of an electron from it would weaken the bonding. The vibrational frequencies are estimated from those for AlOH(g) with somewhat lower frequencies due to the weaker bonding. Similarly, the Al-O bond length is slightly increased over that in AlOH(g). The enthalpy at 0°K is -2.138 kcal/mol.

Bond Distance: Al-O = [1.90] Å
Bond Angle: Al-O-H = [120°]
Product of the moments of Inertia: I_AI_BI_C = [4.554 × 10⁻¹¹⁷] g³ cm⁶ σ = 1

Heat of Formation

The heat of formation is obtained from ΔHf°(AlOH, g) and its electron affinity, which is estimated to be 0.5 ± 0.9 eV (12 ± 20 kcal). The electron affinity is estimated to be small, or even negative, since the additional electron must go into an antibonding orbital, according to the correlation diagram of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953).

Heat Capacity and Entropy

Since the molecule now has 11 valence electrons, the Walsh correlation diagram predicts a bent molecule. The extra electron is antibonding thus making the bonds weaker than in AlOH(g). Thus the vibrational frequencies and bond lengths are taken to be the same as in AlOH⁻(g), which is also less strongly bound than AlOH(g). The bond angle is arbitrarily chosen as 120°. The principal moments of inertia are I_A = 6.536 × 10⁻³⁹ g cm², I_B = 0.105 × 10⁻³⁹ g cm² and I_C = 6.641 × 10⁻³⁹ g cm². The enthalpy at 0°K is -2.419 kcal/mol.

GFW = 59.98827

(IDEAL GAS)

ALUMINUM DIOXYDRIDE (AlO₂H)

Point Group [C_s]

$\Delta H_f^\circ = [-109 \pm 15] \text{ kcal/mol}$

$S_{298.15}^\circ [60.6 \pm 1.5] \text{ gibbs/mol}$

$\Delta H_f^\circ [298.15] = [-110 \pm 15] \text{ kcal/mol}$

Ground State Quantum Weight = 1

(3400) (1)	(700) (1)
(1200) (1)	(500) (1)
(1100) (1)	(400) (1)

Bond Distances: Al-O = [1.62] Å Al-O = [1.87] Å O-H = [0.94] Å

Bond Angles: O-Al-O = [180°] Al-O-H = [105°] $\sigma = 1$

Product of the Moments of Inertia: $I_A I_B I_C = [37.349 \times 10^{-117}] \text{ g}^3 \text{ cm}^6$

Heat of Formation

The hydroxyl group can often be considered as intermediate between F and Cl as is illustrated by the following examples of bond energies from these tables.

D(F-H) = 136 kcal, D(Cl-H) = 103 kcal and D(HO-H) = 119 kcal; also D(F-BO) = 163 kcal, D(Cl-BO) = 105 kcal and D(HO-BO) = 143 kcal. Thus from D(F-AlO) = 181 kcal and D(Cl-AlO) = 134 kcal we estimate D(HO-AlO) = 158 ± 20 kcal. This yields $\Delta H_f^\circ(\text{HOAlO}, g) = -127 \pm 20 \text{ kcal/mol}$.

Consider also D(FB-O) = 175 kcal and D(CIB-O) = 169 kcal; and D(FAl-O) = 138 kcal and D(ClAl-O) = 132 kcal; it is evident that the substituent F or Cl has little effect on the B-O and Al-O bonds. Thus, we assume that D(HOAl-O) = 135 ± 10 kcal/mol which leads to $\Delta H_f^\circ(\text{HOAlO}, g) = -119 \pm 10 \text{ kcal/mol}$.

M. Farber, M. A. Frisch, G. Grenier, and H. C. Ko, "Investigation of the Thermodynamic Properties of Rocket Combustion Products," AFRL-TR-67-244, Nov. 1967, found no evidence for the ion DOAlO⁺ when reacting D₂O(g) + Al₂O₃(c). From estimates of the pressure needed to ensure detection of DOAlO and a knowledge of the D₂O pressure, they calculated the most negative value of $\Delta H_f^\circ(\text{DOAlO}, g) = -104 \pm 10 \text{ kcal/mol}$. The absence of DOAlO⁺ may be caused by fragmentation by the ionizing electrons and thus the value quoted may not be a real limit.

We adopt $\Delta H_f^\circ(\text{HOAlO}, g) = -110 \pm 15 \text{ kcal/mol}$ which encompasses all the values.

Heat Capacity and Entropy

Vibrational Frequencies, bond distances, bond angles, and the product of the moments of inertia were taken from "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum, and Their Compounds with Oxygen, Hydrogen, Fluorine, and Chlorine," National Bureau of Standards Report No. 6797, January 1, 1959. The individual moments of inertia are: $I_A = 0.13 \times 10^{-39} \text{ g cm}^2$, $I_B = 16.9 \times 10^{-39} \text{ g cm}^2$, and $I_C = 17.0 \times 10^{-39} \text{ g cm}^2$.

June 30, 1963; Mar. 31, 1964

LITHIUM TETRAHYDROALUMINATE (LiAlH₄)

(CRYSTAL)

MOL. WT. = 37.952

ΔH_f° 0 = UnknownΔH_f° 298.15 = -28.0 ± 2.0 kcal. mole⁻¹

S° 298.15 = [21.0 ± 2.0]

T_d = [410 ± 10]°K.

Heat of Formation.

The heats of solution of LiAlH₄(c) in HCl(aq.) were measured calorimetrically by the following investigators: W. D. Davis, L. S. Maen and G. Stegeman, J. Am. Chem. Soc. 71, 2775 (1949), L. G. Fasolino, et al., "Heat of Formation of Lithium Aluminum Hydride," Special Report, National Research Corporation, Mo., April 26, 1963, and M. B. Smith and G. E. Bess, Jr., J. Chem. Eng. Data, 6, 342 (1963). The results are given in the following table. ΔH_f° 298.15, kcal. mole⁻¹

Chemical Reaction

(1) LiAlH₄(c) + 10(HCl·50H₂O) → (LiCl + AlCl₃ + 6HCl)·500H₂O + 4H₂(g) -165.87(2) (AlCl₃ + LiCl + 6HCl)·500 H₂O + 41020 H₂O(l) -4.43(3) (AlCl₃ + LiCl + 6HCl)·41520 H₂O → AlCl₃·5190 H₂O

(1) + (2) + (3) -170.30

(4) Al + 60(HCl·14H₂O) → (AlCl₃ + 57 HCl)·840 H₂O + 3/2 H₂ -128.14(5) Li + 80(HCl·14H₂O) → (LiCl + 59 HCl)·840 H₂O + 1/2 H₂ -87.05(6) LiAlH₄ + 80(HCl·14 H₂O) → (LiCl + AlCl₃ + 56 HCl)·840 H₂O + 4H₂ -170.52

(4) + (5) - (6) -24.67

(7) LiAlH₄(c) + 39.715(HCl·11.624 H₂O) → [LiCl + AlCl₃ + 35.715 (HCl·12.926 H₂O)] + 4H₂(g) -164.6(8) LiCl(c) + [AlCl₃ + 35.715(HCl·12.926 H₂O)] → [LiCl + AlCl₃ + 35.715 (HCl·12.926 H₂O)] -6.75

(7) - (8) -157.85

Smith and Bess

Fasolino, et al.

Incorporating appropriate auxiliary thermal data, the heats of formation (ΔH_f° 298.15) for LiAlH₄(c) were derived as -28.51 (recalculated value, by Smith and Bess, loc. cit.), -24.67 ± 1.31 and -28.4 ± 1.5 kcal. mole⁻¹, resp. The adopted value, -28.0 ± 2.0 kcal. mole⁻¹, is the weighted average of the above three values.

Heat Capacity and Entropy.

Heat capacities were estimated by comparison with those for LiBH₄(c), LiBO₂(c) and LiAlO₂(c). The entropy value (S° 298.15) was calculated from that for LiBH₄(c) by the substitution of the entropy contribution of B atom by that of Al atom in the LiAlH₄(c) molecule. The entropy values of the constituent B and Al atoms in crystalline compounds were taken from O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958.

Temperature of Decomposition.

T_d was reported by A. E. Finholt, A. C. Bond, Jr. and H. I. Schlesinger, J. Am. Chem. Soc. 69, 1199 (1947). The decomposition products are aluminum, hydrogen, and lithium hydride. This reaction is apparently kinetically controlled since the free energy for the decomposition is negative even at room temperature.

AlH₄Li

Dec. 31, 1961; Sept. 30, 1964

ALUMINUM MONIODIDE (AlI)

(IDEAL GAS)

MOL. WT. = 153.89

Ground State Configuration Σ^+
 $S_{298.15}^o = [59.243] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o = 14.6 \pm 2.0 \text{ kcal. mole}^{-1}$
 $\Delta H_f^o = 14.3 \pm 2.0 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{\epsilon}{\text{cm.}^{-1}} = \frac{g_i}{1}$$

$$\omega_e x_e = 1.0 \text{ cm.}^{-1}$$

$$\alpha_e = [0.1156] \text{ cm.}^{-1}$$

$$r_e = [2.56] \text{ \AA}$$

$$\sigma = 1$$

Heat of Formation.

The dissociation energy (D_0^o) of AlI(ϵ) was reported by A. G. Gaydon¹, R. F. Barrow², and G. Herzberg³, respectively. Hence the corresponding values of ΔH_f^o 298.15 for AlI(ϵ) were derived. The results are given as follows.

Investigator	e.v.	D_0^o kcal. mole ⁻¹	ΔH_f^o 298.15 kcal. mole ⁻¹
Gaydon ¹	3.92	90.4	12.7
Barrow ²	—	87.0	16.0
Herzberg ³	2.9	66.9	36.2

¹ A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall Ltd., London, 1953.

² R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960).

³ G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950.

The adopted value of ΔH_f^o 298.15 for AlI(ϵ) is the average of the first two ΔH_f^o 298.15 values listed in the above table.

Heat Capacity and Entropy.

The spectroscopic constants, ω_e and $\omega_e x_e$, and ground state configuration were taken from G. Herzberg, loc. cit. The values of B_e and α_e were estimated. The bond length (r_e) was estimated by comparison with those for $Al_2I_6(g)$ reported by K. J. Palmer and N. Elliott, J. Am. Chem. Soc. 80, 1852 (1958).

ALUMINUM TRIIODIDE (AlI₃) (CRYSTAL) MOL. WT. = 407.71

ΔH_f^o = Unknown
S_{298.15}^o = {45.3 ± 2.0} cal. deg.⁻¹ mole⁻¹
ΔH_f^o 298.15 = -73.9 ± 1.5 kcal. mole⁻¹
ΔH_m^o = 3.8 kcal. mole⁻¹
ΔH_a^o 298.15 (to dimer) = 28.8 ± 1.8 kcal. mole⁻¹

Heat of Formation.

J. D. Corbett and N. W. Gregory, J. Am. Chem. Soc. 76, 1446 (1954) reported the free energy change, ΔF_{298.15}^o = -8.7 ± 0.2 kcal. mole⁻¹, for the reaction AlI₃(c) + 3HCl(g) → AlCl₃(c) + 3HI(g). By the relationship ΔH = ΔF + TΔS the value of ΔH_f^o 298.15 was derived as -10.1 ± 0.2 kcal. mole⁻¹. The heat of formation (ΔH_f^o 298.15) for AlI₃(c) was evaluated to be -73.86 ± 0.30 kcal. mole⁻¹. The heat of solution of AlI₃(c) in water was measured by D. J. A. Dear and D. D. Eley, J. Chem. Soc., 4684 (1954). From the value, ΔH_f^o 298.15 = -91.4 ± 1.5 kcal. mole⁻¹ for the reaction AlI₃(c) → Al³⁺(aq.) + 3I⁻(aq.), the heat of formation for AlI₃(c) was calculated to be -74.1 ± 1.5 kcal. mole⁻¹. The adopted value of ΔH_f^o 298.15 for AlI₃(c) is the average of the above two values.

Heat Capacity and Entropy.

The heat capacities, S_{298.15}-464°K., were taken from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). They were derived from the enthalpy data measured by W. Fischer, Z. anorg. Chem. 200, 332 (1931). Above 464°K. the C_p values were obtained by graphical extrapolation. The entropy, S_{298.15}^o for AlI₃(c) was calculated from S_{298.15}^o for AlI₃(l) by subtracting ΔS_m^o and the difference between S_{298.15}^o for crystal and liquid.

Melting Data.

Temperature and heat of melting were reported by W. Fischer, loc. cit.

Heat of Sublimation.

Heat of sublimation was calculated from vapor pressure data reported by W. Fischer, O. Rahlfs, and B. Benze, Z. anorg. allgem. Chemie, 205, 1 (1932), by both the second and third law methods. See Al₂I₆(g) table for details.

ALUMINUM TRIIODIDE (AlI₃)

(LIQUID)

MOL. WT. = 407.71

S°_{298.15} = [52.45] cal. deg.⁻¹ mole⁻¹
 T_m = 464.15°K.
 ΔH_f°_{298.15} = -70.77 ± 1.5 kcal. mole⁻¹
 ΔH_m° = 3.8 kcal. mole⁻¹

Heat of Formation.

ΔH_f°_{298.15}(l) was obtained from ΔH_f°_{298.15}(c) by adding ΔH_m° and the difference between H_{464.15}-H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity, 464-500°K., was obtained from K. K. Kelley, U. S. Bur. Minea Bull. 584 (1960). It was derived based on the enthalpy data measured by W. Flacher, Z. anorg. Chem. 200, 332 (1931). The C_p values above 500°K. were assumed to be the same as that at 500°K. The entropy, S°_{298.15}, was estimated so that the values of ΔH_f° calculated from vapor pressure data by the second and third law methods were in reasonable agreement.

Melting Data.

T_m and ΔH_m° were reported by W. Flacher, loc. cit.

[170] (1) [450] (2)

Bond Distance: Al-I = 2.44 ± 0.02 Å

Bond Angle: I-Al-I = [120]°K.

Product of the Moments of Inertia: I_AI_BI_C = 1.33213 X 10⁻¹¹⁰ g.³ cm.⁶

Heat of Formation.

The equilibrium pressures of the reaction Al₂I₆(g) → 2AlI₃(g) at several temperatures were determined by W. Fischer, O. Rehlfis and B. Benze, Z. anorg. allgem. Chem. 205, 1 (1932). The heats of dissociation of Al₂I₆(g) were calculated by both second and third law methods. The heats of vaporization, i.e. AlI₃(l) → AlI₃(g), were also evaluated using the calculated partial pressure of AlI₃(g) over AlI₃(l). See AlI₃(g) table for detail. The results obtained are summarized as follows:

Chemical Reaction or Process Temperature Range (°K.) Second Law Value Third Law Value Kcal. Mole⁻¹ ΔH_f⁰ 298.15, Kcal. mole⁻¹ ΔH_f⁰ 298.15(AlI₃, g)

Al₂I₆(g) → 2AlI₃(g) 614 - 744 25.18 23.34 -47.9
Al₂I₆(g) → 2AlI₃(g) 482.8 - 578.0 23.07 23.34 -49.0
AlI₃(l) → AlI₃(g) 493.8 - 645.2 21.45 22.69 -49.2

The three ΔH_f⁰ 298.15(AlI₃, g) values were calculated using the respective second law values of ΔH_f⁰ 298.15. The adopted value, ΔH_f⁰ 298.15 = -49.0 ± 1.6 kcal. mole⁻¹, is the weighted average of the above three values.

Heat Capacity and Entropy.

The molecular structure, bond distances and angle were obtained from P. A. Akshahin, N. G. Rambidi, and E. L. Zecorin, Kristallografiya, 4, 186 (1959). The vibrational frequencies were estimated such that the values of ΔH_f⁰ obtained by the third law method are in reasonable agreement with the corresponding values calculated by the second law method. The three principal moments of inertia are: I_A = I_B = 1.8815 X 10⁻³⁷ and I_C = 3.7630 X 10⁻³⁷ g.² cm.².

LITHIUM ALUMINATE (LiAlO₂)

MOL. WT. = 65.92

(CRYSTAL)

AlLiO₂

ΔH_f° = -282.78 kcal. mole⁻¹
S_{298.15}° = 12.75 cal. deg.⁻¹ mole⁻¹
ΔH_m° = [6000] cal. mole⁻¹
T_m = 1663°K

Heat of Formation.
ΔH_f 298.15 was measured by J. P. Coughlin, J. Am. Chem. Soc. 79, 2397 (1957).

Heat Capacity and Extrapolation.

Thermodynamic Functions are based on the low temperature heat capacity data of E. O. King, J. Am. Chem. Soc. 77, 3189 (1955), and on the high temperature heat content results of A. O. Christensen, K. O. Conway, and K. K. Kelley, U. S. Bur. Mines Rept. Invest. 5565 (1960).

Melting.

R. Ballo and E. Dittler, Z. anorg. u. allgem. Chem. 76, 39 (1912), list the melting point as between 1900° to 2000°K. More recently, K. H. Kim and P. A. Hummel, J. Am. Ceram. Soc. 43, 611 (1960), determined the melting point as 1883° ± 15°K. by rapidly heating a small sample on a Pt-Rh strip furnace. The value, which was used in this report, was derived from an average of ten measurements by Kim and Hummel.

H. Prophet, The Dow Chemical Company, private communication March 9, 1961, using an arc-omega furnace reports the melting point to be about 1875°K. After seven successive runs on the same sample the melting point approached that of Al₂O₃ at 2308°K. The sample, therefore is decomposed upon fusion to Li₂O vapor and Al₂O₃(c). See O. N. Salmon and L. Marcus J. Am. Ceram. Soc. 43, 549 (1960), and P. A. Hummel, B. S. R. Sastry and D. Watring, Ibid., 41, 88 (1958).

$$\Delta H_f^o = -74.8 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^o = -76.0 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = 4.816 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_D = [2790^\circ \text{K}]$$

Heat of Formation.

The selected heat of formation is the average of two independent calorimetric determinations. The heat of formation was reported to be $-76.5 \pm 0.2 \text{ kcal. mole}^{-1}$ and $-75.6 \pm 0.4 \text{ kcal. mole}^{-1}$. The former value was reported by C. A. Neugebauer and J. L. Margrave, *Z. Anorg. Allgem. Chem.* **290**, 82 (1957). The latter value was reported by A. D. Mah, E. G. King, W. W. Weller, and A. V. Christensen, U. S. Bureau of Mines Report of Investigations **5716** (1961).

Vapor pressure measurements agree with the selected heat of formation. For instance $\Delta H_f^o 298.15 = -75.5 \text{ kcal. mole}^{-1}$ for AlN(c) was calculated from the heat for the reaction $2\text{AlN(c)} \rightarrow 2\text{Al(g)} + \text{N}_2(\text{g})$ and the heat of sublimation, $78.0 \text{ kcal. mole}^{-1}$, for Al(c). This heat of reaction was obtained from a third law calculation using JANAP values for the free energy functions and torsion effusion pressures measured by D. L. Hildenbrand and L. P. Theard, *Aeronutronic Technical Report U-1497* (1961). Vapor pressure measurements with a microbalance in a vacuum system by L. H. Dreger, V. V. Dedape, and J. L. Margrave, *J. Phys. Chem.* **66**, 1556 (1962) agree with the selected $\Delta H_f^o 298.15$. When recalculated with the sublimation coefficient ($Q \times 2.2 \times 10^{-5}$) reported by Hildenbrand and Theard, some of the Knudsen cell measurements by M. Hoch and D. White, "The Vaporization of Boron Nitride and Aluminum Nitride," *ASTIA Unclassified Report 142616*, October 29, 1956, agree with the selected heat of formation.

Earlier determinations of the heat of formation which apparently are in error are summarized by C. A. Neugebauer and J. L. Margrave (*loc. cit.*) and by L. H. Dreger et al. (*loc. cit.*).

Heat Capacity and Entropy.

The heat capacity and entropy were reported by A. D. Mah et al. (*loc. cit.*). They measured the low temperature (51-298.15°K) and high temperature (298.15-1800°K) heat capacities and extrapolated the heat capacity from 0 to 51°K using the T^3 law. A smooth extrapolation of the heat capacity was made from 1800° to 3000°K. The heat content of AlN(c) was recently determined from 300 to 1200°K by R. Mezaki, "Heat Contents of Inorganic Substances at High Temperatures," M. S. Thesis, University of Wisconsin (1961). The enthalpies reported by Mezaki are about 1% greater than those of Mah et al.

Decomposition Data.

P. O. Schissel and W. S. Williams, *Bull. Am. Phys. Soc. II*, **4**, 139 (1959) studied the vaporization of AlN with the mass spectrometer and detected only the gaseous species Al and N_2 . The temperature at which the ΔH_f^o of AlN(c) and Al(g) were equal, 2788.9°K, was taken as the temperature of decomposition.

(Ideal Gas)

GFW = 40.9882

ALUMINUM NITRIDE (AlN)

(IDEAL GAS)

OPW = 40.9882

$$\frac{e_1, \text{ cm}^{-1}}{0} \frac{g_1}{1}$$

$$w_{e_e} = [930] \text{ cm}^{-1}$$

$$w_{e_e} = [6.9] \text{ cm}^{-1}$$

$$\sigma = 1$$

$$B_e = [0.6748] \text{ cm}^{-1}$$

$$\alpha_e = [0.0064] \text{ cm}^{-1}$$

$$r_e = [1.65] \text{ Å}$$

Heat of Formation.

The heat of formation is calculated from the estimated w_e and w_{e_e} using $D_0 = w/2w_{e_e}$, as 89 kcal/mol.J. L. Margrave and P. Stephitanonda, J. Phys. Chem. 59, 1231 (1955) estimated values of the bond length as 1.23 - 1.65 Å and calculated from an ionic model D_0 values of 137 - 82 kcal/mol. Using an estimated bond length of 1.65 Å and a $D_0 = 87$ kcal/mol leads to ΔH_f^o₂₉₈ = 104 kcal/mol.

Heat Capacity and Entropy.

The bond length is estimated as 1.65 Å from a comparison with the bond lengths of SO, PO, SiO, AlO, MgO, S₂, SiS, AlS, PN, SiN, and the sums of covalent radii. This bond length is then used with Ouggenheimer's Relation[K. M. Ouggenheimer, Proc. Phys. Soc. (London), 59, 456 (1946)] to calculate a value for w_e . By analogy with SiN(g) it is taken to closely approach the multiple bonding case, which gives $w_e = 960 \text{ cm}^{-1}$. The anharmonicity correction x_e is calculated by assuming the product $x_e \mu_e^{1/2}$ equal to that for AlO(g). The value of α_e is calculated using the relation:

$$\alpha_e = 6(w_e x_e \mu_e^{3/2})^{1/2} / 2 - B_e^2 / w_e$$

SODIUM ALUMINATE (NaAlO₂)

(CRYSTAL)

MOL. WT. = 81.971

$$\Delta H_f^0 = -268.97 \pm 0.17 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = -270.84 \pm 0.17 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = 0.310 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = \text{Unknown}$$

$$S_{298.15}^0 = 16.826 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_c = 740^\circ \text{K.}$$

$$T_m = \text{above } 1925^\circ \text{K.}$$

Heat of Formation.

ΔH_f^0 298.15 was reported by J. P. Coughlin, J. Am. Chem. Soc. 79, 2397 (1957). The value was calculated from the measured heat of solution of NaAlO₂(c) at 303.15°K. in 4.36M hydrochloric acid solution.

Heat Capacity and Entropy.

The low temperature heat capacities, below 350°K., were measured by E. F. Westrum, University of Michigan, Ann Arbor, Michigan, private communication, May 19, 1960. Heat capacities above 350°K. 399.4 - 1698.6°K., were measured by A. U. Christensen, K. C. Conway, and K. K. Kelley, U. S. Bur. Mines Rept. Invest. 5565 (1960).

These two sets of C_p data were plotted graphically and joined smoothly at 350°K. Low temperature heat capacities $S_{298.15}^0$ were also determined by E. O. King, J. Am. Chem. Soc. 77, 3189 (1955), which agree very well with those reported by E. F. Westrum, loc. cit. $S_{298.15}^0$ was reported by E. F. Westrum, loc. cit., using $S_{298.15}^0(\text{extrap.}) = 0.01 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

T_c and ΔH_f^0 were obtained from A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit.

Temperature of Melting.

T_m was taken from K. Kammermeyer and A. B. Peck, J. Am. Ceram. Soc. 15, 363 (1933).

Heat of Formation

The ionization potential of AlO has been reported as 9.5 ± 0.5eV(219 kcal) by J. Drowart, G. DeMaria, R. P. Burns, and M. G. Inghram, J. Chem. Phys. 32, 1366 (1960), and by G. DeMaria, J. Drowart and M. G. Inghram, J. Chem. Phys. 30, 318 (1959). Using this value in conjunction with ΔHf₀[°](AlO, g) = 20 ± 4 kcal/mol, we obtain ΔHf₂₉₈[°](AlO⁺) = 239 ± 15 kcal/mol.

Heat Capacity and Entropy

AlO⁺ is isoelectronic with MgO and we estimated the electronic ground state and excited states by comparison with those for MgO as reported by H. G. Richards, G. Verhaegen and C. M. Moser, J. Chem. Phys. 45, 3226 (1966). The bond length is estimated to be longer than that in AlO since the dissociation energy of AlO⁺ is less than that of AlO. The vibrational frequency and anharmonicity are estimated between those for MgO and AlO and the rotational constant, α_e, is derived from the above quantities assuming a Morse potential function.

The enthalpy at 0°K is -2.118 kcal/mol.

Heat of Formation

The OH bond strength in H₂O is 119 kcal and in HOBO it is 118 kcal. Thus, it appears very reasonable to assume 118 kcal for the value in HOAlO. This assumption leads to $\Delta H_f^\circ \text{g}(\text{AlO}_2, g) = -44 \pm 20 \text{ kcal/mol}$, using the JANAF $\Delta H_f^\circ \text{g}(\text{HOAlO}, g) = -110 \text{ kcal/mol}$. This value is consistent with the independently estimated $\Delta H_f^\circ \text{g}(\text{AlO}_2, g) = -130 \pm 15 \text{ kcal/mol}$, since it yields an electron affinity for AlO₂ of 46 kcal in good agreement with the value 98 kcal for BO₂.

Heat Capacity and Entropy

The electronic ground and excited states and molecular configuration are estimated to be similar to those for BO₂. The AlO bond length is assumed to be equal to that in Al₂O₃. The vibrational frequencies are estimated from a valence force field treatment using k_1 from BO₂ modified by the ratio $K(\text{AlO})/K(\text{BO})$ and using the same ratio of bending to stretch force constants as in BO₂.

The adopted molecular configuration and electronic ground state are in accord with the predictions of A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953).

σ = 2

Heat of Formation

The heat of formation of AlO₂⁻ is estimated from the following considerations. The heats of the following reactions are calculated from the tables:

BO₂ → B⁺ + 2O ΔH = 411 kcal
CO₂ → C + 2O ΔH = 384 kcal
BO₂ → B + O + O⁻ ΔH = 382 kcal
BOF → B + O + F ΔH = 355 kcal

It is apparent that the heat of dissociation of BO₂⁻ is closely predicted by use of the corresponding isoelectronic decomposition. Thus using

SiO₂ + Si + 2O ΔH = 299
we predict AlO₂⁻ + Al⁺ + 2O ΔH = [320]
and using AlOF → Al + O + F ΔH = 297
we predict AlO₂⁻ + Al + O + O⁻ ΔH = [320]

From these two reactions we estimate ΔHf(AlO₂⁻, g) = -158 and -135 kcal/mol and we adopt the value -145 ± 15 kcal/mol. From the value adopted for AlO₂(g) we obtain an electron affinity of 4.38 eV (101 kcal) which is comparable to that for BO₂(g).

Heat Capacity and Entropy

The configuration of the molecule is assumed to be linear using the correlations of Walsh, (1) for 16 electron XY₂ molecules; the ground state is assumed to be ¹Σ_g from the same correlation diagrams. The bond length is taken to be that in Al₂O₃ and the vibrational frequencies are estimated between those for AlO₂ and SiO₂.

The enthalpy at 0°K is -2.630 kcal/mol.

ALUMINUM SULFIDE (AIS)

(IDEAL GAS)

MOL. WT. = 59.046

Ground State Configuration $\sum^+$
 $\Delta H_f^0 = 48 \pm 20$ kcal. mole⁻¹
 $\Delta H_f^0 = 55.09$ cal. deg. mole⁻¹
 $\Delta H_f^0 = 298.15 = 48 \pm 20$ kcal. mole⁻¹

Electronic Levels and Quantum Weights

$$\frac{E_i, \text{ cm.}^{-1}}{0} \quad \frac{g_i}{2}$$

$$\omega_e x_e = 3.33 \text{ cm.}^{-1}$$

$$\sigma = 1$$

$$\omega_e = 617.12 \text{ cm.}^{-1}$$

$$r_e = 2.03 \text{ \AA}$$

$$\alpha_e = 0.0018 \text{ cm.}^{-1}$$

$$B_e = 0.2799 \text{ cm.}^{-1}$$

Heat of Formation.

The dissociation energy of 4.1 e.v. was calculated by adding 1.7% to the dissociation energy obtained from a linear extrapolation of the vibrational levels, 3.5 e.v. This was done by analogy with the molecule AlO(g) whose observed D_0 is 1.7% larger than the linear extrapolation. The adopted value of 4.1 e.v. corresponds to a heat of formation of 48 kcal. mole⁻¹.

Heat Capacity and Entropy.

The vibrational and rotational constants were reported by C. N. McKinney and K. K. Innes, J. Mol. Spect. 3, 235 (1959) from an analysis of 6 bands of the $A^2\Sigma^+ - X^2\Sigma^+$ system.

Beryllium Aluminate (BeAl₂O₄)
(Crystal) Mol. Wt. = 126.973BERYLLIUM ALUMINATE (BeAl₂O₄) (CRYSTAL)

ΔH_f[°] 0 = -541 ± 5 kcal. mole⁻¹
 ΔH_f[°] 298.15 = -545 ± 5 kcal. mole⁻¹
 ΔH_m[°] = [42] kcal. mole⁻¹
 S_{298.15} = 15.84 cal. deg.⁻¹ mole⁻¹
 T_m[°] = 2143°K.

Heat of Formation.

W. A. Young, J. Phys. Chem. **64**, 1003 (1960) studied the equilibria

from his results one obtains ΔH_f[°] 1673 = -379 kcal. mole⁻¹, which corresponds to ΔH_f[°] 298 = -545 kcal. mole⁻¹.

Heat Capacity and Entropy.

G. T. Furawaka and W. O. Saba, and T. B. Douglas and W. H. Payne, National Bureau of Standards Report 6186, Jan. 1964 have measured the low temperature heat capacities and the high temperature enthalpy in the range 15 - 1173°K.

Melting Data.

The temperature of melting was taken from National Bureau of Standards Circular 500, Washington (1952).

The heat of melting was estimated as the sum of the ΔH_f[°] of the constituent oxides at 2100°K.

Point Group D_{2h} $\Delta H_f^\circ = -221.0 \pm 7 \text{ kcal/mol}$ $S_{298}^\circ = 130.8 \text{ gibbs/mol}$ $\Delta H_f^\circ = -231.5 \pm 7 \text{ kcal/mol}$

Ground State Quantum Weight = [1]

Bond Distances: Al-Br = $2.21 \pm 0.4 \text{ \AA}$ Al-Br₂ bridge = $2.33 \pm 0.4 \text{ \AA}$ Bond Angles: Br-Al-Br = $114^\circ 38'$ Br-bridge-Al-Br bridge = $86^\circ 44'$ Product of the Moments of Inertia: $I_A I_B I_C = 8.80123 \times 10^{-110} \text{ g}^3 \text{ cm}^6$

Heat of Formation

The vapor pressures of AlBr₃(c) and AlBr₃(l) have been measured by Dunne and Gregory (1) and Fischer et al. (2), respectively. Using these data, the heats of vaporization were calculated by both second and third law methods. The adopted value of ΔH_f° for AlBr₃(g) is $-231.5 \pm 7 \text{ kcal/mol}$. The results of these calculations are as follows with reaction (A) corresponding to 2AlBr₃(c) = Al₂Br₆(c) and reaction (B) corresponding to 2AlBr₃(l) = Al₂Br₆(g):

Source	Reac.	Method	No. Pts.	Range T ^o K	ΔH_f° , kcal/mol 2nd Law 3rd Law	Drift, au	ΔH_f° , kcal/mol 2nd Law 3rd Law
1	A	Effusion	3	273-310	19.7±0.7 20.25	2.2±2.4	-231.7
2	B	Weight Loss	18**	413-523	15.6±0.1 15.61	0.1±0.1	-231.5

*Calculation based on third law ΔH_f°

**One point rejected due to failure of a statistical test.

Heat Capacity and Entropy

The molecular structure, bond distances and angles were obtained from the electron diffraction work of Palmer and Elliott (3). The bond distances and angles have also been reported by Akishin et al. (4), and these values are in good agreement with those given by Palmer and Elliott (3). The principal moments of inertia are $I_A = 6.38492 \times 10^{-37}$, $I_B = 2.51547 \times 10^{-37}$, and $I_C = 6.52171 \times 10^{-37} \text{ g cm}^2$. It has been established that the condensed phases of AlBr₃ are dimeric (5), (6), thus spectroscopic studies of the crystal and liquid pertain to the structure of Al₂Br₆(g). Gerding and Smit (7) have studied the Raman spectra of Al₂Br₆(l). The eighteen fundamental vibrational frequencies of Al₂Br₆(g) have been predicted by Miller (8) based on seven of the frequencies reported by Gerding and Smit (7). Webb (9) has measured the infrared spectra of AlBr₃(c) in the 40-800 cm⁻¹ region, the results being in general accord with the predictions of Miller (8). The vibrational frequencies used are adjusted so that the values of ΔH_f° obtained by the third law method are in agreement with the corresponding second law values. These adjustments are based on the assumption that vibrations with a wave number below 300 cm⁻¹ have a lower wave number in the gas phase than they have in the condensed phase.

Bond Lengths: Al-Cl = 2.05 Å, Al-Cl-bridge = 2.23 Å
 Bond Angles: Cl-Al-Cl = 120°, Cl-bridge-Al-Cl-bridge = 83°
 Product of the Moments of Inertia: $I_A I_B I_C = 5.988 \times 10^{-111}$ g cm⁶
 $\sigma = 4$

Heat of Formation

The heat of formation is calculated from the value adopted for AlCl₃(g) and the heat of sublimation as derived from vapor pressure data. Vapor pressures were corrected for vapor non-ideality by means of the equation $\log^* P = -R \ln P - BP/T$. The Berthelot equation of state and critical constants $T_c = 625.7^\circ K$ and $P_c = 26.1$ atm reported by Denisova and Baskova (1) were used to calculate B. Boston et al. (2) and Nisels' son and Sokolova (3) confirm T_c within $\pm 2^\circ K$. The corrected vapor pressures were used to derive $\Delta H_{298.15}^{\circ}$ by both second law and third law methods.

^aNine points reported, points at 420.8° and 433.5°K rejected by statistical test.

^bFourteen points reported, points at 385.2° and 441.3°K rejected by statistical test.

^cThirteen points reported, point at 472.2°K rejected by statistical test.

^dFive points reported, point at 342.0°K rejected by statistical test.

^eEight points not reported; their vapor pressure equation was used to calculate 2 points at extremes of temperature range covered.

The first seven data sets show good agreement between second and third law values and an average of $\Delta H_{298.15}^{\circ} = 27.66 \pm 0.55$ kcal/mol Al₂Cl₆ is adopted. The remaining data sets show serious discrepancies between second and third law values, indicating temperature dependent errors in measurement, and are given no weight.

Heat Capacity and Entropy

Electron diffraction data by Palmer and Elliott (11) and by Akishin et al. (12) are in agreement within experimental error and average values for bond angles and distances as given above are selected. The principal moments of inertia are: $I_A = 2.2172 \times 10^{-37}$, $I_B = 9.991 \times 10^{-38}$, and $I_C = 2.7023 \times 10^{-37}$ g cm². Klemperer (13) observed three frequencies in the infrared spectrum of Al₂Cl₆ vapor, Beattie and Horder (14) and Maroni et al. (15) reported gas phase Raman spectra, and Gerding and Sait (16) and Pershina and Raskin (17) measured liquid phase Raman frequencies. With previous vibrational assignments and normal coordinate calculations by Onishi and Shimizu (18), Miller (19), and Maroni et al. (15) as a starting point, a new assignment was made (see above) which incorporates additional frequencies observed by Beattie and Horder (14) and Pershina and Raskin (17).

Raman and infrared spectra of Al₂Br₆ and Al₂I₆ determined by Beattie, et al. (20) were very helpful. The new assignment differs with earlier calculations primarily in the assumption that the frequencies at 36 cm⁻¹ and 19 cm⁻¹ observed by Pershina and Raskin in the liquid can be assigned to modes not ordinarily Raman active. This assumption is supported by the compatibility of thermodynamic functions based on the new assignment with vapor pressure data as listed above. Use of the frequencies 89 cm⁻¹ and 56 cm⁻¹ of Miller (19) gives 3rd law heats of sublimation nearly 2 kcal/mol Al₂Cl₆ higher than the average of 2nd law values.

TRIPOTASSIUM NONACHLOROALUMINATE (K₃Al₂Cl₉) (CRYSTAL)

MOL. WT. = 490.373

Al₂Cl₉K₃

$\Delta H_f^0 =$ Unknown

$\Delta H_f^0 298.15 = -683.6 \pm 3$ kcal. mole⁻¹

$\Delta H_m^0 =$ Unknown

$S_{298.15}^0 = [112]$ cal. deg.⁻¹ mole⁻¹

$T_m =$ Unknown

Heat of Formation.

The value of $\Delta H_f^0 298.15$ for K₃Al₂Cl₉(c) was calculated from the heat of solution, $\Delta H_r^0 = -112.07$ kcal. mole⁻¹, of K₃Al₂Cl₉(c) in water (one mole of solute in 36 l. of water) determined by E. Baud, Ann. chim. phys. 1, 8 (1904).

Heat Capacity and Entropy.

Heat capacities and $S_{298.15}^0$ were estimated based on an assumption that the property of the mixed chloride (2AlCl₃ · 3KCl) is the sum of the corresponding values for its component chlorides, i.e. AlCl₃(c) and KCl(c).

Al₂Cl₉K₃

Point Group {D_{2h}}

$$S_{298.15}^0 = 92.5 \pm 3 \text{ gibbs/mol}$$

$$\Delta H_f^0 = -627.3 \pm 4 \text{ kcal/mol}$$

$$\Delta H_f^{298.15} = -629.45 \pm 4 \text{ kcal/mol}$$

June 30, 1970

Heat of Formation
The existence of small amounts of dimer in the saturated vapor was inferred from the intensities of AlF₃⁺, AlF₂⁺, and AlF₂⁺ observed by mass spectrometry (1, 2, 3). Büchler et al. (1) concluded that the precursor of the first two ions was mainly AlF₃⁺, while the dimer was the precursor of AlF₂⁺. Intensities of AlF₂⁺ relative to those of AlF₃⁺ were observed as 0.0057 (1), 0.007 (2) and 0.025 (3) at ionizing energies of 60, 90 and 100 V for vapor at 1025, 1100 and 1025°K, respectively.

The temperature dependence of ion intensities was used to derive 2nd-law values of ΔH_f⁰ for monomer and dimer (1, 2) and a value of ΔH(dimerization) based on an estimate for the entropy of dimerization (3). The absolute pressure of the monomer was obtained (2) from integration of the intensity of AlF₂⁺ during total sublimation at 1100°K, then the pressure of dimer was estimated from the relative ion intensity assuming a relative ionization cross section equal to two and neglecting other effects. Krause and Douglas (4) reported ΔH_f⁰(monomer) plus ΔH⁰ and ΔS⁰ for dimerization; these were derived by combination of ΔH_f⁰(dimer) (1) with precise sublimation pressures from entrainment data near 1200°K, where the dimer is more abundant. After reduction to 1000 K with JANAF functions, these results may be summarized as follows:

Source	Method	ΔH _f ⁰ , kcal/mol*	ΔS _f ⁰ , gibbs/mol*
Krause (4)	Entrainment	c + m	c + m
Büchler (1)	Ion Intensities	68.1 ± 0.4	2c + d
Erkolin (2)	Ion Intensities	67.3 ± 3	2c + d
Porter (3)	Ion Intensities	70.5	2c + d
JANAF	Adopted	68.4	2c + d
		87.8	2c + d
		[-49]	2c + d
		[52.83]	2c + d
		[-35.9]	2c + d

* Reactions are abbreviated by c = crystal, d = dimer gas and m = monomer gas. Brackets enclose those values assumed in deriving the other values.

JANAF values are given in the last line. These are based on JANAF entropies, on ΔH⁰(dimerization) = -49 kcal/mol for which there is close agreement, and on the entrainment pressures of Krause and Douglas (4). Reduction of the dimer value to 298.15°K gives ΔH_f⁰ = 92.55 ± 4 and ΔH_f⁰ = -629.45 ± 4 kcal/mol. The table for AlF₃(g) gives a detailed comparison of observed and predicted total pressures along with predictions of the mole fraction of dimer in the saturated vapor. The latter are reasonably consistent with the relative ion intensities.

Heat Capacity and Entropy

The molecular structure is assumed to be similar to that of Al₂Cl₆. Bond distances and bond angles are estimated by comparison with AlF₃(g), AlCl₃(g) and Al₂Cl₆(g). Principal moments of inertia are I_A = 35.36 × 10⁻³⁹, I_B = 79.74 × 10⁻³⁹ and I_C = 94.66 × 10⁻³⁹ g cm².

Six observed vibrational frequencies are from infrared spectra of the dimer isolated in rare-gas matrices (2). Unobserved fundamentals (2) in infrared, 9 in Raman and 1 inactive) are estimated such that the entropy is consistent with the result of Krause and Douglas (4) as given above. The estimated fundamentals are based on comparisons with Al₂Cl₆, Al₂Br₆ and Al₂I₆ which have been restudied extensively (9-11) since the calculations of Miller (12). Assignments used in the comparisons are minor modifications of those given by Beattie et al. (3).

Bond Distance: Al-I = 2.53 Å Al-I-bridge = 2.58 Å

Bond Angle: I-Al-I = 112 ± 1° I-bridge-Al-I-bridge = 68 ± 1°

Product of the Moments of Inertia: I_AI_BI_C = 5.2175 X 10⁻¹⁰⁹ g.³ cm.⁶

Heat of Formation.

W. Fischer, O. Rahlfs and B. Benze, Z. anorg. allgem. Chem. 205, 1 (1932) measured the vapor pressure of AlI₃(l). The vapor consists of both Al₂I₆(g) and AlI₃(g) species. The partial pressures of Al₂I₆(g) and AlI₃(g) at different temperatures for the equilibrium Al₂I₆(g) → 2AlI₃(g) were determined by W. Fischer, O. Rahlfs and B. Benze, loc. cit. From these partial pressures the mole ratios of Al₂I₆(g) and AlI₃(g) at other temperatures were estimated. The partial pressures of Al₂I₆(g) over AlI₃(l) were calculated from the total pressure using the estimated mole ratio values. The heat of vaporization, ΔH_v 298.15 = 20.5 ± 1.0 kcal. mole⁻¹, was evaluated employing the vapor pressures obtained by second law method. The corresponding third law value is 22.4 kcal. mole⁻¹. It was not used due to the uncertainties involved in the estimation of the vibrational frequencies. The heat of formation for Al₂I₆(g) was calculated from ΔH_f^o(l) and ΔH_v^o obtained.

Heat Capacity and Entropy.

Molecular structure, bond distances and angles were reported by K. J. Palmer and N. Elliott, J. Am. Chem. Soc. 60, 1852 (1938). Five vibrational frequencies (344, 146, 94, 53 and 410 cm.⁻¹) were adopted from the Raman spectrum of Al₂I₆(l) measured by H. Gerding and E. Smit, Z. physik. Chem. 50B, 171 (1941). The remaining ones were estimated by comparison with those for Al₂O₆(g) and Al₂Br₆(g) and adjusted so that the value of ΔH_f^o 298.15 obtained by the third law method is in reasonable agreement with the corresponding second law value. The three principal moments of inertia are: I_A = 9.32506 X 10⁻³⁷, I_B = 4.60285 X 10⁻³⁷, and I_C = 1.21558 X 10⁻³⁶ g. cm.².

Al_2MgO_4

MOL. WT. = 142.28

(CRYSTAL)

MAGNESIUM ALUMINATE (MgAl_2O_4)

$\Delta H_f^\circ \text{ O} = -547.3 \pm 1.9 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ \text{ 298.15} = -551.2 \pm 1.9 \text{ kcal. mole}^{-1}$
 $\Delta H_m^\circ = \text{Unknown}$

$S_{298.15}^\circ = 19.27 \pm 0.10 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 2408^\circ\text{K.}$

Heat of Formation.

The value of $\Delta H_f^\circ \text{ 298.15}$ was calculated from $\Delta H_f^\circ \text{ 298.15} = 124.6 \pm 1.5 \text{ kcal. mole}^{-1}$ for the reaction:
 $4\text{MgO(c)} + 2\text{Al(l)} = \text{MgAl}_2\text{O}_4\text{(c)} + 3\text{Mg(g)}$. The value of $\Delta H_f^\circ \text{ 298.15}$ was obtained by the third-law method, using
vapor pressure data reported by K. Grjotheim, O. Horstad, and J. M. Toguri, Can. J. Chem. **39**, 443 (1961). From
the Knudsen experiments with $\text{MgAl}_2\text{O}_4\text{(c)}$, R. L. Altman, J. Phys. Chem., **57**, 366 (1963) calculated the value of
 $\Delta H_f^\circ \text{ 298.15}$ as $-552 \text{ kcal. mole}^{-1}$ which agrees with the value used.

Heat Capacity and Entropy.

The low temperature heat capacity, $53\text{--}296^\circ\text{K.}$, was measured by E. G. King, J. Phys. Chem. **59**, 218 (1955).
The high temperature heat capacity, $400\text{--}1800^\circ\text{K.}$, was reported by K. R. Bórnicksen, J. Phys. Chem. **59**, 220 (1955).
These two sets of data were joined smoothly and extrapolated to 3000°K. $S_{298.15}^\circ$ was reported by E. G. King, loc.
cit., based on S_{21}° (extrap.) = $0.32 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Temperature of Melting.

T_m was taken from "Data on Chemicals for Ceramic Use," U. S. National Research Council Bulletin 118, 1949.

Bond Distance: Al-O = 1.66 Å

Bond Angle: Al-O-Al = 145°

Product of the Moments of Inertia: I_AI_BI_C = 263.2477 X 10⁻¹¹⁷ g.³ cm.⁶

Heat of Formation.

The value of ΔH°_f 298 = -31.4 ± 7 kcal. mole⁻¹ for Al₂O(g) was calculated from ΔH°_f 298 = 247 ± 7 kcal. mole⁻¹ for the reaction Al₂O(g) = 2Al(g) + O(g); and ΔH°_f 298 = 131 ± 7 kcal. mole⁻¹ for the reaction Al₂O(g) = AlO(g) + Al(g). The value of ΔH°_f 298 were obtained by the third law method, using the partial pressure data reported by J. Drowart, G. Delmaris, R. Burns and M. Ingraham, *J. Chem. Phys.* **32**, 1368 (1960). (The second law values which are in poor agreement with the third law values, are ΔH°_f 298 = 271 ± 10 kcal. mole⁻¹ and ΔH°_f = 154 ± 10 kcal. mole⁻¹, respectively.) L. Brewer and A. Searcy, *J. Am. Chem. Soc.*, **73**, 5308 (1951), reported that under reducing condition, Al₂O₃ vaporizes mostly to Al₂O(g), but under neutral condition AlO(g) and O(g) are the major products. Brewer and Searcy also measured the vapor pressures of the Al-Al₂O₃ system by Knudsen effusion method, and obtained the heat of formation of Al₂O(g) from gaseous atoms as ΔH°_f 298 = -248 kcal. mole⁻¹. This value leads the heat of formation for Al₂O(g), ΔH°_f 298 = -32.4 ± 7, which agrees with the value selected.

Heat Capacity and Entropy.

The matrix isolation of high temperature vapors for the investigation of the infrared spectrum of Al₂O has been used to determine the bond distance, angle and vibrational frequencies by M. Linevsky, D. White and D. Mann, *J. Chem. Phys.*, **41**, 542 (1964). These reported data have been adopted in this table. The symmetric structure Al-O-Al instead of Al-Al-O for Al₂O(g) was chosen for two reasons: (1) The dissociation energy of Al₂O(g), D°₂₉₈ = 247 ± 7 kcal/mole, is approximately twice the dissociation energy of AlO(g), D°₂₉₈ = 115 ± 5 kcal. mole⁻¹, which implies that the symmetric structure is more reasonable. (2) The dissociation energy of Al₂O(g) has been estimated to be only 39 kcal. mole⁻¹ by J. Drowart and R. Honig, *J. Phys. Chem.*, **61**, 980 (1957). This implies that the Al-O bond energy in "Al-Al-O" structure would be as large as 208 kcal. mole⁻¹ if D°Al-Al = 39 kcal. mole⁻¹. Therefore Al₂O(g) must have a symmetric structure. Linevsky et al., loc. cit., have also concluded the bent symmetric structure (instead of a linear one) and the calculated ω₂ from the observed infrared spectra and the re-analysis of the ultraviolet spectra. The three principal moments of inertia are I_A = 0.5105 X 10⁻³⁹ g.², I_B = 22.4539 X 10⁻³⁹ and I_C = 22.9644 X 10⁻³⁹ g.²

Drowart, et al. (loc. cit.), also postulated a bent asymmetric molecule for Al₂O(g), and estimated the bond distance Al-O = [1.0176] Å and angle Al-O-Al = [110]° and the vibrational frequencies as [1079] cm.⁻¹, [351] cm.⁻¹ and [921] cm.⁻¹

The National Bureau of Standards Report No. 6494 "Preliminary Report on the Thermodynamic Properties of Li, Be, Mg, Al and Their Compounds with Hydrogen, Oxygen, Nitrogen, Fluorine and Chlorine" July, 1959, has proposed a trigonal structure for Al₂O(g) with bond distance Al-O = [1.87] Å, and Al-Al = [2.0] Å. Its vibration frequencies were estimated as [450] cm.⁻¹, [1000] cm.⁻¹ and [1000] cm.⁻¹.

Bond Distance: Al-O = [1.86] Å

Bond Angle: Al-O-Al = [155°]

Product of the Moments of Inertia: I_AI_BI_C = [1.481 x 10⁻¹¹⁵] g³ cm⁶

Heat of Formation

The ionization potential of Al₂O has been reported as 7.7 ± 0.2eV (177.6 kcal) by R. F. Porter, P. Schissel, and M. G. Inghram, J. Chem. Phys. 23, 339 (1955), and has been confirmed as 7.7 ± 0.5eV by G. DeMaria, J. Drowart, M. G. Inghram, J. Chem. Phys. 30, 318 (1959). Using this value with ΔH°₂₉₈(Al₂O, g) = -31.4 kcal/mol, we obtain ΔH°₂₉₈(Al₂O⁺, g) = 146 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecule is assumed to be bent by analogy with Al₂O, although both these molecules are predicted to be linear according to A. D. Walsh, J. Chem. Soc. 2266 (1953). The electronic ground state is doublet, since there is an odd number of electrons. The bond length is estimated to be the same as that in Al₂O and the vibrational frequencies are also assumed to be close to those for Al₂O. Since normally the molecule Al₂O ought to be linear, the bending must occur due to the occupancy of an outermost orbital with strong angular variation. Presumably this orbital is occupied by a pair of electrons, one of which will be removed in Al₂O⁺, thus causing an opening of the bond angle. On this basis the angle is estimated to be greater than that in Al₂O. The individual moments of inertia are: I_A = 2.645 x 10⁻⁴⁰ g cm², I_B = 2.353 x 10⁻³⁸ g cm² and I_C = 2.380 x 10⁻³⁸ g cm². The enthalpy at 0°K is -2.769 kcal/mol.

σ = [4]

Heat of Formation.

The value of ΔH_f⁰ 298 = -97 ± 7 kcal. mole⁻¹ for Al₂O₂(g) was calculated from ΔH_f⁰ 298 = 372 ± 7 kcal. mole⁻¹ for the reaction Al₂O₂(g) = 2Al(g) + 2O(g). The value of ΔH_f⁰ 298 was obtained by the third law method, using the partial pressure data reported by J. Drowart, G. Defaria, R. Burna and M. Inghram, J. Chem. Phys. 32, 1386 (1960). (The second law value for ΔH_f⁰ which is in poor agreement with the third law value, is 451 ± 25 kcal. mole⁻¹.)

Heat Capacity and Entropy.

The molecular structure (plane cyclic model) and vibrational frequencies of Al₂O₂(g) were obtained from Drowart, et al., J. Chem. Phys., 32, 1386 (1960). The bond distance Al-O in Al₂O₂ was assumed to be the same as that in AlO (g.). The three principal moments of inertia are I_A = 6.8005 X 10⁻³⁵, I_B = 11.4874 X 10⁻³⁵ and I_C = 19.2879 X 10⁻³⁵ g. cm.²

The configuration was proposed by Drowart, et al., instead of the alternate linear structure OAl-AlO for the reason discussed below. The OB-BO bond 1.2 compares to the B₂ dissociation energy 3.4 in the same way as the NC-CN bond compares to the C-C single bond. However, for Al₂O₂(g), the relationship between OAl-AlO and Al₂ would be quite different.

Bond Angle: Al-O = [1.66] Å

Bond Distance: Al-O = [1.66] Å

Product of the Moments of Inertia: I_AI_BI_C = [1.777 × 10⁻¹¹u³ cm⁶]

Heat of Formation

G. DeMaria, J. Drowart, and M. G. Inghram, J. Chem. Phys. 30, 118 (1959), have reported an ionization potential for Al₂O₂⁺ of 9.9 ± 0.5 eV (228 kcal). Using this value in conjunction with ΔH_f⁰ (Al₂O₂, g) = -97 kcal/mol, we obtain ΔH_f⁰ (Al₂O₂⁺, g) = 131 ± 20 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is assumed to be the same as that used for Al₂O₂. The bond length is assumed to be longer than that in Al₂O₂ and is made equal to that reported for Al₂O. The bond angle is arbitrarily estimated to be the same as that in Al₂O₂. The vibrational frequencies are estimated to be slightly lower than those for Al₂O₂, since the Al₂O₂⁺ molecule should be less rigidly bound. The ground state is assumed to be doublet, since there is an odd number of electrons. The individual moments of inertia are I_A = 7.32 × 10⁻³⁹ g cm², I_B = 1.234 × 10⁻³⁸ g cm², and I_C = 1.965 × 10⁻³⁸ g cm². The enthalpy at 0°K is -3.010 kcal/mole.

Dec. 31, 1960; Sept. 30, 1961; Mar. 31, 1964

$$\Delta H_f^0 = -397.5 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -400.4 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_m = 28.30 \pm 0.55 \text{ kcal. mole}^{-1}$$

$$T_m = 2315^\circ\text{K.}$$

$$S_{298.15}^0 = 12.174 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Heat of Formation.

The value of ΔH_f^0 derived from the direct combustion of pure aluminum in oxygen was taken from A. D. Mah, J. Phys. Chem. **61**, 1572 (1957). Other values for ΔH_f^0 obtained in the same way are: $-399.04 \pm .24$ kcal. mole⁻¹ reported by P. E. Snyder and H. Seitz, J. Am. Chem. Soc. **81**, 683 (1959); $-400.4 \pm .3$ kcal. mole⁻¹ reported by C. E. Holley, Jr., and E. J. Huber, Jr., J. Am. Chem. Soc. **72**, 5577 (1951); and -402 ± 2 kcal. mole⁻¹ reported by A. Schneider and O. Götow, Z. anorg. u. allgem. Chem. **277**, 41 (1954).

Heat Capacity and Entropy.

The heat capacity measurements reported by G. T. Furukawa, T. B. Douglas, R. E. McConkey, and D. C. Ginnings, (15° to 1200°K.), J. Research Natl. Bur. Standards **57**, 67 (1956), were employed in this table. Low temperature measurements were also made by P. Simon and R. C. Swain (30-280°K.), Z. Physik. Chem. **28B**, 189 (1935); E. C. Kerr, H. L. Johnston, and N. C. Hallett (20° to 295°K.), J. Am. Chem. Soc. **72**, 4740 (1950); J. W. Edwards and G. L. Kingdon (53-291°K.), Trans. Faraday Soc. **58**, 1313-22 (1962); E. N. Rodighina and K. Z. Gmel'akii, (100-900°K.), Zhur. Fiz. Khim. **32**, 1859-62 (1956); B. E. Walker, J. A. Grand, and R. R. Miller (300-900°K.), J. Phys. Chem. **60**, 231-3 (1956); R. Dawson, E. B. Brackett (700-1400°K.), J. Phys. Chem. **67**, 1689 (1963), and L. Terbasai (0-1300°K.), Helv. Chim. Acta. **47**, 804 (1934). All of the above low temperature data are in good agreement with Furukawa's work.

The heat capacities above 1200°K. (1200-2500°K.) were taken from the enthalpy measurements of P. B. Kantor, L. S. Lazareva, V. V. Kandyba, and E. M. Pomichov, Ukr. Fiz. Zh. **7**, 205-10 (1962). The heat capacity values above 2500°K. were extrapolated. High temperature measurements were also made by the following investigators: V. Ya. Chekhovskoi (500-2000°K.), Inzh. Fiz. Zh., Akad. Nauk. Belorussk SSR **5**, 62-5 (1962); A. Perrier and M. Olette (1100-2300°K.), Compt. Rend. **254**, 4293-95 (1962); C. H. Shomate and B. P. Naylor (500-1800°K.), J. Am. Chem. Soc. **81**, 72 (1945) and H. L. Johnston and M. Hoch (1000-2000°K.), J. Phys. Chem. **65**, 1184-5 (1961); and V. A. Kirillin, A. E. Sheidlin, and V. Ya. Chekhovskii (500-2000°K.), Doklady Akad. Nauk. SSSR **135**, 125-8 (1960). Numerical values were not available from Kirillin, et al., but graphical values were in close agreement with an extrapolation of Furukawa's data. The entropy at 298.15 was reported by T. Furukawa, et al., loc. cit., using $S_{15}^0 = 0.0105$ cal. deg.⁻¹ mole⁻¹.

Melting Data.

The melting data were obtained from the measurements of P. B. Kantor, L. S. Lazareva, V. V. Kandyba, and E. M. Pomichov, loc. cit. S. J. Schneider "Compilation of the Melting Points of the Metal Oxides," NBS Monograph **68**, p. 6, Oct. 10, 1963, gives a review of the melting points that range from 2287 to 2345°K.

Al_2O_3

MOL. WT. = 101.9612

(CRYSTAL)

ALUMINUM OXIDE, GAMMA (γ - Al_2O_3)

ΔH_f° 0 = Unknown

ΔH_f° 298.15 = [-396.0 $\pm$ 0.5] kcal. mole⁻¹

ΔH_m° = [20.9] kcal. mole⁻¹

$S_{298.15}^\circ$ = [12.55] cal. deg.⁻¹ mole⁻¹

T_m = 2323°K.

Heat of Formation.

The enthalpy change (ΔH_f°) for the transition $\text{Al}_2\text{O}_3(\delta, c) \rightarrow \text{Al}_2\text{O}_3(\alpha', c)$ has been determined by (1) V. Kostomarov and M. Rey, *Silicates Ind.* 29, 9 (1963); and (2) T. Yokokawa and O. J. Kleppa, *J. Phys. Chem.* 68, 3246 (1964). The results obtained are presented in the table. The enthalpies of solution for $\text{Al}_2\text{O}_3(\delta, c)$ and $\text{Al}(c)$ in 2N KOH(aq.) have been measured by (3) K. K. Kelley, C. H. Shonster, F. E. Young, B. F. Naylor, A. E. Salo and E. H. Huffman, U. S. Bur. Mines Tech. Rept. 688 (1946). Based on their reported values, -16.13 $\pm$ 1.0 and -196.02 $\pm$ 0.25 kcal. mole⁻¹, respectively, the heat of formation (ΔH_f° 298.15) for $\text{Al}_2\text{O}_3(\delta, c)$ was evaluated to be -384.84 $\pm$ 1.1 kcal. mole⁻¹. Hence, the enthalpy of transition ($\delta - \alpha'$) was calculated as -15.6 $\pm$ 1.1 kcal. mole⁻¹, using ΔH_f° 298.15 ($\text{Al}_2\text{O}_3, \alpha', c$) = -400.4 kcal. mole⁻¹.

Source	Method	Temperature, °K.	ΔH_f° , kcal. mole ⁻¹	ΔH_t° 298.15, kcal. mole ⁻¹
(2)	solution calorimetry	978	-5.3	-4.4
(1)	differential thermal analysis	1473	-11.0	-9.4
(3)	solution calorimetry	298.15	-15.6	-15.6

The heat of formation for $\text{Al}_2\text{O}_3(\delta, c)$ was calculated from that for $\text{Al}_2\text{O}_3(\alpha', c)$ and the ΔH_t° values reported by Yokokawa and Kleppa, loc. cit., which was arbitrarily selected.

Heat Capacity and Entropy.

The heat capacities were assumed to be larger than those for $\text{Al}_2\text{O}_3(\alpha', c)$ by 5% at each temperature. The value of $S_{298.15}^\circ$ was estimated such that at T_m , ΔH_m° ($\text{Al}_2\text{O}_3, \delta, c$) $>$ ΔH_f° ($\text{Al}_2\text{O}_3, \alpha', c$).

Melting Data.

T_m was reported by M. Plummer, *J. Appl. Chem.* 9, 35 (1959). The difference between ΔH_f° for $\text{Al}_2\text{O}_3(\delta, c)$ and $\text{Al}_2\text{O}_3(1)$ at T_m is ΔH_m° .

$S_{298.15}^{\circ} = [23.728] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_{298.15}^{\circ} = [373.356] \text{ kcal. mole}^{-1}$
 $\Delta F_{298.15}^{\circ} = 28.30 \pm 0.55 \text{ kcal. mole}^{-1}$
 $T_m = 2315^{\circ}\text{K.}$

Heat of Formation.

The heat of formation for the liquid was obtained from $\Delta H_f^{\circ} 298.15$ for Δ crystal by adding on ΔH_m plus the difference between H_{2315}° and $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacities of the liquid alpha-Al₂O₃ was taken from the crystal heat capacities up to 1600°K. where a glass transition was assumed. From 1600°K. to 3500°K. the heat capacities were assumed to be the constant value of 34.623 measured by P. B. Kantor, L. S. Lazareva, V. V. Kandyba and E. M. Pomichev (2300-2500°K.) Ukr. Fiz. Zh. 7, 205-10 (1962).

The entropy at 298.15°K. was obtained in a manner analogous to the heat of formation.

Melting Data.

The melting data was taken from the measurements of P. B. Kantor, et al., loc. cit. S. J. Schneider, "Compilation of the Melting Points of the Metal Oxides," NBS Monograph 68 p. 6, Oct. 10, 1963, gives a review of the melting points that range from 2267 to 2345°K.

SILLIMANITE (Al₂SiO₅)

(CRYSTAL)

GFW = 162.046

$$\Delta H_f^0 = -614.83 \pm 0.5 \text{ kcal/mol}$$

$$\Delta H_f^{298,15} = -618.81 \pm 0.5 \text{ kcal/mol}$$

$$S_{298,15} = 22.987 \pm 0.1 \text{ gibbs/mol}$$

Heat of Formation

The heat of the reaction $\text{Al}_2\text{O}_3(\text{c}) + \text{SiO}_2(\text{quartz}) \rightarrow \text{Al}_2\text{SiO}_5(\text{sillimanite})$ has been determined at 968°K by J. L. Holm and O. J. Kleppa, J. Phys. Chem. **70**, 1690 (1966) and Am. Mineralogist **51**, 1808 (1966), to be -1.51 ± 0.15 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to $\Delta H_f^0 = -0.71$ kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. **145**, 193 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. **40**, 206 (1957) suggested that ΔH_f^0 was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔH_f^0 should lie between 0 and -6 kcal/mol. C. R. Waldhaug, Am. Mineralogist **50**, 186 (1965), calculated $\Delta H_f^0 = -0.356$ kcal/mol from high temperature - high pressure equilibria. These later values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.4° to 286.5°K by S. S. Todd, J. Am. Chem. Soc. **72**, 4742 (1950). The entropy is based on $S_{21}^0 = 0.73$ gibbs/mol. The high temperature enthalpy has been measured to 1500°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot (C. H. Shomate, J. Phys. Chem. **58**, 368 (1954)). The crystal structure of sillimanite, L. Bragg and G. F. Claringbull, "Crystal Structure of Minerals," Vol. IV, G. Bell and Sons Ltd., London, 1965, indicates that there is no mixing of the tetra-coordinated aluminum and silicon atoms. Thus there should be no residual entropy at 0°K.

ΔHf° = -615.46 ± 0.5 kcal/mol

ΔHf°_{298.15} = -619.52 ± 0.5 kcal/mol

S°_{298.15} = 22.28 ± 0.1 gibbs/mol

Heat of Formation

The heat of the reaction Al₂O₃(c) + SiO₂(quartz) + Al₂SiO₅(andalusite) has been determined at 968°K by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be -1.99 ± 0.17 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔHf°₂₉₈ = -1.42 kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. 115, 193 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. 40, 206 (1957), suggested that ΔHf° was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔHf° should lie between 0 and -6 kcal/mol. C. R. Waldbaum, Am. Mineralogist 50, 186 (1965), calculated ΔHf° = -1.108 kcal/mol from high temperature - high pressure equilibria. These latter values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.9° to 296.2°K by S. S. Todd, J. Am. Chem. Soc. 72, 4742 (1950). The entropy is based on S°₂₉₈ = 0.62 gibbs/mol. The high temperature enthalpy has been measured to 1600°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot [C. H. Shomate, J. Phys. Chem. 58, 368 (1954)]. Since all the aluminum and silicon atoms occupy differently coordinated sites, there is no possibility of any residual entropy of mixing in this polymorph.

GF_W = 162.046

Al₂O₅Si

ΔH_f⁰ = -615.75 ± 0.5 kcal/mol

ΔH_f⁰_{298.15} = -620.06 ± 0.5 kcal/mol

S⁰_{298.15} = 20.032 ± 0.1 gibbs/mol

Heat of Formation

The heat of the reaction Al₂O₃(g) + SiO₂(quartz) → Al₂SiO₅(kyanite) has been determined at 968° by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be -2.37 ± 0.15 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔH_f⁰₂₉₈ = -1.95 kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. 145, 183 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. 40, 206 (1957), suggested that ΔH_f⁰ was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔH_f⁰ should lie between 0 and -6 kcal/mol. R. W. Haskell and R. C. DeVries, J. Am. Ceram. Soc. 47, 202 (1964), from phase equilibria obtained ΔH_f⁰ = -2 ± 7 kcal/mol. C. R. Waldbaum, Am. Mineralogist 50, 186 (1965), calculated ΔH_f⁰ = -0.622 kcal/mol from high temperature - high pressure equilibria. These latter values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.8° to 296.3° by S. S. Todd, J. Am. Chem. Soc. 72, 4742 (1950). The entropy is based on S_{298.15}⁰ = 0.33 gibbs/mol. The high temperature enthalpy has been measured to 1500°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot [C. H. Shomate, J. Phys. Chem. 58, 368 (1954)]. The high temperature heat capacity has been measured between 100° and 1200°C by V. Ya. Leonidov, Yu. P. Barskii and N. I. Khitarov, Geochemistry (English Transl.) 1964, 409 (1964). The values reported are in excellent agreement with the adopted functions. Since the aluminum atoms and the silicon atoms occupy different types of sites there is no possibility of any residual entropy of mixing in this polymorph.

MULLITE (Al₆Si₂O₁₃)

GFW = 426.053

(CRYSTAL)

ΔH_f^o = -1619.25 ± 1.5 kcal/mol

ΔH_f^o 298.15 = -1629.83 ± 1.5 kcal/mol

S_{298.15} = 65.7 ± 3 gibbs/mol

T_m = 2023°K

Heat of Formation

The heat of the reaction 3Al₂O₃(s) + 2SiO₂(quartz) → Al₆Si₂O₁₃ has been determined at 968°K by J. L. Holm and G. J. Kleppa, J. Phys. Chem., 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be +5.44 ± 0.35 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔH_f^o 298 = +4.11 kcal/mol, which is used to calculate the adopted value.

Heat Capacity and Entropy

The low temperature heat capacity and high temperature enthalpy of mullite have been measured by L. B. Pankratz, W. W. Waller and K. K. Kelley, U. S. Bur. Mines RI 6287, 1963. The low temperature investigations extended from 53.5°K to 295.4°K; the Debye-Einstein equation 3D(182/T) + 15E(350/T) + 10E(502/T) + 15E(897/T) represented the data from 53.5° to 114.6°K within 1.4 percent and gave a smooth extrapolation to zero. From this equation the entropy at 51°K was found to be 2.17 gibbs/mol as opposed to the value 1.96 gibbs/mol found by Pankratz et al. However, since it is known that mullite has some of its Al atoms on Si sites, there will be configurational entropy remaining at 0°K. This is borne out by the free energy determinations of R. H. Rein and J. Chipman, Trans. Met. Soc. AIME 233, 415 (1965), and D. A. R. Kay and J. Taylor, Trans. Faraday Soc. 56, 1372 (1960), who obtain ΔG_f^o 1823 = -5.7 ± 0.1 kcal/mol for the formation from oxide. If the entropies and enthalpies reported by Pankratz et al. are used with the heat of formation, they yield ΔG_f^o 1823 = +2.9 kcal/mol. Holm and Kleppa, loc. cit., calculate that random mixing of tetra-coordinated aluminum and silicon atoms could produce 7 eu residual entropy. We have added 4.7 eu in order to match the measured ΔG_f^o 1823.

A review of the enthalpy determination indicated that the values might easily be 2 percent low if as little as 4 percent of kyanite remained unchanged in the sample used for measurement. Since X-ray could not detect this amount, it is not an unreasonable assumption. Accordingly we have checked the effect of increasing the heat capacity above 298°K by 2 percent; this then gives ΔG_f^o 1823 = -2.10 kcal/mol. In order to bring this within reasonable agreement with the observations a residual configurational entropy of 2 gibbs/mol would be needed. Thus the uncertainty in the residual entropy is of the order of 2 eu due to possible uncertainty in the high temperature heat capacity.

Melting Data

The congruent melting point of mullite was reported by S. Aramaki and R. Roy, Nature 184, 631 (1959).

Dec. 31, 1960; Dec. 31, 1964

$S_{298.15}^{\circ} = 1.403 \pm 0.01 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 2450 \pm 20^{\circ} \text{K.}$
 $\Delta H_f^{\circ} = 0 \text{ kcal. mole}^{-1}$
 $\Delta H_g^{\circ} = [5.39] \text{ kcal. mole}^{-1}$
 $\Delta H_g^{\circ} 298.15 = 132.8 \pm 4.0 \text{ kcal. mole}^{-1}$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Low temperature heat capacities, 16.90 - 303.71°K., were measured by H. L. Johnston, H. N. Hersh and E. C. Kerr, J. Am. Chem. Soc. 73, 1112 (1951). The high temperature heat capacities, 282.8 - 1667.8°K., were measured by R. A. McDonald and D. R. Stull, J. Chem. Eng. Data, 7, 84 (1962). These two sets of data were joined smoothly at 298.15°K. by graphical method. The heat capacity values above 1667.8°K. were estimated by graphical extrapolation. The high temperature Cp, 530 - 800°K., were also determined by S. S. Wise, J. L. Margrave and R. L. Altman, J. Phys. Chem. 64, 915 (1960). The other principal investigators are: (1) J. A. Robertson, Ph. D. Thesis, Cornell University, 1944; (2) A. Magnus and H. Danz, Ann. Phys. [4] 81, 407 (1926); (3) H. Molau and H. Gautier, Compt. rend. 116, 924 (1893); (4) H. P. Weber, Ann. Phys. [2] 154, 367, 553 (1875); (5) H. Kopp, Trans. Roy. Soc. [London] 155, 71 (1865); and (6) V. Regnault, Ann. chim. et phys. [3] 63, 5 (1861) and Phil. Mag. [4] 23, 103 (1862). The value of S_{298.15} was obtained from H. L. Johnston, H. N. Hersh and E. C. Kerr, loc. cit., based on S₁₇ = 0.00139 cal. deg.⁻¹ mole⁻¹.

Melting Data.

The melting point (T_m) has been measured by many investigators. The values of T_m reported are in the range 2273 - 2673°K. Based on the relationship between the values of T_m determined and the purities of the boron sample used, the value T_m = 2450 ± 20°K. was estimated. The data employed for estimation are those reported by C. F. Glue, J. Electrochem. Soc. 106 (4), 332 (1959), and A. W. Seary and C. E. Myers, J. Phys. Chem. 61, 957 (1957). The estimated value for T_m is in agreement with the value taken by H. L. Schick, et al., "Thermodynamics of Certain Refractory Compounds", ASD-TR-61-260, Part I, Vol. 1, May 1962, in which the reported melting points of boron were reviewed. The heat of melting was calculated assuming entropy of melting is 2.2 cal. deg.⁻¹ mole⁻¹ at 2450°K.

Heat of Sublimation.

The adopted value of ΔH_g^o 298.15 is the weighted average of eight ΔH_g^o 298.15 values derived from vapor pressure data. See B(g) table for details.

BORON (B) (LIQUID) AT. WT. = 10.82

$$\Delta H_f^o 298.15 = [5.260] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^o = [5.39] \text{ kcal. mole}^{-1}$$

$$\Delta H_v^o = [121.3 \pm 4] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = [3.533] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = [2450 \pm 20]^{\circ}\text{K.}$$

$$T_b = [5931]^{\circ}\text{K.}$$

Heat of Formation.

$\Delta H_f^o 298.15$ for B(l) was obtained from $\Delta H_f^o 298.15$ for B(c) by adding ΔH_m^o and the difference between H_m^o - $H_{298.15}^o$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of liquid was estimated by comparison with the heat capacity of solid at the melting temperature. The value of $S_{298.15}^o$ was obtained in a manner analogous to that of the heat of formation. A glass transition temperature at 1800°K. is assumed.

Melting Data.

See B(c) table for details.

Vaporization Data.

The boiling point was calculated as the temperature at which the free energies of formation (ΔF_f^o) for both B(l) and B(g) are equal. The difference in heat of formation (ΔH_f^o) of B(l) and B(g) at the boiling point is the heat of vaporization (ΔH_v^o).

Ground State Configuration $2p_{1/2}^2$
 $S_{298.15}^\circ = 36.649 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 131.6 \pm 4 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 132.8 \pm 4 \text{ kcal. mole}^{-1}$

Dec. 31, 1960; Dec. 31, 1964

Heat of Formation.

The vapor pressures of B(g) over condensed phases B(c) and B₂(c), respectively, were determined by many investigators. Using the vapor pressure data reported, the corresponding heats of sublimation and decomposition were evaluated by both the third and second law methods. The values of ΔH_f° 298.15 for B(g) were then calculated. The results obtained are listed as follows (all calculations were made employing JANAF Functions).

Investigator	Process or Reaction	ΔH _f ° 298.15 ^a kcal. mole ⁻¹	Second Law Value	ΔH _f ° 298.15 ^a kcal. mole ⁻¹
Hildenbrand and Hall ¹	0.25CB ₄ (c) → 0.25C(c) + B(g)	138.5	137.6 ± 1.2	135.3 ± 1.3
Hildenbrand ²	B(c) → B(g)	136.1	136.3 ± 3	136.1 ± 0.3
Paule and Margrave ³	B(c) → B(g)	136.4	135.4 ± 1.6	136.4 ± 1.0
Robson and Gilles ⁴	0.25CB ₄ (c) → 0.25C(c) + B(g)	137.7	142 ± 4	134.5 ± 1.3
Searcy and Myers ⁵	B(c) → B(g)	139.1	148.4 ± 8.4	139.1 ± 2.5
Schissel and Williams ⁶	B(c) → B(g)	129.2	129 ± 5	129 ± 5
Chupka ⁷	B(c) → B(g)	131.7	131.7	129.2
Akshin et al. ⁸	B(am.) → B(g)	131.7	131.7	131.7 ± 5
Linevsky, et al. ¹⁰	0.25CB ₄ (c) → 0.25C(c) + B(g)	—	129.1 ± 5	130.3 ± 5**
Schissel and Trulsson ¹¹	B(c) → B(g)	—	134.4 ± 5	131.2 ± 5
	B(c) → B(g)	—	131.4	131.4
	B(c) → B(g)	—	132.8 ± 1.4	132.8 ± 1.4

^aCalculation based on the third law values available.

^bBased on a heat of transition of 1.2 kcal. mole⁻¹ for B(c) to B(am.).

- 1 D. L. Hildenbrand and W. F. Hall, J. Phys. Chem. **69**, 989 (1964) - torsion-effusion.
- 2 D. L. Hildenbrand, "Thermodynamic Properties of Propellant Combustion Products", QLR-64-10, Philco Corporation, California, 1960-2140°K., torsion-Langmuir method. Listed ΔH_f° 298.15 value is the average of three reported values.
- 3 R. O. Paule and J. L. Margrave, J. Phys. Chem. **67**, 1368 (1963) - 1761-2152°K. - free-evaporation.
- 4 H. E. Robson and P. W. Gilles, J. Phys. Chem. **69**, 983 (1964) - 2164-2522°K. - Knudsen-effusion.
- 5 A. W. Searcy and C. E. Myers, J. Phys. Chem. **61**, 957 (1957) - 2115-2413°K. - Knudsen-effusion.
- 6 P. O. Schissel and W. S. Williams, Bull. Am. Phys. Soc. **4**, 139 (1959). The quoted value of ΔH_f° was derived from vapor pressure data determined by the mass spectrometer-effusion method.
- 7 The third and second law values of ΔH_f° 298.15 were calculated from the respective values of ΔH_f° 0 quoted by O. Verhaegen and J. Drowart, J. Chem. Phys. **37**, 1367 (1962). Vapor pressure data obtained by mass spectrometer-effusion method.
- 8 P. A. Akshin, D. O. Hikitin and L. N. Gorbokhov, Proc. Acad. Sci., USSR, **129**, 1075 (1959). The vapor pressure data (2024 - 2231°K.) were determined by the mass spectrometric method.
- 9 The second law values were recalculated from ΔH_f° 2080 = 127.4 and ΔH_f° 2080 = 133.1 kcal. mole⁻¹ for the first and second reactions in the above table, respectively. The data were reported by O. Verhaegen and J. Drowart, J. Phys. Chem. **51**, 1381 (1952), which were derived from vapor pressures determined by the mass spectrometric method.
- 10 M. J. Linevsky, O. M. Kibler, T. P. Lyon and V. J. Desantis, "Refractory Materials Research", WADD-TR-60-646, Part IV, August 1964, General Electric Co., Ohio.
- 11 P. O. Schissel and O. C. Trulsson, J. Phys. Chem. **66**, 1492 (1962).

The adopted value of ΔH_f° 298.15 for B(g) is the weighted average of the 12 ΔH_f° 298.15 values given in the above table.

Heat Capacity and Entropy.

The electronic levels and quantum weights used were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, National Bureau of Standards Circular 467, 1949.

We calculate the heat of formation at 0°K from the reaction B(g) + e⁻(g) + B⁺(g) using the JANAF auxiliary value for B(g) and an ionization potential of 191.34 kcal/mol from C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, Vol. I, 1949.

Heat Capacity and Entropy

We obtain the electronic levels and quantum weights from C. E. Moore, loc. cit. $H_0^\circ - H_{298}^\circ = -1.481$ kcal/mol at 0°K.

$\omega_e = 669.04 \text{ cm.}^{-1}$

$\omega_e = 0.0036 \text{ cm.}^{-1}$

$\omega_e = 0.497 \text{ cm.}^{-1}$

$\omega_e = 1.887 \text{ Å}$

Heat of Formation.

G. Herzberg, "Spectra of Diatomic Molecules" D. Van Nostrand Co. New York 1950 reports a D_0 of 4.1 e.v. which corresponds to a heat of formation of 64 kcal. mole⁻¹ A. G. Gaydon "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, London 1953, gives essentially the same value, with a rider that the value is unreliable due to the ionic nature of the bonding. R. F. Barrow, Trans. Farad. Soc. 56, 952 (1960) made a critical evaluation of the bond dissociation energies of the group III halides and concluded $D_0 \text{ BBr} = 103.5$ which gives $\Delta H_f^o = 56 \text{ kcal. mole}^{-1}$. An estimate of the dissociation energy by taking the ratio $D(\text{Br})/(\Delta H_f^o(\text{Br}_2)/3) = 1.177$ and applying this to Br_2 yields $D(\text{BBR}) = 103 \text{ kcal. mole}^{-1}$, this was the value adopted.

Heat Capacity and Entropy.

The vibrational and rotational constants were all taken from National Bureau Standards Report 7033, Jan. 1, 1962.

BBR

Boron Bromide Chloride (BBrCl)

(Ideal Gas) Mol. Wt. = 126.193

BORON BROMIDE CHLORIDE (BBrCl)

Bond Distance B-Cl = $[1.73] \text{ \AA}$ B-Br = $[1.87] \text{ \AA}$
 Bond Angle Cl-B-Br = $[120^\circ]$
 $\sigma = 1$

Product of the Moments of Inertia: $I_A I_B I_C = [2.192176] \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_f^\circ = 0$ for the reaction $\text{BCl}_2 + \text{Br}_2 \rightarrow 2\text{BBrCl}$.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for BBr_2 and BCl_2 . The bond distances, angles, and quantum weight were assumed the same as in the dihalides. The individual moments of inertia were $I_A = 1.2937 \times 10^{-39} \text{ g. cm.}^2$, $I_B = 40.4239 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 41.7236 \times 10^{-39} \text{ g. cm.}^2$.

$\sigma = 2$

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_f^\circ = 0$ for the reaction

Heat Capacity and Entropy.

Vibrational frequencies were obtained from L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956). The b_1 mode was the only unobserved frequency and was calculated from a normal coordinate treatment. Bond distances were reported by T. Wentink and V. H. Tienau, J. Chem. Phys. 28, 826 (1956). Bond angles were estimated by analogy with the other trihalides of boron. The individual moments of inertia were $I_A = 26.4242 \times 10^{-39} \text{ g. cm.}^2$, $I_B = 47.3327 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 73.6569 \times 10^{-39} \text{ g. cm.}^2$.

[1140](1)

Bond Distance: B-Br = $[1.3] \text{ \AA}$ B-Br = $[1.87] \text{ \AA}$

Bond Angle: Br-B-Br = $[120^\circ]$

Product of the Moments of Inertia: $I_A I_B I_C = [4.13196] \times 10^{-115} \text{ g. cm.}^6$

$\sigma = 1$

Heat of Formation

The heat of formation was estimated by assuming $\Delta H_f^\circ = 0$ for the reaction $\text{BBr}_2 + \text{BrF}_2 \rightarrow 2\text{BBrF}$.

Heat Capacity and Entropy

The vibrational frequencies, bond lengths, angles and quantum weight were estimated by comparison with the respective dihalides. The individual moments of inertia were $I_A = 0.8407 \times 10^{-39} \text{ g. cm.}^2$, $I_B = 21.7537 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 22.5944 \times 10^{-39} \text{ g. cm.}^2$.

Sept. 30, 1962, Dec. 31, 1964

Boron Bromide Difluoride (BBrF₂)
(Ideal Gas)

MOL. WT. = 128.736

Point Group C_{2v}
S_{298.15} = 68.424 cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight [1]
ΔH_f⁰ = [-193.7 ± 10] kcal. mole⁻¹
ΔH_f⁰ 298.15 = [-196.0 ± 10] kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω _i , cm. ⁻¹	ω _i , cm. ⁻¹
1215 (1)	1427 (1)
653 (1)	[346](1)
[330](1)	575 (1)

Bond Distance: B-F = 1.295 Å B-Br = 1.87 Å

Bond Angle: F-B-F = [120°] Br-B-F = [120°]

Product of the Moments of Inertia: I_AI_BI_C = 8.46916 X 10⁻¹¹⁴ g.³ cm.⁶

σ = 2

Heat of Formation.

The heat of formation was estimated by assuming ΔH_f = 0 for the reaction 2BF₃ + BBr₃ → 3BBrF₂.

Heat Capacity and Entropy.

All but two of the vibrational frequencies have been observed and assigned by L. P. Lindeman and M. K. Wilson J. Chem. Phys. 24, 242 (1956), the two remaining frequencies were calculated by a normal coordinate treatment. The bond distances were reported by T. Kuntink and V. H. Tienau, J. Chem. Phys. 28, 826 (1958). The bond angles were estimated by analogy with the other boron trihalides. The individual moments of inertia were I_A = 7.9349 X 10⁻³⁹ g. cm.², I_B = 28.9426 X 10⁻²⁹ g. cm.² and I_C = 36.8775 X 10⁻³⁹ g. cm.².

Boron Oxide Bromide (BOBr)

(Ideal Gas) Mol. Wt. = 106.736

BORON OXIDE BROMIDE (BOBr)

(IDEAL GAS)

MOL. WT. = 106.736

$$\Delta H_f^\circ 0 = [-58 \pm 7] \text{ kcal. mole}^{-1}$$

$$\Delta H_f^\circ 298.15 = [-60 \pm 7] \text{ kcal. mole}^{-1}$$

Point Group [C_{∞v}]

$$S_{298.15}^\circ = [59.48] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Ground State Quantum Weight = [1]

$$[370] (2)$$

$$[1800] (1)$$

$$\text{Bond Distance: O-B} = [1.20] \text{ \AA} \quad \text{B-Br} = [1.87] \text{ \AA}$$

$$\text{Bond Angle: O-B-Br} = [180]^\circ$$

$$\text{Rotation Constant: } B_0 = [0.11742] \text{ cm.}^{-1}$$

$$\sigma^- = 1$$

Heat of Formation.

The value of $\Delta H_f^\circ 298.15$ for BOBr (g) was calculated based on an assumption that $D(\text{BO-Br}) = 92.5 \text{ kcal. mole}^{-1}$ which was estimated by comparison with the following related bond energy values: $D(\text{BF}_2\text{-F}) = 159$, $D(\text{BO-F}) = 169$, $D(\text{BCl}_2\text{-Cl}) = 105$, $D(\text{BO-Cl}) = 110$ and $D(\text{BBr}_2\text{-Br}) = 90.5 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, $k_1 = 4.2 \times 10^5$, $k_2 = 16.9 \times 10^5 \text{ dynes cm.}^{-1}$ and $k_3 = 0.37 \times 10^{-11} \text{ dynes cm. rad.}^{-1}$. The B-O and B-Br bond distances were assumed to be the same as those in BO(g) and BBr₃(g), respectively. The moment of inertia is $2.58357 \times 10^{-38} \text{ g. cm.}^2$.

Mar. 31, 1962; Dec. 31, 1962; Dec. 31, 1964

BORON DIBROMIDE (BBr₂) (IDEAL GAS)

MOL. WT. = 170.652

Point Group [C_{2v}]
 $\Delta H_f^0 = [18.2 \pm 15] \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = [70.402] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 = [15.0 \pm 15] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight [2]

Vibrational Frequencies and Degeneracies

ω , cm.⁻¹
 [600](1)
 [150](1)
 [830](1)

Bond Distance: [1.87] Å

Bond Angle: [120°]

Product of the Moments of Inertia: $I_A I_B I_C = 7.26584 \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$ $\sigma = 2$

Heat of Formation.

The heat of formation was estimated by analogy with BP₃, specifically the ratio

$$\Delta H_f^0(\text{BX}_3) \rightarrow \text{BX}_2 + \text{X} / \Delta H_f^0(\text{BX}_3) \rightarrow \text{B} + 3\text{X}$$

was taken as 0.347.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from force constants transferred from the trihalide given by G. Herzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono and trihalide and the angle was estimated to be the same as that in the trihalides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were $I_B = 1.4708 \times 10^{-39} \text{ g. cm.}^2$, $I_A = 69.5532 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 71.0240 \times 10^{-39} \text{ g. cm.}^2$

Bond Distance: B-Br = 1.87 Å B-Cl = 1.75 Å
 Bond Angle: Br-B-Br = [120°] Cl-B-Br = [120°]
 Product of the Moments of Inertia: $I_A I_B I_C = 2.55478 \times 10^{-112} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation

The heat of formation was estimated by assuming $\Delta H_f^0 = 0$ for the reaction
 $2\text{BBr}_2 + \text{BCl}_3 \rightarrow 3\text{BBr}_2\text{Cl}$

Heat Capacity and Entropy

The vibrational frequencies have all been observed and assigned by L. P. Lindeman and M. K. Wilson, J. Chem. Phys., 24, 242 (1956). The bond lengths were reported by T. Wentink and V. H. Tienau, J. Chem. Phys., 28, 826 (1958). Bond angles were estimated by analogy with the other trihalides of boron. Individual moments of inertia are $I_B = 35.0754 \times 10^{-39} \text{ g. cm.}^2$, $I_A = 69.5934 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 104.6668 \times 10^{-39} \text{ g. cm.}^2$.

[418](1)	[283](1)
[183](1)	[496](1)

Bond Distance: B-Br = 1.87 Å B-Cl = 1.295 Å
 Bond Angle: Br-B-Br = [120°] Br-B-F = [120°]
 $\sigma = 2$

Product of the Moments of Inertia: $I_A I_B I_C = 8.72359 \times 10^{-113} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_f^\circ = 0$ for the reaction $2\text{BBr}_3 + \text{BF}_3 \rightarrow 3\text{BBr}_2\text{F}$.

Heat Capacity and Entropy.

Two of the vibrational frequencies were observed and assigned by L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956), the remaining frequencies were calculated by a normal coordinate treatment using force constants obtained by comparison with the other mixed trihalides. The bond distances were reported by T. Wentink and V. H. Hienau, J. Chem. Phys. 28, 826 (1958). The bond angles were estimated by analogy with the other trihalides. The individual moments of inertia were $I_B = 14.8452 \times 10^{-59} \text{ g. cm.}^2$, $I_A = 69.5934 \times 10^{-59} \text{ g. cm.}^2$ and $I_C = 84.4386 \times 10^{-59} \text{ g. cm.}^2$.

Bond Distance : B-H = 1.20 Å B-Br = [1.87] Å

Bond Angle: Br-B-Br = 119.3 ± 2° Br-B-H = 120.3 ± 1°

Product of the Moments of Inertia: $I_A I_B I_C = 1.08645 \times 10^{-113} \text{ g.}^3 \text{ cm.}^6$

$\sigma = 2$

Heat of Formation.

The value of $\Delta H_f^\circ 298.15$ (BBr₂H₂, g) was derived by assuming the B-H bond strength to be 92 kcal. mole⁻¹, the same as that in BCl₂H(g).

Heat Capacity and Entropy.

The molecular structure, B-H bond distance and bond angle were obtained from L. Lynds and C. D. Bass, J. Chem. Phys. 41, 3165 (1964). The B-Br bond distance was taken from that in BBr₃(g) molecule. The vibrational frequencies adopted and corrected to the average isotopic species were assigned by O. Brioux de Mandirola and J. F. Westerkamp, Spectrochim. Acta, 21, 1101 (1965), from infrared spectrum. The values in brackets are calculated by the Wilson's FO-method. Infrared spectrum of BBr₂H(g) was also reported by S. K. Mason and R. P. Porter, J. Phys. Chem. 69, 2461 (1965), and three frequencies, ν_1 , ν_2 and ν_3 , were assigned. The three principal moments of inertia are: $I_A = 6.87842 \times 10^{-38}$, $I_B = 2.2244 \times 10^{-38}$ and $I_C = 7.10086 \times 10^{-38} \text{ g. cm.}^2$

BORON TRIBROMIDE (BB₃)

(LIQUID)

MOL. WT. = 250.568

$S_{298.15}^o = 54.7 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 227.2^\circ\text{K}$
 $T_b = 364.4^\circ\text{K}$
 $\Delta H_f^o = 298.15 = -57.0 \pm 0.2 \text{ kcal. mole}^{-1}$
 $\Delta H_m^o = \text{Unknown}$
 $\Delta H_v^o = 7.30 \text{ kcal. mole}^{-1}$

Heat of Formation.

The heat of formation of boron tribromide liquid has been determined by H. A. Skinner and N. B. Smith, Trans. Farad. Soc. 51, 19 (1955) by hydrolysis to H₃BO₃ and HBr. The adopted heat of formation was calculated from Skinner's hydrolysis data using $\Delta H_f^o \text{ H}_3\text{BO}_3(\text{c})$ from these tables, $\Delta H_{\text{soln}}^o \text{ H}_3\text{BO}_3$ from L. G. Faallino, National Research Corporation Special Report NMR-3608 (OO) June 2, 1964, with the dilution data of J. Smisko and L. S. Mason, J. Am. Chem. Soc. 72, 3679 (1950). The $\Delta H_f^o \text{ HBr}(\text{aq})$ was taken from W. H. Evans, Appendix III, Natl. Bureau of Standards Report 8504, 1 July 1964.

Heat Capacity and Entropy.

The heat capacity was estimated from that of the gas by K. K. Kelley USNM Bulletin 383. The entropy was back calculated from that of the gas by adjusting the free energy functions to give the best fit of the vapor pressure data.

Melting Data.

The temperature of melting was reported by J. Goubeau and H. Keller, Z. anorg. allgem. Chem. 267, 1 (1951) and A. Stock and E. Kusa, Ber. 47, 3113 (1914). This value was recently confirmed by the triple point measurement of 227.31°K by W. F. Barber, C. F. Boynton and P. E. Gallagher J. Chem. Eng. Data 9, 137 (1964).

Boiling Data.

The boiling point is from the data of Stock and Kusa, loc. cit. A second and third law analysis of the vapor pressure data of Stock and Kusa (1) and Barber et. al. (2) loc. cit. indicated that the data of Stock gave the best agreement as indicated below.

	Second Law	Third Law
$\Delta H_v^o 298.15 \text{ kcal. mole}^{-1}$	$S_{298}^o = 54.7$	$S_{298}^o = 54.26$
Ref. 1.	8.175 $\pm$ 0.03	8.222 (-0.02)
Ref. 2.	8.229 $\pm$ 0.03	8.203 (-0.44)
		8.361 (0.42)
		8.347 (0.00)

Ref. 1. had the first eight data points rejected due to a statistical test on the third law values. The values in parentheses are values of the third law drift measured as $\Delta(\Delta H) / \Delta T$. The second law entropy also confirmed the choice of the data of ref. 1 and an entropy of 54.7 cal. deg.⁻¹ mole⁻¹.

Heat of Formation.

ΔH_f^o 298 was obtained from the heat of formation of the liquid plus the heat of vaporization at 298°K, taken as 8.20 kcal. mole⁻¹ as the average second and third law values derived from the vapor pressures of A. Stock and E. Kuas, Ber. 47, 3113 (1914). See BBr₃(1) for details.

Heat Capacity and Entropy.

Vibrational frequencies were obtained from T. Wentink, Jr., and V. H. Tiensuu, J. Chem. Phys., 28, 825 (1958) modified for the natural isotopic abundances (B10 16.83%, B11 81.17%) given by J. R. Bredford, "Handbook of Chemistry and Physics", Chemical Rubber Publishing Co., 1958. B-Br bond distance was reported by T. Wentink, Jr., and V. H. Tiensuu, loc. cit. Br-B-Br angle was taken from L. E. Sutton (editor), "Tables of Interatomic Distances and Configurations in Molecules and Ions," Special Publication No. 11, The Chemical Society, London, 1958. The individual moments of inertia were $I_A = I_B = 419.167 \times 10^{-39} \text{ g. cm.}^2$, $I_C = 836.375 \times 10^{-39} \text{ g. cm.}^2$.

Boron Monochloride (BCl)

(Ideal Gas) Mol. Wt. = 46.277

Ground State Configuration 1^2

$$\Delta H_f^0 = 33.1 \pm 4.0 \text{ kcal mole}^{-1}$$

$$\Delta H_f^{298.15} = 50.942 \text{ cal deg}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^{298.15} = 33.8 \pm 4.0 \text{ kcal mole}^{-1}$$

Electronic Levels and Quantum Weight

$$\frac{g_i}{g_0} \text{ cm}^{-1}$$

$$\frac{g_i}{g_0}$$

$$\omega_e x_e = 5.167 \text{ cm}^{-1}$$

$$\sigma = 1$$

$$\omega_e = 843.65 \text{ cm}^{-1}$$

$$B_e = 0.6914 \text{ cm}^{-1}$$

$$a_e = 0.00857 \text{ cm}^{-1}$$

$$r_e = 1.7157 \text{ \AA}$$

Heat of Formation

The dissociation energy (D_0^0) of BCl(g) has been reported by G. Herzberg¹, A. G. Gaydon² and R. F. Barrow³, respectively. Hence the corresponding values of $\Delta H_f^{298.15}$ for BCl(g) were derived. The results are given as follows.

$$\Delta H_f^{298.15}$$

$$\text{kcal mole}^{-1}$$

1 G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950.

2 A. G. Gaydon, "Association Energies", Chapman and Hall Ltd., London, 1953.

3 R. F. Barrow, Trans. Faraday Soc. **56**, 952 (1960).

The last value of $\Delta H_f^{298.15}$ listed in the above table is adopted. Using the bond energy, $D^0(\text{B-Cl})$, obtained from BCl₃(g) molecule, the heat of formation ($\Delta H_f^{298.15}$) for BCl(g) was calculated as $37.8 \text{ kcal mole}^{-1}$ employing the same ratio of $D^0(\text{B-X})$ /average bond energy of B₃ as found in B₂(g) and B₃(g), which is within the uncertainty of the value evaluated from dissociation energy.

Heat Capacity and Entropy

The spectroscopic constants were obtained from G. Herzberg, loc. cit. and corrected to the average isotopic species. The principal moment of inertia (I) is $4.0514 \times 10^{-39} \text{ g cm}^2$.

(IDEAL GAS)

BORON MONOCHLORIDE UNIPosITIVE ION (BCl⁺)

Ground State Configuration [2_g]

ΔH_f^o = [299.3 ± 10] kcal/mol

GFW = 42.2634

S_{298.15} = [52.3 ± 0.5] gibbs/mol

ΔH_f^o_{298.15} = [295 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	g_i
0	[2]
[28000]	[4]
ω_e = [845] cm ⁻¹	$\sigma = 1$
B_e = [0.68] cm ⁻¹	$r_g = [1.73] \text{ \AA}$
$\omega_e x_e$ = [5] cm ⁻¹	
a_g = [0.0056] cm ⁻¹	

Heat of Formation

Several values of the appearance potential of BCl⁺ from BCl₃ have been reported. Oberghaus (1) gave 19.2eV, Harriott and Craggs (2) reported 16.54 ± 0.07eV, and Koski et al. (3) obtained two values of 17.2 ± 0.2eV and 20 ± 0.2eV. We make the presumption that the higher values, 19.2 and 20, refer to the reaction BCl₃(g) + e⁻ → BCl⁺ + 2Cl₂(g) + 2e⁻ and the other values to BCl₃(g) + e⁻ → BCl⁺ + Cl₂(g) + 2e⁻. Using the lower value in each case to help eliminate any excess kinetic energy, we obtain ΔH_f^o₂₉₈(BCl⁺, g) = 289 and 300 kcal/mol, respectively. We adopt an average value of ΔH_f^o₂₉₈(BCl⁺, g) = 295 ± 10 kcal/mol, which corresponds to an ionization potential for BCl(g) of 11.3 ± 0.3eV.

Heat Capacity and Entropy

BCl⁺ is isoelectronic with BaCl and the ground state configuration and electronic levels are estimated by comparison with BaCl. The bond length, frequency and anharmonicity constant are estimated between the values for BCl and BaCl; the rotational constant is calculated from the bond length and atomic masses, and σ_e is obtained from the above constants assuming a Morse potential function.

The enthalpy at 0°K is -2.118 kcal/mol.

Bond Distances B-Cl = [1.73] Å B-F = [1.295] Å

Bond Angle: F-B-Cl = [120°] F-B-F = [120°]

Product of the Moments of Inertia: $I_{AB}I_C = 3567.6 \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The values for BCl₂F and BClF₂ of $\Delta H_f^o 298.15 = -154$ and $\Delta H_f^o 298.15 = -211.6 \text{ kcal. mole}^{-1}$, respectively, are obtained from the average bond energies of BF₃ and BCl₃. The calculated values were each made less negative by about 0.8 kcal. mole⁻¹ in order to make them consistent with the equilibrium measurements of T. H. Higgins, E. C. Leisegang, C. J. G. Raw, and A. J. Rosauw, J. Chem. Phys. **23**, 1544 (1955) and S. R. Gunn and R. H. Sanborn, J. Chem. Phys. **33**, 955 (1960) for the reaction

Values for the heat of reaction are $\Delta H_{298.15}^o = +1.68 \text{ kcal. mole}^{-1}$ and $\Delta H_{298.15}^o = 1.1$ (uncertainty of -0.5 to +0.8 kcal. mole⁻¹), the former calculated from the measured equilibrium constant and the statistical entropy change and the latter obtained from the variation of the equilibrium constant with temperature. Selection of $\Delta H_{298.15}^o = 1.6 \text{ kcal. mole}^{-1}$ fixes the sum of the heats of formation of BClF₂ and BCl₂F as -385.6 kcal. mole⁻¹, but it does not determine the individual values. Thus, the selected heats of formation are only as accurate as the average bond energy calculations on which they are based. A reasonable estimate of the uncertainty would be $\pm 5 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The observed frequencies of L. P. Lindeman and M. K. Wilson, J. Chem. Phys. **24**, 242 (1956), were adjusted to the normal isotopic composition of 81.2% ¹⁰B and 18.8% ¹¹B. The bond angles were assumed to be 120° and the bond lengths were taken to be the same as in the respective trihalides. As a result, the principal moments of inertia are: $I_A = 17.6044 \times 10^{-39}$, $I_B = 7.335 \times 10^{-39}$, and $I_C = 25.5394 \times 10^{-39} \text{ g. cm.}^2$.

Bond Distance: Cl-B = [1.75] Å B-O [1.20] Å

Bond Angle: Cl-B-O = [180]°

Rotational Constant: B₀ = [0.18504] cm.⁻¹

σ = 1

Heat of Formation.

The vapor-phase equilibria existing in the B₂O₃ + BCl₃ system were determined by an effusion method in the temperature range 1234-1389°K. by J. Blauer and M. Farber, Trans. Faraday Soc. 60, 301 (1964). Based on the equilibrium constants reported for the reaction 1/3 B₂O₃(l) + 1/3 BCl₃(g) = BCl(g), the second and third law values of ΔH_f⁰ 298.15 were evaluated as 57.7 and 56.3 kcal. mole⁻¹, respectively. The third law value for ΔH_f⁰ 298.15 was adopted for the calculation of the heat of formation (ΔH_f⁰ 298.15) for BCl(g).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, k₁ = 5.2 X 10⁵, k₂ = 16.7 X 10⁵ dynes cm.⁻¹ and k₃ = 0.40 X 10⁻¹¹ dynes cm. rad.⁻¹. The B-O and B-Cl bond distances were assumed to be the same as those in BO(g) and BCl₃(g), respectively. The moment of inertia is 1.6958 X 10⁻³⁸ g. cm.²

Bond Distances: B-Cl = [1.73] Å

Bond Angle: Cl-B-Cl = [120°]

Product of the Moments of Inertia: I_AI_BI_C = [9.49841 X 10⁻¹¹⁵] g.³ cm.⁶

$\sigma = 2$

Heat of Formation

The heat of formation was estimated by analogy with BF₃, specifically the ratio

$$\Delta H_f(BX_3) \rightarrow BX_2 + X) / \Delta H_f(BX_3) \rightarrow B + 3X$$

was taken as 0.347.

Heat Capacity and Entropy

The vibrational frequencies were obtained from force constants transferred from the trichloride given by O. Harzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono and trichlorides and the angle was estimated to be the same as that in the trichlorides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were I_B = 1.1661 X 10⁻³⁹ g. cm.², I_A = 26.4189 X 10⁻³⁹ g. cm.² and I_C = 27.5851 X 10⁻³⁹ g. cm.²

Bond Distance: B-Cl = [1.74] Å

Bond Angle: Cl-B-Cl = [180°]

Rotational Constant: B₀ = [0.0785] cm⁻¹

σ = 2

Heat of Formation

The appearance potential (AP) of the positive ion fragment BCl₂⁺ from BCl₃(g) was determined mass spectrometrically by Oberhaus (1), Marriott (2), and Koski (3) as 13.2 ± 0.5, 13.01 ± 0.02, and 11.8 ± 0.2 eV, respectively. From the reaction BCl₃ + e⁻ = BCl₂⁺ + Cl + 2e⁻, the corresponding values of ΔH_f⁰₂₉₈ for BCl₂⁺(g) are derived to be 180.4 ± 11.5, 176.0 ± 0.5, and 148.1 ± 4.6 kcal/mol, using ΔH_f⁰ = -96.078 and 28.520 kcal/mol for BCl₃(g) and Cl(g). The value of ΔH_f⁰ for BCl₂⁺(g) is adopted as 148 ± 5 kcal/mol, since the lowest value is likely to have the least excess kinetic energy in the fragment.

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Waleh (4) predictions for 16 valence electron XY₂ molecules. The electronic states, levels and vibrational frequencies are estimated by comparison with those for CO₂(g). The B-Cl bond distance is estimated using the method of Krasnov (5). The moment of inertia is 3.564 × 10⁻³⁸ g cm². The enthalpy at 0°K is -3.07 kcal/mol.

Heat of Formation

The electron captured by BCl₂ should go into a non-bonding orbital according to the correlation diagrams of Walsh (1), thus one expects a small electron affinity. In fact one reasonable estimate of the dissociation energy yields a negative electron affinity (EA). Consider the isoelectronic reactions BCl₂⁻ → B⁺ + 2Cl and CCl₂ → C + 2Cl, if we make the assumption that these binding energies are the same then $\Delta H_f^0(\text{BCl}_2^-)$ = -32 kcal. Another possible estimate is obtained from the isoelectronic reactions BCl₂⁻ + BCl → BCl₃ + Cl⁻ and BClAr → BCl + Ar, although the latter reaction is unknown we expect a zero bond strength; applying this to the first reaction yields $\Delta H_f^0(\text{BCl}_2^-)$ = -22 kcal/mol or $\text{EA}(\text{BCl}_2^-)$ = 2 kcal. In consideration of the above arguments we choose $\text{EA}(\text{BCl}_2^-)$ = 6 kcal (2) which gives $\Delta H_f^0(\text{BCl}_2^-)$ = -26 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be bent using the correlations of A. D. Walsh (1) for 18 valence electron XY₂ molecules. The B-Cl bond distance is estimated using the method of Krasnov (3). The Cl-B-Cl bond angle is taken as 120°. The electronic levels, quantum weights and vibrational frequencies are estimated by comparison with those for CF₂(1) and other related isoelectronic molecules. The three principal moments of inertia are $I_A = 1.179 \times 10^{-39}$, $I_B = 2.873 \times 10^{-38}$ and $I_C = 2.791 \times 10^{-38} \text{ g cm}^2$. The enthalpy at 0°K is -2.76 kcal/mol.

Dec. 31, 1960; Mar. 31, 1961; Dec. 31, 1963; Dec. 31, 1964

Heat of Formation.

The values for BCl₂F and BClF₂ of $\Delta H_f^\circ 298.15 = -154$ and $\Delta H_f^\circ 298.15 = -211.6 \text{ kcal. mole}^{-1}$, respectively, are obtained from the average bond energies of BF₃ and BCl₃. The calculated values were each made less negative by about 0.8 kcal. mole⁻¹ in order to make them consistent with the equilibrium measurements of T. H. S. Higgins, E. C. Zeigang, C. J. O. Raw, and A. J. Roseau, J. Chem. Phys. 23, 1544 (1955) and S. R. Oum and R. H. Sanborn, J. Chem. Phys. 33, 955 (1960) for the reaction

Values for the heat of reaction are $\Delta H_{298.15} = +1.68 \text{ kcal. mole}^{-1}$ and $\Delta H_{298.15} = 1.1$ (uncertainty of -0.5 to +0.8) kcal. mole⁻¹, the former calculated from the measured equilibrium constant and the statistical entropy change and the latter obtained from the variation of the equilibrium constant with temperature. Selection of $\Delta H_{298.15} = 1.6 \text{ kcal. mole}^{-1}$ fixes the sum of the heats of formation of BClF₂ and BCl₂F as -365.6 kcal. mole⁻¹, but it does not determine the individual values. Thus, the selected heats of formation are only as accurate as the average bond energy calculations on which they are based. A reasonable estimate of the uncertainty would be ± 5 kcal. mole⁻¹.

Heat Capacity and Entropy.

The spectroscopic constants are based on the work of L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956), who observed ν_1 , ν_2 , and ν_3 and calculated ν_1 , ν_2 , ν_3 , and ν_4 . The frequencies were adjusted to the normal isotopic composition of 61.2% ¹⁰B and 38.8% ¹¹B. The bond angles were taken to be 120° while the bond lengths were assumed to be the same as in the respective trihalides. As a result, the principal moments of inertia are $I_A = 11.8748 \times 10^{-39}$, $I_B = 26.4268 \times 10^{-39}$, and $I_C = 38.3016 \times 10^{-39} \text{ g. cm}^2$.

Boron Monofluoride (BF)

BORON MONOFLUORIDE (BF)

(IDEAL GAS)

MOL. WT. = 29.82

(Ideal Gas) Mol. Wt. = 29.82

Ground State Configuration $1\Sigma^+$ $\Delta H_f^\circ = -28.4 \pm 3.3 \text{ kcal. mole}^{-1}$ $S^\circ_{298.15} = 47.890 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^\circ = -27.7 \pm 3.3 \text{ kcal. mole}^{-1}$

Heat of Formation

The equilibria of the reaction $2/3 \text{ B(c)} + 1/3 \text{ BF}_3(\text{g}) = \text{BF}(\text{g})$ were studied by J. Blauer, M. A. Greenbaum and M. Parber¹, by means of transpiration at pressures below 300μ . The values of $\log K_p$ at 1375 and 1476°K. were reported as -3.99 ± 0.02 and -3.30 ± 0.05 , respectively. By the third law method the value of ΔH_f° 298.15 for the reaction was derived to be $61.38 \text{ kcal. mole}^{-1}$, yielding ΔH_f° 298.15 = $-28.7 \pm 2.6 \text{ kcal. mole}^{-1}$ for $\text{BF}(\text{g})$. The system $\text{B} + \text{CaF}_2$ was studied mass spectrometrically in a graphite Knudsen cell by D. L. Hildenbrand. The equilibria involving $\text{BF}(\text{g})$ were observed. Intensity measurements were made at temperatures, 1583–1734°K. From the third law value, ΔH_f° 298.15 = $12.2 \pm 0.3 \text{ kcal. mole}^{-1}$, for the reaction $\text{BF}_3(\text{g}) + \text{Ca}(\text{g}) = \text{BF}(\text{g}) + \text{CaF}_2(\text{g})$, the value of ΔH_f° 298.15 for $\text{BF}(\text{g})$ was derived as $-26.7 \pm 2 \text{ kcal. mole}^{-1}$. The dissociation energy (D_0°) of $\text{BF}(\text{g})$ molecule has been reported by O. Herzberg², A. G. Gaydon³ and R. F. Barrow⁴, respectively. Hence the corresponding values of ΔH_f° 298.15 for $\text{BF}(\text{g})$ were derived. The results are compared with those obtained from equilibrium data as follows.

Investigator	Reaction	ΔH_f° 298.15, kcal. mole ⁻¹	ΔH_f° 298.15, kcal. mole ⁻¹
Parber, et al. ¹	$2/3 \text{ B(c)} + 1/3 \text{ BF}_3(\text{g}) = \text{BF}(\text{g})$	61.38	-28.7 ± 2.6
Herzberg ²	$\text{BF}(\text{g}) = \text{B(g)} + \text{F(g)}$	100.2	$+51.5$
Gaydon ³	$\text{BF}(\text{g}) = \text{B(g)} + \text{F(g)}$	197.0	-45.3 ± 11.5
Barrow ⁴	$\text{BF}(\text{g}) = \text{B(g)} + \text{F(g)}$	186.0	-34.3
Oross, et al. ⁵	$2/3 \text{ B(c)} + 1/3 \text{ BF}_3(\text{g}) = \text{BF}(\text{g})$	—	-28 ± 3
Hildenbrand ⁶	$\text{BF}_3(\text{g}) + \text{Ca(g)} = \text{BF(g)} + \text{CaF}_2(\text{g})$	12.2	-26.7 ± 2

1 J. Blauer, M. A. Greenbaum and M. Parber, J. Phys. Chem. 58, 2332 (1964).

2 O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, New York, 1950. ΔH_f° 298.15 was calculated based on $D_0^\circ = 4.3 \text{ e.v.}$

3 A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. ΔH_f° 298.15 was derived from $D_0^\circ = 8.5 \pm 0.5 \text{ e.v.}$

4 R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960). ΔH_f° 298.15 was calculated based on $D_0^\circ = 185 \text{ kcal. mole}^{-1}$.

5 F. Oross, C. Gayman, D. L. Levi and R. H. Lewin, "Stability of Lower Boron Halides", Final Technical Report, August 24, 1963, Fulmer Research Institute Limited, England. The reported value, ΔH_f° 298.15 = $-28 \pm 3 \text{ kcal. mole}^{-1}$, is a preliminary estimated one.

6 D. L. Hildenbrand, "Thermodynamic Properties of Propellant Combustion Products", QLR-65-3, Philco Corporation, California.

The value of ΔH_f° 298.15 adopted is the average of the first and last ΔH_f° 298.15 values listed in the above table.

Heat Capacity and Entropy

The spectroscopic constants used were obtained from R. Onaka, J. Chem. Phys. 21, 374 (1957) and corrected to the average isotopic species. Spectroscopic constants for $\text{BF}(\text{g})$ were also reported by O. Herzberg, loc. cit. The moment of inertia (I) is $1.8321 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation

The equilibrium constants for the reaction B₂O₃(l) + BF₃(g) = 3BOF(g) in the temperature range 1054-1253°K. were determined by M. Parber and J. Blauer, Trans. Faraday Soc. 59, 2080 (1962), using the so-called Molecular Flow Reaction Method. The value of ΔH_f⁰ for this reaction was evaluated by both the second and third law methods, using the equilibrium constants corrected for the trimer and correcting K_p at 1200°K. from 9.6 X 10⁻¹¹ to 9.6 X 10⁻¹⁰.

D. L. Hildenbrand, L. P. Theard and A. M. Saul, J. Chem. Phys. 39, 1973 (1963) analyzed the vapor above mixture of MgP₂ and B₂O₃ contained in a Knudsen cell with a mass spectrometer and found that in the temperature range 980-1230°K. the vapor is composed of BF₃(g), (BOF)₂(g) and BOF(g) species. From the reported temperature dependence of appropriate ion intensities the enthalpy change of the reaction (BOF)₂(g) = 3BOF(g) was derived by the second law method as 127.9 kcal. mole⁻¹ at 1115°K. or 129.75 kcal. mole⁻¹ at 298.15°K. The results obtained are presented as follows, using JANAP free energy functions and auxiliary data.

ΔH_f⁰ 298.15, kcal. mole⁻¹

Second law value Third law value

Kcal. mole⁻¹

Reaction

Parber and Blauer B₂O₃(l) + BF₃(g) = 3BOF(g) 150.2 ± 16.6 149.0 -140.1 ± 6*

Hildenbrand, et al. (BOF)₂(g) = 3BOF(g) 129.8 ± 3 -145.2 ± 1.5

*Calculation based on the third law value and one point rejected due to statistical test.

The adopted value of ΔH_f⁰ 298.15 for BOF(g) is the weighted average of the two ΔH_f⁰ 298.15 values listed above.

Heat Capacity and Entropy

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, k₁ = 10 X 10⁵, k₂ = 25.6 X 10⁵ dynes cm.⁻¹ and k₃ = 0.47 X 10⁻¹¹ dynes cm. rad.⁻¹. The B-O and B-P bond distances were assumed to be the same as those in BO(g) and BP₃(g) molecules.

The moment of inertia is 9.0464 X 10⁻³⁹ g. cm.².

σ = 2

Heat of Formation.

The heat of formation (ΔH_f⁰ 298.15) was obtained from J. L. Margrave, J. Phys. Chem. 66, 1209 (1962), from appearance potentials.

Heat Capacity and Entropy.

The bond distance and angle were assumed to be the same as those in BF₃(g) molecule. The vibrational frequencies were calculated using force constants transferred from those for BF₃(g) given by G. Herzberg, "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., 1945. The three principal moments of inertia are: I_A = 7.9278 X 10⁻³⁹, I_B = 5.8710 X 10⁻⁴⁰ and I_C = 8.5149 X 10⁻³⁹ g. cm.²

σ = 2

Heat of Formation

The electron impact reaction at low pressure in BF₃(g) has been studied with a mass spectrometer by Osberghaus (1), Law (2), and Harriott (3). From the reported appearance potentials 17.0 ± 0.5, 16.2 ± 0.2, and 16.7 ± 0.05 eV and assumed process BF₂⁺ + e = BF₂⁺ + F + 2e, we calculate the corresponding values of ΔH_f^o₂₉₈ (BF₂⁺, g) as 102.8 ± 11.5, 84.4 ± 4.6, and 83.7 ± 1.2 kcal/mol, using ΔH_f^o = 270.977 and 18.357 kcal/mol for BF₃(g) and F(g). The adopted value of ΔH_f^o for BF₂⁺(g) is 84 ± 2 kcal/mol, since the lower values are likely to have the least excess kinetic energy in the fragments.

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Walsh (4) prediction for 16 valence electron XY₂ molecules. The electronic states and levels, and vibrational frequencies are estimated by comparison with those for CO₂(3). The B-F bond distance is calculated by the method recommended by Krasnov (5). The moment of inertia is 1.083 × 10⁻³⁸ g cm². The enthalpy at 0°K is -2.54 kcal/mol.

Heat of Formation

The electron captured by BF₂ should go into a non-bonding orbital according to the correlation diagrams of Walsh (1), thus we would expect a small electron affinity. Two estimates of the dissociation energy of BF₂⁻ indicate a negative electron affinity (EA); consider the isoelectronic reactions BF₂⁻ → B⁻ + 2F and CF₂ → C + 2F if we make the reasonable assumption that the atomization energies are the same then ΔH_{f298}(BF₂⁻, g) = -86 kcal/mol, or EA(BF₂⁻) = -44 kcal. Another approach is to consider the isoelectronic reactions BF₂⁻ → BF + F⁻ and BFHe → BF + He, although the latter reaction is unknown we would expect zero bond strength, and if used in the first reaction this yields ΔH_{f298}(BF₂⁻, g) = -90 kcal/mol, or EA(BF₂⁻) = -40 kcal.

In consideration of the above we choose EA(BF₂⁻) = EA(B, g) = 6 kcal (2), which gives ΔH_{f298}(BF₂⁻, g) = -136 kcal/mol.

Heat Capacity and Entropy

The molecular structure and B-F bond distance are assumed to be the same as those for the BF₂(g) molecule. The electronic levels, quantum heights and vibrational frequencies are estimated by comparison with those for CF₂(g) which is isoelectronic with BF₂⁻. The three principal moments of inertia are: I_A = 5.904 × 10⁻⁴⁰, I_B = 7.997 × 10⁻³⁹ and I_C = 8.587 × 10⁻³⁹ g cm². The enthalpy at 0°K is -2.52 kcal/mol.

Bond Distance: B-F = [1.30] Å B-O = [1.36] Å O-H = [0.96] Å

Bond Angle: F-B-F = [120]° F-B-O = [120]° B-O-H = [105]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.05094 \times 10^{-114}] \text{ g}^3 \text{ cm}^6$

$\sigma^- = 1$

Heat of Formation: $\Delta H_f^\circ 298.15$ was calculated based on an assumption that $\Delta H_f^\circ 298.15 = 0$ for the reaction $2/3 \text{ BF}_3(\text{g}) + 1/3 \text{ B(OH)}_3(\text{g}) = \text{BOHF}_2(\text{g})$.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from J. S. Gorden, Astrocyetene International, Inc., private communication, November 2, 1982. The B-F and O-H bond distances were assumed to be the same as those in $\text{BF}_3(\text{g})$ and $\text{H}_2\text{O}(\text{g})$ molecules, respectively. The B-O bond distance and the bond angles were estimated from related molecules. The three principal moments of inertia are: $I_A = 7.8114 \times 10^{-39}$, $I_B = 8.3333 \times 10^{-39}$ and $I_C = 1.61447 \times 10^{-38} \text{ g. cm}^2$.

Bond Distance : B-F = 1.30 ± 0.05 Å

Bond Angle : F-B-O = 117 ± 5°

Product of the Moments of Inertia: I_AI_BI_C = 9.9464 × 10⁻¹¹⁵ g³ cm⁶

Heat of Formation

The molecule BF₂O(g) is similar to BO₂(g) in that both have an extra electron. Based on an assumption that D₀(F₂B-O) = D₀(OB-O) = 10 = 134.3 kcal/mol, where the quantity -10 kcal/mol is estimated as the resonance stabilization energy in BO₂(g), the heat of formation (ΔH_f⁰_{298.15}) for BF₂O(g) is calculated to be -208 kcal/mol.

Assuming D₀(F₂BO-H) = D₀(HO-H) = 118 kcal/mol, the value of ΔH_f⁰_{298.15}(F₂BO,g) is evaluated as -191.6 kcal/mol, using ΔH_f⁰ = 51.63 and -257.35 kcal/mol for H(g) and F₂BOH(g), respectively.

The value of ΔH_f⁰_{298.15} for BOF₂(g) is tentatively adopted as -200 ± 15 kcal/mol.

Heat Capacity and Entropy

The 4465-Å emission spectrum was observed in a discharge through BF₃ and O₂ by C. W. Mathews, J. Mol. Spectry, **19**, 203 (1966). The emitter of the discharge was shown to be either the planar BOF₂ molecule or molecule-ion BOF₂⁺. No experimental evidence has been found to distinguish between them. The molecular structure, bond distances and angles were reported by Mathews, based on a rotational analysis of the emission spectrum. These values are adopted here.

Three vibrational frequencies for both 11P₁BOF₂ and 10P₁BOF₂ molecules (or ions) were determined by vibrational analysis of the 5800 - Å bands of the emission spectrum by C. W. Mathews and K. K. Innes, J. Mol. Spectry, **15**, 199 (1965). These values are corrected to the average isotopic species and adopted. The last three frequencies are estimated from values calculated by the valence-force method, using force constants transferred from COF₂(g).

The ground state quantum weight is taken as 2 because of the extra electron. The other two electronic levels are estimated from the band systems at 5800 and 4465 Å, assuming that the two systems have a common lower state, i.e. the ground state.

The three principal moments of inertia are: I_A = 8.4647 × 10⁻³⁹, I_B = 7.4045 × 10⁻³⁹ and I_C = 1.5869 × 10⁻³⁸ g cm².

Heat of Formation

The adopted heat of formation was selected by a simultaneous adjustment of several interrelated pieces of data relating to the heat of formation of HF (see HF, § table 11-11-60). The data which were considered relating directly to BF₃ were as follows.
A. NF₃(g) + B(c, β) + BF₃(g) + 0.5 H₂ ΔH₂₉₈⁰ = -231.46 ± 1.2 kcal/mol
Ludwig and Cooper (1) report the above value after correction for 0.44 percent impurities in the boron. As much as 5 percent unburned boron was determined by analysis.

B. 1.5 F₂(g) + B(c, β) + BF₃(g)
Wise et al. (2) originally reported ΔH₂₉₈⁰ = -270.1 ± 0.24 kcal/mol but later reanalysis (3) of the impurities and due allowance for their effect changed this to -271.6 ± 0.9 kcal/mol. Johnson et al. (3) using zone refined boron obtained ΔH₂₉₈⁰ = -271.65 ± 0.22 kcal/mol after correction for 0.12 percent impurities. Domalski and Armstrong (4) obtained ΔH₂₉₈⁰ = -271.03 ± 0.51 kcal/mol from a combustion in the presence of Teflon, the boron contained 0.32 percent impurities and corrections were included. The above reaction constituted about 0.35 of the total energy measured. The measurements of Gross et al. (5), although on a zone refined sample, did not include a complete purity analysis and their data were not included since probable impurities could introduce serious errors.

C. 3HF(50 H₂O) + B(c, β) + 0.75 O₂(g) + BF₃(g) + 1.5 H₂O(l)
From the measurements of Gunn (6) on the reaction of BF₃(g) + 15.67 HF(3.747 H₂O) + [solution] and Good and Månsson (7) for the reaction B(c, β) + 0.75 O₂(g) + 18.57 HF(3.085 H₂O) + [solution] + 1.5 H₂O(l), where this resulting solutions have the same composition, we obtain ΔH₂₉₈⁰ = -142.77 ± 0.5 kcal/mol. Further details of the simultaneous solution are given by Syverud (8).

Heat Capacity and Entropy

The fundamental frequencies were selected from the measurements of Lindeman and Wilson (9), McKean (10), Nielsen (11), Anderson et al. (12) and Yost et al. (13). The bond lengths and structure are those reported by Gin et al. (14) which are in agreement with those of Kuchitsu and Konaka (15) from gas phase electron diffraction. These measurements disagree with the earlier determinations of Nielson (11) and Levy and Brockway (16) but are considerably more precise and are adopted.
The individual moments of inertia are I_A = I_B = 8.083 × 10⁻³⁹ g cm² and I_C = 16.186 × 10⁻³⁹ g cm².

Sept. 30, 1962; Dec. 31, 1963; Mar. 31, 1965; Dec. 31, 1969

 ΔH°_0 = Unknown $\Delta H^\circ_{298.15} = -451.0 \pm 1 \text{ kcal/mol}$ $\Delta H^\circ = 3.36 \pm 0.04 \text{ kcal/mol}$ $\Delta H_m^\circ = 4.22 \pm 0.04 \text{ kcal/mol}$ $\Delta H^\circ_{298.15} = [80] \text{ kcal/mol}$

Heat of Formation

Bills and Cotton (1) measured the enthalpies of several reactions at 25°C which led to the following result:

$$\text{H}_3\text{BO}_3(\text{c}) + 4(\text{HF} \cdot 23 \text{ H}_2\text{O}) + \text{KNO}_3(\text{c}) \rightarrow \text{KBF}_4(\text{c}) + \text{HNO}_3 \cdot 92 \text{ H}_2\text{O} + 3\text{H}_2\text{O}$$
 $\Delta H^\circ = -19.26 \pm 0.6 \text{ kcal/mol}$

Combining this result with the following heat of formation data,

 $\Delta H^\circ(\text{H}_3\text{BO}_3, \text{c}) = -261.47 \pm 0.2 \text{ kcal/mol (2)}$ $\Delta H^\circ(\text{HF} \cdot 23 \text{ H}_2\text{O}) = -76.75 \pm 0.1 \text{ kcal/mol (3)}$ $\Delta H^\circ(\text{KNO}_3, \text{c}) = -118.22 \text{ kcal/mol (4)}$ $\Delta H^\circ(\text{HNO}_3 \cdot 92 \text{ H}_2\text{O}) = -49.44 \text{ kcal/mol (5)}$ $\Delta H^\circ(\text{H}_2\text{O}, \text{l}) = -68.315 \text{ kcal/mol (5)}$

We derive, $\Delta H^\circ(\text{KBF}_4, \text{c}) = -451.6 \pm 1.2 \text{ kcal/mol}$.

Gross, Hayman, and Joël (6) recently measured the following heats of reaction:

 $\text{NaF}(\text{c}) + \text{BF}_3(\text{g}) \rightarrow \text{NaBF}_4(\text{c})$ $\Delta H^\circ = -32.04 \pm 0.12 \text{ kcal/mol}$ $\text{NaF}(\text{c}) + \text{HF}(\text{aq.}) \rightarrow \text{Solin A}$ $\Delta H^\circ = +8.14 \pm 0.18 \text{ kcal/mol}$ $\text{NaBF}_4(\text{c}) + \text{HF}(\text{aq.}) \rightarrow \text{Solin A}$ $\Delta H^\circ = -2.94 \pm 0.13 \text{ kcal/mol}$

These data combine to give, $\Delta H^\circ = -43.13 \pm 0.22 \text{ kcal/mol}$, for the reaction

 $\text{KF}(\text{c}) + \text{BF}_3(\text{g}) \rightarrow \text{KBF}_4(\text{c})$

Combining this result with the following heats of formation,

 $\Delta H^\circ(\text{KF}, \text{c}) = -135.9 \pm 0.1 \text{ kcal/mol (7)}$ $\Delta H^\circ(\text{BF}_3, \text{g}) = -271.42 \pm 0.4 \text{ kcal/mol (7)}$

We derive, $\Delta H^\circ(\text{KBF}_4, \text{c}) = -450.5 \pm 0.7 \text{ kcal/mol}$. An average value, $\Delta H^\circ(\text{KBF}_4, \text{c}) = -451.0 \pm 1 \text{ kcal/mol}$, of these two results is adopted here.

Heat Capacity and Entropy

The heat capacity data are calculated from the high temperature enthalpy data of Dworin and Bredig (8). S°_{298} is chosen such that a third-law analysis of the equilibrium data for the reaction

 $\text{KBF}_4(\text{c}, \text{l}) \rightleftharpoons \text{KF}(\text{c}, \text{l}) + \text{BF}_3(\text{g})$

reported by de Boer and van Liempt (9) gives the experimentally determined heat of reaction at 25°C (8).

Transition Data

It is from the high temperature studies of Dworin and Bredig (8). ΔH° is calculated from their high temperature enthalpy data.

Melting Data

T_m has been reported as 803°K by de Boer and van Liempt (9) and 843°K by Dworin and Bredig (8). Dworin and Bredig's value is adopted here. ΔH_m° is calculated from their high temperature enthalpy data.

Sublimation Data

ΔH°_{298} is estimated by comparison with data for LiAlF₄(c) reported by Hildenbrand and Theard (10).

POTASSIUM TETRAFLUOROBORATE (KBF₄) (LIQUID)

GFW = 125.907

Potassium Tetrafluoroborate (KBF₄)

GFW = 125.907

 $\Delta H_f^\circ = \text{Unknown}$ $S_{298.15}^\circ = 35.88 \pm 4.0 \text{ gibbs/mol}$ $\Delta H_f^\circ = -446.8 \pm 1.5 \text{ kcal/mol}$ $T_m = 843^\circ\text{K}$ $\Delta H_m^\circ = 4.22 \pm 0.04 \text{ kcal/mol}$

Heat of Formation

$\Delta H_f^\circ(l)$ is calculated from $\Delta H_f^\circ(c)$ by adding the heat of melting and the difference in $H_{843} - H_{298}$ between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity data are calculated from the high temperature enthalpy data of Dworkin and Bredig (1). S_{298}° is calculated in a manner analogous to the heat of formation.

Melting Data

T_m has been reported as 803°K by de Boer and van Liempt (2) and 843°K by Dworkin and Bredig (1). Dworkin and Bredig's value is adopted here. ΔH_m° is calculated from their high temperature enthalpy data.

Sept. 30, 1962; Dec. 31, 1963; Mar. 31, 1965; Dec. 31, 1969

Raman spectra of BF₄ in various phases have been reported by (1, 2, 3, 4). The molecular structure is assumed to be the same as for LiAlF₄ as discussed by Porter and Zeller (5). The B-F and K-F bond lengths and F-B-F bond angle are average values of the crystallographic data recently reported by Clark and Lynton (6). The B-K bond length is calculated from the above structural data according to the assumed molecular model. The individual moments of inertia are $I_A = I_B = 5.292 \times 10^{-38} \text{ g cm}^2$ and $I_C = 1.617 \times 10^{-38} \text{ g cm}^2$.

 $\omega_e x_e = [49] \text{ cm.}^{-1}$
 $\sigma = 1$
 $B_e = 12.036 \text{ cm.}^{-1}$
 $\alpha_e = .413 \text{ cm.}^{-1}$
 $r_e = 1.2325 \text{ \AA}$

Heat of Formation.

$\Delta H_f^\circ 298.15$ was calculated from D_0 (BH) = 3.39 ± 0.04 e.v. reported by A. C. Hurley, Proc. Royal Soc. (London), A281, 237 (1961). Hurley stated "by combining an analysis of the spectroscopic data with theoretical calculations we obtain a greatly improved estimate of D_0 (BH)". This value and the other D_0 (BH) values which are tabulated below are based on the same spectroscopic data but differ due to different methods of analysis.

D_0 (BH)	Method	Reference
3.0 ± 0.4 e.v.	Birge-Sponner extrapolations	A. G. Heydon "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, Ltd., London, 1955.
3.5 e.v.	Observed predissociation by rotation in BH, A ¹ Π and deduced D_0 (BH).	G. M. Alley and R. B. Horsfall Jr., Phys. Rev., 51, 491 (1937).

< 3.51 e.v.

Pre-dissociation limit. This is only an upper limit due to a maximum in the potential curve of the A¹Π state.

3.38 ± 0.04 e.v.

The potential energy curve of the A¹Π state was determined and was found to have a maximum and a minimum in agreement with Herzberg and Mundle (loc. cit.)

Heat Capacity and Entropy.

The molecular constants from G. Herzberg (loc. cit.) were adjusted for the natural abundance of B^{10} and B^{11} . Because the constants ω_e and $\omega_e x_e$ could not be determined directly from the spectrum, Alley and Horsfall (loc. cit.) obtained estimates for the ground state $X\ 1\Sigma^+$ from the rotational contents for this state and the relations $D_e = 4 B_e^2 / \omega_e^2$ and $\omega_e x_e / \omega_e = 0.6 \alpha_e / B_e$.

Heat of Formation

The heat of formation of the hypothetical species HBO(g) is controversial. Using $\Delta H_f^\circ 298.15 = [255] \text{ kcal. mole}^{-1}$ for the reaction $\text{HBO(g)} = \text{H(g)} + \text{O(g)}$, the value of $\Delta H_f^\circ 298.15$ for HBO(g) is calculated as $[-13] \text{ kcal. mole}^{-1}$. The value of $\Delta H_f^\circ 298.15$ is the sum of the constituent bond energies, i.e. $D(\text{H-B}) = 87$ and $D(\text{B-O}) = 168 \text{ kcal. mole}^{-1}$. The $D(\text{H-B})$ value is derived from the dissociation of $\text{BH}_3(\text{g})$ and $D(\text{B-O})$ value is calculated as the average value of the B-O bond energies, 175 and 161 kcal. mole^{-1} , in BO(g) and $\text{BO}_2(\text{g})$ molecules, respectively.

However, by comparison with the following dissociation reactions:

$(\text{FBO})_3(\text{g}) \rightarrow 3 \text{ FBO(g)}$ $\Delta H_f^\circ 298.15 = 135 \text{ kcal. mole}^{-1}$ or 45 kcal. mole^{-1} per mole of FBO(g)
 $(\text{HBO})_3(\text{g}) \rightarrow 3 \text{ HBO(g)}$ $\Delta H_f^\circ 298.15 = 141.8 \text{ kcal. mole}^{-1}$ or 47 kcal. mole^{-1} per mole of HBO(g)
 $(\text{ClBO})_3(\text{g}) \rightarrow 3 \text{ ClBO(g)}$ $\Delta H_f^\circ 298.15 = 170.6 \text{ kcal. mole}^{-1}$ or 57 kcal. mole^{-1} per mole of ClBO(g)

It is estimated $\Delta H_f^\circ 298.15 = [70] \text{ kcal. mole}^{-1}$ for the reaction $1/3(\text{HBO})_3(\text{g}) \rightarrow \text{HBO(g)}$, based on the electronegativity difference among the F, Cl and H atoms. Hence the value of $\Delta H_f^\circ 298.15$ for HBO(g) is calculated to be $-27 \text{ kcal. mole}^{-1}$. The adopted value of $\Delta H_f^\circ 298.15$ for HBO(g) is $1/2(-13-27) = -20 \text{ kcal. mole}^{-1}$. The uncertainty is given as $\pm 20 \text{ kcal. mole}^{-1}$. Other methods of estimation have been tried such as the comparison of the difference in $\Delta H_f^\circ 298.15$ between H-CH_3 and HO-CH_3 with the corresponding difference between H-BO and HO-BO , etc. They lead to very large negative values for $\Delta H_f^\circ 298.15(\text{HBO, g})$. However, a value of $260 \pm 15 \text{ kcal. mole}^{-1}$ for the atomization of HBO(g) was used by L. V. Ourvech, et al., "Thermodynamic Properties of Individual Substances," Vol. I, Academy of Science, USSR, Moscow, 1962, which was obtained by comparison with the dissociation energies for BO, BH, CH and HCN molecules.

Heat Capacity and Entropy

The vibrational frequencies and molecular structure were obtained from W. H. Evans, private communication, October 6, 1960. The bond lengths of H-B and B-O in the HBO(g) molecule were assumed to be the same as those in the BH(g) and BO(g) molecules, respectively. The moment of inertia (I) is calculated as $2.1561 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation

Using the correlations developed by A. D. Walsh, J. Chem. Soc. 2288 (1933) for HAO molecules the electron removed by ionization ought to be a bonding electron. This indicates a high ionization potential and also the bond dissociation energy of BO-H⁺ should be significantly less than BO-H. Assuming a decrease of 40 kcal we obtain ΔH^o_f(HBO⁺, g) = 335 ± 20 kcal/mol, which corresponds to an ionization potential of 355 kcal or 15.4 ± 1 eV. This is in accord with the ionization potential of BO, 12.8 eV, from National Bureau of Standards Report 8628, Jan. 1, 1965, which should be less than HBO since this electron in BO is unpaired.

Heat Capacity and Entropy

According to the correlations of Walsh loc.cit., the molecule should be linear and since the unpaired electron is in a pi orbital, the ground state should be ²Π. A first excited state is estimated at 20000 cm⁻¹ to be ²Σ by analogy with the isoelectronic molecule CO⁺. Since HBO⁺ is lacking a bonding electron compared to HBO, we assume that the bond lengths will be slightly longer than in HBO. The vibrational frequencies are also estimated from those in HBO by assuming all values to be 10 per cent lower due to the weaker bonding.

The enthalpy at 0°K is -2.275 kcal/mol.

BHO⁺

Metaboric Acid (HBO₂)

METABORIC ACID (HBO₂)

(CRYSTAL)

MOL. WT. = 43.828

ΔH_f° O = Unknown

ΔH_f° 298.15 = -191.87 ± 0.20 kcal. mole⁻¹

ΔH_m° = Unknown

ΔH_s° 298.15 = 57.9 ± 1.0 kcal. mole⁻¹

S° 298.15 = [11.7 ± 1.0] cal. deg.⁻¹ mole⁻¹

T_m = 509 ± 1°K

Heat of Formation.

The enthalpy change (ΔH_f°) of the reaction HBO₂ (c, I) + H₂O(l) = H₃BO₃(c) has been determined by M. V. Kilday and E. J. Prosen, J. Am. Chem. Soc. 82, 5508 (1960). From the value, ΔH_f° 298.15 = -1.28 kcal. mole⁻¹, the heat of formation (ΔH_f° 298.15) for HBO₂ (c, I) is derived to be -191.87 ± 0.20 kcal. mole⁻¹ which is adopted. The heats of solution of HBO₂ (c, I) in H₂O(l) was measured by N. D. Sokolova, S. M. Skuratov, A. M. Shemonaeva and Y. M. Yuldasheva, Russ. J. Inorg. Chem. 6, 395 (1961). Based on the reported value, ΔH_f° 298.15 = 1.76 ± 0.01 kcal. mole⁻¹ for the reaction HBO₂(c, I) + 501 H₂O(l) = H₃BO₃·500 H₂O(sol.), the heat of formation for HBO₂(c, I) was derived as -189.46 ± 0.20 kcal. mole⁻¹, using ΔH_f° 298.15(H₂O, l) = -68.317 and ΔH_f° 298.15(H₃BO₃·500 H₂O, sol.) = -286.02 ± 0.20 kcal. mole⁻¹.

Heat Capacity and Entropy.

The values of heat capacity for HBO₂(c, I) were estimated by comparison with those of its constituent oxides. S° 298.15 was calculated as the sum of the entropy contributions from H⁺ and BO₂⁻ in HBO₂(c) suggested by K. K. Kelley, private communication, June 1960, and O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958.

Melting Data.

P. C. Kreczek, O. M. Morey and H. E. Merwin, Am. J. Sci. (5) 35A, 143 (1938) reported the existence of three crystal forms of HBO₂(c), namely HBO₂(c, I), m.p. 503 ± 1°K; HBO₂(c, II), m.p. 474.1 ± 0.5°K; and HBO₂(c, III), m.p. 449.2 ± 0.2°K. However, there was no solid phase equilibrium found among these three crystals. N. D. Sokolova, S. M. Skuratov, A. M. Shemonaeva and Y. M. Yuldasheva, loc. cit., measured the heats of solution in water of HBO₂(c, I) and HBO₂(c, II) and derived the heat of transition as ΔH_t° 298.15(II → I) = 1.29 kcal. mole⁻¹.

Heat of Sublimation.

The value of ΔH_s° 298.15 was calculated as the difference between the ΔH_f° 298.15 values for HBO₂(g) and HBO₂(c).

Bond Distances: H-O = [1.0] Å

Bond Angles: H-O-B = [120]°

Product of the Moments of Inertia: I_AI_BI_C = 9.6851 X 10⁻¹¹⁷ g.³ cm.⁶

Heat of Formation.

The equilibrium pressures of the reaction 1/2 B₂O₃(l) + 1/2 H₂O(g) = HBO₂(g) have been measured by several investigators. Using the equilibrium data reported, the heats of reaction (ΔH_f^o 298.15) were evaluated by both the second and third law methods. The corresponding heats of formation for HBO₂(g) were derived based on the ΔH_f^o 298.15 values obtained by the third law method. The results obtained are presented as follows.

Rotational Constant: B₀ = 5.80683 cm.⁻¹

σ = 2

Heat of Formation.

ΔH_f⁰ 298.15 was calculated from appearance potentials reported by T. P. Fehlner and W. S. Koski, J. Am. Chem. Soc. **86**, 2733 (1964) and the JANAF (B₂H₆(g)) ΔH_f⁰ 298.15 = +9.8 kcal. mole⁻¹. For example

The ΔH_f⁰ data is summarized below.

Investigator	Method	ΔH _f ⁰ 298.15 kcal. mole ⁻¹
T. P. Fehlner and W. S. Koski (loc. cit.)	Appearance Potentials	48
C. J. Olmstead and J. R. Perrin, Marquardt Corp., Van Nuys, Calif., and J. Ferrier, Oilin Matheson Chemical Corp., New York 22, N.Y., "Estimation of the Heats of Formation of Gaseous Combustion Product Molecules", October 1959.	Estimate	66
P. C. H. Jordan and H. C. Longuet-Higgins, Mol. Phys. 5 , 121 (1962).	Estimate	93

The bond distance B-H = 1.20 Å was estimated from a consideration of BH(g), BH₂(g) and other molecules. The bond angle H-B-H = 180° and the electronic configuration of the ground state [2_g] were estimated by P. C. H. Jordan and H. C. Longuet-Higgins (loc. cit.). The frequencies were estimated assuming valence forces [G. Herzberg, "Molecular Spectra and Molecular Structure II Infrared and Raman Spectra of Polyatomic Molecules" D. Van Nostrand Co. Inc., N. Y. (1945) pgs 172] and using force constants, k₁ = 3.5 × 10⁵ dynes cm.⁻¹ and k_f = 0.35 × 10⁵ dynes cm.⁻¹, estimated from BH₃, (see A. Shepp and S. H. Bauer, J. Am. Chem. Soc. **76**, 265 (1954)).

Heat Capacity and Entropy.

The bond distance B-H = 1.20 Å was estimated from a consideration of BH(g), BH₂(g) and other molecules. The bond angle H-B-H = 180° and the electronic configuration of the ground state [2_g] were estimated by P. C. H. Jordan and H. C. Longuet-Higgins (loc. cit.). The frequencies were estimated assuming valence forces [G. Herzberg, "Molecular Spectra and Molecular Structure II Infrared and Raman Spectra of Polyatomic Molecules" D. Van Nostrand Co. Inc., N. Y. (1945) pgs 172] and using force constants, k₁ = 3.5 × 10⁵ dynes cm.⁻¹ and k_f = 0.35 × 10⁵ dynes cm.⁻¹, estimated from BH₃, (see A. Shepp and S. H. Bauer, J. Am. Chem. Soc. **76**, 265 (1954)).

Bond Distance: B-O = [1.27] Å O-H = [0.97] Å

Bond Angle: H-O-B = [105]° O-B-O = [180]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.42627 \times 10^{-116}] \text{ g.}^3 \text{ cm.}^6$

σ = 2

Heat of Formation.

The value of $\Delta H_f^\circ 298.15$ for B(OH)₂(g) was calculated by using the bond energy, D°(B-OH) = 132.7 kcal. mole⁻¹, and the heats of formation for B(g) and OH(g) as 132.80 and 9.33 kcal. mole⁻¹, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for B(OH)₃(g) and other related molecules. The bond distances and angles were estimated by comparison with those for B(OH)₃(g) and H₂O₂(g) molecules. The molecular configuration is assumed to be trans which is considered as more stable than the cis-form. The three principal moments of inertia are: $I_A = 2.6870 \times 10^{-40}$, $I_B = 9.3682 \times 10^{-39}$ and $I_C = 9.6369 \times 10^{-39} \text{ g. cm.}^2$

Boron Trihydride (BH₃)

σ = 6

Heat of Formation

ΔH_f⁰ 298.15 was calculated from appearance potentials reported by T. P. Fehlner and W. S. Koski J. Am. Chem. Soc. 86, 2733 (1964). For example

The heat of formation data is summarized below.

Reaction: B₂H₆(g) → 2BH₃(g)*

*The auxiliary ΔH_f⁰ 298.15(B₂H₆) was from the JANAP Table dated Dec. 31, 1964

Investigator	Method	ΔH _f ⁰
P. C. H. Jordan and H. C. Longuet-Higgins	Bond energy parameters obtained by linear extrapolation from NH and CH bonds	59.9 kcal. mole ⁻¹
Bayley, and P. E. Stafford, J. Chem. Phys. 41, 2207(1964)	Apparent equilibrium constants	55 ± 8 kcal. mole ⁻¹

		18 kcal. mole ⁻¹

Heat Capacity and Entropy

The molecular configuration, [planar, H-B-H angle = 120°], was estimated by A. Shepp and S. H. Bauer, J. Am. Chem. Soc. 76, 265 (1954) as well as by P. C. H. Jordan and H. C. Longuet-Higgins, (loc. cit.). In addition Shepp and Bauer estimated the bond distance and the vibrational frequencies. Jordan and Longuet-Higgins estimated the electronic configuration [A₁]. The principal moments of inertia calculated from these molecular constants are, I_A = I_B = 3.378 X 10⁻⁴⁰ and I_C = 6.756 X 10⁻⁴⁰ gm.²

Heat of Formation (ΔH_f⁰) of H₃BO₃(c) was taken from W. D. Good, M. Mansson and J. P. McCullough, Quarterly Technical Report No. 9, Nov. 4, 1963, U. S. Bur. Mines, Bartlesville, Oklahoma. The value was derived based on the following measurements

B(c) + 0.75 O₂(g) + 18.674 HF-57.219 H₂O(l) = HBF₄·14.674 HF-58.719 H₂O(l)
 H₃BO₃(c) + 18.674 HF-55.719 H₂O(l) = HBF₄·14.675 HF-58.719 H₂O(l)
 The heats of solution of H₃BO₃(c) in water have been measured by many investigators. L. G. Fasolino, "Heat of Formation of B₂O₃(c) and B₂O₃(am.)" NONR-3608 (OO), June 2, 1964, National Research Corporation, Massachusetts, obtained the value, ΔH_f⁰ 298.15 = 5.45 ± 0.01 kcal mole⁻¹ for the reaction H₃BO₃(c) + 504 H₂O(l) = H₃BO₃·504 H₂O(sol.) which leads to ΔH_f⁰ 298.15 (H₃BO₃·504 H₂O, sol.) = -256.02 kcal mole⁻¹. The ΔH_f⁰ 298.15 value is in reasonable agreement with the value reported by J. Smieko and L. S. Mason, J. Am. Chem. Soc. 72, 3679 (1950) in which the heats of solution and dilution of H₃BO₃(c) were given. The heats of solution of H₃BO₃(c) in water measured by other previous investigators were reviewed by L. G. Fasolino, loc. cit.

Heat Capacity and Entropy

The low temperature (16-295°K) heat capacities were reported by H. L. Johnston and E. C. Kerr, J. Am. Chem. Soc. 72, 4733 (1950). The heat capacities above 300°K were estimated by comparison with those of its constituent oxides. S_{298.15} was obtained from H. L. Johnston and E. C. Kerr, loc. cit., using S₁₇ = 0.18 cal deg⁻¹ mole⁻¹.

Melting Data

The value of T_m was taken from F. C. Krack, G. W. Morey and H. E. Merwin, Am. J. Sci. [5] 35A, 143 (1938). However, H₃BO₃(c) is in a metastable state at T_m. Measurements of the decomposition pressure of H₃BO₃(c) to form HBO₂(c, II or III) and H₂O(g) have been made by H. Menzel, H. Schulz and H. Deckert, Z. anorg. allgem. Chem. 220, 49 (1934); A. Thiel and H. Siebenack, Z. anorg. allgem. Chem. 220, 236 (1934); M. V. Stachelberg, F. Outram and J. Dussel, Z. Elektrochem. 43, 14 (1937); S. Bezzi, Gazz. chim. ital. 65, 766 (1935); and H. Tazaki, J. Sci. Hiroshima Univ. Ser. A 10, 37, 55, 63, 109, 113 (1939). The decomposition pressures of the system H₃BO₃(c) = H₂O(g) + HBO₂(c, I), at the temperatures of 312 to 352°K, have been reported by E. D. West, "The properties of Boron Compounds", ARL Technical Report 60-278, May 1960, National Bureau of Standards.

Temperature of Decomposition

The decomposition temperature (T_d) is calculated as the temperature at which the free energy change of the reaction H₃BO₃(c) + HBO₂(c) + H₂O(g) approaches zero.

Heat of Sublimation

The heat of sublimation (ΔH_s⁰ 298.15) is derived as the difference between the ΔH_f⁰ 298.15 values for H₃BO₃(g) and H₃BO₃(c).

Heat of Formation.

The vapor pressures of $\text{H}_3\text{BO}_3(\text{c})$, 109 - 140°C, were measured by M. V. Stackelberg, F. Quatram and J. Dressel, Z. Elektrochem. 53, 14 (1957). Using the vapor pressures reported, the heats of sublimation of $\text{H}_3\text{BO}_3(\text{c})$ were evaluated to be 24.4 ± 0.6 and $24.22 \text{ kcal. mole}^{-1}$ by the second and third law methods, respectively. The heat of formation ($\Delta H_f^\circ 298.15$) for $\text{H}_3\text{BO}_3(\text{c})$ was calculated from the $\Delta H_f^\circ 298.15$ and $\Delta H^\circ 298.15$ for $\text{H}_3\text{BO}_3(\text{c})$. The $\Delta H^\circ 298.15$ value adopted is the average of the second and third law values mentioned previously.

Heat Capacity and Entropy.

The molecular structure and constants were taken from O. W. F. T. Pistorius, J. Chem. Phys. 21, 1454 (1959) based on an X-ray diffraction study on $\text{H}_3\text{BO}_3(\text{c})$ by W. H. Zachariasen, Acta Cryst. 1, 305 (1954). The O-H bond distance was reestimated as 0.96 Å instead of 0.88 Å reported. From the existing infrared and Raman spectra data on $\text{H}_3\text{BO}_3(\text{c})$ and its aqueous solution C. W. F. T. Pistorius, loc. cit., carried out a normal coordinate treatment by means of Wilson's F-O matrix method and calculated the fifteen fundamental frequencies for $\text{H}_3\text{BO}_3(\text{c})$. For $\text{H}_3\text{BO}_3(\text{g})$ twelve reported frequencies were used and corrected to the average isotopic species. The three torsional frequencies, 824(1) and 209(2) cm.⁻¹, were not used based on an assumption that there are three internal rotations, i.e. three OH groups, each rotates about its own B-O bond. Employing the model of having three free rotating OH tops, the value of S_{400} was evaluated statistically as 75.522 cal. deg.⁻¹ mole.⁻¹. The corresponding value obtained by using the second law value of ΔS_{400}° , $48.39 \pm 1.42 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, for the reaction $\text{H}_3\text{BO}_3(\text{c}) = \text{H}_3\text{BO}_3(\text{g})$, is $75.97 \pm 1.42 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ which is in good agreement with the S_{400}° value based on a model having three free rotating groups. Thus the assumed model is adopted to evaluate the thermodynamic functions. The three principal moments of inertia are: $I_A = I_C = 8.3320 \times 10^{-2} \text{ g. cm.}^2$ and $I_B = 1.6664 \times 10^{-35} \text{ g. cm.}^2$. The reduced moment of inertia for OH top is $I_r = 1.15321 \times 10^{-40} \text{ g. cm.}^2$. The infrared absorption spectrum of $\text{H}_3\text{BO}_3(\text{g})$ was observed under conditions where one atmosphere of water vapor with a path length of approximately one meter as background, by F. T. Greene, O. E. Leroy, S. P. Randall, J. R. Soulen, L. H. Spinar and J. L. Margrave, "Spectra and Thermodynamic Properties of Light-Element Oxides and Hydroxides", Proceedings of the Conference on Propellant Thermodynamics and Handling, Columbus, Ohio, July, 1959. The following fundamentals were obtained: 3220 cm.⁻¹ S., 1490 cm.⁻¹ S., 1199 cm.⁻¹ S., 881 cm.⁻¹ W., and 669 cm.⁻¹ W.

POTASSIUM TETRAHYDROBORATE (KBH₄) (CRYSTAL)

MOL. WT. = 53.952

$\Delta H_f^0 = -52.15 \pm .55 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 298.15 = -54.23 \pm .55 \text{ kcal. mole}^{-1}$
 $T_d = [770]^{\circ}\text{K}$

$S_{298.15} = 25.48 \text{ cal. deg.}^{-1} \text{ mole}$

Heat of Formation.

The heat of reaction of KBH₄(c) with hydrochloric acid has been measured by solution calorimetry and reported by W. H. Johnson, R. H. Schumm, I. H. Wilson, and E. J. Prosen, J. Res. Nat'l. Bur. Std. 65A, 97 (1961)

$\text{KBH}_4(\text{c}) + \text{HCl}(\text{g}) + 3\text{H}_2\text{O}(\text{liq}) \rightarrow \text{KCl}(\text{c}) + \text{H}_3\text{BO}_3(\text{c}) + 4\text{H}_2(\text{g}) \quad \Delta H_r = -84.82 \pm .44 \text{ kcal. mole}$
The ΔH_f 298.15 value for HCl(g) and H₃BO₃(c) were obtained from the JANAP Tables. The ΔH_f 298.15 value for KCl(c) was calculated from ΔH_f 298.15 K° = -60.52 kcal. mole⁻¹, ΔH_f 298.15 Cl° = -39.952 kcal. mole⁻¹ and ΔH dilution = 4.12 kcal. mole⁻¹ obtained from NES. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans. ΔH_f 298.15 for H₂O(liq) was obtained from W. H. Evans, loc. cit. Unpublished data of The Dow Chemical Company Thermal Laboratory give a value of ΔH_f 298.15 = -55.0 ± 1.0 kcal. mole⁻¹ by solution calorimetry.

Heat Capacity and Entropy.

C_p and S° at temperatures below 298.15°K were reported by G. T. Furukawa, M. L. Reilly, and J. H. Piciorelli, J. Res. Nat'l. Bur. Std. 68A, 651 (1964). The values of C_p in the range from 298.15 to 700°K were obtained from T. B. Douglas and A. W. Harman, J. Res. Nat'l. Bur. Std. 69, 117 (1965). These two sets of C_p data were plotted and joined smoothly at 298.15°K. The values of C_p above 700°K were estimated by graphical extrapolation.

Temperature of Decomposition.

The temperature of decomposition (into constituent elements) was estimated according to a report by T. B. Douglas and A. W. Harman, loc. cit.

 $T_m = [750^\circ \text{K.}]$

Heat of Formation.

The heat of formation of $\text{LiBH}_4(\text{c})$ was calculated from the solution calorimetry of W. D. Davis, L. S. Mason, and G. Stegeman J. Am. Chem. Soc. **71**, 2775 (1949). The heats of reaction were measured for the following reactions:

$\text{LiBH}_4(\text{c}) + 1.25(\text{HCl} \cdot 200 \text{ H}_2\text{O}) + 3 \text{ H}_2\text{O}(l) \rightarrow (\text{NaCl} + \text{H}_3\text{BO}_3 + 0.25 \text{ HCl}) \cdot 247 \text{ H}_2\text{O} + 4 \text{ H}_2(\text{g})$ $\Delta H_{298.15}^0 = -72.14 \text{ kcal.}$

$\text{LiCl} \cdot 60 \text{ H}_2\text{O} + \text{H}_3\text{BO}_3 \cdot 60 \text{ H}_2\text{O} + 0.25(\text{HCl} \cdot 508 \text{ H}_2\text{O}) \rightarrow (\text{LiCl} + \text{H}_3\text{BO}_3 + 0.25 \text{ HCl}) \cdot 247 \text{ H}_2\text{O}$ $\Delta H_{298.15}^0 = 0.00 \text{ kcal.}$

$\text{H}_3\text{BO}_3 \cdot 60 \text{ H}_2\text{O} + \infty \text{ H}_2\text{O} \rightarrow \text{H}_3\text{BO}_3 \cdot \infty \text{ H}_2\text{O}$ $\Delta H_{298.15}^0 = 0.200 \text{ kcal.}$

The summation of the above reactions yields:

$\text{LiBH}_4(\text{c}) + 1.25(\text{HCl} \cdot 200 \text{ H}_2\text{O}) + 3 \text{ H}_2\text{O}(l) + \infty \text{ H}_2\text{O} \rightarrow \text{LiCl} \cdot 60 \text{ H}_2\text{O} + \text{H}_3\text{BO}_3 \cdot \infty \text{ H}_2\text{O} + 0.25(\text{HCl} \cdot 508 \text{ H}_2\text{O}) + 4 \text{ H}_2(\text{g})$

The heat of formation of Lithium Borohydride crystal was calculated to be -45.522 kcal. mole⁻¹ with the following auxiliary data:

Heat Capacity and Entropy.

The low temperature heat capacities, 15-72 - 302.88 °K were obtained from the measurements by N.C. Hallett and H. L. Johnston, J. Am. Chem. Soc., **75**, 1496 (1953). The C_p values above 298.15°K were estimated by comparison with the C_p 's for NaBH_4 .

The entropy was based on S_{15}^0 (extrap) = 0.0874 reported by N. C. Hallett and H. L. Johnston loc. cit.

Melting Data.

T_m was estimated by comparison with the T_m for NaBH_4 .

$$\Delta H_m^o = \text{Unknown}$$

Heat of Formation.

The heat of formation was calculated from the solution calorimetry of W. D. Davis, L. S. Mason and G. Stegeman, J. Am. Chem. Soc. **71**, 2775 (1949). The heats of reaction and mixing were measured for the following reactions:

The summation of the above equations yields:

$$\Delta H_r = -63.889 \text{ kcal. mole}^{-1}$$

The ΔH_f 298.15 values for HCl were obtained from JANAF values for HCl(g) and heat of dilution data of NBS. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans. The ΔH_f 298.15 $\text{H}_2\text{O}(l)$ value was obtained from W. H. Evans loc. cit. The ΔH_f 298.15 value for NaCl was obtained from JANAF value of NaCl(c) together with dilution data from W. H. Evans, loc. cit. The ΔH_f 298.15 value for H_3BO_3 was obtained from JANAF value for $\text{H}_3\text{BO}_3(c)$ together with dilution data of J. Smisko and L. S. Mason, J. of Am. Chem. Soc. **72**, 3679 (1950).

Heat Capacity and Entropy.

The low temperature heat capacity (15.76 - 301.26) was obtained from H. L. Johnston and N. C. Hallett, J. Am. Chem. Soc. **75**, 1467 (1953). In the area of transition (169-193.5°K) the average $\Delta H = 635.3$ cal./mole and the average $\Delta S = 3.35$ cal./mole °K were adopted from H. L. Johnston and N. C. Hallett, loc. cit. Using the present base line these ΔH and ΔS values yield a heat of transition of 0.2388 kcal. mole⁻¹. The low temperature heat capacity was fitted with the smoothed heat capacity data (288.15 - 700°K) of T. B. Douglas and A. W. Harman, J. Research Natl. Bur. Standards **60**, 117 (1956). The heat capacity above 700°K was extrapolated from the plot of both sets of data.

Transition Data.

The temperature and heat of transition were obtained from H. L. Johnston and N. C. Hallett loc. cit.

Melting Data.

The melting data was obtained from T. B. Douglas and A. W. Harman loc. cit.

Ground State Configuration [1Σ⁺]

S_{298.15}° = [55.604] cal. deg.⁻¹ mole⁻¹

ΔH_f° 298.15 = [73.0 ± 10] kcal. mole⁻¹

Electronic Levels and Quantum Weight

E _i	E _i
0	[1]

ω_e = [600] cm.⁻¹

σ = 1

α_e = [0.3912] cm.⁻¹

r_e = [2.08] Å

Heat of Formation.

The ratio D(BI) / (ΔH_f(BI₃)/3) = 1.177, where ΔH_f signifies the heat of atomization, was applied to BI₃ giving D(BI) = 84.4 kcal. mole⁻¹ and ΔH_f 298 = 75 ± 10 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond length was first estimated by comparison with the ratio of the bond lengths in the other boron trihalides and monohalides. The vibrational frequency was then calculated using Guggenheim's Relation [Proc. Phys. Soc. (London) 58, 456 (1946)] which was checked using BBr and shown to give an excellent fit. The quantity X_eμ^{1/2}, where μ is the reduced mass, has been shown to be constant for similar molecules and its value was transferred from BBr to give X_e and ω_e for BI. α_e was then calculated using the Morse potential function and E_e was determined from the bond length. The ground state configuration was assumed to be the same as that in BBr.

Point Group [C_{2v}]
 $S^{\circ}_{298.15} = [73.964] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H^{\circ}_{f, 0} = [58.5 \pm 15] \text{ kcal. mole}^{-1}$
 $\Delta H^{\circ}_{f, 298.15} = [58.0 \pm 15] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight [2]

Vibrational Levels and Degeneracies

ω , cm.⁻¹
 (550)(1)
 (110)(1)
 (770)(1)

Bond Distance: B-I = [2.06] Å
 Bond Angle: I-B-I = [120°]
 Product of the Moments of Inertia: $I_A I_B I_C = 3.33503 \times 10^{-113} \text{ g. cm.}^2$
 $\sigma = 2$

Heat of Formation

The heat of formation was estimated by analogy with BF₃, specifically the ratio

$$\Delta H_f(BX_3) \rightarrow BX_2 + X / \Delta H_f(BX_3) \rightarrow B + 3X$$

was taken as 0.347.

Heat Capacity and Entropy

The vibrational frequencies were obtained from force constants transferred from the trihalide given by O. Herzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono end trihalide and the angle was estimated to be the same as that in the trihalides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were $I_B = 1.8278 \times 10^{-39} \text{ g. cm.}^2$, $I_A = 134.1670 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 135.9946 \times 10^{-39} \text{ g. cm.}^2$

MOL. WT. = 391.55

(IDEAL GAS)

BORON TRIIODIDE (BI₃)

Point Group D_{3h}
S_{298.15} = 83.322 cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight [1]
ΔH_f⁰ = 18.0 ± 12 kcal. mole⁻¹
ΔH_f⁰ 298.15 = 17.0 ± 12 kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	Deg.
190(1)	339(1)
710(2)	100(2)
100(2)	100(2)

Bond Distances: B-I = [2.03 ± 0.03] Å
Bond Angle: I-B-I = [120°]

Product of the Moments of Inertia = [4.418202] X 10⁻¹¹¹ g.³ cm.⁶
σ = 6

Heat of Formation.

W. S. Koski, J. J. Kaufman and C. F. Pachuki, J. Am. Chem. Soc. 81, 1326 (1959) measured the appearance potential of the B⁺ ion from BI₃. Assuming the reaction

one can calculate the heat of atomization of BI₃ as 8.31 ± 0.5 e.v. The analogous reaction for BI₃ can be checked independently and shows the process to be valid. This value leads to a ΔH_f⁰ 298 = 17.0 ± 12 kcal. mole⁻¹, if the process is assumed to occur at 298°K.

Heat Capacity and Entropy.

Vibrational frequencies were taken from T. Wentink and V. H. Tienau, J. Chem. Phys. 28, 828 (1958) modified according to the natural abundance of boron. The B-I distance was estimated by Koski et al., loc. cit., and the angle was estimated by analogy with the other boron trihalides. The three principal moments of inertia are: I_A = I_B = 1.30238 X 10⁻³⁷ and I_C = 2.60476 X 10⁻³⁷ g. cm.²

June 30, 1961; Dec. 31, 1964

$S_{298.15}^0 = 12.351 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1117 \pm 1^\circ \text{K.}$

Heat of Formation.

O. C. Sinke, Thermal Research Laboratory, The Dow Chemical Co., private communication, July 1980 has measured ΔH_f^0 298.15 for the following reaction:

$$\Delta H_f^0 298.15 = -10.93 \pm 0.05 \text{ kcal. mole}^{-1}$$

From this heat of reaction the ΔH_f^0 298.15 for $\text{LiBO}_2(c)$ is calculated to be $-243.29 \text{ kcal. mole}^{-1}$ with the following auxiliary heats of formation:

$$\Delta H_f^0 298.15 (\text{kcal. mole}^{-1})$$

$$-258.23$$

$$-49.44$$

$$-68.315$$

$$-115.747$$

Source

Dilution data from J. Sinaka and L. S. Mason, J. of Am. Chem. Soc. 72, 3879 (1950)

NBS. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans

 July, 1958.

**Dilution and other auxiliary data from W. H. Evans, loc. cit.

L. Shartsa and W. Cappa, J. Am. Ceram. Soc. 37, 27 (1954), measured the heats of solution in nitric acid of various $\text{Li}_2\text{O}-\text{B}_2\text{O}_3$ glasses and crystalline mixtures containing 0 to 46 mole % Li_2O . These results were extrapolated to 50 mole % and yielded ΔH_f^0 298.15 = $-45.20 \text{ kcal. mole}^{-1}$ for the following reaction:

With JANAF values for $\text{Li}_2\text{O}(c)$ and $\text{B}_2\text{O}_3(c)$ the ΔH_f^0 298.15 for $\text{LiBO}_2(c)$ was calculated to be $-245.97 \pm .80 \text{ kcal. mole}^{-1}$. This value is in fair agreement with the value adopted for the table.

$$\Delta H_f^0 298.15 = -53.115 \pm 0.019 \text{ kcal. mole}^{-1}$$

$$\Delta H_{\text{dilution}}^0 298.15 = +102 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 298.15 = 0.00$$

$$\Delta H_f^0 298.15 = 0.00$$

$$\Delta H_f^0 \text{ dilution} = .171 \text{ kcal. mole}^{-1}$$

Heat Capacity and Entropy.

P. L. Oetting and W. E. Hutton, The Dow Chemical Company, private communication, April, 1961, have measured C_p from 13° to 328°K. R. A. McDonald, Thermal Research Laboratory The Dow Chemical Company, private communication, April, 1961 has measured H_f^0 - $H_{298.15}^0$ from 289° to 1116°K. The above data were adopted for the table. The C_p values above T_m were obtained by graphical extrapolation.

The entropy was based on $S^\circ = .013 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$ at 15°K. calculated from the low temperature C_p values of P. L. Oetting and W. E. Hutton loc. cit.

Melting Data.

The T_m and ΔH_m adopted for this table were obtained from R. A. McDonald loc. cit. The following cryoscopic data have been published: C. Petit and M. Jaeger, Compt. rend. 244, 1734 (1957), $T_m = 1109^\circ \text{K.}$, $\Delta H_m = 7.4 \text{ kcal. mole}^{-1}$; O. Zarsky, colloques Intern, centre, nat'l. recherche sci. (Paris) 39, Electrolyse 634-637 (1952), $\Delta H_m = 8.3 \pm 0.8 \text{ kcal. mole}^{-1}$; C. Sutra, Compt. rend. 234, 1283 (1952), $T_m = 1113^\circ \text{K.}$ and $\Delta H_m = 8.3 \text{ kcal. mole}^{-1}$.

$\Delta H_f^o = [50.79] \text{ kcal. mole}^{-1}$
 $\Delta F_f^o = [-238.819] \text{ kcal. mole}^{-1}$
 $\Delta H_m^o = 8.09 \pm .10 \text{ kcal. mole}^{-1}$
 $\Delta F_m^o = [50.79] \text{ kcal. mole}^{-1}$

Heat of Formation.

$\Delta H_f^o(l)$ was obtained from $\Delta H_f^o(c)$ by addition of ΔH_m^o end difference between ($H_{1117}^o - H_{298.15}^o$) for the crystal and liquid.

Heat Capacity and Entropy.

R. A. McDonald, Thermal Research Laboratory, The Dow Chemical Company, private communication, April 1961, has measured $H_m^o - H_{298.15}^o$ from 1118° to 1707°K. The constant value of C_p measured between 1118° and 1707°K. has been extrapolated above and below this range. Lithium metaborate is assumed to have a glass transformation temperature at 745°K. below which C_p of the glass is assumed equal to that of the crystal.

The entropy of the liquid was calculated from the entropy of the crystal in a manner analogous to the heat of formation.

Melting Data.

The ΔH_m^o and T_m values were obtained from R. A. McDonald loc. cit.

Vaporization Data.

The boiling point was found from graphing the ΔF_f^o of the liquid and gas. The heat of vaporization was found from the difference in ΔH_f^o of the liquid and gas at T_b .

Point Group C_s

$$\Delta H_f^\circ = -159.54 \pm 1.1 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^\circ = -160.38 \pm 1.1 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = [61.742] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\text{Ground State Quantum Weight} = [1]$$

$$\text{Bond Distances: Li-O} = 1.82 \text{ \AA}, \text{ O-B} = 1.36 \text{ \AA}, \text{ B-O} = 1.20 \text{ \AA}$$

$$\text{Bond Angles: LiOB} = 100^\circ, \text{ O-B-O} = 180^\circ$$

$$\text{Product of the Moments of Inertia: } I_A I_B I_C = 4.01933 \times 10^{-115} \text{ g. cm.}^6$$

Heat of Formation.

The adopted heat of formation at 298.15 was evaluated by the third-law method using vapor pressure data reported by D. L. Hildenbrand, M. P. Hall and N. D. Potter, J. Chem. Phys. **39**, No. 2, 296 (1963). The heat of reaction at 298.15 was found to be 82.908 kcal. mole⁻¹ thus giving the value $\Delta H_f^\circ = -160.382$ kcal. mole⁻¹. A second-law method was also used on the data of D. L. Hildenbrand et. al., loc. cit. and yielded a $\Delta H_f^\circ = 91.375$ kcal. mole⁻¹ thus giving $\Delta H_f^\circ = -161.915$ kcal. mole⁻¹. A. Buehler and J. B. Berkowitz-Mattuck, J. Chem. Phys. **39**, No. 2, 286 (1963), have measured the vaporization of lithium metaborate mass spectrometrically in an effusion cell. The second law value reported by A. Buehler and J. B. Berkowitz-Mattuck, loc. cit. for ΔH_f° was 79 ± 3 kcal. mole⁻¹ which yields $\Delta H_f^\circ = 84.078$ kcal. mole⁻¹ thus giving $\Delta H_f^\circ = -159.212$ kcal. mole⁻¹ with JANAF auxiliary values.

Heat Capacity and Entropy.

A. Buehler and E. P. Merram, J. Chem Phys. **39**, No. 2, 292, (1963), observed and assigned two vibrational frequencies to lithium metaborate which were adopted for this table. The other vibrational frequencies were estimated by comparison with similar molecules. D. White, Ohio State University, in a private communication quoted in D. L. Hildenbrand et. al. loc. cit. assigned vibrational frequencies from matrix-isolation experiments. When these frequencies were used in a third and second law analysis of Hildenbrand's data, the drift in the third law was much larger and the agreement between the second and third law was also much poorer than that using the frequencies employed in this table. The molecular constants were obtained from P. A. Akishin and V. P. Spiridonov, Zhur. Strukt. Khim. **2**, 63 (1961). The individual moments of inertia are: $I_A = 1.22164 \times 10^{-38} \text{ g. cm.}^2$, $I_B = 2.2710 \times 10^{-39} \text{ g. cm.}^2$, and $I_C = 1.44875 \times 10^{-38} \text{ g. cm.}^2$.

BORON NITRIDE (BN)

(CRYSTAL)

OFW = 24.8177

$$\Delta H_f^\circ = -59.27 \pm 0.37 \text{ kcal/mol}$$

$$\Delta H_f^{298} = -59.97 \pm 0.37 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 3.556 \text{ gibbs/mol}$$

$$T_D = 2600 \pm 100^\circ\text{K}$$

Heat of Formation.

The adopted heat of formation was determined by Wise et al. using combustion in fluorine. Other recent calorimetric values are in good agreement as summarized below. Torsion-effusion studies of the decomposition $\text{BN(c)} \rightarrow \text{B(am)} + 0.5 \text{ N}_2(\text{g})$ by D. L. Hildenbrand and W. F. Hall, *J. Phys. Chem.* **67**, 888 (1963), yield essentially the same ΔH_f° and indicate that the condensation coefficient, α , is $< 6 \times 10^{-3}$ for $\text{N}_2(\text{g})$ on the surface of the sample. Use of $\alpha = 6 \times 10^{-3}$ brings the following decomposition studies into reasonable agreement: Langmuir studies by L. H. Dreyer, V. V. Dadape and J. L. Margrave, *J. Phys. Chem.* **66**, 1556 (1962); mass spectrometric studies by P. O. Schissel and W. S. Williams, *Bull. Am. Phys. Soc.*, **II**, 4, 139 (1959); and Knudsen effusion studies by M. Hoch and D. White, Technical Research Report MCC-1023-TM-214, Ohio State University Research Foundation, Columbus, Ohio, October, 1956.

Heat Capacity and Entropy.

The low temperature heat capacity was taken from E. F. Westrum, Jr., private communication, May 19, 1960. The intermediate heat capacity (300-1650°K) was obtained from R. A. McDonald and D. R. Stull, *J. Phys. Chem.* **65**, 1918 (1961). The high temperature Cp was taken from H. Prophet and D. R. Stull, *J. Chem. Eng. Data* **8**, No. 1, 78, January 1963. The heat capacities in the three temperature ranges were plotted and then graphically smoothed. A. S. Dworkin, D. J. Samor, and A. R. Van Arsdale, loc. cit., also reported heat capacity (50-300°K) not employed in this table.

The entropy was obtained by integration of the heat capacity data from E. F. Westrum, Jr., loc. cit., based upon $S_{10}^\circ = 0.0028 \text{ eu}$.

Temperature of Decomposition.

Observations by The Dow Chemical Company under Contract No. AF 33(616)-6149 show decomposition to elements at 1 atm total pressure at $2600 \pm 100^\circ\text{K}$. The decomposition temperature calculated from these tables is 2832°K ; presumably this discrepancy is associated with uncertainties in the high temperature enthalpies of BN(c) , B(c) and E(1) and the enthalpy of melting of B(c) .

Heat of Formation.

The heat of formation is based on $D_0 = 5.7$ eV which was calculated from ω_e and $\omega_e x_e$ observed by A. E. Douglas and G. Herzberg, Can. J. Research 18A, 179 (1940). An uncertainty of ± 1.3 eV was assigned from consideration of other information which places the dissociation energy between 4 and 7 eV. The value $D_0 = 4.0 \pm 0.5$ eV was selected by A. G. Gaydon, "Dissociation Energies," second edition, Chapman and Hall Ltd, London, 1953, from his own extrapolation of the spectroscopic data. An upper limit of $D_0 \leq 7.0$ eV results from the upper limit for the pressure of BN(c) $\rightarrow$ BN(g) obtained from the B^+ ion intensity at 1600°C observed by P.A. Akhahin and Yu. S. Klodeev, Zh. Neorgan. Khim. 7, 941 (1962). It is likely that the BN(g) pressure is even smaller since it is known that BN(c) $\rightarrow$ B(s) + 0.5 N₂(g) and Akhahin's pressure limit are the same magnitude as that of B(s) $\rightarrow$ B(g). V. V. Pesenko, Forshkovaya Met., Akad. Nauk Ukr. S. S. R. 3, No. 4, 80-5 (1961) [cf. Chem. Aba. 56, 10997 (1962)], reports a standard heat of sublimation of 160 kcal/mol for BN(c) $\rightarrow$ BN(g) and also gives pressures for BN(g) at 2500 and 3000°K which are stated to be two orders less than the equilibrium pressure of nitrogen. Pesenko's original article is not yet available to us and it is not clear from the abstract whether the values are based on new data or are mere calculations. The reported pressures yield $D_0 = 6.2$ eV, but here again the BN(g) pressures are of the same magnitude as the JANAP values for B(s) $\rightarrow$ B(g).

Some estimated values for D_0 (ranging from 5.4 to 6.4 eV) are summarized below along with the experimental evidence.

Source	D_0 (eV)	ΔH°_{298} (kcal/mol)	ΔH°_{298} (kcal/mol)
Gaydon's extrapolation of spectroscopic data	4.0 $\pm$ 0.5	213	153
Linear Birge-Sponer extrapolation	5.7	174	114
Pesenko's "BN(g) pressures"	6.2	161	101
Akhahin's upper limit for BN(g) pressure	7.0	145	85
Estimate from geometric mean of D_0 for B ₂ and N ₂	5.4	180	120
Estimate from D_0 for series N ₂ , CN, BN, Ben	5.6	177	117
Estimate M ₂ + N ₂ = 2 MN for M-B from M-C	6.0	166	106
Estimate from arithmetic mean of D_0 for B ₂ and N ₂	6.4	158	98

Heat Capacity and Entropy.

The molecular constants are based on emission spectra of the $3\pi - 3\pi$ transition obtained by Douglas and Herzberg, loc. cit. Observation of the same triplet in absorption by B. A. Thrush, Nature 160, 1044 (1960), strongly suggests that the ground state of BN is 3π in contrast to 1Σ as observed for the isoelectronic molecules BeO and C₂. Electronic levels for the 3π states are taken from Douglas and Herzberg while values for $1\Sigma^+$ and 1π have been estimated from the SCF calculations of J. L. Mease and M. Barlocher, Helv. Chim. Acta 47, 314 (1964).

$$T_m = 1239^\circ \text{K.}$$

Heat of Formation.

W. H. Evans, D. D. Magman and E. J. Prosen in NBS Report No. 4943, "Thermodynamic Properties of Some Boron Compounds", August, 1956, extrapolated from the graph of L. Shartais and W. Cappa, J. Am. Ceram. Soc. **37**, 27 (1954) the heat of solution to be -25.4 kcal. mole⁻¹ for the first reaction in 2N nitric acid. G. Grenier and D. White, J. Chem. Phys. **51**, 1661 (1957) measured the heat of solution at 273.15°K. in 2N nitric acid for the first reaction and found a value of -20.43 kcal. mole⁻¹. The heats of solution for the second and third reactions were obtained from L. Shartais and W. Cappa, loc. cit.

1. Na₂O·B₂O₃(c) + Solvent I = end Solution I
2. B₂O₃(c) + Solvent II = end Solution I
3. Na₂O(c) + Solvent I = Solvent II

The combination of the above reactions yields:

$$\text{Na}_2\text{O}(c) + \text{B}_2\text{O}_3(c) = \text{Na}_2\text{O} \cdot \text{B}_2\text{O}_3(c)$$

$$1/2 \text{ Na}_2\text{O}(c) + 1/2 \text{ B}_2\text{O}_3(c) = \text{NaBO}_2(c)$$

The ΔH_f⁰ 298.15's for Na₂O and B₂O₃ are JANAF values. The ΔH_f⁰ 298.15 value of -234.000 kcal. mole⁻¹ employed in this table was obtained by taking the average of the values given above for reaction 1. Since there were uncertainties in the extrapolation and in assuming no correction for the measurements at 273.15°K., an average value was considered preferable.

Heat Capacity and Entropy.

The low temperature heat capacities (5-298.15°K.) and S_{298.15}⁰ were obtained from G. Grenier and E. P. Westrum, J. Am. Chem. Soc. **78**, 6226 (1956). The heat capacities at the higher temperatures were altered slightly from the estimate of K. K. Kelley, U. S. Bureau of Mines Bulletin 393 (1936).

Melting Data.

The T_m was obtained from H. S. Van Klooster, Z. Anorg. Chem. **53**, 122 (1911). The adopted ΔH_m⁰ was calculated by K. K. Kelley loc. cit. from H. S. Van Klooster's work. K. K. Kelley also calculated a ΔH_m⁰ of 9.3 kcal. mole⁻¹ from M. H. LaChâtelier, Compt. rend. **118**, 800 (1894).

Sublimation Data.

The ΔH_g⁰ was obtained from the mass spectrometric investigations of A. Büchler and J. B. Berkowitz-Mattuck, J. Chem. Phys. **39**, 286 (1963).

Sodium Metaborate (NaBO₂)

(Liquid) Mol. Wt. = 65.811

SODIUM METABORATE (NaBO₂)

(LIQUID)

MOL. WT. = 65.811

$\Delta H_f^{298.15} = 20.560 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1239^\circ\text{K.}$
 $\Delta H_f^{298.15} = [-229.339] \text{ kcal. mole}^{-1}$
 $\Delta H_m^0 = 8.66 \text{ kcal. mole}^{-1}$

$\Delta H_f^{298.15(1)}$ was obtained from $\Delta H_f^0(c)$ by addition of ΔH_m^0 end difference between ($H_{1239}^0-H_{298.15}^0$) for the crystal end liquid.

Heat Capacity and Entropy.

Sodium metaborate is assumed to have a glass transformation at 826°K. below which C_p of the glass is assumed equal to that of the crystal. Above 826°K. the heat capacity was estimated as a constant value by assuming 8.75 calories contribution from each atom. The $S_{298.15}$ was obtained in a manner analogous with $\Delta H_f^{298.15}$.

Melting Data.

See crystal table.

 $\sigma = 1$

Heat of Formation.

The heat of formation was calculated from the heat of sublimation of $73 \pm 3 \text{ kcal. mole}^{-1}$ measured mass spectrometrically at 1070°K. by A. Eichler and J. B. Berkowitz - Mattuck, *J. of Chem. Phys.* 39, 286 (1963) by addition of the difference between ($1070^\circ\text{H}_{298.15}^\circ$) for the crystal and gas.

Heat Capacity and Entropy.

A. Eichler and E. P. Murrell, *J. Chem. Phys.* 32, No. 2, 292, (1963), observed and assigned two vibrational metaborate frequencies, which were adopted for this table. The other vibrational frequencies were estimated by comparison with lithium metaborate. The molecular constants were obtained from P. A. Akishin and V. P. Spiridonov, *Zhur. Strukt. Khim.* 2, 63 (1961). The individual moments of inertia are: $I_A = 4.2923 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 26.6933 \times 10^{-39} \text{ g. cm.}^2$

Heat Capacity and Entropy

The molecular and vibrational constants for the ground etate are from G. Herzberg "Spectra of Diatomic Molecules,"

D. Van Nostrand Co., Inc., New York, 1950. The electronic levels are also given by Herzberg with the exception of the level at 3395957, a $\frac{1}{2}$ level designated B' by A. Mal'tsev and D. I. Kataev, *Vestn. Mosk. Univ. Ser. II* 22, 2 (1967). The molecular constants were all adjusted to reflect normal isotopic abundances.

BORON DIOXIDE UNINEGATIVE ION (BO₂⁻) (IDEAL GAS) GFN = 42.81035

$$\Delta H_f^\circ = -166 \pm 6 \text{ kcal/mol}$$

$$\Delta H_f^{298.15} = -166 \pm 6 \text{ kcal/mol}$$

Point Group {D_{oh}}

$$S_{298.15}^\circ = [51.6 \pm 2] \text{ gibbs/mol}$$

Electronic Levels and Quantum Weights

[2200] (1)

Bond Distances: B-O = [1.25] Å

Bond Angle: O-B-O = [180]°

Rotational Constant: B₀ = [0.3172] cm⁻¹

Heat of Formation

D. E. Jensen, AeroChem TP-187A, Dec. 1968, AeroChem Research Laboratories, Inc., Princeton, N. J., has obtained equilibrium constants for the reaction $\text{HBO}_2 + e^- \rightarrow \text{H} + \text{BO}_2^-$. This involves several assumptions the most basic of which is that boron added to H_2/O_2 flames is converted completely to HBO_2 . The free electrons are produced by addition of potassium to the flames, and their concentration is measured directly by a microwave cavity resonance method. The hydrogen atom concentration is taken from previous studies on such flames. The BO_2^- concentration is obtained from the difference between the K' concentration and the free electron measurement. The K' concentration is measured by an electrostatic probe.

By 2nd and 3rd law analysis of the data, 11 points read back from a plot, we obtain $\Delta H_f^{298}(\text{II}) = 27.5 \pm 4 \text{ kcal/mol}$ and $\Delta H_f^{298}(\text{III}) = 20 \pm 2 \text{ kcal/mol}$ with a drift of $-3.7 \pm 1.5 \text{ eu}$. The third law value yields $\Delta H_f^{298}(\text{BO}_2^-) = -166 \pm 6 \text{ kcal/mol}$ where the uncertainty includes possible errors in the functions. This corresponds to an electron affinity of BO_2^- equal to $98 \pm 6 \text{ kcal/mol}$ (4.25 eV).

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Walsh (1) prediction for 16 valence electron XV_2 molecules.

The electronic states are taken from those for $\text{CO}_2(\text{g})$ (2), which is isoelectronic with $\text{BO}_2^-(\text{g})$. The electronic level 35000 cm⁻¹ and vibrational frequencies are estimated by comparison with the corresponding values for CO_2 , CO_2^+ , and BO_2 , and, the data of Vasco and Spb (3) on the BO_2^- ion in alkali halide lattices. The B-O bond distance in $\text{BO}_2^-(\text{g})$ is assumed to be smaller than the B-O bond in $\text{BO}_2(\text{g})$, because the $\text{BO}_2^-(\text{g})$ molecule has one more bonding electron than the $\text{BO}_2(\text{g})$ molecule. The moment of inertia is $8.302 \times 10^{-39} \text{ g cm}^2$. The enthalpy at 0°K is -2.30 kcal/mol .

BORON MONOSULFIDE (BS)

(IDEAL GAS)

MOL. WT. = 42.89

Ground State Configuration 2Σ $\Delta H_f^0 = 79 \pm 18 \text{ kcal. mole}^{-1}$ $S_{298.15}^0 = 51.645 \text{ cal. deg}^{-1} \text{ mole}^{-1}$ $\Delta H_f^0 = 80 \pm 18 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

 $\frac{E_1}{0}$ $\omega_e = 1188.23 \text{ cm}^{-1}$ $\omega_e x_e = 6.396 \text{ cm}^{-1}$ $\sigma = 1$ $B_e = 0.80596 \text{ cm}^{-1}$ $\alpha'_e = 0.00618 \text{ cm}^{-1}$ $r_e = 1.609 \text{ \AA}$

Heat of Formation.

The value of ΔH_f^0 298.15 for BS(g) was calculated based on $D_0^0 = 5.1 \pm 0.8 \text{ e.v.}$ for BS(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy.

The ground state configuration, ω_e , $\omega_e x_e$, B_e , α'_e and r_e were reported by P. B. Zeeman, Can. J. Phys. 29, 336 (1951). The molecular constants used for calculation were corrected to the average isotopic species. The moment of inertia is $3.4762 \times 10^{-39} \text{ g. cm}^2$.

TITANIUM MONOBORIDE (TiB)

(CRYSTAL)

MOL. WT. = 58.711

 $\Delta H_f^\circ O = \text{Unknown}$ $\Delta H_f^\circ 298.15 = -38.3 \pm 9 \text{ kcal. mole}^{-1}$ $S_{298.15}^\circ = [8.3 \pm 1.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $T_d = [2500]^\circ K.$

Heat of Formation.

P. O. Schuessel and O. C. Trulsen, *J. Phys. Chem.*, **66**, 1492 (1962) used a mass spectrometer with Knudsen cells to study the vaporization of the titanium-boron system and obtained $\Delta F_{2340}^\circ = -118.54 \text{ kcal. mole}^{-1}$ for the reaction $\text{TiB}(c) = \text{Ti}(g) + \text{B}(g)$. This corresponds to $\Delta F_{2340}^\circ(\text{TiB}(c)) = -33.266 \pm 9 \text{ kcal. mole}^{-1}$, where 4 kcal. mole⁻¹ of the uncertainty is due to the heat of sublimation of boron. When this is reduced to 298°K. one obtains $\Delta H_f^\circ 298(\text{TiB}(c)) = -38.3 \pm 9 \text{ kcal. mole}^{-1}$. This value implies a high stability for TiB. This is also indicated by the phase studies of H. Nowotny, P. Benesovsky, C. Bruckl and O. Schob, *Monatshefte für Chemie* **92**, 403 (1961).

Heat Capacity and Entropy.

The heat capacities from 298 to 1200°K. were estimated from that of TiB₂ by assuming the difference to be the same as that between CrB and CrB₂ as determined by R. Mezaki, E. W. Tillieux, D. W. Barnes and J. L. Margrave (Paper presented at the International Symposium on Nuclear Materials, Vienna, May 1962). A linear extrapolation was assumed above 1200°K.

The heat capacities above 298°K. were also estimated from the relationship $C_p(\text{Ti}) + C_p(2\text{B}) - C_p(\text{TiB}_2) = 2/3 [C_p(\text{Ti}) + C_p(\text{B}) - C_p(\text{TiB})]$. This estimation agreed with the above to 4% over the temperature range 400 to 1000°K.

$S_{298}^\circ(\text{TiB}, c) = 8.3 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$ was calculated by the method of W. M. Latimer, *J. Am. Chem. Soc.*, **73**, 1480 (1951). Using JANAP $S_{298}^\circ(\text{TiB}_2, c) = 6.8 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$ and Latimer's value of 9.8 e.u. for the entropy contribution of Ti, an entropy contribution of -1.5 e.u. per Boron atom was calculated.

Decomposition Data.

The phase diagram given in, "The Metallurgy of the Rarer Metals - No. 4 Titanium", by A. D. McQuillan and M. K. McQuillan, Academic Press, New York (1956) was used to estimate the decomposition temperature. This diagram shows the decomposition products are TiB₂ and Ti₃B. However, Nowotny et al. (loc. cit.) have shown Ti₃B to be nonexistent and so the decomposition products are not defined, probably a eutectic of TiB and TiB₂ is involved.

Dec. 31, 1960; Dec. 31, 1964

BORON, DIATOMIC (B₂)

MOL. WT. = 21.64

(IDEAL GAS)

Ground State Configuration Σ_g^-
 $\Delta H_f^0 = 193.5 \pm 6.4$ kcal. mole⁻¹
 $S_{298.15}^0 = 48.228$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^0 298.15 = 195.0 \pm 6.4$ kcal. mole⁻¹

Electronic Levels and Quantum Weight

ϵ	ϵ , cm. ⁻¹	g_i
0	0	3
$\omega_e x_e = 9.59$ cm. ⁻¹		
$\omega_e = 1081.0$ cm. ⁻¹		
$B_e = 1.235$ cm. ⁻¹		
$\alpha_e = 0.0144$ cm. ⁻¹		
$r_e = 1.589$ Å		
$\sigma = 2$		

Heat of Formation.

The equilibrium vapor pressure of the reaction $B_2(g) \rightarrow B(g) + B(g)$ was determined by O. Verhaegen and J. Drowart, J. Chem. Phys. 37, 1367 (1962). Using the value, $P_{B_2}(g)/P_{B(g)} = 9 \times 10^{-5}$ at 2330°K. where P is partial pressure, the heat of reaction ($\Delta H_f^0 298.15$) was evaluated to be -62.2 ± 5.0 kcal. mole⁻¹. This leads to $\Delta H_f^0 298.15 = 195.0 \pm 6.4$ kcal. mole⁻¹ for B₂(g) or B₀ = 3.0 e.v. which is in excellent agreement with the value, B₀ = 3.0 ± 0.5 e.v. reported by A. O. Oeydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The value, B₀ = 3.6 e.v., estimated by O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950, yields $\Delta H_f^0 298.15 = 181.6$ kcal. mole⁻¹ for B₂(g) which is not used.

Heat Capacity and Entropy.

Molecular and spectroscopic constants were obtained from O. Herzberg, loc. cit. and corrected to the average isotopic species. The principal moment of inertia (I) is 2.26779×10^{-39} g. cm.²

Product of Moments of Inertia: I_AI_BI_C = 5.3801 X 10⁻¹¹³ g.³ cm.⁶

Heat of Formation.
The heat of formation was obtained from mass spectrometric studies; the following reactions at 1500°K. were reported by P. E. Blackburn and A. Eichler, Interim Technical Report No. 1, March 1965:

1. B₂O₃(l) → B₂O₃(g) ΔH₁ = 92.226 kcal/mole
2. 1/3 Be₃P₂O₆(c) + 2/3 B₂O₃(l) → Be(BO₂)₂(g) ΔH₂ = 118 ± 2 kcal/mole
3. Be₃P₂O₆(c) → 3BeO(c) + B₂O₃(g) ΔH₃ = 112 ± 1 kcal/mole
4. Be₃P₂O₆(c) → 2BeO(c) + Be(BO₂)₂(g) ΔH₄ = 137 ± 3 kcal/mole
5. 3BeO(c) + B₂O₃(l) → Be₃P₂O₆(c) ΔH₅ = -23 kcal/mole
6. BeO(c) + B₂O₃(g) → Be(BO₂)₂(g) ΔH₆ = 22 kcal/mole

The value of ΔH₁ was obtained from JANAP values for B₂O₃(l) and B₂O₃(g). The values for ΔH₂, ΔH₃ and ΔH₄ were obtained from P. E. Blackburn and A. Eichler loc. cit. The value for ΔH₅ was obtained by taking the average of ΔH₂-ΔH₁ + 1/3 ΔH₃ = -19.774 kcal/mole, and ΔH₅ = 3/2 (ΔH₂-ΔH₄) = -28.5 kcal/mole. The ΔH₆ value was obtained by taking the average of ΔH₆ = ΔH₄-ΔH₃ = 25 kcal/mole and ΔH₆ = ΔH₂-ΔH₁ + 1/3 ΔH₃ = 18.107 kcal/mole. The ΔH_f 298.15 of BeB₂O₄ was calculated from reaction 6 with auxiliary JANAP values.

Heat Capacity and Entropy.

The vibrational frequencies estimated by comparison with B₂O₃, were adjusted to obtain an S₂₉₈ = 127 obtained in a manner analogous with ΔH_f from the report of P. E. Blackburn and A. Eichler loc. cit. The frequencies listed are not in point group order. All other molecular constants were estimated by comparison with related boron oxide molecules. The individual moments of inertia are I_A = 8.5561 X 10⁻³⁹ g.² cm.², I_B = 75.1345 X 10⁻³⁹ g.² cm.² and I_C = 83.6903 X 10⁻³⁹ g.² cm.²

Dihedral angle between two BCl₂ planes = 90°Product of the Moments of Inertia: I_AI_BI_C = 5.33449 X 10⁻¹¹² g.³ cm.⁶

Heat of Formation

S. R. Gunn, L. G. Green and A. I. Von Egidy, J. Phys. Chem. 63, 1787 (1959) determined the enthalpy change (ΔH_f⁰) of the reaction B₂Cl₄(l) + Cl₂(g) = 2BCl₃(g). From the value, ΔH_f⁰ 298.15 = -87.3 ± 0.6 kcal. mole⁻¹, the heat of formation for B₂Cl₄(l) was calculated as -125.32 ± 1.20 kcal. mole⁻¹. Based on ΔH_f⁰ 318.7 = 8.029 kcal. mole⁻¹ reported by G. Urry, T. Sarti, R. E. Moore and H. I. Schlesinger, J. Am. Chem. Soc. 76, 5293 (1954), the heat of formation for B₂Cl₄(g) was derived to be -116.9 ± 1.2 kcal. mole⁻¹.

Heat Capacity and Entropy

The vibrational frequencies, molecular structure and constants were taken from D. E. Mann and L. Pano, J. Chem. Phys. 25, 1665 (1957). The barrier restricting internal rotation about the B-B single bond is fixed at 1.53 ± 0.60 kcal. mole⁻¹ obtained from E. A. Mason and M. Kreevy, J. Am. Chem. Soc. 77, 5608 (1955). The three principal moments of inertia are: I_A = 1.00465 X 10⁻³⁷, I_B = 5.28520 X 10⁻³⁸ and I_C = 1.00465 X 10⁻³⁷ g. cm.². The reduced moment of inertia for BCl₂ top is I_r = 1.3213 X 10⁻³⁸ g. cm.².

Bond Distance: B-B = 1.67 Å B-P = 1.32 Å
Bond Angle: P-B-P = 120° P-B-B = 120°
Product of the Moments of Inertia: I_AI_BI_C = 2.50147 × 10⁻¹¹³ g.³ cm.⁶

Heat of Formation

The heat of formation was calculated based on the value, ΔH_f° = -82.0 ± 1.0 kcal. mole⁻¹ for the reaction B₂F₄(g) + Cl₂(g) = 0.92 BP₃(g) + 0.46 BP₂Cl(g) + 0.32 BP₂Cl₂(g) + 0.30 BP₂Cl₃(g) reported by S. R. Gunn and L. G. Green, J. Phys. Chem. 65, 178 (1961).

Heat Capacity and Entropy

The molecular and spectroscopic constants were obtained from J. N. Gayles and J. Self, J. Chem. Phys. 40, 3530 (1964). The vibrational frequencies were corrected to the average isotopic species. The molecular configuration was reported to be staggered, analogous to that observed for BCl₃(g). The angle between two B-P₂ planes is approximately 90°. The thermodynamic functions were evaluated based on an assumption that there is free rotation at B-B bond between the two BP₂ rotating tops. The internal moment of inertia is 4.12218 × 10⁻³⁹ g. cm.². The three principal moments of inertia are: I_A = 3.89497 × 10⁻³⁸ g. cm.², I_B = 1.64887 × 10⁻³⁸ g. cm.², and I_C = 3.89497 × 10⁻³⁸ g. cm.². The reduced moment of inertia for BP₂ top is I_r = 4.12218 × 10⁻³⁹ g. cm.².

BORON DIHYDROXIDE, DIMERIC (B₂(OH)₄)
(CRYSTAL)

MOL. WT. = 89.65148

$\Delta H_f^\circ 0$ = Unknown
 $\Delta H_f^\circ 298.15 = -337.1 \pm 2.0$ kcal. mole⁻¹
 $S_{298.15}^\circ = [30 \pm 1]$ cal. deg.⁻¹ mole⁻¹
 T_m = Unknown
 ΔH_m° = Unknown
 $\Delta H_g^\circ 298.15 = [30.1]$ kcal. mole⁻¹

Heat of Formation.

The enthalpy change, $\Delta H_f^\circ 298.15 = -91.3 \pm 1.0$ kcal. mole⁻¹, for the reaction $B_2(OH)_4(c) + (m + 2) \cdot AgNO_3(aq.) + (n + 2) \cdot H_2O(l) = 2Ag(c) + \{2m_3BO_3 + 2HNO_3 + mAgNO_3\} \cdot nH_2O(aq.)$ was determined calorimetrically by A. Finch, P. J. Gardner and I. J. Hyams, Trans. Faraday Soc. 61, 649 (1965). The heat of formation of $B_2(OH)_4(c)$ was reported to be -335.1 kcal. mole⁻¹. This value was corrected to be -337.1 $\pm$ 2 kcal. mole⁻¹ by use of more recent data on the $\Delta H_f^\circ 298.15$ values used for calculation.

Heat Capacity and Entropy.

The heat capacity for $B_2(OH)_4(c)$ was estimated by comparison with those for $B(OH)_3(c)$. The value of $S_{298.15}^\circ$ was calculated based on 3 cal. deg.⁻¹ mole⁻¹ per atom for $B_2(OH)_4(c)$, which was obtained from the corresponding values for $HBO_2(c)$ and $B(OH)_3(c)$.

Heat of Sublimation.

The value, $\Delta H_g^\circ 298.15$, was calculated as the difference between $\Delta H_f^\circ 298.15$ for $B_2(OH)_4(g)$ and $B_2(OH)_4(c)$.

Bond Distances: B-B = $[1.67]$ Å O-B-O = $[120]^\circ$ O-B-B = $[120]^\circ$ O = 2

Bond Angles: H-O-B = $[114]^\circ$ O-B-O = $[120]^\circ$ O-B-B = $[120]^\circ$

Product of the Moments of Inertia: $I_A I_B I_C = [2.2995 \times 10^{-41}] \text{g.}^3 \text{cm.}^6$

Heat of Formation.

The heat of formation (ΔH_f° 298.15) for $\text{B}_2(\text{OH})_4(\text{g})$ was calculated, using bond energies, $D(\text{B-OH}) = 132$ and $D(\text{B-B}) = 79$ kcal. mole $^{-1}$. The bond energy $D(\text{B-OH})$ was taken from that in $\text{B}(\text{OH})_3(\text{g})$ and $D(\text{B-B})$ was estimated by comparison with that in $\text{B}_2\text{P}_4(\text{g})$.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that for $\text{B}_2\text{P}_4(\text{g})$, i.e. the two $\text{B}(\text{OH})_2$ units have staggered configuration, and free rotation about B-B bond. The B-B bond distance was taken as that in B_2P_4 molecule. Those for B-O and B-H bond and bond angles were adopted from H_2BO_3 molecule. Eleven vibrational frequencies were assumed to be the same as those for $\text{B}_2\text{P}_4(\text{g})$. In addition to these were added four OH torsion frequencies, 824(2) and 209(2), four OH stretching, 3200(4), and four B-O-H bending frequencies, 1200(2) and 880(2). The thermodynamic functions were evaluated based on a molecular model having free internal rotation of two $\text{B}(\text{OH})_2$ groups about B-B bond. The reduced moment of inertia for the rotation is calculated as $4.10146 \times 10^{-39} \text{g.}^2 \text{cm.}^2$. The three principal moments of inertia are: $I_A = 1.64037 \times 10^{-38}$ and $I_B = I_C = 3.7441 \times 10^{-38} \text{g.}^2 \text{cm.}^2$.

Heat Capacity and Entropy.

The molecular constants reported by B. L. Gornoll, "Electron Diffraction Investigation of Diborane and Boron-alkyls", Thesis, Iowa State University of Science and Technology, 1963, were selected. They agree well with those reported by K. Hedberg, and V. Schomaker, J. Chem. Phys. **22**, 985 (1954). The principal moments are I_A = 1.0578 × 10⁻³⁹, I_B = 4.6416 × 10⁻³⁹, and I_C = 5.0229 × 10⁻³⁹ g. cm.²

The vibrational frequencies for B₂H₆ were those listed by E. C. Wu, Thesis, University of Minn. 1962, "Assignments and Force Constants of Diborane and Isotopic Derivatives" except for ν₈, ν₁₀ and ν₁₄ which were taken from the calculated frequency column of table VIII-1 page 55 of the Thesis.

Heat of Formation.

The equilibrium constants (933 - 1108°K.) for the reaction $2\text{MgB}_2(c) = \text{Mg}(g) + \text{MgB}_4(c)$ were determined by M. Wright and P. N. Walsh, "The Vaporization of $\text{MgB}_4(c)$ ", Technical Research Report OMCO-HEP-55, Jan. 9, 1958, Ohio State University Research Foundation. The corresponding second and third law values of $\Delta H^\circ_f 298.15$ for this reaction were derived as 53.1 ± 4.7 and $54.1 \text{ kcal. mole}^{-1}$, respectively. Using the third law value obtained, i.e. $\Delta H^\circ_f 298.15 = 54.1 \text{ kcal. mole}^{-1}$, for the reaction, the $\Delta H^\circ_f 298.15$ for $\text{MgB}_2(c)$ was evaluated as $-22.0 \pm 2.0 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The low temperature (21.12 - 304.22°K.) heat capacities were measured by R. M. Swift and D. White, J. Am. Chem. Soc. **79**, 3641 (1957). Above 298.15°K. the values of C_p were estimated by comparison with those of other related borides. $S^\circ_{298.15}$ was reported by R. M. Swift and D. White, loc. cit., using S°_{20} (extrap.) = 0.005 cal. deg.⁻¹ mole⁻¹.

Temperature of Decomposition.

T_d was taken from L. Y. Markovskiy, Y. D. Kondrashev, and G. V. Kaputovskaya, Zhur. Obshchei Khim., **25**, 409 (1955). On heating to high temperatures $\text{MgB}_2(c)$ decomposes into boride phases A, B, and C with the separation of Mg. The composition of phase A is close to MgB_6 and that of C is close to MgB_{12} .

Product of the Moments of Inertia: $I_A I_B I_C = [4.7324] \times 10^{-117}$ g³ cm⁶

$\sigma = [2]$

Heat of Formation.

The heat of formation was calculated from the estimated heat of reaction $\Delta H^{\circ}_0 = 300 \pm 25$ kcal/mol for B₂O(g) → 2B(g) + O(g), using the JANAF auxiliary data for B(g) and O(g). The value of ΔH°_0 was assumed to be the sum of the heats of dissociation, 120 kcal/mol for B₂O(g) → B₂(g) + B(g) and 180 kcal/mol for B₂(g) → B(g) + O(g). The former was estimated and the latter was derived from the JANAF values.

The possible existence of B₂O(g) in the burning of boron under reducing conditions was discussed by Gilbert S. Bohn in a paper presented at the Combustion Institute, at University of Denver, Apr. 25-27, 1966. He estimated the heat of formation to lie between -27 and +23 kcal/mol, but favored the value of +23 kcal/mol in the theoretical calculations of boron burning in air.

Heat Capacity and Entropy.

The bent molecular structure and the molecular constants were estimated by comparison with those in BO(g), AlO(g) and Al₂O(g).² The three principal moments of inertia are $I_A = 0.1624 \times 10^{-39}$, $I_B = 5.319 \times 10^{-39}$ and $I_C = 5.4804 \times 10^{-39}$ g cm².

Dec. 31, 1960; Dec. 31, 1964

Heat of Formation.

The heat of formation (ΔH_f° 298.15°) for B₂O₃(c) has been reported by many investigators. However, the values obtained were not in good agreement. The value of ΔH_f° 298.15° for B₂O₃(c) adopted was taken from L. G. Fasolino, "Heats of Formation of B₂O₃(c) and B₂O₃(am.)", NMR-3608 (OO), National Research Corporation, Massachusetts, June 2, 1964. The other derived values of ΔH_f° 298.15° for B₂O₃(c) are listed in the following table.

Investigator	Reaction	ΔH_f° 298.15° kcal. mole ⁻¹	ΔH_f° 298.15° kcal. mole ⁻¹
Roth ¹	B ₂ O ₃ (gl) + 3 H ₂ O(l) = 2 H ₃ BO ₃ (c)	-18.15	-304.2 ± 0.4
Eggersgluessa et al. ²	2B(am.) + 3/2 O ₂ (g) = B ₂ O ₃ (gl.)	-281.1 ± 3.1	-283.1 ± 3.1
Artadalen and Anderson ³	1/2 B ₂ O ₃ (am.) + 3/2 H ₂ O(l) = H ₃ BO ₃ (c)	-9.13 ± 0.04	-304.1 ± 0.4
Ekstein and Artadalen ⁴	2B(c) + 3/2 O ₂ (g) = B ₂ O ₃ (gl.)	-304.6 ± 4.2	-309.0 ± 4.2
Gal'chenko et al. ⁵	2B(am.) + 3/2 O ₂ (g) = B ₂ O ₃ (gl.)	-298.7 ± 1.8	-300.7 ± 2.0
Fasolino	B ₂ O ₃ (c) + 348 H ₂ O(l) = 2 H ₃ BO ₃ ·348 H ₂ O(Sol.)	-3.45 ± 0.03	-303.64 ± 0.40

¹W. A. Roth, Z. Naturforsch., **1**, 574 (1946).²V. Eggersgluessa, A. G. Monroe and W. G. Parker, Trans. Faraday Soc., **45**, 661 (1949).³E. R. Vsn Artadalen and K. P. Anderson, J. Am. Chem. Soc., **73**, 579 (1951).⁴B. H. Eckstein and E. R. Van Artadalen, J. Am. Chem. Soc., **80**, 1352 (1958).⁵S. L. Gal'chenko, A. N. Kornilov and S. M. Skuratov, Russ. J. Inorg. Chem., **5**, 1039 (1960).

In order to evaluate the values of ΔH_f° 298.15° for B₂O₃(c) from the corresponding ΔH_f° 298.15° values, the following auxiliary data (298.15°K) were used: ΔH_f° (B₂am.) = 1.2 ± 0.4 kcal. mole⁻¹, ΔH_f° = 4.36 kcal. mole⁻¹ for the reaction B₂O₃(c) = B₂O₃(gl.), ΔH_f° (H₃BO₃, c) = -261.47 ± 0.20 kcal. mole⁻¹, ΔH_f° (2 H₃BO₃·348 H₂O, Sol.) = -512.04 ± 0.40 kcal. mole⁻¹ and ΔH_f° (H₂O, l) = -68.317 kcal. mole⁻¹.

Heat Capacity and Entropy.

The low temperature (18.08 - 296.60°K.) heat capacities used were reported by E. C. Kerr, H. N. Hersh and H. L. Johnston, J. Am. Chem. Soc., **72**, 4738 (1950). The high temperature (350.6 - 718.4°K.) heat capacities were derived from the heat content measurements determined by J. C. Southard, J. Am. Chem. Soc., **63**, 3147 (1941). These two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 718.4°K. were estimated by graphical extrapolation. ΔH_f° 298.15° was obtained from E. C. Kerr, H. N. Hersh and H. L. Johnston, loc. cit., based on S₂₉₈^o = 0.027 cal. deg.⁻¹ mole⁻¹. The specific heats of B₂O₃(c) in the temperature range 51 to 298°K. were also determined by K. K. Kelley, J. Am. Chem. Soc., **63**, 1137 (1941). The C_p values reported are in good agreement with the values adopted.

Melting Data.

Melting temperature (T_m) was taken from P. C. Kracek, O. W. Morey and H. E. Merwin, Am. J. Sci. [S] **35A**, 143 (1938). The heat of melting (ΔH_m°) was converted from ΔH_m° 298.15° = 4.36 ± 0.02 kcal. mole⁻¹ reported by J. C. Southard, loc. cit.

Heat of Sublimation.

The value of heat of sublimation (ΔH_s° 298.15°) was calculated as the difference in the heats of formation (ΔH_f° 298.15°) for B₂O₃(g) and B₂O₃(c).

 $T_m = 723 \pm 2^\circ \text{K.}$
 $T_b = 2316^\circ \text{K.}$

Heat of Formation

$\Delta H_f^\circ 298.15$ for B₂O₃(l) was obtained from $\Delta H_f^\circ 298.15$ for B₂O₃(c) by adding ΔH_v° and the difference between $H_{298.15}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

The heat content ($H^\circ - H_{298.15}^\circ$) measurements on B₂O₃(glass) and B₂O₃(l) were determined, from 381.7 to 1778.8°K., by J. C. Southard, J. Am. Chem. Soc. **63**, 3147 (1941) and, from 1015 to 2154°K., by R. M. Krasovitskaya, P. B. Kantor, L. S. Kan, V. V. Kandyba, L. M. Fomichev, Russ. J. Phys. Chem. **35**, 737 (1961). Based on these data the corresponding heat capacities (C_p) were derived. The C_p values thus obtained were plotted and joined smoothly, assuming a glass transition temperature at 550°K. The heat capacities above 2154°K. were estimated by graphical extrapolation. The entropy was obtained in a manner analogous to that of the heat of formation. The heat capacities of B₂O₃ glass and liquid have also been measured between 35 and 350°C with a radiation calorimeter by S. B. Thomas and G. S. Parks, J. Phys. Chem. **35**, 2091 (1931). The heat capacity curves obtained have been compared and discussed.

Melting Data

See the B₂O₃(c) table.

Vaporization Data

The boiling point (T_b) was calculated as the temperature at which the difference in ΔH_f° values for B₂O₃(g) and B₂O₃(l) becomes zero. The corresponding difference in ΔH_f° values at T_b is the heat of vaporization (ΔH_v°).

Heat of Formation

The heat of formation (ΔH_f⁰ 298.15) for B₂O₃(g) was calculated from the values of ΔH_f⁰ 298.15 and ΔH_f⁰ 298.15 for B₂O₃(l). The ΔH_f⁰ 298.15 value was obtained from the analyses of the vapor pressure data of B₂O₃(l) by both the second and third law methods. Ten sets vapor pressure data were employed for examination. The results obtained are presented as follows.

Investigator

Chem. Phys. **39**, 296 (1963).¹¹A. Büchler and J. B. Berkowitz-Matuck, J. Chem. Phys. **39**, 286 (1963).

The free energy functions of B₂O₃(g) used for calculation are based on two estimated vibrational frequencies, 172 and 460 cm.⁻¹. Similar evaluations were made using 259 and 460 cm.⁻¹ instead, each corresponding third law values of ΔH_f⁰ obtained was lower by more than 1 kcal. mole⁻¹ than that of the previous ones. The value of ΔH_f⁰ 298.15 for B₂O₃(g) adopted is the third law value based on the vapor pressures reported by D. L. Hildenbrand, M. P. Hall and N. D. Potter, loc. cit.

Heat Capacity and Entropy

The bond distances were reported by P. A. Akshin and V. P. Spiridonov, Doklady Akad. Nauk. S.S.S.R. **131**, 557 (1960). The bond angle was taken from W. Leitner, Jr. and J. R. W. Mann, J. Chem. Phys. **37**, 292 (1962). The vibrational frequencies were obtained from A. Sommer, D. White, M. J. Linevsky and D. E. Mann, J. Chem. Phys. **38**, 87 (1963) and corrected to the average isotopic species. The three principal moments of inertia are: I_A = 3.10959 X 10⁻³⁸, I_B = 2.9758 X 10⁻³⁹ and I_C = 3.40717 X 10⁻³⁸ g. cm.²

Lead Diborate (PbB_2O_4)
(Crystal) Mol. Wt. = 292.85

MOL. WT. = 292.85

LEAD DIBORATE (PbB_2O_4) (CRYSTAL)

$\Delta H_f^\circ = \text{Unknown}$

$\Delta H_f^\circ 298.15 = -372 \pm 1.5 \text{ kcal. mole}^{-1}$

$S_{298.15}^\circ = [31.2 \pm 3] \text{ cal. deg}^{-1} \text{ mole}^{-1}$

Heat of Formation.

W. H. Evans in NBS Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system. L. Shartsis and E. Newman, J. Am. Ceram. Soc. 31, 213 (1948) measured heats of solution of the lead borate glasses in 2 N HNO_3 . In their phase studies C. Mazzetti and P. De Carli, Gazz. chim. Ital. 56, 19 (1926) established that the compounds formed were $\text{PbO} \cdot \text{B}_2\text{O}_3$, $\text{PbO} \cdot 2\text{B}_2\text{O}_3$, $\text{PbO} \cdot 3\text{B}_2\text{O}_3$ and 2 $\text{PbO} \cdot 5\text{B}_2\text{O}_3$. From the Shartsis and Newman paper loc. cit. Evans obtained the following:

$\Delta H_r^\circ = -16.2 \text{ kcal. mole}^{-1}$

and estimated a $\Delta H_{298.15}^\circ$ of 7.0 kcal. mole⁻¹ for the conversion to the $\text{PbO} \cdot \text{B}_2\text{O}_3(\text{crystal})$. With auxiliary JANAF values the $\Delta H_f^\circ 298.15$ was calculated to be -372 kcal./mole. The results of B. M. Lepinskikh and O. A. Esin, Zhur. Neorg. Khim. 5, 1223 (1961) studying the lead borate system at 1000°K. with cells of the type $\text{Pb(lig.)}/\text{PbO} \cdot \text{B}_2\text{O}_3/\text{Pt}/\text{O}_2(\text{g})$ were in fair agreement with this results of Shartsis and Newman.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities for B_2O_3 and PbO .

The entropy at 298.15 was obtained from a consideration of the entropies of sodium and calcium borates and those of the constituent oxides, as given by K. K. Kailley and E. G. King, Bureau of Mines Bull. 592 (1961). These indicate for the reaction:

that the simple addition of entropies will give values at least 2.7 e.u. too low for the reaction. The reason for this is probably structural, the $\text{B}_2\text{O}_4^{--}$ ion is a flexible chain. Therefore, the $S_{298.15}^\circ$ for PbB_2O_4 was obtained from the summation of JANAF $S_{298.15}^\circ$ for constituent oxides and the addition of 2.7 e.u.

TITANIUM DIBORIDE (TiB₂)

(CRYSTAL)

B₂Ti

MOL. WT. = 69.522

ΔH_f⁰ = -66.4 ± 4.0 kcal. mole⁻¹ΔH_f^{298.15} = -68.8 ± 4.0 kcal. mole⁻¹ΔH_m⁰ = [24] kcal. mole⁻¹S^{298.15} = 6.808 ± 0.1 cal. deg.⁻¹ mole⁻¹T_m = 3193°K.

Heat of Formation.

G. M. Kibler, T. P. Lyon, M. J. Linevsky, and V. J. DeSantis, General Electric Co., report No. WADD-TR-60-646, Part IV (August 1964) studied the vapor pressure of the reaction TiB₂(c) + 1/2 C(c) = Ti(g) + 1/2 B₂(c) by comparing the absorption intensity of the 3371.4 Å Ti resonance line of the above reaction at temperature T₁ to Ti(g) over pure titanium metal at temperature T₂. Using JANAF auxiliary data ΔH₂₉₇₅ = 81.612 kcal. mole⁻¹ for the above reaction and ΔH₂₉₈⁰(TiB₂(c)) = -66.9 kcal. mole⁻¹ were calculated.

W. S. Williams, J. Phys. Chem. 65, 2213 (1961) found 2150 ± 25°K. to be the temperature at which TiB₂(c) was formed from a mixture of Ti(c) and B(c). If ΔH₂₁₅₀⁰ is assumed for the reaction TiN(c) + 2B(c) = TiB₂(c) + 3/2 N₂(g) then ΔH₂₉₈⁰(TiB₂(c)) = -70.7 kcal. mole⁻¹. If, however, N₂(g) is 1/2 atm. then ΔH₂₁₅₀⁰ = 4.4 kcal. mole⁻¹ and ΔH₂₉₈⁰(TiB₂(c)) = -66.3 kcal. mole⁻¹. He has also shown by stability comparisons that ΔF and ΔH > 0 for the reaction TiB₂ + 3/2 C = TiC + 1/2 B₂. Thus ΔH₂₉₈⁰ TiB₂ < -51 kcal. mole⁻¹.

F. O. Schissel and O. C. Truison, J. Phys. Chem. 65, 1492 (1962) used a mass spectrometer with Knudsen cells to study the vaporization of the titanium-boron system. Only the set of measurements without excess boron or titanium was used. The value ΔH₂₉₈⁰ = 194.9 kcal. mole⁻¹ for the reaction TiB₂(c) = Ti(g) + 2B(g) was obtained. This corresponds to ΔH₂₉₈⁰(TiB₂(c)) = -62.9 kcal. mole⁻¹ using JANAF auxiliary data.

V. A. Epeibaum and M. I. Starostina, Bor Trudy Konf. Khim. Bora 1 Ego Soedinenii 57 (1955-pub.1956) report ΔH₂₉₈⁰(TiB₂(c)) = -66.85 ± 2.7 kcal. mole⁻¹ from combustion calorimetry.

C. E. Lowell and W. S. Williams, Rev. Sci. Instr. 32, 1120 (1961) used high temperature calorimetry to obtain the heat of formation of TiB₂(c). From their data and JANAF auxiliary data ΔH₂₉₈⁰ TiB₂(c) = -48.2 ± 5 kcal. mole⁻¹ was calculated. We question the adiabaticity of the experiment and believe their value is an upper limit.

ΔH₂₉₈⁰(TiB₂(c)) = -66.8 ± 4 kcal. mole⁻¹ was chosen as representative of the first four investigations.

Heat Capacity and Entropy.

The heat capacity of TiB₂(c) has been determined by the following investigators:

Investigator	Method	Temperature Range
Westrum ¹	Adiabatic Calorimetry	5- 850°K.
Walker et al. ²	Drop calorimeter	373- 377°K.
Southern Research Institute ³	Drop type ice calorimeter	586-2689°K.
Mezaki ⁴	Copper-block drop calorimeter	420-1180°K.
Prophet ⁵	Arc-Imaging furnace	1300-2150°K.
Barriault et al. ⁶	Fulac-method	1733-2417°K.

¹L. Kaufman and E. V. Clougherty, Technical Documentary Report No. RDT-TDR-63-4086 Part 1 p. 239 (Dec. 1963).

²G. E. Walker, C. T. Ewing, and R. R. Miller, J. Phys. Chem. 61, 1682 (1957).

³Southern Research Institute, Technical Documentary Report No. ASD-TDR-62-675 p. 253 (Jan. 1963).

⁴R. Mezaki, M. S. Theiss, University of Wisconsin (1961).

⁵H. Prophet, Annual Report for 1962 of the Dow Chemical Co. to ARPA under Contract AF 04(611)7554.

⁶R. J. Barriault et al., Thermodynamics of Certain Refractory Compounds, AVCO Corporation, report ASD-TDR-61-260, Part I, Vol. 1, (May 1962).

The low temperature data of Westrum¹ and the medium range data of Walker et al.² were used to obtain the C_p of this tabulation. Their data were fitted to a Shomate plot and extrapolated to 4000°K.

S^{298.15} = 6.808 cal. deg.⁻¹ mole⁻¹ was determined by Westrum¹.

Melting Data.

The melting point has been reported as 3063°, 3193°, and 3203°K. by P. W. Glaeser, Trans. AIME 194, 391 (1952), E. Post, F. W. Glaeser, and D. Moskowitz, Acta. Met. 2, 20 (1954), and by O. V. Samonov and O. V. Petrushin, Metalloved. Obrabotka Metalov No. 4, 19 (1955) respectively. The heat of melting is derived from an estimated ΔS_m = 2.5 cal. deg.⁻¹ g. atom⁻¹ at 3193°K. It should be pointed out that an error of 0.5 cal. deg.⁻¹ g. atom⁻¹ in the estimation of ΔS_m is 5 kcal. mole⁻¹ in ΔH_m⁰.

TITANIUM DIBORIDE (TiB₂)

(LIQUID)

B₂Ti

MOL. WT. = 69.522

S_f^{298.15} = [13.455] cal. deg.⁻¹ mole⁻¹ΔH_f^{298.15} = [-44.99] kcal. mole⁻¹T_m = 3193°K.ΔH_m^{298.15} [24] kcal. mole⁻¹T_d = [4250]°K.

Heat of Formation.

ΔH_f^{298.15}(l) was calculated from ΔH_f^{298.15}(c) by adding ΔH_m^{298.15} and the difference between ΔH_m^{298.15} for crystal and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2100°K. C_p(l) at and below 2100°K. were assumed to be equal to those of TiB₂(c). Above 2100°K. the heat capacities were estimated to be constant. S_f^{298.15}(l) is calculated based on S_f^{298.15}(c) and an estimated ΔS_m^{298.15} = 2.5 cal. deg.⁻¹ gm. atom⁻¹.

Melting Data.

See TiB₂(c) table for details.

Decomposition Data.

T_d estimated from ΔP_{Td}^{298.15} = 0 for the reaction TiB₂(l) = Ti(g) + 2B(g).B₂Ti

Sept. 30, 1962; Mar. 31, 1963; June 30, 1965

ZIRCONIUM DIBORIDE (ZrB₂) (CRYSTAL)

MOL. WT. = 112.842

$\Delta H_f^0 = -76.8 \pm 1.6$ kcal. mole⁻¹
 $\Delta H_f^{298.15} = -77.1 \pm 1.6$ kcal. mole⁻¹
 $\Delta H_m^0 = [25]$ kcal. mole⁻¹
 $T_m = 3323^\circ K.$

Heat of Formation.

G. K. Johnson, Argonne National Laboratory, private communication, May 1965, reported ΔH_f^{298} (ZrB₂) = -76.7 ± 1.5 kcal. mole⁻¹. Their value was obtained by fluorine bomb calorimetry and was based on their recently redetermined value of $\Delta H_f^{298}(BF_3(g)) = -271.90 \pm 0.20$ kcal. mole⁻¹.
 G. M. Kibler, T. P. Lyon, M. J. Linavsky, and V. J. De Santis, General Electric Co., report No. WADD-TR-60-646, Part IV (August 1964) studied the vaporization of ZrB₂ by the Knudsen effusion method. Over the range 2260 to 2500°K., $\log K_p = 22.038 - \frac{10118}{T}$. For the reaction ZrB₂(s) = Zr(g) + 1.331 B(g), JANAP auxiliary data were used to calculate $\Delta H_f^{298} = 478.5 \pm 1.5$ kcal. mole⁻¹ by the 3rd law method and ΔH_f^{298} (ZrB₂(s)) = -76.7 ± 3.2 kcal. mole⁻¹.
 O. C. Trulsson and H. M. Goldstein, Union Carbide Res. Inat., report No. C-25 (October 1964), investigated the decomposition vapor pressure of the reaction ZrB₂(s) = Zr(g) + 2B(g) and reported ΔH_f^{298} (ZrB₂(s)) = -72.1 ± 5.3 kcal. mole⁻¹. They also reported ΔH_f^{298} = 289.7 kcal. mole⁻¹ for the reaction ZrB₂(s) + C(s) = ZrC(s) + 2B(g). Using the JANAP ΔH_f^{298} (ZrC(s)) = -47.0 ± 3 kcal. mole⁻¹, ΔH_f^{298} (ZrB₂(s)) = -76.1 ± 3 kcal. mole⁻¹ was calculated. JANAP values for ΔH_f^{298} B(g) and Zr(g) were not used since their independent determinations serve to cancel instrumental constants.
 From oxygen bomb calorimetry, E. J. Huber, Jr., E. L. Head, and C. E. Hollay, Jr., J. Phys. Chem. **68**, 3040 (1964) reported ΔH_f^{298} (ZrB₂(s)) = -77.2 ± 1.2 kcal. mole⁻¹.
 ΔH_f^{298} (ZrB₂(s)) = -77.1 ± 1.6 was chosen as a value representative of the above.

Heat Capacity and Entropy.

The heat capacity of ZrB₂(s) has been determined by the following investigators:

Investigator	Method	Temperature Range
Westrum and Feick ¹	Adiabatic calorimetry	5-350°K.
Valentine et al. ²	Copper-block drop calorimeter	410-1125°K.
Mazaki ³	Copper-block drop calorimeter	430-1170°K.
Prophet ⁴	Arc-furnace furnace	1300-2150°K.
Barriault et al. ⁵	Pulse-method	1740-2520°K.
Southern Research Institute ⁶	Drop type ica calorimeter	500-2500°K.

1. E. F. Westrum, Jr. and G. Feick, J. Chem. Eng. Data **8**(2), 183 (1963).
2. R. H. Valentine, T. P. Jambois, and J. L. Margrave, J. Chem. Eng. Data **9**(2), 182 (1964).
3. R. Mazaki, M. S. Thesis, University of Wisconsin (1961).
4. H. Prophet, Annual Report for 1962 of the Dow Chemical Co. to ARPA under Contract AF 04(611)7554.
5. R. J. Barriault et al., Thermodynamics of Certain Refractory Compounds, AVCO Corporation, report ASD-TR-61-260, Part I, Vol. 1, (May 1962).
6. D. Neel, C. Peers, and S. Oglesby, Southern Research Institute, report ASD-TRD-62-675 (August 1962).

Westrum and Feick's C_p values were adopted to 350°K. The disparities in heat capacities above room temperatures seem too great to be errors in measurement and are probably due to sample differences. Since the samples used by Westrum and Feick¹ and by Valentine et al.² were from the same batch, Valentine's data were used above 350°K. The two sets of data were fitted to a Shomate plot which was extrapolated to 4000°K. However, in consideration of the results of Mazaki³, Prophet⁴, and Southern Research Institute⁶, the C_p extrapolation ran somewhat higher than a direct extrapolation of Valentine's data would yield.

$S_{298.15}^{298.15}(ZrB_2) = 6.59$ cal. mole⁻¹ °K.⁻¹ was determined by Westrum¹.

Melting Data.

The melting point has been reported as 3313°, 3323°, and 3285°K. by P. Glaeser and B. Post, J. of Metals, **5**, 1117 (1953), B. Post, P. Glaeser, and D. W. Moskowitz, Acta. Met. **2**, 70 (1954) and H. Greenwood, Engineer **137**, 349 (1949) respectively. The heat of melting is derived from an estimated $\Delta S_m = 2.5$ cal. deg.⁻¹ g. atom⁻¹ at 3323°K. It should be pointed out that an error of 0.5 cal. deg.⁻¹ g. atom⁻¹ in the estimation of ΔS_m is 5 kcal. mole⁻¹ in ΔH_m^0 .

Zirconium Diboride (ZrB₂)

(Liquid) Mol. Wt. = 112.842

B₂Zr

MOL. WT. = 112.842

ZIRCONIUM DIBORIDE (ZrB₂)

(LIQUID)

$$\Delta H_f^{298.15} = [15.448] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^{298.15} = [25] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = [15.448] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 3323^\circ\text{K.}$$

$$T_d = [4466]^\circ\text{K.}$$

Heat of Formation.

$\Delta H_f^{298.15}(l)$ was calculated from $\Delta H_f^{298.15}(c)$ by adding $\Delta H_m^{298.15}$ and the difference between $\Delta H_m^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2200°K. $C_p(l)$ at and below 2200°K. were assumed to be equal to those of ZrB₂(c). Above 2200°K. the heat capacities were estimated to be constant. $S_{298.15}^{298.15}(c)$ and an estimated $\Delta S_m^{298.15} = 2.5 \text{ cal. deg.}^{-1} \text{ gm. atom}^{-1}$.

Melting Data.

See ZrB₂(c) table for details.

Decomposition Data.

T_d estimated from $\Delta F_{T_d}^{298.15} = 0$ for the reaction $\text{ZrB}_2(l) = \text{Zr}(g) + 2\text{B}(g)$.

Bond Distances: B-Cl = [1.75]Å B-O = [1.36]Å

Bond Angle: Cl-B-O = [120°] B-O-B = [120°]

Product of the Moments of Inertia: $I_A I_B I_C = [1.86850 \times 10^{-111}] \text{ g.}^3 \text{ cm.}^6$

$\sigma = 6$

Heat of Formation.

The equilibrium constants for the reaction $\text{B}_2\text{O}_3(1) + \text{BCl}_3(g) = (\text{BOCl})_3(g)$ were determined in the temperature range 536-825°K. by a transpiration method by J. Blauer and M. Farber, J. Chem. Phys. **39**, 158 (1963) and in the temperature range 1234-1309°K. by an effusion method by the same investigators, Trans. Faraday Soc. **50**, 301 (1964). Using the reported equilibrium constants, the enthalpy changes for this reaction were evaluated by both the second and third law methods. The results obtained are given in the following table.

Method Used	$\Delta H_f^\circ 298.15^\circ \text{ kcal. mole}^{-1}$	
	Third Law Value	Second Law Value
Transpiration	5.31	5.07 ± 0.4
Effusion	12.57	5.85 ± 3.3
*Based on the third law values		

By a mass spectroscopic method the enthalpy change, $\Delta H_f^\circ 1000 = 16.6 \pm 2.5 \text{ kcal. mole}^{-1}$, for the reaction $\text{BOCl}_3(g) + \text{B}_2\text{O}_3(1) = (\text{BOCl})_3(g)$ was determined by R. P. Porter and S. K. Gupta, J. Phys. Chem. **68**, 280 (1964). The $\Delta H_f^\circ 298.15$ value for $(\text{BOCl})_3(g)$ was derived as $-377 \pm 3 \text{ kcal. mole}^{-1}$. However, it is possible that the intensity of $\text{B}_2\text{O}_3\text{Cl}_3^+$ employed to plot the ion ratios $[(\text{B}_2\text{O}_3\text{Cl}_3^+)/(\text{BOCl}_2^+)]$ versus $\frac{1}{M}$ does not fully reflect the concentration of $\text{B}_2\text{O}_3\text{Cl}_3$ especially at the highest temperatures, due to changes in the fragmentation pattern with temperature.

The value of $\Delta H_f^\circ 298.15$ adopted for $(\text{BOCl})_3(g)$ is $-390 \pm 2 \text{ kcal. mole}^{-1}$ derived from transpiration data. The effusion data were measured in the temperature range where Porter and Gupta, loc. cit. found the presence of $(\text{BOCl})_4(g)$. However, this point was not taken into consideration in the report. Hence, the corresponding $\Delta H_f^\circ 298.15$ value was not adopted.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with related molecules such as $\text{B}_2\text{O}_3(g)$ and $(\text{BH}_2\text{O})_3(g)$. The B-Cl bond distance was assumed to be the same as that in $\text{BOCl}_3(g)$. The B-O bond distance and all bond angles were estimated. The three principal moments of inertia are: $I_A = I_B = 9.7785 \times 10^{-38}$ and $I_C = 1.95517 \times 10^{-37} \text{ g. cm.}^2$

$\sigma^- = [2]$

Heat of Formation.

The equilibrium constants (K), 1246-1396°K. for the two reactions $2B_3O_3 \cdot 2H_2(g) = B_3O_3 \cdot 2H_2(g) + B_3O_3 \cdot 2H_2(g)$ and $2B_3O_3 \cdot 2H_2(g) = B_3O_3 \cdot 2H_2(g) + B_3O_3 \cdot 2H_2(g)$ were reported by P. R. Porter and W. F. Sholette, J. Chem. Phys. 57, 198 (1962). The $\Delta H_f^0 298.15$ for $B_3O_3 \cdot 2H_2(g)$ adopted was evaluated by use of K values slightly outside the ranges given by Porter and Sholette. See the table for $B_3O_3 \cdot 2H_2(g)$ for details.

Heat Capacity and Entropy.

The structure was assumed to be a planar six membered ring structure of C_{2v} symmetry, which has 21 vibrations of the type B_{1g} , B_{2g} , $2A_{2g}$, and $4B_{2g}$. These frequencies were estimated from the values for boroxin and trifluoroboroxin, the symmetry being reduced from D_{3h} as follows: $2A_{1g} \rightarrow 3A_{1g}$, $2A_{2g} \rightarrow 2B_{1g}$, $5E_{1g} \rightarrow 5B_{1g}$, $2A_{2g} \rightarrow 2B_{2g}$ and $2E_{2g} \rightarrow 2A_{2g} + 2B_{2g}$.

The B-F distance was taken as approximately equal to that in $(CH_3)_2O \cdot BF_3$ reported by S. H. Bauer, O. R. Fendley and A. W. Leubengayer, J. Am. Chem. Soc. 57, 339 (1945). The other bond lengths and angles were taken equal to those in boroxin. The individual moments of inertia were calculated to be $I_A = 32.995 \times 10^{-39}$, $I_B = 13.973 \times 10^{-39}$, and $I_C = 46.968 \times 10^{-39} \text{ g. cm.}^2$.

Heat of Formation.

The stabilities of gaseous boroxin (B₃O₃H₃) and its fluoro derivatives have been studied by R. P. Porter and W. P. Sholette, J. Chem. Phys. 31, 198 (1959). From the mass spectra of the gaseous reaction products generated by reaction of an H₂-B₃O₃ mixture on B₂O₃ at 1250°K, the equilibrium constants (K) for the following proposed reactions were reported.

Reaction	Temperature, °K.	K	ΔH_f° , kcal. mole ⁻¹
(1) H ₂ (g) + B ₃ O ₃ H ₃ (g) = HF(g) + B ₃ O ₃ H ₂ (g)	1246 - 1326	4.2×10^{-3}	20.45 - 17.17
(2) 2B ₃ O ₃ H ₂ (g) = B ₃ O ₃ H ₂ (g) + B ₃ O ₃ H ₃ (g)	1246 - 1326	0.62 - 0.46	1.28 - 2.15
(3) 2B ₃ O ₃ H ₂ (g) = B ₃ O ₃ H ₂ (g) + B ₃ O ₃ H ₃ (g)	1246 - 1326	1.0 - 0.63	-2.56 - -1.51

Using these reported K values the corresponding enthalpy changes (ΔH_f° , 298.15°) were evaluated by the third law method. The results obtained are listed in the above table. Based on ΔH_f° , 298.15° = -565.3 and -64.8 kcal. mole⁻¹ for B₃O₃H₂(g) and HF(g), respectively, the value of ΔH_f° , 298.15° for B₃O₃H₃(g) was calculated from Reaction (1) as -482 kcal. mole⁻¹. From Reaction (2), the ΔH_f° , 298.15° value for B₃O₃H₂(g) was calculated as -397 kcal. mole⁻¹. However, employing ΔH_f° , 298.15° (B₃O₃H₃, g) = -591 kcal. mole⁻¹, the values of ΔH_f° , 298.15° for B₃O₃H₂(g) and B₃O₃H₃(g) thus obtained do not fit properly for Reaction (3). Therefore the ΔH_f° , 298.15° for B₃O₃H₂(g) and B₃O₃H₃(g) adopted were evaluated by use of K values slightly outside the ranges given by Porter and Sholette.

Heat Capacity and Entropy.

The vibrational frequencies were obtained by comparison with B₃O₃F₃(g) and B₃H₃O₃(g). The type of vibration and symmetry are identical to those given for B₃O₃F₃(g). The bond angles and lengths were taken equal to those for B₃O₃F₃(g). The individual moments of inertia were calculated to be $I_A = 22.051 \times 10^{-35}$, $I_B = 46.659 \times 10^{-35}$ and $I_C = 70.710 \times 10^{-35} \text{ g. cm.}^2$

BORON OXIDE FLUORIDE, TRIMERIC ((BOF)₃)

MOL. WT. = 137.46

ΔH_f⁰ 0 = Unknown
 ΔH_f⁰ 298.15 = -586.5 ± 3.0 kcal. mole⁻¹
 ΔH_f⁰ = Unknown
 ΔH_f⁰ 298.15 = 21.2 ± 3.2 kcal. mole⁻¹
 T_m = 353°K.

Heat of Formation.

The heats of solution of the compounds: B₂O₃(gl), BF₃(g) and (BOF)₃(c) in water and methanol, respectively, were reported by E. M. Magee, J. Inorg. Nucl. Chem. 22, 156 (1961). The corresponding enthalpy changes for the reaction B₂O₃(gl) + BF₃(g) = (BOF)₃(c) were derived as -19.8 and -14.4 kcal. mole⁻¹, yielding ΔH_f⁰ 298.15 for (BOF)₃(c) -589.18 and -585.78 kcal. mole⁻¹, respectively. The adopted value of ΔH_f⁰ 298.15 for (BOF)₃(c) is the average of these two values obtained.

Heat Capacity and Entropy.

The heat capacities (C_p) for (BOF)₃(c) were estimated from the C_p values for B₂O₃(c) and BF₃(g), according to the method suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958. S° 298.15 for (BOF)₃(c) was estimated by E. M. Magee, loc. cit.

Melting Data.

The value of T_m was reported by E. M. Magee, loc. cit.

Heat of Sublimation.

The heat of sublimation (ΔH_g⁰ 298.15) for (BOF)₃(c) is calculated as the difference between ΔH_f⁰ 298.15 for crystal and gas.

Bond Distance: B-F = [1.3] Å B-O = [1.36] Å

Bond Angle: F-B-O = [120]° B-O-B = [120]° O-B-O = [120]°

Product of the Moments of Inertia: I_AI_BI_C = [1.9254 X 10⁻¹¹²] g.³ cm.⁶

Heat of Formation.

The enthalpy changes (ΔH_f°) of the reaction B₂O₃(l) + BF₃(g) = (BOF)₃(g) were derived by both the second and third law methods, using the equilibrium constant data reported by several investigators. The results are given as follows.

Investigator	Third Law Value	Second Law Value	ΔH _f ° 298.15° kcal. mole ⁻¹
Hildenbrand, et al. ¹	4.06	4.01 ± 0.3	-565.32 ± 1.0
Fisher, et al. ²	3.41	6.45 ± 0.6	-565.97 ± 1.5
Smith and Lawrence ³	4.03	—	-565.35 ± 1.3
Farber ⁴	5.25	—	-564.13 ± 2.0
Porter, et al. ⁵	—	7.58 ± 0.2	-565.82 ± 2.0
	—	4.33 ± 0.30	-565.05 ± 1.0

*Calculation based on the third law values available.

- 1 D. L. Hildenbrand, L. P. Theard and A. M. Saul, J. Chem. Phys. **39**, 1973 (1963).
- 2 H. D. Fisher, J. Kiehl and A. Cane, Report HTC-61-90, June 1961, Hughes Tool Company, Culver City, California.
- 3 D. D. Smith and R. W. Lawrence, Aerojet Report No. 1952, February 1961, Aerojet-General Corporation.
- 4 M. Farber, J. Chem. Phys. **35**, 661 (1962). The first ΔH_f° 298.15 value was evaluated based on K₁₀₀₀ = 11.8. The second ΔH_f° 298.15 values refer to the reaction B₂O₃(c) + BF₃(g) = (BOF)₃(g).
- 5 R. P. Porter, D. R. Biddisat and K. P. Watterson, J. Chem. Phys. **35**, 2104 (1962). The ΔH_f° 298.15 value was derived from ΔH_f° 700 = 3.46 ± 0.30 kcal. mole⁻¹.

The adopted value of ΔH_f° 298.15 for (BOF)₃(g) is the weighted average of the six ΔH_f° 298.15 values listed above.

Heat Capacity and Entropy.

The infra-red spectrum has been reported by D. D. Smith and R. L. Lawrence, loc. cit., and by H. D. Fisher, W. J. Lehmann, and I. Shapiro, J. Phys. Chem. **65**, 1166 (1961) who also made a partial assignment. The unassigned bands at 1280 and 1233 from Fisher, et al., can be assigned to the A₁ and A₂ species which may be observed if the selection rules are not rigorously obeyed in the solid. All the unobserved frequencies were estimated by comparison with B₂O₃(OH)₃, B₂O₃(OD)₃ from J. L. Parsons, J. Chem. Phys. **33**, 1860 (1960) and B₂O₃-H₂O from S. K. Gupta and R. P. Porter, J. Phys. Chem. **57**, 1286 (1953) and G. H. Lee, W. H. Bauer and S. E. Wiberley, J. Phys. Chem. **57**, 1742 (1953). The D_{3h} assumed symmetry has 14 vibrations of the type 3A₁, 2A₂, 5E₁, 2A₂ and 2E₁ which are given in order above. The B-F bond distance was assumed to be the same as that in BF₃. The B-O bond distance was estimated by comparison with other related compounds. The three principal moments of inertia are: I_A = I_B = 4.5832 X 10⁻³⁸ g. cm.²

MOL. WT. = 83.484

(Crystal) Mol. Wt. = 83.484

BOROXIN ($\text{B}_3\text{O}_3\text{H}_3$) (CRYSTAL)

$\Delta H_f^\circ 0$ = Unknown
 $\Delta H_f^\circ 298.15$ = -301.7 ± 10 kcal. mole⁻¹
 ΔH_g° = Unknown
 $\Delta H_g^\circ 298.15$ = 10.7 ± 0.5 kcal. mole⁻¹

$S^\circ 298.15$ = $[40 \pm 10]$ cal. deg.⁻¹ mole⁻¹
 T_m = Unknown

Heat of Formation.

The value of $\Delta H_f^\circ 298.15$ for $\text{B}_3\text{O}_3\text{H}_3(\text{c})$ was calculated from the $\Delta H_f^\circ 298.15$ for $\text{B}_3\text{O}_3\text{H}_3(\text{g})$ and $\Delta H_g^\circ 298.15$ for $\text{B}_3\text{O}_3\text{H}_3(\text{c})$ reported by R. P. Porter and S. K. Gupta, J. Phys. Chem. **68**, 280 (1964).

Heat Capacity and Entropy.

The heat capacities (C_p) were estimated from those for $\text{P}_2\text{O}_5(\text{c})$ and $1/2 \text{P}_2\text{H}_6(\text{g})$, according to the method suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958. The value of $S^\circ 298.15$ for $\text{B}_3\text{O}_3\text{H}_3(\text{c})$ was calculated based on $\Delta S_f^\circ 298.15 = 6.6$ cal. deg.⁻¹ mole⁻¹ for the reaction $\text{B}_3\text{O}_3\text{H}_3(\text{c}) = \text{P}_2\text{O}_5(\text{am}) + 1/2 \text{P}_2\text{H}_6(\text{g})$, which was obtained from the calculated $\Delta H_f^\circ 298.15$ and measured $\Delta H_f^\circ 298.15$ evaluated from the vapor pressure reported by W. P. Shollette and R. P. Porter, J. Phys. Chem. **67**, 177 (1963).

Heat of Sublimation.

$\Delta H_g^\circ 298.15$ was taken from R. P. Porter and S. K. Gupta, loc. cit.

Bond Distance: B-O = $1.36 \text{ \AA}$ B-H = $1.18 \text{ \AA}$

Bond Angle: B-O-B = 120° O-B-H = 120°

Product of the Moments of Inertia: $I_A I_B I_C = [5.4563] \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The equilibrium constants (1290-1461°K.) for the reaction (1) $3/2 \text{ H}_2(\text{g}) + \text{B(am)} + \text{B}_2\text{O}_3(\text{l}) = \text{B}_3\text{O}_3\text{H}_3(\text{g})$ were determined by W. P. Sholette and R. F. Porter, J. Phys. Chem. 67, 177 (1963). The equilibrium pressures of $\text{B}_3\text{O}_3\text{H}_3(\text{g})$ and $\text{B}_2\text{O}_3\text{H}_3(\text{g})$ for the reaction (2) $\text{B}_2\text{O}_3\text{H}_3(\text{g}) + \text{B}_2\text{O}_3(\text{c}) = 1/2 \text{ B}_3\text{O}_3\text{H}_3(\text{g}) + \text{B}_2\text{O}_3(\text{c})$ were measured at 300°K. by R. F. Porter and S. K. Gupta, J. Phys. Chem. 68, 280 (1964). The equilibrium constants (1246-1328°K.) for the reaction (3) $2\text{B}_3\text{O}_3\text{H}_3(\text{g}) = \text{B}_3\text{O}_3\text{H}_3(\text{g}) + \text{B}_2\text{O}_3\text{H}_3(\text{g})$ were reported by R. F. Porter and W. P. Sholette, J. Chem. Phys. 37, 198 (1962). Using these data the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Reaction	Third Law Value	Second Law Value	$\Delta H_f^{298.15^\circ}$ kcal. mole ⁻¹
(1)	-5.90	+6.52 ± 4.5	-304.0 ± 5.0
(2)**	-11.11	—	-287.6 ± 2.0
(3)	-2.0	—	-282.5 ± 2.0
			-314 ± 12.0

*Calculation based on the third law values.

**The initial system for the first set of measurements was $\text{B}_2\text{H}_6(\text{g}) + \text{B(OH)}_3(\text{c})$.

That for the second set was $\text{B}_2\text{H}_6(\text{g}) + \text{B}_2\text{O}_3(\text{g})$.

The value of $\Delta H_f^{298.15}$ for $\text{B}_3\text{O}_3\text{H}_3(\text{g})$ adopted is a weighted average of these $\Delta H_f^{298.15}$ values listed.

Heat Capacity and Entropy.

The infra-red spectrum of solid boroxin has been determined by S. K. Gupta and R. F. Porter, J. Phys. Chem. 67, 1286 (1963) and a partial assignment was made. The infra-red spectra of the gas has also been reported by G. H. Lee, W. H. Bauer, and S. E. Miberley, J. Phys. Chem. 67, 1742 (1963) and in an agreement with the solid. The assignment of the frequencies has been changed slightly due to the non-appearance of the band at 1115 cm.⁻¹ in the gas phase. The assumed D_{3h} symmetry has 14 vibrations of the type $3A_1$, $2A_2$, $5E$, $2A_2$, and $2E$, the 7 estimated frequencies were obtained by comparison with $\text{B}_3\text{O}_3\text{H}_3$ by J. L. Parsons, J. Chem. Phys. 33, 1860 (1960).

The point group, bond angles and bond lengths were assumed to be the same as for $\text{BOP}(\text{g})$. The B-H bond length was taken as the sum of the angle covalent radii of the atoms. The individual moments of inertia were calculated to be $I_A = I_B = 13.973 \times 10^{-39}$, and $I_C = 27.949 \times 10^{-39} \text{ g.}^2 \text{ cm.}^2$.

Bond Distance: B-O = [1.36] Å O-H = [1.0] Å

Bond Angle: H-O-B = [120]° O-B-O = [120]° B-O-B = [120]°

Product of the Moments of Inertia: I_AI_BI_C = [1.7712 X 10⁻¹¹] g.³ cm.⁶

Heat of Formation.

The equilibrium constant, K_p 1451 = 0.9, for the reaction H₃BO₃(l) + B₂O₃(l) = (HBO₂)₃(g) was reported by D. J. Meschi, W. A. Chupka and J. Berkowitz, J. Chem. Phys. 33, 530 (1960), which was determined by means of mass spectrometry. The equilibrium constants of the reactions between water vapor and liquid B₂O₃ were determined at 1147°K. by J. A. Blauer and M. Farber, J. Phys. Chem. 68, 2357 (1964), by use of a transpiration method. From the reported value, 1.5 K₂ + 0.5 K₃ = 0.0342 ± 0.0095, the equilibrium constant, K₂, for the reaction 1.5 B₂O₃(l) + 1.5 H₂O(g) = (HBO₂)₃(g) was derived as 0.0168, using K₃ = 0.0181 for the reaction 0.5 B₂O₃(l) + 1.5 H₂O(g) = H₃BO₃(g) evaluated by use of JANAF values of ΔH_f⁰ for B₂O₃(l), H₂O(g) and H₃BO₃(g). Employing the equilibrium constants obtained the respective enthalpy changes (ΔH_f⁰ 298.15) for the two reactions were calculated by the third law method. The corresponding values of ΔH_f⁰ for (HBO₂)₃(g) were also derived. The results are presented as follows.

Investigator	Chemical Reaction	ΔH _f ⁰ 298.15 kcal. mole ⁻¹	ΔH _f ⁰ 298.15 kcal. mole ⁻¹
Meschi, et al.	H ₃ BO ₃ (l) + B ₂ O ₃ (l) = (HBO ₂) ₃ (g)	-7.31	-543.8
Blauer and Farber	1.5 B ₂ O ₃ (l) + 1.5 H ₂ O(g) = (HBO ₂) ₃ (g)	-6.67	-542.3

The adopted value of ΔH_f⁰ 298.15 for (HBO₂)₃(g) is the average of these two listed in the above table. The equilibrium constants for the same reactions between B₂O₃(l) and H₂O(g) were also determined by a transpiration method in the temperature region 1000°-1273°K. by S. F. Randall and J. L. Margrave, J. Inorg. Nucl. Chem. 15, 29 (1960). The reported value, ΔH_f⁰ = -537.5 ± 3 kcal. mole⁻¹ for (HBO₂)₃(g), is in good agreement with the value adopted.

Heat Capacity and Entropy.

All the molecular and spectroscopic constants were estimated by D. White, D. E. Mann, F. N. Walsh and A. Sommer, J. Chem. Phys. 32, 468 (1960). The three principal moments of inertia are: I_A = I_B = 4.4823 X 10⁻³⁸ and I_C = 8.9247 X 10⁻³⁸ g. cm.². The infrared absorption spectra for B₃O₃(OH)₃(c) in the 430 to 4000 cm.⁻¹ was reported by L. J. Parsons, J. Chem. Phys. 33, 1860 (1960). A partial Raman spectrum was also given.

Product of Moments of Inertia: I_AI_BI_C = 0.3303 X 10⁻¹⁴ g.³ cm.⁶

Heat of Formation.

The heat of combustion for the reaction B₃N₃H₆(l) + 15/4 O₂(g) + 3/2 H₂O(l) = 3 H₃BO₃(c) + 3/2 N₂(g) was reported to be -552.9 ± 3.0 kcal. mole⁻¹ by M. V. Kilday, W. H. Johnson and E. J. Prosen, J. Res. Natl. Bur. Std. 65A, 101 (1961). ΔH_f^o 298.15 H₂O(l) = -68.317 kcal. mole⁻¹ from Natl. Bur. Std. Circ. 500, "Selected Values of Chemical Thermodynamic Properties", 1952 and ΔH_f^o 298.15 H₃BO₃(c) = -261.47 kcal. mole⁻¹ from JANAF tables were used to calculate ΔH_f^o 298.15 B₃N₃H₆(l) = -129.0 ± 3.0 kcal. mole⁻¹. Vapor pressure data on B₃N₃H₆(l) reported by A. Stock and E. Pohland, Ber. 59, 2215 (1926) were fitted to a linear least squares. ΔC_p(1-g) for borazine was approximated by benzene to calculate a 2nd law ΔH_v 298 = 7.1 ± 0.1 kcal. mole⁻¹.

Heat Capacity and Entropy.

The fundamental frequency assignment was made by B. L. Crawford, Jr. and J. T. Edsall, J. Chem. Phys. 7, 223 (1939). The three frequencies enclosed by brackets are calculated values. The moments of inertia were calculated from molecular constants given by S. H. Bauer, J. Am. Chem. Soc. 80, 524 (1958). The three principal moments of inertia are: I_A = I_B = 16.09 X 10⁻³⁹ and I_C = 32.18 X 10⁻³⁹ g. cm.².

$\Delta H_m^* = 24.9 \pm 1 \text{ kcal. mole}^{-1}$

$S_{298.15}^* = [49.8 \pm 1.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_m = 1098^\circ K.$

Heat of Formation.

$\Delta H_f^* 298.15$ was recalculated from the experimental data of L. Shartais and W. Capps, J. Am. Ceram. Soc. **37**, 27-32 (1954). They studied the heat of solution of various alkali borates in 2N nitric acid. Average molecular weights were used for physical mixtures of the oxides B_2O_3 and R_2O (where R is either Li, Na, or K) rather than for the borate compounds $R_2O \cdot nB_2O_3$ present. These incorrect molecular weights led to spurious correlations and faulty conclusions. In reinterpreting the data, the steps followed were: (1) The calculation of the correct molecular weights and molar heats of reaction; (2) The establishment that the heat of formation of the borates from the oxides is linear with the mole fraction of B_2O_3 in the total original moles of oxides for the reactions

with the heat of formation being zero at 100 percent R_2O ; (3) The evaluation of the least square fit of the line through the heat of reaction data for reaction I and for reaction II; (4) The use of the proper weighting factors in applying least squares to adjust for both the sample size and the molecular weight of the mixture of borates used in each solution experiment.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic. 59-2916, in the range 298-973°K were smoothed graphically and were used to obtain a smooth set of C_p data. The heat capacity was extrapolated smoothly above this region. The entropy at 298°K was estimated from that of $Na_2B_4O_7(c)$ by using an average entropy change of $4.5 \pm 1.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ on substituting Na by K.

Melting Data.

T_m was given by A. P. Rollet, Comp. Rend. **200**, 1763 (1955). The heat of melting was obtained from the heats of formation of the crystal and glass at 298°K combined with the enthalpy differences between 298 and 1098°K. This involves a slight extrapolation of the crystal data and an uncertainty of about 1.0 kcal. mole⁻¹.

$S_{298.15}^o = [56.7 \pm 2.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o = -786.1 \text{ kcal. mole}^{-1}$
 $\Delta F_f^o = -740.0 \text{ kcal. mole}^{-1}$
 $T_m = 1088^\circ\text{K.}$

Heat of Formation.

The heat of formation was obtained from reaction (1) given on the crystal table.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1375°K on the glass and liquid were smoothed graphically and used to determine C_p . There is a discontinuity (glass transition) in the C_p curve at 678°K. Above 1375°K the C_p values were extrapolated smoothly.

The entropy at 298°K was obtained from that of the crystal by adding ΔS_m^o and the difference between S_{1088}^o for crystal and liquid.

Melting Data.

ΔH_f° 0 = Unknown

ΔH_f° 298.15 = -803.6 ± 1.5 kcal. mole⁻¹

ΔH_m° = 28.8 ± 1.5 kcal. mole⁻¹

S° 298.15 = [37.2 ± 1.0] cal. deg.⁻¹ mole⁻¹

T_m = 1190 ± 2°K.

Heat of Formation.

The heat of formation was calculated from ΔH_f° 298 = -12.2 kcal. for the reaction $\text{Li}_2\text{B}_4\text{O}_7(\text{c}) + 2\text{HNO}_3(\text{aq.}) + 5\text{H}_2\text{O}(\text{l.}) = 4\text{H}_3\text{BO}_3(\text{aq.}) + 2\text{LiNO}_3(\text{aq.})$. The heat of solution (ΔH_f°) was interpolated from the heat of solution data of L. Shartels and W. Ceppa, J. Am. Ceram. Soc. 37, 27 (1954). Auxiliary data are from National Bureau of Standards Circular 500 (1952).

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph. D. Thesis, Penn. State Univ., Jan. 1953, L. C. Card No. Mic 59-2916 in the range 298 to 1190°K. were smoothed graphically and used to determine C_p. A linear extrapolation of C_p was used from 1190 to 2000°K.

S° 298 was estimated by three routes: (1) S° 298 ($\text{Li}_2\text{B}_4\text{O}_7$) = 37.3 cal. mole⁻¹ deg.⁻¹ based on JANAP S° 298 ($\text{Na}_2\text{B}_4\text{O}_7$) = 45.3 and ΔS° 298 (2Na-2Li) = 8 cal. deg.⁻¹ from W. M. Latimer, J. Am. Chem. Soc. 73, 1490 (1951); (2) S° 298 ($\text{Li}_2\text{B}_4\text{O}_7$) = 36.7 cal. mole⁻¹ deg.⁻¹ in a similar manner based on ΔS° 298 (2Na-2Li) = 8.6 cal. deg.⁻¹ from K. K. Kelley, Bureau of Mines, private communication, June 1960; and (3) S° 298 ($\text{Li}_2\text{B}_4\text{O}_7$) = 37.6 cal. mole⁻¹ deg.⁻¹ based on addition of the JANAP entropies for 2LiBO₂ and B₂O₃. The value adopted is an average of these estimates.

Melting Data.

The value for T_m is from B. S. R. Sastry and P. A. Hummel, J. Am. Chem. Soc. 42, 216 (1959). A. P. Rollet and R. Bousziz, Compt. rend. 240, 2417 (1955) earlier reported T_m = 1188°K. ΔH_m = 28.8 kcal. mole⁻¹ is from G. S. Smith loc. cit.

DILITHIUM TETRABORATE (Li₂B₄O₇) (LIQUID)

MOL. WT. = 169.1178

$S_{298.15}^{\circ} = [41.564 \pm 1.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H_f^{\circ} 298.15 = -792.79 \pm 1.5 \text{ kcal. mole}^{-1}$

$\Delta H_m^{\circ} = 26.3 \pm 1.5 \text{ kcal. mole}^{-1}$

$T_m = 1190 \pm 2^{\circ}\text{K.}$

Heat of Formation.

$\Delta H_f^{\circ} 298.15(1)$ was calculated from $\Delta H_f^{\circ} 298.15(c)$ by adding ΔH_m° and the difference between H_m° and H_f° for crystal and liquid.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph. D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. M1c 58-2918 in the range 298 to 1373°K. were smoothed graphically and used to determine C_p . The C_p data have a discontinuity at about 756°K. A linear extrapolation of C_p was used from 1373 to 3000°K.

The entropy at 298°K. is set so that ΔP is equal at T_m for the crystal and liquid.

Melting Data.

See crystal table for details.

MAGNESIUM TETRABORIDE (MgB_4)
(CRYSTAL)

MOL. WT. = 67.60

$$\Delta F_f^\circ 0 = -25.0 \pm 2.0 \text{ kcal. mole}^{-1}$$

$$\Delta F_f^\circ 298.15 = -25.1 \pm 2.0 \text{ kcal. mole}^{-1}$$

$$S^\circ_{298.15} = 12.41 \pm 0.06 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_d = [1100]^\circ\text{K.}$$

Heat of Formation.

The equilibrium pressures (1169-1177°K.) of the reaction $\text{MgB}_4(\text{c}) \rightarrow \text{Mg}(\text{g}) + 4\text{B}(\text{c})$ were measured by M. Wright and P. N. Walsh, "The Vaporization of $\text{MgB}_4(\text{c})$ ", Technical Research Report OMCC-HEF-55, Jan. 9, 1958, Ohio State University Research Foundation. The third law value of $\Delta H_f^\circ 298.15$ for this reaction was derived as 60.40 ± 1.5 kcal. mole⁻¹. This leads to a $\Delta F_f^\circ 298.15 = -25.1 \pm 2.0$ kcal. mole⁻¹ for $\text{MgB}_4(\text{c})$. The unit of equilibrium pressures reported should be in atmosphere not in mm Hg as printed. The diameter of the hole drilled through the center of the lid served as the effusion orifice should be 1/16 inch rather than the reported value 1/8 inch.

Heat Capacity and Entropy.

The low temperature (17.34-299.53°K.) heat capacities were measured by R. M. Swift and D. White, J. Am. Chem. Soc. 79, 3641 (1957). Above 298.15°K. the C_p values were estimated by comparison with those of other related borides. $S^\circ_{298.15}$ was reported by R. M. Swift and D. White, loc. cit., using $S^\circ_{20}(\text{extrap.}) = 0.022 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Temperature of Decomposition.

T_d was estimated from the decomposition reaction reported by M. Wright and P. N. Walsh, loc. cit.

B_4Mg

$\Delta H_f^o = -778.31 \text{ kcal. mole}^{-1}$
 $\Delta H_f^o \text{ 298.15} = -793.16 \pm 2.0 \text{ kcal. mole}^{-1}$
 $\Delta H_m^o = 19.4 \pm 1.5 \text{ kcal. mole}^{-1}$
 $T_m = 1015.6^\circ \text{K}$

Heat of Formation.

The heat of the reaction $\text{Na}_2\text{O}(c) + 2\text{B}_2\text{O}_3(l) \rightarrow \text{Na}_2\text{B}_4\text{O}_7(c)$ was reported by L. Spatola and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAP values for $\text{B}_2\text{O}_3(l)$ (Dec. 31, 1964) and for $\text{Na}_2\text{O}(c)$ (June 30, 1962). The above $\Delta H_f^o = -85.2 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

In the low temperature region (5-344°K) the C_p values are those determined by E. P. Westrum, Jr., and O. Grenier, J. Am. Chem. Soc. 79, 1799 (1957). The enthalpy measurements of O. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic S9-2916 in the range 298 to 1015.6°K were smoothed graphically and used to determine C_p ; the values did not join smoothly with those of Westrum and Grenier and the low temperature values were given greater weight. Above T_m the heat capacity was extrapolated. $S_{298.15}^o$ was derived from low temperature heat capacities.

Melting.

The value for T_m is from O. W. Morey and H. E. Merwin, J. Am. Chem. Soc. 59, 2248 (1936). Other reported values for T_m are: 1008 ± 5°K by S. S. Coles, S. R. Scholtes, and C. R. Amberg, J. Am. Ceram. Soc. 19, 58 (1935); 1011°K by H. Menzel, Z. anorg. Chem., 224, 1 (1935); 1005°K by J. P. Ponomareff, Z. anorg. Chem. 89, 383 (1924); 1015°K by A. L. Day and E. T. Allen, "The Isomorphism and Thermal Properties of the Feldspars", Carnegie Inst. of Washington, Publ. No. 31 (1905) p. 23; and 1064°K by C. H. Burgeas and A. Holt, Proc. Roy. Soc. (London) 74, 285 (1904). ΔH_m^o was obtained from the values of ΔH_f^o for $\text{Na}_2\text{B}_4\text{O}_7(c)$ and $\text{Na}_2\text{B}_2\text{O}_5(l)$ at 298°K as described above and the difference between $H_{1015.6}^o$ and H_{298}^o for crystal and liquid.

$\text{B}_4\text{Na}_{207}$
MOL. WT. = 201.262

DISODIUM TETRABORATE ($\text{Na}_2\text{B}_4\text{O}_7$) (LIQUID)

$$S_{298.15}^\circ = 47.513 \pm 1.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1} \quad \Delta H_f^\circ 298.15 = -778.36 \pm 2.0 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = 19.4 \pm 1.5 \text{ kcal. mole}^{-1}$$

$$T_m = 1015.6^\circ\text{K.}$$

Heat of Formation.

The heat of reaction $\text{Na}_2\text{O}(c) + 2\text{B}_2\text{O}_3(l) \rightarrow \text{Na}_2\text{B}_4\text{O}_7(l)$ was reported by L. Shartala and W. Capps, J. Am. Ceram. Soc. 57, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $\text{B}_2\text{O}_3(l)$ (Dec. 31, 1964) and for $\text{Na}_2\text{O}(c)$ (June 30, 1962). The above $\Delta H_f^\circ = -80.4 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916, in the range 298 to 1373°K, were smoothed graphically and used to determine C_p . These were joined smoothly with the low temperature data of E. P. Westrum and G. Grenier, J. Am. Chem. Soc. 79, 1799 (1957). At 743°K a glass transition was observed and above this temperature the C_p adopted as constant.

The entropy at 298°K obtained from that of the crystal by adding ΔS_m° and the difference between S_{1015}° and S_{298}° for crystal and liquid.

Melting.

See the crystal for details.

Heat of Formation. See lead diborate table for the complete writeup. W. H. Evans in NBS Report 7192, July 1, 1981, analysed the heats of formation of the lead borate system based upon Shertels and Newman's heats of solution and Mazzetti and DeCarli's phase studies. From the Shertels and Newman paper Evans obtained the following:
 $PbO(c) + 2B_2O_3(ql.) \rightarrow PbO \cdot 2B_2O_3(c)$ $\Delta H_f^\circ = -11.9$ kcal. mole⁻¹
end estimated a ΔH_{298}° of 11.4 kcal. mole⁻¹ for the conversion to the $PbO \cdot 2B_2O_3$ (crystal). With auxiliary JANAF values the ΔH_f° 298.15 was calculated to be -683.00 kcal./mole.

Heat Capacity and Entropy. The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities of the constituent oxides.

The entropy at 298.15 was obtained from a consideration of the entropies of sodium and calcium borates and those of the constituent oxides, as given by K. K. Kelley and E. O. King, Bureau of Mines Bull. 592 (1961). These indicate for the reaction:

that the simple addition of entropies will give values at least 2.7 e.u. in the case of Na borates and 5.7 e.u. for Ca borates too high for the reaction. The reason for this is probably structural, the $B_4O_7^{--}$ ion is a rigid chain of rings. It was assumed that additional B_2O_3 would extend the ring structure into a rigid plane and thus the average entropy difference of 4.2 for the reaction was assumed to hold for each additional mole of B_2O_3 . Therefore the entropy at 298.15 was obtained from $S_{298.15}^\circ$ for PbB_2O_4 and B_2O_3 and the subtraction of 4.2 e.u.

(LIQUID)

PENTABORANE (B₅H₉)

$$\Delta H_f^{298.15} = 10.240 \pm 1.6 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 1.466 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{\circ} = 6.79 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{\circ} = 44.056$$

$$T_m = 226.34^{\circ}\text{K.}$$

$$T_b = 335^{\circ}\text{K.}$$

Heat of Formation.

The vapor pressures of B₅H₉(l) were measured by H. E. Wirth and E. D. Palmer, J. Phys. Chem. 60, 914 (1956) and H. L. Johnston, E. C. Kerr, J. T. Clarke and N. C. Hallett, "Calorimetric Investigation with the Condensed Gas Calorimeter. IV. The Heat Capacities, Latent Heats and Entropies of Pentaborane from 13 to 298°K.; Heats of Transition, Fusion and Vaporization; Vapor Pressures of the Liquid", TR-6, July 8, 1949, The Ohio State University. By use of both the second and third law methods, the respective heats of vaporization (ΔH_v^{298.15}) were evaluated. The ΔH_f^{298.15} values for B₅H₉(l) were calculated from ΔH_f^{298.15} for B₅H₉(g) and ΔH_v^{298.15} for B₅H₉(l) obtained previously. The results are presented as follows.

Investigator	ΔH _f ^{298.15} , kcal. mole ⁻¹	ΔH _f ^{298.15} , kcal. mole ⁻¹
	Second Law Value	Third Law Value
Wirth and Palmer	7.26 ± 0.02	7.26
Johnston, et al.	7.23 ± 0.04	7.25

*Calculation based on the third law ΔH_f^{298.15} values.

The adopted value is the average of the two ΔH_f^{298.15} values obtained.

Heat Capacity and Entropy.

The heat capacities (C_p), 231.34 - 290.19°K., for B₅H₉(l) were measured by Johnston, Kerr, Clarke and Hallett, loc. cit. The C_p values above 290.19°K. were estimated by graphical extrapolation of the C_p curve plotted using the experimental data. The value of S_{298.15}[°] was derived based on the low temperature C_p, 13.29 - 221.61°K., and ΔH_m[°] for B₅H₉(c) reported by Johnston, Kerr, Clarke and Hallett, loc. cit. and C_p values, 226.34 - 298.15°K., for B₅H₉(l), using S_{13.29}[°] = 0.236 cal. deg.⁻¹ mole⁻¹ for B₅H₉(c).

Melting Data.

The values of T_m and ΔH_m[°] were taken from Johnston, Kerr, Clarke and Hallett, loc. cit.

Vaporization Data.

The boiling point (T_b) is calculated as the temperature at which the free energy change of the reaction B₅H₉(l) - B₅H₉(g) becomes zero. The enthalpy change of the reaction at T_b is heat of vaporization (ΔH_v[°]).

Heat of Formation

The enthalpy change (ΔH_f^o) of the reaction $\text{B}_5\text{H}_9(\text{g}) \rightarrow 5\text{B}(\text{am.}) + 9/2 \text{ H}_2(\text{g})$ was reported to be -12.99 ± 0.39 and $-9.9 \pm 1 \text{ kcal. mole}^{-1}$ by E. J. Prosen, W. H. Johnson and P. V. Pergiel, J. Res. Natl. Bur. Std. 61, 247 (1958) and S. R. Omm and L. O. Green, J. Phys. Chem. 65, 2175 (1961), respectively. Using ΔH_f^o 298.15 = $1.2 \pm 0.4 \text{ kcal. mole}^{-1}$ for the reaction $\text{B}(\text{c}) \rightarrow \text{B}(\text{am.})$, the corresponding ΔH_f^o 298.15 values for $\text{B}_5\text{H}_9(\text{g})$ were derived as 18.99 and 15.9 kcal. mole⁻¹. The adopted value is the average of these two.

Heat Capacity and Entropy

The molecular structure, a tetragonal pyramid of boron atoms, and constants were obtained from H. J. Hrostowski and R. J. Myers, J. Chem. Phys. 22, 262 (1954). The vibrational frequencies were reported by H. J. Hrostowski and O. C. Finantel, J. Am. Chem. Soc. 76, 998 (1954). The earlier models of pentaborane were assumed to have a hydrocarbon - like structure of low symmetry by S. H. Bauer and L. Pauling, J. Am. Chem. Soc. 58, 2403 (1936) and K. S. Pitzer, J. Am. Chem. Soc. 67, 1126 (1945). However, the electron diffraction and X-ray data by K. Hedberg, M. E. Jones and V. Schomaker, Proc. Natl. Acad. Sci., U. S. 39, 679 (1952) and W. J. Dulmage and W. N. Lipscomb, Acta Cryst. 5, 260 (1952) revealed an unusual pyramidal structure of C_{4v} symmetry. The Raman spectrum of liquid B_5H_9 and the infrared spectrum of the gas B_5H_9 from 3 to 25 microns have been obtained by W. J. Taylor, C. W. Beckett, J. Y. Rung, R. B. Holden and H. L. Johnson, Phys. Rev. 79, 234 (1950). The near infrared spectrum of $\text{B}_5\text{H}_9(\text{l})$ have been examined at high resolution by F. R. Pondy and H. C. Beechell, J. Chem. Phys. 25, 238 (1956). Ten bands were observed. The three principal moments of inertia are: $I_A = I_B = 1.18344 \times 10^{-38} \text{ g. cm.}^2$ and $I_C = 1.69172 \times 10^{-38} \text{ g. cm.}^2$

B_6K_{20}
MOL. WT. = 303.12

(CRYSTAL)

DIPOTASSIUM HEXABORATE ($K_2B_{10}O_{10}$)

$\Delta H_f^\circ 0$ = Unknown

$\Delta H_f^\circ 298.15 = -1,107.44 \pm 2.4$ kcal. mole⁻¹

$T_D = 1098^\circ K$

Heat of Formation.

The heat of reaction $K_2O(c) + 3B_2O_3(l) \rightarrow K_2B_{10}O_{10}(c)$ was reported by L. Shwarts and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above $\Delta H_f^\circ = -122.8$ kcal. mole⁻¹.

Heat Capacity and Entropy.

The enthalpy measurements of O. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Cerd No. Mic 59-2916 in the range 288 to 973°K were graphically smoothed and used to determine C_p . Above this range C_p was extrapolated.

The entropy at 298°K was obtained from a consideration of the entropies of sodium end calcium borates and those of the constituent oxides, as given by K. K. Kelley and E. G. King, Bureau of Mines Bull. 592 (1961). These indicate that for the reactions

the simple addition of entropies will give values at least 2.7 e.u. too low for reaction (1) and at least 2.7 e.u. too high for reaction (2). The reason for this is probably structural, the $B_2O_4^{--}$ ion being a flexible chain while the $B_4O_7^{--}$ ion probably is a rigid chain of rings. It was assumed that additional B_2O_3 would extend the ring structure into a rigid plane and thus the entropy difference for reaction (2) was assumed to hold for each additional mole of B_2O_3 added. Thus a value for $MO \cdot B_2O_3$ was estimated to be 55.5 ± 1.5 and then using an average value of 4.5 ± 1.5 e.u. for the difference between K_2 and Na_2 gave 60 ± 3 e.u. for the entropy of $K_2B_{10}O_{10}$.

Decomposition Temperature.

The incongruent melting point was given by A.-P. Rollat, Comp. rend. 200, 1763 (1935), the decomposition products being $K_2B_4O_7(l)$ and $K_2B_{10}O_{13}(c)$.

T_d = 1107 $\pm$ 4°K.

Heat of Formation.

The heat of reaction $\text{Li}_2\text{O}(c) + 3\text{B}_2\text{O}_3(l) \rightarrow \text{Li}_2\text{B}_6\text{O}_{10}(c)$ was reported by L. Shartais and W. Capps, J. Am. Ceram. Soc. 37, 21-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $\text{B}_2\text{O}_3(l)$ (Dec. 31, 1964) and $\text{Li}_2\text{O}(c)$ (March 31, 1964). The above ΔH_f° = -72.80 kcal. mole⁻¹.

Heat Capacity and Entropy.

The enthalpy measurement of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 823°K. were used to determine C_p . Above this range C_p is extrapolated. Entropy at 298°K. is estimated from that of the component oxides and the difference from the oxides observed for twice $\text{LiBO}_2(c)$.

Temperature of Decomposition.

The incongruent melting point reported by E. S. R. Sastry and P. A. Hummel, J. Am. Ceram. Soc. 42, 216-8 (1959) is used here.

$\text{B}_6\text{Li}_2\text{O}_{10}$

$$T_A = 1039^\circ\text{K}.$$

Heat of Formation.

The heat of reaction $\text{Na}_2\text{O}(c) + 3\text{B}_2\text{O}_3(l) \rightarrow \text{Na}_2\text{B}_6\text{O}_{10}(c)$ was reported by L. Shartais and W. Osppas, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $\text{B}_2\text{O}_3(l)$ (Dec. 31, 1954) and for $\text{Na}_2\text{O}(c)$ (June 30, 1952). The above $\Delta H_f^\circ = -97.52$ kcal./mole.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. M1c 59-2916 in the range 298 to 1039°K were smoothed graphically and used to determine C_p . Above this range C_p was extrapolated. Entropy at 298°K was estimated as described in detail for $K_2PbO_1(c)$.

Decomposition Temperature.

The incongruent melting point was reported by G. W. Morey and H. E. Merwin, J. Am. Chem. Soc. **58**, 2248 (1936), the products are $\text{Na}_2\text{B}_4\text{O}_{11}$ (1) and $\text{Na}_2\text{B}_8\text{O}_{13}$ (c).

 $\Delta H_f^{\circ} 298.15 = -1003 \pm 2.0 \text{ kcal mole}^{-1}$

$S^{\circ} 298.15 = \{48.6 \pm 3\} \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

Heat of Formation.

See lead diborate table for the complete writeup. W. H. Evans in NBS Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system based upon Shartsis and Newman's heats of solution and Mazzetti and De Carli's phase studies. From the Shartsis and Newman paper Evans obtained the following:

and estimated a ΔH_f° of 16.0 kcal. mole⁻¹ for the conversion to the $\text{PbO} \cdot 3\text{B}_2\text{O}_3(\text{crystal})$. With auxiliary JANAF values the $\Delta H_f^{\circ} 298.15$ was calculated to be -1003.00 kcal./mole.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of heat capacities of the constituent oxides.

The entropy at 298.15 was obtained in the manner described in the $\text{PbB}_6\text{O}_{10}$ table from $S_{298.15}^{\circ}$ for $\text{PbB}_6\text{O}_{10}$ and B_2O_3 and the subtraction of 4.2 e.u.

ΔH_f° = Unknown
 ΔH_f° 298.15 = -1,420.92 ± 1.4 kcal. mole⁻¹
 ΔH_m° = 29.9 ± 1.0 kcal. mole⁻¹
 T_m = 1130°K.
 $S_{298.15}^\circ$ = [70.2 ± 4] cal. deg.⁻¹ mole⁻¹

Heat of Formation.
 The heat of reaction $K_2O(c) + 4B_2O_3(l) \rightarrow K_2B_8O_{13}(c)$ was reported by L. Shartala and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above ΔH_f° = -137.00 kcal. mole⁻¹.

Heat Capacity and Entropy.
 The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1130°K were smoothed graphically and used to determine C_p . Above this range C_p is extrapolated.
 The entropy at 298°K was obtained by estimating the entropy of $Na_2B_8O_{13}(c)$ as 65.7 ± 2.5 e.u., as described on the table for $K_2B_8O_{10}(c)$ and then using an average value of 4.5 ± 1.5 e.u. for the replacement of Na_2 by K_2 .

Melting Data.
 T_m is given by A.-P. Rollet, Comp. rend., 200, 1763 (1935). ΔH_m° was obtained from the values of ΔH_f° for $K_2B_8O_{13}(c)$ and $K_2B_8O_{13}(l)$ at 298°K reported above and the enthalpy of the crystal and liquid at T_m .

$S_{298.15}^{\circ} = [71.295] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = -1,403.57 \pm 2.4 \text{ kcal. mole}^{-1}$
 $\Delta H_m = 29.9 \pm 1.0 \text{ kcal. mole}^{-1}$
 $T_m = 1130^{\circ}\text{K.}$

Heat of Formation.

The heat of reaction $K_2O(c) + 4B_2O_3(l) \rightarrow K_2B_8O_{13}(l)$ was reported by L. Shartais and W. Ceppa, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxida have been converted to the heats of formation using JANAP values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above $\Delta H_f^{\circ} = -119.65 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2910 in the range 298 to 1373°K on the glass and liquid were smoothed graphically and used to determine C_p . There is a discontinuity in the C_p curve, a glass transition at about 873°K. Above 873°K the C_p values were estimated to be constant.

The entropy was obtained from that of the crystal by adding ΔS_m° and the difference between $S_{1130-298}$ for crystal and liquid.

Melting Data.

Li_2O

(CRYSTAL)

LITHIUM OCTABORATE ($\text{Li}_2\text{B}_8\text{O}_{13}$)

MOL. WT. = 308.44

ΔH_f° = UNKNOWN

ΔH_f° 298.15 = -1413.57 ± 2.50 kcal. mole⁻¹

$S_{298.15}^\circ$ = [63.4 ± 1.0] cal. deg.⁻¹ mole⁻¹

T_d = 908 ± 10°K.

Heat of Formation.

The heat of the reaction $\text{Li}_2\text{O}(c) + 4\text{B}_2\text{O}_3(l) \rightarrow \text{Li}_2\text{B}_8\text{O}_{13}(c)$ was reported by L. Shartsis and V. Cappe, J. Am. Ceram. Soc. 51, 27-32 (1964) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAP values for $\text{B}_2\text{O}_3(l)$ (Dec. 51, 1964) and for $\text{Li}_2\text{O}(c)$ (March 51, 1964). The above ΔH_f° = -73.35 kcal. mole⁻¹.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1968, L. C. Card No. Mic 59-2316 in the range of 298 to 823°K. were used to determine C_p . Above this range C_p is extrapolated. Entropy at 298°K. is estimated from that of the component oxides and the difference from the oxides observed for twice $\text{LiB}_2\text{O}_4(c)$.

Temperature of Decomposition. The incongruent melting point reported by B. S. R. Sastry and P. A. Hummel, J. Am. Ceram. Soc. 42, 216-8 (1959) is used here.

$\Delta H_f^{\circ} 0 = 3.4 \pm 4.5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = -6.9 \pm 4.5 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{\circ} = 5.25 \pm 0.01 \text{ kcal. mole}^{-1}$
 $\Delta H_g^{\circ} 298 = 19.2 \pm 0.2 \text{ kcal. mole}^{-1}$

$S_{298.15}^{\circ} = 42.20 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 371.93^{\circ}\text{K}$

Heat of Formation.
The enthalpy change ($\Delta H_f^{\circ} 298.15$) of the reaction $B_{10}H_{14}(c) \rightarrow 10B(am) + 7H_2(g)$ was reported to be 19.8 ± 1.4 and $18.0 \pm 1.0 \text{ kcal. mole}^{-1}$ by W. H. Johnson, M. V. Kilday and E. J. Prosen, *J. Res. Natl. Bur. Std.* **54A**, 521 (1960) and G. L. Gal'chenko, B. I. Timofeev and S. M. Shursov, *Doklady Akademii Nauk. USSR*, **142**, 1077 (1962), respectively. Using $\Delta H_f^{\circ} 298.15 = 1.2 \pm 0.4 \text{ kcal. mole}^{-1}$ for the reaction $B(c) \rightarrow B(am)$, the corresponding $\Delta H_f^{\circ} 298.15$ values for $B_{10}H_{14}(c)$ were calculated to be -7.8 and $-6.0 \text{ kcal. mole}^{-1}$. The adopted value of $\Delta H_f^{\circ} 298.15$ for $B_{10}H_{14}(c)$ is the average of these two.

Heat Capacity and Entropy.
 C_p (60° to 371.93°K.) was given by G. T. Furukawa and R. P. Park, *J. Res. Natl. Bur. Standards*, **55**, 255 (1955). The heat capacity above 371.93° was estimated by comparison with that of the liquid decaborane. Heat capacity (14° to 205°K.) was also reported by E. C. Kerr, N. C. Hallett and H. L. Johnston, *J. Am. Chem. Soc.*, **73**, 1117 (1951). The value of $S_{298.15}^{\circ}$ was taken from G. T. Furukawa and R. P. Park, loc. cit.

Melting Data.
 T_m and ΔH_m° were obtained from G. T. Furukawa and R. P. Park, loc. cit.

Heat of Sublimation.
 $\Delta H_g^{\circ} 298.15$ was calculated from free energy functions and vapor pressure reported by G. T. Furukawa and R. P. Park, loc. cit. See $B_{10}H_{14}(g)$ table for details.

B₁₀H₁₄
MOL. WT. = 122.312

DECABORANE (B₁₀H₁₄) (LIQUID)

S_{298.15} = 56.299 cal. deg.⁻¹ mole⁻¹
 T_m = 371.93°K.
 T_b = [492]°K.

Heat of Formation.

ΔH_f° 298.15 was calculated from ΔH_f° 298.15 for B₁₀H₁₄(c) and ΔH_m° reported by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Standards, 55, 255 (1955) and the difference H_m° - H_f° 298.15 for crystal and liquid.

Heat Capacity and Entropy.

C_p (371.93° to 380°K) was measured by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Standards, 55, 255 (1955). Heat capacities below 371.93° and above 380°K. were estimated by comparison with that of the gaseous decaborane. S_{298.15} was calculated from that of crystal in a manner analogous to that of the heat of formation.

Melting and Vaporization Data.

T_m and ΔH_m° were obtained from G. T. Furukawa and R. P. Park, loc. cit. T_b and ΔH_v° were calculated from functions for B₁₀H₁₄(l) and B₁₀H₁₄(g), respectively.

Product of the Moments of Inertia: I_AI_BI_C = 8.6710 X 10⁻¹¹⁵ g.³ cm.⁶

Heat of Formation.

The vapor pressures of decaborane (B₁₀H₁₄) were measured by O. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Std. 55, 255 (1955) and O. A. Miller, J. Phys. Chem. 57, 1353 (1953). The heats of vaporization (ΔH_v⁰) were derived by both the second and third law methods. Using the average value of ΔH_v⁰, the respective heats of formation (ΔH_f⁰ 298.15) for B₁₀H₁₄(g) were calculated. The results are presented as follows.

Investigator

Furukawa and Park

Miller

The adopted value of ΔH_f⁰ 298.15 for B₁₀H₁₄(g) is the weighted average of the three ΔH_f⁰ 298.15 values listed in the above table.

Heat Capacity and Entropy.

The molecular structure of B₁₀H₁₄(c) were reported by J. S. Kasper, C. M. Lucht and D. Harker, Acta Cryst. 3, 436 (1950); E. B. Moore, Jr., R. E. Dickerson and W. N. Lipscomb, J. Chem. Phys. 21, 209 (1957) and W. N. Lipscomb, Boron Hydrides, W. A. Benjamin, Inc., New York, 1953. For the calculation of the moments of inertia for B₁₀H₁₄(g) a simplified molecular model is adopted. The molecule is assumed to be composed of two regular pentagonal pyramids with a common base edge. The angle between the base planes of these pyramids is 73° 30'. Each of 10 H atoms is attached to a single B atom above the base plane. The remaining 4 H atoms, each bridge two B atoms. The vibrational frequencies were obtained from W. H. Evans, National Bureau of Standards Report 7033 (Jan. 1, 1961), which were derived based on the infrared and Raman spectra reported by J. E. Stewart, National Bureau of Standards, private communication, 1957 and W. E. Kaller and H. L. Johnston, J. Chem. Phys. 20, 1749 (1952). The three principal moments of inertia are I_A = 4.53925 X 10⁻³⁸, I_B = 3.51508 X 10⁻³⁸ and I_C = 5.43559 X 10⁻³⁸ g.² cm.²

DILEAD DECARBORATE ($\text{Pb}_2\text{B}_{10}\text{O}_{17}$) (CRYSTAL)

$S^\circ_{298.15} = [84.3 \pm 3] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H^\circ_f 0 = \text{Unknown}$
 $\Delta H^\circ_f 298.15 = -1694 \pm 3 \text{ kcal. mole}^{-1}$

Heat of Formation.

See lead diborate for the complete writeup. W. H. Evans in NBS. Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system based upon Sharvats and Newman's heats of solution and Mazzetti and DeCarli's phase studies. From the Sharvats and Newman paper Evans obtained the following:

$2\text{PbO}(c) + 5\text{B}_2\text{O}_3(c) \rightarrow 2\text{PbO} \cdot 5\text{B}_2\text{O}_3(c)$ $\Delta H^\circ_f = -45.2 \text{ kcal./mole}$
and estimated a ΔH°_{298} of 28.8 kcal. mole⁻¹ for the conversion to the $2\text{PbO} \cdot 5\text{B}_2\text{O}_3(\text{crystal})$. With auxiliary JANAF values the $\Delta H^\circ_f 298.15$ was calculated to be -1694.00 kcal./mole.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities of the constituent oxides.

The entropy at 298.15 was obtained in the manner described in the $\text{Pb}_2\text{B}_{10}\text{O}_{17}$ table from $S^\circ_{298.15}$ of $\text{Pb} \cdot 2\text{B}_2\text{O}_3$ and $\text{Pb} \cdot 3\text{B}_2\text{O}_3$ and the subtraction of 4.2 e.u.

$\text{B}_{10}\text{O}_{17}\text{Pb}_2$

September 30, 1961

 ΔH_f^o 238.15 = [2.881] kcal. mole⁻¹ ΔH_m^o = 2800 ± 500 cal. mole⁻¹ ΔH_v^o = 71.137 kcal. mole⁻¹ $S_{298.15}^o$ = [3.954] cal. deg.⁻¹ mole⁻¹ T_m = 1556°K. T_b = 2757°K.

Heat of Formation.

Obtained from ΔH_m 1556°K.

Heat Capacity and Extrapolation.

Heat capacity from T_m to 2200°K. taken from P. B. Kantor, R. M. Krasovitskaya and A. N. Kisel, Fiz. Metal. i Metalloved., Akad. Nauk S.S.S.R. 10, 635 (1960). C_p values below T_m and above 2200°K. were extrapolated.

Entropy.

Third law entropies between T_m and T_b extrapolated in both directions by means of extrapolated heat capacities.

Vaporization Phenomena.

 T_b and ΔH_v derived from a third law analysis of the vapor pressure data of E. A. Gulbransen and K. F. Andrews, J. Electrochem. Soc. 97, 363 (1952), and of R. B. Holden, R. Speiser, and H. L. Johnston, J. Am. Chem. Soc. 70, 3897 (1948).

A mass spectrometric study and review undertaken by O. T. Mikitin and L. N. Gorokhov, Zhur. Neorg. Khim. 8, 224 (1961), on the composition of beryllium vapor reveals that beryllium vaporizing both below and above the melting point, 1556°K., consists only of monatomic Be.

Heat of Formation.

The heat of formation was calculated from the equation: Be(g) + e⁻ → Be⁺(g) with the JANAP auxiliary value for Be(g) using an I.P. = 7.519229 X 10⁶ cm⁻¹ (215.001 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore loc. cit. The electronic levels above 1 X 10⁶ cm⁻¹ were omitted because their contribution is negligible below 6000°K. The H⁺-H⁺ value at 0°K. is -1.481 kcal./mole.

June 30, 1965

Dec. 31, 1961; Sept. 30, 1964

Ground State Configuration $2s^2 +$ $S_{298.15}^{\circ} = [54.84] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^{\circ} 0 = [10.1 \pm 5.0] \text{ kcal. mole}^{-1}$ $\Delta H_f^{\circ} 298.15 = [6.6 \pm 5.0] \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

$$\frac{\epsilon_1 \text{ cm.}^{-1}}{0} = \frac{\epsilon_2}{2}$$

 $\omega_2 = [743] \text{ cm.}^{-1}$ $\omega_2 = [4.08] \text{ cm.}^{-1}$ $\sigma = 1$ $B_0 = [0.55780] \text{ cm.}^{-1}$ $\omega_e = [0.00293] \text{ cm.}^{-1}$ $r_e = [1.97] \text{ \AA}$

Heat of Formation.

The dissociation energy was estimated from the experimental energies for BeF(g), BeCl(g), and the gaseous lithium halides. The resulting value, 97.1 kcal. mole⁻¹, was combined with JANAF heats of formation for Be(g) and Br(g) in arriving at $\Delta H_f^{\circ} 298.15^{\circ}$.

Heat Capacity and Entropy.

The vibrational frequency was estimated from those of BeF(g), BeCl(g), and the gaseous lithium halides. The ground term was assumed to be similar to that of BeCl(g) and BeF(g), tabulated by G. Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950. A correlation of the interatomic distances for the alkali halides, BeF(g), and BeCl(g) was employed in deriving r_e .

BERYLLIUM DIBROMIDE (BeBr₂)

MOL. WT. = 168.8302

(CRYSTAL)

ΔH_f^0 = Unknown
 ΔH_f^0 298.15 = [-88.4 ± 8] kcal. mole⁻¹
 ΔH_m^0 = [4.5] kcal. mole⁻¹
 ΔH_g^0 298.15 = 29.8 ± 1.5 kcal. mole⁻¹
 $S_{298.15}^0$ = [25.4 ± 2.0] cal. mole⁻¹ deg.⁻¹
 T_m = 761°K.
Heat of Formation.
The heat of formation was estimated from the work of W. Blitz and C. Messerkecht, Z. Anorg. Chem. 148, 157 (1925) and Blitz, Klatte and Rahlfs, Z. Anorg. Chem. 166, 339 (1927) as reported in N. B. S. Circular 500, Washington, 1952. They measured the heat of solution of BeBr₂ in aq. HCl to an unknown concentration. This value was apparently adjusted and used with Be⁺⁺ and 2Br⁻ to obtain ΔH_f^0 of the crystal. However Be⁺⁺ was estimated by N. B. S. An uncertainty of 8 kcal. is thought to be realistic.

Heat Capacity and Entropy.

The heat capacity was estimated graphically by comparison with BeCl₂ and BeF₂. The entropy was also estimated by comparing with CC-BeCl₂ and BeF₂ and using additive entropy values for the halide ions.

Melting Data.

The melting point has been reported by O. Rahlfs and W. Fischer, Z. Anorg. Chem. 211, 351 (1933) and by Lebean, Ann. Chim. Phys. 16, 472 (1899) as reported in N. B. S. Circular 500, Washington, 1952. The heat of melting was estimated by comparison with the sum of the heat of transition and melting for BeF₂ and BeCl₂.

Sublimation Data.

The heat of sublimation was obtained from an analysis of the vapor pressure data of Rahlfs and Fischer, loc. cit. from 624-695°K. The 3rd law analysis gave ΔH_{sub}^0 298 = 29.78 with a drift of -2.1 ± 0.8 cal. mole⁻¹ deg.⁻¹. A 2nd law analysis gave ΔH_{sub}^0 298 = 31.1 ± 0.5 kcal. mole⁻¹. The 2nd law result was adopted in order to yield a real liquid region, no attempt was made to eliminate the drift since this would have caused the liquid region to become unreal.

BeBr₂

MOL. WT. = 168.8302

(LIQUID)

BERYLLIUM DIBROMIDE (BeBr₂)

ΔH_f^o 298.15 = [-85.88 ± 3] kcal. mole⁻¹
 ΔH_m^o = [4.5] kcal. mole⁻¹
 ΔH_v^o = [23.9] kcal. mole⁻¹

S_{298.15} = [28.07] cal. mole⁻¹ deg.⁻¹
 T_m = 761°K.
 T_b = [794]°K.

Heat of Formation.

The heat of formation was obtained from that of BeBr₂(c) by adding ΔH_m^o and the difference between H₂₉₈ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with the measured value for BeCl₂. A glass transition was assumed at 500°K. below which the heat capacity is that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See BeBr₂(c) table for details.

Vaporization Data.

The temperature and heat of vaporization were calculated from the cross over between BeBr₂(l) and (g).

Rotational Constant: B ₀ = 0.02922 cm. ⁻¹									
Heat of Formation.									
The heat of formation was obtained from that of the crystal plus ΔH _f ⁰ 298.15, see BeBr ₂ (c) for details.									
Heat Capacity and Entropy.									
The linear structure was assumed by analogy with BeCl ₂ . The bond length was reported by F. A. Akhshin, V. P. Spirodinov and O. A. Sobolev, Dokl. Akad. Nauk. SSSR 118, 1134 (1956) from electron diffraction measurements. The vibrational frequencies were estimated by assuming a set of force constants k _i for the BeF ₂ , BeCl ₂ , BeBr ₂ , BeI ₂ series and also assuming k _i /k ₀ ^{1/2} = 50 as for BeF ₂ . The principal moment of inertia is 95.7984 x 10 ⁻³⁹ g. cm. ²									
σ = 2

BERYLLIUM MONOCHLORIDE (BeCl)

(IDEAL GAS)

OPW = 44.4652

Ground State Configuration $2\Sigma^+$

$\Delta H_f^\circ = 13.9 \pm 3.0$ kcal/mol

$S_{298.15}^\circ = 51.984$ gibbs/mol

$\Delta H_f^\circ = 14.5 \pm 3.0$ kcal/mol

Electronic Levels and Quantum Weights

ϵ , cm ⁻¹	g_i
0	2
27970	4

$\omega_e = 845.29$ cm⁻¹

$\sigma = 1$

$B_e = [0.769]$ cm⁻¹

$\alpha_e = [0.0083]$

$r_e = [1.75]$ Å

Heat of Formation.

Novikov¹ measured 39 bands in the ultraviolet spectrum of BeCl(g). A linear extrapolation leads to a ground state dissociation energy of 36,555 cm⁻¹. The authors assumed that the non-crossing rule applied and that the ground and first excited states had a common dissociation limit. However, in the analogous case of BeF, treated in the same way by the above authors, it was shown by Mann² that these assumptions were not correct. If it is assumed that the excited state dissociates $A''\pi \rightarrow Be(^3P) + p(^2P)$ and the ground state $X^2\Sigma \rightarrow Be(^1S) + p(^2P)$, then $V_{00} + D'$ should equal D'' + excitation energy of Be atom. We find $V_{00} + D' = 27,960 + 30,390 = 58,350$ and $D'' + E_e = 36,555 + 21,981 = 58,536$ which is in excellent agreement. Thus the dissociation energy to ground state atoms is taken as 104.5 kcal/mol, which leads to a heat of formation of 3 kcal/mol using reaction a.

Greenbaum et al.³ report equilibrium constants for reaction b in the temperature range 1573 - 1724°K using the molecular flow effusion method. Also Hildenbrand et al.⁴ report equilibrium constants for reactions c and d which were calculated from mass spectrometric ion intensities. The $\Delta H_{298.15}^\circ$ values by second and third law analysis for these data and the corresponding $\Delta H_{298.15}^\circ$ values are listed below.

Author	Method	Reaction	$T^\circ K$	$\Delta H_{298.15}^\circ$ kcal/mol	Drift	$\Delta H_{298.15}^\circ$ kcal/mol
		(a) BeCl(g) $\rightarrow$ Be(g) + Cl(g)		Second Law	Third Law	eu

1. Novikov Spectroscopic 37-544 2.647 104.5 2.7

3. Greenbaum Kp 1573-1724 93.56 $\pm$ 7 85.87 -4.521 1.3

4. Hildenbrand Kp from Mass Spectroscopy 1382-1554 27.5 $\pm$ 2 28.25 - .779 15.3 $\pm$ 2

(d) Be(g) + BeCl₂(g) $\rightarrow$ 2 BeCl(g) 1382-1556 33.41 $\pm$ 8 36.08 2.198 14.1 $\pm$ 2.5

The equilibrium data of Greenbaum et al.³ was not weighted, since calculations indicated the possibility of reaction of BeCl(g) with the Al₂O₃ tube at the temperatures and pressures used. The data of Hildenbrand et al.⁴, which reflect the true gas phase equilibria and appear consistent with each other, were adopted, yielding $\Delta H_{298.15}^\circ = 14.5$ kcal/mol.

Heat Capacity and Entropy.

The vibrational constants used to calculate the functions were derived by Novikov¹ from a two constant equation $(\omega_e - (2v'' + 1)\omega_e x_e'' = \omega_0'' - (v'' + 1)\omega_e x_e'')$. The electronic levels were obtained from Herzberg⁵. E_e was obtained from the estimated bond length, which was taken to be slightly less than that in BeCl₂(g), and α_e was estimated from the Morse potential function.

Heat of Formation

Krasnov (1) has reported calculations of the ionization potentials(IP) for the monohalides (MX, where X = F, Cl, Br, and I) of Group IIA elements (M = Mg, Ca, Sr, and Ba). Based on his data we obtain graphically the value IP(BeCl, g) = 8.9 ± 0.5 eV. The value of ΔHf°₂₉₈(BeCl⁺, g) is derived as 219 ± 15 kcal/mol, using ΔHf°₂₉₈(BeCl, g) = 13.9 kcal/mol. Beckett (2) reported the ionization potential of BeCl(g) to be approximately 9 ± 1 eV, yielding ΔHf°₂₉₈(BeCl⁺, g) = 222 ± 23 kcal/mol. Hildenbrand (3) measured the appearance potential (AP) of BeCl⁺(g) to be 9.5 ± 0.7 eV which is on the same order of the above IP values, and assumed that IP(BeCl⁺, g) = AP(BeCl⁺, g) = 9.5 ± 0.7 eV. Using this IP value, we obtain ΔHf°₂₉₈(BeCl⁺, g) = 234 ± 20 kcal/mol which is adopted.

Heat Capacity and Entropy

The six electronic states are obtained from Fougere (3). The electronic levels are estimated by comparison with those of isoelectronic molecules, BeS (4), BeO (5, 6), and MgO (5, 7). The values of ω_e, ω_ex_e are estimated by comparison with those for BeCl(g) and LiCl(g). B_e and α_e are calculated using the method suggested by Herzberg (8). The bond distance is estimated (8). The moment of inertia is 3.865 x 10⁻³⁹ cm². The enthalpy at 0°K is -2.15 kcal/mol.

 [270](2)
 [1300](1)

Be-F = [1.43] Å

σ = 1

Bond Distance: Be-Cl = [1.77] Å
 Bond Angle: Cl-Be-F = [180°]
 Rotational Constant: B₀ = 0.12970 cm.⁻¹

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_f^o = 0$ for the reaction $\text{BeF}_2 + \text{BeCl}_2 \rightarrow 2\text{BeClF}$

Heat Capacity and Entropy.

The structure, bond lengths and frequencies were all estimated from the properties of BeCl₂ and BeF₂.
 The principal moment of inertia is $21.579 \times 10^{-39} \text{ g. cm.}^2$

 $T_m = 688^\circ\text{K}.$

Heat of Formation.

W. H. Johnson and A. A. Olliland, J. Res. Nat'l. Bur. Stand. 65A, 59 (1961) have directly reacted beryllium and chlorine and obtained $\Delta H_f^o = -118.03 \pm 0.56$ though the crystal form of the product was unknown. P. Oross, C. Hayman, P. D. Greene and J. T. Bingham, Fulmar Research Institute, Report R. 163/SR.1/Sept. 1964 under Contract AF61(052)-447 also by direct combustion of the elements obtain $\Delta H_f^o = -117.1 \pm 0.4$ kcal. mole⁻¹. The crystal form of the sample was deduced to be α' by a comparison experiment, the assumption is made here that α and α' are identical. C. J. Thompson, O. C. Sinka and D. R. Stull, J. Chem. Eng. Data 7, 380 (1962) by solution calorimetry report a $\Delta H_f^o = -118.25 \pm 0.5$ kcal. mole⁻¹. Initially this sample was reported to be of unknown crystal form. However, O. C. Sinka, private communication February 1965, reports that an x-ray of the sample used has been reinterpreted, in the light of more recent data, as being approximately 50% α' and 50% β . Using the heats of transition adopted for these tables heats of formation of -117.3 $\pm$ 0.8 kcal. mole⁻¹ for α and -118.6 $\pm$ 0.8 kcal. mole⁻¹ for β have been adopted as being the most consistent with all measurements.

Heat Capacity and Entropy.

R. A. McDonald and F. L. Oetting, J. Phys. Chem. scheduled for publication in the Nov. 1955 issue have measured the heat capacity of the α' form from 13° to 304°K. and the enthalpy (relative to the α' form) from 678° to 688°K. The assumption has been made that the α and α' forms are identical and the heat capacity curve between 304° and 678°K. has been estimated graphically. The entropy was obtained by integration of the heat capacity curve assuming $S_{13} = 0.16$ cal. mole⁻¹ deg.⁻¹. The sample was identified as α' by x-ray diffraction both before and after the experiments.

Melting Data.

The temperature and heat of melting were reported by McDonald and Oetting, loc. cit. Several investigations of the melting point are in disagreement mainly due to the uncertainty of the crystal form of the material and a solid state transition just below the pure α -liquid melting point.

Sublimation Data.

The adopted heat of sublimation was derived from that of the β form and heat of the α - β transition at 298°K.

$$T_c^0 = 676^\circ\text{K. } (\beta \rightarrow \alpha)$$

Heat of Formation.

See table for α -BeCl₂ for details.

Heat Capacity and Entropy.

R. A. McDonald and P. L. Oetting, J. Phys. Chem. scheduled for publication in the November 1965 issue have measured the heat capacity of the β -form from 13 to 304°K. and the enthalpy of the β -form from 298° to 676°K. The entropy was obtained by integration of the heat capacity curve based on $S_{13} = 0.06 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$. The sample was identified as β -BeCl₂ both before and after the low temperature experiments.

Melting Data.

The temperature and heat of melting were obtained from cross over point of the tables for β -BeCl₂ and liquid BeCl₂.

Transition Data.

The temperature of the β to α transition was obtained from McDonald and Oetting, loc. cit. The heat of the transition is a function of the heat capacity curve chosen for α -BeCl₂ between 298 and 676°K. A straight line interpolation was used by McDonald and Oetting, which gives a different result (1.49 kcal. mole⁻¹) than the curve employed here. It should also be noted that the transitional heat is not included in this table, which is for β -BeCl₂ only.

Sublimation Data.

The heat of sublimation was determined by 2nd and 3rd law analysis of vapor pressure data as described fully on the table for BeCl₂ (g).

BeCl_2

MOL. WT. = 79.9182

(LIQUID)

BERYLLIUM DICHLORIDE (BeCl_2)
$$\Delta H_f^{298,15} = 19.085 \pm 1 \text{ cal. mole}^{-1} \text{ deg.}^{-1} \quad \Delta H_f^{298,15} = -117.4 \pm 1.5 \text{ kcal. mole}^{-1}$$
$$T_m = 688^\circ\text{K}.$$
$$\Delta H_b^\circ = 25.0 + 2 \text{ kcal. mole}^{-1}$$

Point of Formation:

The heat of formation was obtained from that of the α - BeCl_2 plus the difference of H_{699}^{crystal} and liquid.

Heat Capacity and Entropy.

H. A. McDonald and P. L. Oetting, *J. Phys. Chem.*, scheduled for publication in the November 1995 issue have measured the enthalpy of the liquid, relative to α -BeCl₂, from 600° to 713°K. The heat capacity was assumed constant above this point and also below the melting point to 430°K, where a glass transition was assumed. Below 430°K, the heat capacity was assumed to be that of β -BeCl₂. The entropy was calculated in a manner analogous to the heat of formation.

Melting Data.

See the table for α -BeCl₂ (c) for details.

Vaporization Date.

The boiling point and heat of vaporization were obtained from the cross over point of the BeCl_2 (1) and (2) anben. The anelyala of the liquid vapor pressure data is given on the table for BeCl_2 (7).

 Bond Angle: Cl-Be-Cl = 180°
 Rotational Constant: B₀ = 0.0759 cm.⁻¹
 $\sigma = 2$

Heat of Formation

The vapor pressure data over the crystal was assumed to be for the β -form. The 2nd and 3rd law analyses of the data are summarized below after conversion to a common process. The data were also analyzed using gasous free energy functions based on a bending frequency of 170 cm.⁻¹ but no significant improvement of the results was noted.

It is obvious that there is no real agreement between the data sets, and some of this is undoubtedly due to the difficulty of keeping a single crystal form throughout a series of measurements. It is also doubtful that water vapor was adequately excluded in some experiments. We have adopted the only piece of work which shows adequate 2nd and 3rd law agreement, and no third law trend, that is $\Delta H_{298}^0 = 32.5 \pm 1 \text{ kcal. mole}^{-1}$ from ref. 4. It is interesting to note that all the other data can be made much more precise and its drift removed if a constant pressure is added to all points. The addition which varied from 20-30% of the lowest pressure in each data set serves to indicate the magnitude of possible systematic errors.

Heat Capacity and Entropy

The linear structure of BeCl₂(g) has been confirmed by the electric deflection experiments of A. Buchler, A. D. Little, Inc. Progress Report No. 8, 31st Dec. 1963 under contract No. DA-19-020-ORD-5584. The bond length was obtained from the electron diffraction data of F. A. Akhain, V. P. Spiridonov and O. A. Sobolev, Dokl. Akad. Nauk SSSR **118**, 1134 (1958). A Buchler and W. Klempner, J. Chem. Phys. **29**, 121 (1958) have reported the infra-red spectrum and assigned 1113 as the asymmetric stretch ν_3 and 462 as the bending frequency ν_2 . However, A. Shellen, IIT Research Institute, Report No. ITRI-C6013-4 May 1964 under contract No. DA-31-124-AO(D)-111 using matrix isolation experiments has shown this second band to be due to beryllium chloride solid. The unobserved frequencies were estimated from a valence force field treatment by assuming that the ratio of stretching to bending force constant was 50:1 the same as for BeF₂(g). This gives 230 cm.⁻¹ for ν_2 and 375 cm.⁻¹ for the asymmetric stretch. The principal moment of inertia is 36.884 x 10⁻³⁹ g. cm.²

Heat of Formation

ΔH_f° is the value selected by Parker (1), based on a thorough review of data for BeF₂(c, vitreous, aqueous) and BeO(c). Parker's analysis remains essentially unchanged for BeO(c) and BeF₂(c), even though the results for BeF₂(HF, aqueous) become more negative by 0.93 kcal/mol due to JANAF selections for HF(aqueous). Three values derived by Parker for BeF₂(c) from PbF₂(c) are changed due to JANAF auxiliary data; these values become -246.9, -246.0 and -247.2 for the three paths used by Parker.

The adopted ΔH_f° was derived by combination of calorimetric data for Be(c) + F₂(g) → BeF₂(vitreous) and BeF₂(c) → BeF₂(vitreous). Churney and Armstrong (2) obtained $\Delta H_f^\circ_{298.15} = -244.32 \pm 0.8$ kcal/mol for vitreous BeF₂ by combustion in fluorine of polytetrafluoroethylene and mixtures of Be(c) with polytetrafluoroethylene. $\Delta H_f^\circ_{298.15}(c \rightarrow \text{vitreous}) = 1.125 \pm 0.016$ kcal/mol was measured via solution calorimetry by Taylor and Gardner (3).

Heat Capacity and Entropy

C_p° is based on JANAF curve fits of measurements by adiabatic calorimetry (8-300°K) and by ice calorimetry (354-776°K) as reported by Taylor and Gardner (3). The sample was estimated as approximately 99.5% BeF₂. Analyses indicated that the major impurity was about 0.3% oxygen, mainly in the form of absorbed water. Petrographic examination and X-ray diffraction showed the sample to be composed almost completely of quartz-type crystals. The entropy is derived from the smoothed C_p° based on the extrapolation $S_0^\circ = 0.0065$ gibbs/mol. The adopted C_p° above 300°K agrees closely with the relative enthalpy data and shows a remarkable similarity to that of SiO₂ (low quartz, high quartz).

Transition Data

It is the value selected by Taylor and Gardner (3) from their relative enthalpy data. ΔH_t° is the corresponding difference in relative enthalpy from the JANAF curve fits for the two crystalline forms. Levina (4) studied the polymorphism of BeF₂ by observing the peaks in C_p near the transition temperatures. For low quartz → high quartz, Levina's peak began near 438°K, was complete near 503°K, and gave $\Delta H_t = 0.17$ kcal/mol. Levina found a second transition attributed to a form analogous to tridymite; this began above 670°K, was complete by 740°K, and gave $\Delta H_t = 0.24$ kcal/mol. There is no evidence for this transition in the relative enthalpy data, so we suspect that its occurrence may be due to impurities in Levina's sample. Levina also found that the cristobalite-like phase transformed in the region 380 to 420°K with $\Delta H_t = 1.27$ kcal/mol.

Melting Data

See the table for BeF₂(t).

Heat of Sublimation

See the table for BeF₂(g).

Sept. 30, 1951; June 30, 1963; Dec. 31, 1963; June 30, 1964

Heat of Formation

ΔH_f° is obtained from that of the crystal by means of $\Delta H_r^\circ = 1.125 \pm 0.016$ kcal/mol for $\text{BeF}_2(\text{c}) \rightarrow \text{BeF}_2(\text{vitreous})$ at 298.15°K. Further details are given in the section on Melting Data. $\Delta H_f^\circ(\text{c})$ actually is based on the direct determination of $\Delta H_f^\circ(\text{vitreous})$ by Churney and Armstrong (1) as discussed on the crystal table.

Heat Capacity and Entropy

C_p° is based on a JANAF curve fit of relative enthalpies of Taylor and Gardner (2) for the liquid (828-1183°K) and vitreous (320-473°K) forms of BeF_2 . The combined data yield a normal C_p° curve and reveal no need for a glass transition. Scatter in the data is somewhat larger than for the crystal, presumably due to minor variations in the vitreous state at the conclusion of each drop. $S_{298.15}^\circ(\text{c})$ is calculated from that of the crystal by addition of ΔS_m° and the difference for crystal and liquid of $(S_{828}^\circ - S_{298.15}^\circ)$.

Melting Data

T_m is the value selected by Taylor and Gardner (2) from their relative enthalpy data. These showed premelting starting near 804°K and complete melting above 828°K. Cooling of the liquid produced the vitreous state. T_m has also been reported as 815 (3), 821 (4), 818 (5) and $816 \pm 5^\circ\text{K}$ (6).

Solution calorimetry (2) gave $\Delta H_r^\circ = 1.125 \pm 0.016$ kcal/mol for $\text{BeF}_2(\text{low quartz}) \rightarrow \text{BeF}_2(\text{vitreous})$ at 298.15°K. Confirmation of this result came from transposed temperature-drop calorimetry (1) and calorimetric conversion (3). These gave 1.1 ± 0.2 and 1.1 ± 0.5 kcal/mol, respectively. Combination of $\Delta H_r^\circ = 1.125$ with JANAF enthalpies yields $\Delta H_m^\circ = 1.137$ kcal/mol.

Vaporization Data

T_b is the calculated temperature at which $\Delta G_r^\circ = 0$ for $\text{BeF}_2(\text{l}) \rightarrow \text{BeF}_2(\text{g})$. ΔH_v° is the corresponding value of ΔH_r° . These calculations neglect the presence of dimer, which is assumed to be negligible based on extrapolation of the equations of Belousov (3). Cantor (10) obtained $T_b = 1442^\circ\text{K}$ by extrapolation of his vapor pressures (1146-1372°K).

Vibrational Frequencies and Degeneracies

ω, cm⁻¹

σ = 2

Bond Distance: Be-F = 1.40 ± 0.03 Å

Bond Angle: F-Be-F = 180°

Rotational Constant: B₀ = 0.22635 cm⁻¹

Heat of Formation

ΔH_f⁰ is calculated from that of the crystal by means of ΔH_{298.15} = 55.15 ± 0.1 kcal/mol. The selected value of ΔH_f⁰ is an average of those obtained by third-law analysis of vapor pressures measured by manometry (3), torsion effusion (4) and entrainment (8-10). Mass-spectrometric data (1, 2) are in reasonable agreement and so is the average of two Knudsen-effusion studies (6, 7). Several techniques (1, 2, 5) were used to show that the amount of dimer in the vapor is negligible up to at least 1000°K. JANAF analyses of the vaporization data are summarized as follows:

Source	Method	T, °K	ΔH _f ⁰ /mol	ΔS ⁰

*ΔS = ΔS ⁰ (2nd law) - ΔS ⁰ (3rd law)				

Heat Capacity and Entropy

The bond length and angle are those derived by Aikshin et al. (11) from electron-diffraction data for the vapor. Linearity of BeF₂ was confirmed by electric-deflection studies (12) of the vapor and by infrared studies (13) of matrix-isolated BeF₂. Infrared absorptions were found near 330 and 1540 cm⁻¹ in neon matrices, leading to gas-phase estimates of 345 and 1555 cm⁻¹ (13). The latter absorption was observed (14) at 1520 cm⁻¹ in the infrared spectra of the vapor at 1000°C. We adopt a compromise of 1530 cm⁻¹ and use this value in the valence-force-field approximation to estimate 670 cm⁻¹ for the symmetric stretching mode.

LITHIUM TRIFLUOROBERYLLATE (LiBeF₃) (CRYSTAL) GFW = 72.9464

ΔHf° = Unknown
ΔHf°_{298.15} = -390.2 ± 0.7 kcal/mol
ΔHm° = Unknown

S°_{298.15} = [21.3 ± 2] gibbs/mol
Tm = 633°K

Heat of Formation.

The ΔHf°_{298.15} = -390.2 ± 0.7 kcal/mol was calculated from the ΔHr°_{298.15} = -2.24 ± 0.08 kcal/mol of the reaction $\text{LiF}(c) + \text{LiBeF}_3(c) = \text{Li}_2\text{BeF}_4(c)$ measured (calorimetrically) by P. Gross, Fulmer Research Institute, Administrative Report No. 4, January 1966.

Heat Capacity and Entropy.

The heat capacity (298 - 1100°K) was estimated from the difference of the Cp° values for $\text{Li}_2\text{BeF}_4(c)$ and $\text{LiF}(c)$. Above 1100°K the values were extrapolated graphically. The entropy was estimated by addition of S°₂₉₈ for $\text{BeF}_2(c)$ and $\text{LiF}(c)$.

Melting Data.

Tm was obtained from the phase diagram of a mixture of $\text{LiF}(c)$ and $\text{BeF}_2(c)$ reported by A. L. Mathews and C. F. Bass, Jr., ORNL-TM 1129, May 1955.

Bond distance: Be-F = [1.40] Å Li-Be = [1.205] Å
Li-F = [1.85] Å
Bond angle: F-Be-F = [120]° Li-Be-F = [90]°
Moment of inertia: I_{ABIC} = 2.1604 X 10⁻¹¹⁴ g. cm² σ = (5)
72, 1075 (1960).

Heat of Formation. ΔH°_f 298.15 was calculated from ΔH°_f 900 = 53 kcal. mole for the reaction: LiF(g) + BeF₂(g) = LiBeF₃(g) reported by J. Berkowitz and N. A. Chupka, Ann. N. Y. Acad. Sci., 72, 1075 (1960).

Heat Capacity and Entropy. The molecular structure was assumed to be pyramidal with Li atom at the top and BeF₃ located at the bottom. Beryllium atom was taken at the center of the equilateral triangle formed by the three F atoms. The Be-F distance was estimated from that of BeF₂(g). The bond distance of Li-F was taken from R. P. Porter and E. Zeller, J. Chem. Phys., 33, 888 (1960). Vibrational frequencies were estimated by comparison with related fluorides.

DILITHIUM TETRAFLUOROBERYLLATE (Li_2BeF_4) (CRYSTAL)

$\Delta H^\circ_{\text{f}} = \text{Unknown}$

$\Delta H^\circ_{\text{f}} 298.15 = -539.0 \pm 1.3 \text{ kcal/mol}$

$\Delta H^\circ_{\text{f}} = 10.606 \text{ kcal/mol}$

$S^\circ_{298.15} = [29.8 \pm 2] \text{ gibbs/mol}$

$T_m = 745^\circ\text{K}$

Heat of Formation.

The $\Delta H^\circ_{\text{f}} 298.15 = -539.0 \pm 1.3 \text{ kcal/mol}$ was calculated from the $\Delta H^\circ_{\text{f}} 298.15 = -5.05 \pm 0.06 \text{ kcal/mol}$ of the reaction $2\text{LiF}(c) + \text{BeF}_2(c) = \text{Li}_2\text{BeF}_4(c)$ measured (calorimetrically) by F. Gross, Fulmer Research Institute, R.163/23/May 1966. A value of $\Delta H^\circ_{\text{f}} 298 = 1.17 \text{ kcal/mol}$ was used for $\text{BeF}_2(c) \rightarrow \text{BeF}_2(g)$.

Heat Capacity and Entropy.

The heat capacity is based on the enthalpy data ($323\text{--}723^\circ\text{K}$) of T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report 8186, January, 1964. The entropy was estimated by addition of values for the component fluorides.

Melting Data.

T_m and ΔH_m° were obtained from Douglas et al., loc. cit., who measured the high temperature enthalpies.

DILITHIUM TETRAFLUOROBERYLLATE (Li_2BeF_4)

(LIQUID)

GFW = 98.8838

$$\Delta H^\circ_{298.15} = -531.2 \pm 1.3 \text{ kcal/mol}$$

$$\Delta H^\circ = -10.506 \text{ kcal/mol}$$

$$S^\circ_{298.15} = [39.3 \pm 2] \text{ gibbs/mol}$$

$$T_m = 745^\circ\text{K}$$

Heat of Formation.

The $\Delta H^\circ_{298.15}$ was obtained from $\Delta H^\circ_{298.15}(c)$ by adding ΔH°_f and the difference between $H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 500°K . The heat capacity below 500°K was obtained from the heat capacity of the crystal. Above 500°K the heat capacity was assumed constant at 55.5 gibbs/mol calculated from the liquid enthalpy equation given by T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report No. 8186, Washington, 1964. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $\text{Li}_2\text{BeF}_4(c)$ table.

Dec. 31, 1960 Mar. 31, 1963

BERYLLIUM MONOHYDRIDE (BeH)

(IDEAL GAS)

MOL. WT. = 10.021

Ground State Configuration $2s^+$
 $\Delta H_f^0 = 42.236 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 = 76 \pm 7 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 77 \pm 7 \text{ kcal. mole}^{-1}$

Electronic Level and Multiplicity

$$\epsilon, \text{ cm.}^{-1} = \frac{g_1}{2}$$

$$\omega_e x_e = 35.5 \text{ cm.}^{-1}$$

$$\sigma^- = 1$$

$$\omega_e = 10.308 \text{ cm.}^{-1}$$

$$r_e = 1.3431 \text{ \AA}$$

Heat of Formation.

Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall Ltd., London, 1953, selected a value of $2.3 \pm 0.3 \text{ e.v. (53} \pm 7 \text{ kcal. mole}^{-1})$ for D_0 . Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950, estimated D_0 as being $2.2 \text{ e.v. (50.7 kcal. mole}^{-1})$. Gaydon's value was used in this table.

Heat Capacity and Entropy.

Molecular constants were found in Herzberg, op. cit.

BeH

BeH⁺

OPW = 10.01962

BERYLLIUM MONOHYDRIDE UNIPosITIVE ION (BeH⁺) (IDEAL GAS)

Ground State Configuration 1 Σ
 $\Delta H_f^\circ = 274.3 \pm 10$ kcal/mol
 $\Delta H_f^\circ = 276.4 \pm 10$ kcal/mol
 $S_{298.15}^\circ = 40.75$ gibbs/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	g_i
0	1
[20000]	[3]
$\omega_e x_e = 39.79$ cm ⁻¹	
$\sigma = 1$	
$r_e = 1.31216$ Å	
$\omega_e = 2221.7$ cm ⁻¹	
$B_e = 10.7998$ cm ⁻¹	
$\omega_e^2 = 0.2935$ cm ⁻¹	

Heat of Formation.

The heat of formation was calculated from the equation $\text{BeH}(g) \rightarrow \text{BeH}^+(g) + e^-$ with the JANAP auxiliary data for $\text{BeH}(g)$, using an ionization potential = 8.6 ± 0.4 eV (198.34 ± 9.23 kcal/mol) obtained from C. W. Beckett, NBS Report 8828, Jan. 1, 1985.

The dissociation energy, D_0 ($\text{Be}^+ - \text{H}$) = 3.2 ± 0.2 eV (73.8 kcal/mol), has been reported by A. G. Gaydon, "Dissociation Energies," 2nd Ed., Chapman and Hall Ltd., London, 1953. This yields $\Delta H_f^\circ(\text{BeH}^+, g) = 270.0$ kcal/mol, which is in agreement with the value adopted.

Heat Capacity and Entropy.

The molecular constants were obtained from the ultraviolet spectroscopic studies by W. W. Watson and R. P. Humphreys, Phys. Rev. 52, 318 (1937).

The ground state configuration was given by O. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, New York, 1950. The estimated electronic level and quantum weight were obtained by assuming that a 3Σ level lies below the first observed excited state ($1\Sigma^-$) at 40,000 cm⁻¹.

Bond Angle: Be-O-H = [180°]
Rotational Constant: B₀ = [1.2602] cm⁻¹
σ = 1

Heat of Formation

The ionization potential (IP) of BeOH(g) is estimated as 9.5 ± 1 eV by comparison with the values IP(BeI, g) = 9.1 ± 0.5, IP(NgF, g) = 7.8 ± 0.3 (1) and IP(MgOH, g) = 8.5 eV. (JANAF values). Based on IP(BeOH, g) = 9.5 eV or 219 kcal/mol and ΔH_f^o(BeOH, g) = -25 ± 10 kcal/mol, we derive the heat of formation at 298°K for BeOH(g) as 194 ± 30 kcal/mol, which is tentatively adopted.

Heat Capacity and Entropy

The BeOH⁺(g) molecule has eight valence electrons. Based on the criterion given by Walsh (2) that ABH molecules (H = hydrogen atom) containing ten or less valence electrons will be linear in their ground state, we assume that the structure of BeOH⁺(g) is linear. The vibrational frequencies are estimated by comparison with those for BeOH(g) and LiOH(g). The Be-O and O-H bond distances are assumed to be the same as those in BeOH and H₂O molecules, respectively. The ground state quantum weight of BeOH⁺(g) is assumed to be the same as that of the isoelectronic molecule LiOH(g). The moment of inertia is 2.221 × 10⁻⁴⁰ g cm². The enthalpy at 0°K is -2.11 kcal/mol.

BERYLLIUM DIHYDROXIDE, ALPHA (α -Be(OH)₂)
(CRYSTAL)

OPW = 43.02694

ΔH_f^o = Unknown

ΔH_f^o_{298.15} = -215.75 ± 0.5 kcal/mol

S^o_{298.15} = [11.8 ± 2] gibbs/mol

Td = [407]°K

Heat of Formation.

The heat of formation is based on ΔH_f^o_{298.15} = -79.16 ± 0.5 kcal/mol for the reaction Be(c) + 2H₂O(l) = Be(OH)₂(_{a,c}) + H₂(g). The heat of this reaction is obtained by combination of the calorimetric heats of solution for pure beryllium metal and α-Be(OH)₂ in aqueous HP, measured by I. J. Bear and A. G. Turnbull, J. Phys. Chem. **69**, 2828-33 (1965).

Heat Capacity and Entropy.

The heat capacity was assumed the same as that of the beta phase. The entropy is calculated from the value of ΔG^o_{298.15} = -0.50 kcal/mol for the change α-Be(OH)₂ → β-Be(OH)₂ which is obtained from the solubilities in concentrated alkali measured by R. Fricke and H. Humme, Z. Anorg. Allgem. Chem. **178**, 400 (1929). This is combined with the ΔH_f^o_{298.15} difference and gives a change in entropy, ΔS^o_{298.15} = -0.8 eu and an entropy of α-Be(OH)₂, S^o_{298.15} = 11.8 ± 2 eu.

Decomposition Data.

Td is calculated as the temperature at which ΔG_f^o equals zero for Be(OH)₂(_{a,c}) = BeO(c) + H₂O(g).

BERYLLIUM DIHYDROXIDE, BETA (β -Be(OH)₂) (CRYSTAL)
OFW = 43.02694
 $\Delta H_f^\circ =$ Unknown
 $\Delta H_f^\circ_{298.15} = -216.50 \pm 0.5$ kcal/mol
 $S^\circ_{298.15} = [11.0 \pm 2]$ gibbs/mol
Td = [417] °K

Heat of Formation.

The heat of formation is based on $\Delta H_f^\circ_{298.15} = -79.89 \pm 0.5$ kcal/mol for the reaction $\text{Be}(c) + 2\text{H}_2\text{O}(l) = \text{Be}(\text{OH})_2(\beta, c) + \text{H}_2(g)$. The heat of this reaction is obtained by combination of the calorimetric heats of solution measured by Bear and Turnbull for pure beryllium metal and β -Be(OH)₂ in aqueous HF. Third law analyses of two studies of the decomposition pressure of water vapor over the β -phase are in good agreement with the selected heat of formation, as summarized below. Fricke and Severin observed a decomposition temperature of 105°C at a pressure of 100 mm, while Bear and Lecocq found 223°C for equilibrium with saturated water vapor at 24.2 atm. We have reduced the latter data to a standard state value of $\Delta G^\circ_{196.15} = -3028$ cal/mol for the decomposition reaction given below.

Source	Method	Reaction	T, °K	$\Delta H^\circ_{298.15}$ kcal/mol	$\Delta H^\circ_{298.15}$ kcal/mol

Heat Capacity and Entropy.

The heat capacity is estimated from that for $\text{Mg}(\text{OH})_2$ by subtracting the values for MgO and adding those for BeO.

The entropy is estimated by extrapolation to beryllium of the differences in S°_{298} between the chlorides and hydroxides of magnesium and calcium. Entropies of $\text{Mg}(\text{OH})_2$, MgCl_2 and BeCl_2 are taken from the JANAP tables, while those of $\text{Ca}(\text{OH})_2$ and CaCl_2 are taken to be 19.9 ± 0.1 and 25.0 ± 1.0 eu, respectively. [Recent low temperature data for SrCl_2 and BaCl_2 suggest that the CaCl_2 extrapolation should be $S^\circ_{50} = 2.4 \pm 1.0$ eu rather than the original value of $S^\circ_{50} = 4.59$ eu used by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. **65**, 782 (1943)]. Confirmation of the adopted entropy is obtained from the good agreement between the calorimetric heat of formation and the third law values derived from the equilibrium data.

Decomposition Data.

Td is calculated as the temperature at which ΔG_r° equals zero for $\text{Be}(\text{OH})_2(\beta, c) = \text{BeO}(c) + \text{H}_2\text{O}(g)$.

Angle between Be-O-H planes = [95°]

Product of the Moments of Inertia: I_AI_BI_C = [32.26] x 10⁻¹¹⁷ g³cm⁶

Heat of Formation.

The equilibrium reaction (A) BeO(c) + H₂O(g) → Be(OH)₂(g) has been studied by several investigators; all of them inferred that Be(OH)₂(g) was the major product, but there has been no direct proof of this. D. P. Hildenbrand, L. P. Theard and F. Ju, Aeronautics, 3rd Quarterly Technical Report No. U-2231, Contract AF 04(611)-8523, 31 July 1963, have examined the BeO-H₂O system at 2300°C mass-spectroscopically and report only BeOH and Be(OH)₂. They report a maximum value of the equilibrium constant for reaction (B) BeO(g) + H₂O(g) → Be(OH)₂(g) of 3.5 x 10⁻¹ atm⁻¹ at 2327°K; this yields ΔH^o 298.15 (Be(OH)₂, g) ≥ -157.7 ± 10 kcal/mol using JANAF functions.

L. I. Grossweiner and R. L. Seifert, J. Am. Chem. Soc. 74, 2701 (1952); W. A. Young, J. Phys. Chem. 54, 1003 (1950); and W. I. Stuart and O. H. Price, J. Nucl. Mater. 14, 417 (1964), have all studied reaction (A) under similar conditions. Each of these investigators varied and H₂O(g) flow rate without detectable change of K_p values. However, Grossweiner and Seifert used a considerably larger flow rate than the other investigators, and the reaction that they studied may not have been quite at equilibrium. The residence times in all cases were quite comparable. A second and third law analysis of the above data are shown below.

J. Blauer, M. A. Greenbaum and M. Farber, J. Phys. Chem. 70, 973 (1966), have also studied reaction (A) using the molecular flow effusion technique. They obtained a large variation of K_p with surface area, although the sample area and size were comparable to that in the earlier investigations. They operated at 300μ pressure, which is at the upper limits of the molecular flow regime. Also encountered was an unexpected variation of the blank experiments with sample size. All the samples investigated were relatively coarse with surface areas <60 cm²/g; it seems likely that surface area effects would have been found in the three earlier investigations with up to threefold variation in sample weights. We conclude that the variation observed by Blauer et al. is not wholly caused by sample size. A second and third law analysis of the data are shown below.

O.R.B. Elliott, UCRL 1831 (1952), has also investigated reaction (A), but details of the sample are not available and the results show considerable scatter.

A. Baur and A. Lecoq, Comm. Energie At. (France), Rappt. CEA-R2611, Direction des Matériaux et Combustibles Nucleaires, Nov. 1964, cite the results of Morize, Roudier and Elison, DM/948, in equation form.

*calculated using the 3rd law ΔH^o 298^o

ΔH^o 298 (Be(OH)₂, g) = -156.4 ± 5 kcal/mol is adopted, with a large uncertainty to cover errors due to the functions as well as the experimental uncertainty.

Heat Capacity and Entropy.

The structure is that assumed by R. L. Altman, J. Chem. Eng. Data 8, 534 (1965). One vibrational frequency was reported by M. Farber, M. A. Greenbaum, M. A. Frisch et al., Rocket Power, Inc., Final Report AFRL-TR-66-220, Contract AF 04(611)-10929, September 1966. The remaining frequencies were estimated and adjusted to give reasonable agreement between the second and third law heats of reaction. The three principal moments of inertia are I_A = 2.865 x 10⁻⁴⁰, I_B = 10.60 x 10⁻³⁹, and I_C = 10.62 x 10⁻³⁹ g cm².

$$E_e = [0.41894] \text{ cm.}^{-1} \quad \alpha_e = [0.00249] \text{ cm.}^{-1}$$

$$r_e = [2.19] \text{ \AA}$$

Heat of Formation.

The dissociation energy was estimated from the experimental energies for BeF(g) , BeCl(g) , and the gaseous lithium halides. The resulting value, $79.1 \text{ kcal. mole}^{-1}$, was combined with JANAF heats of formation for Be(g) and I(g) in arriving at ΔH_f^0 298.15.

Heat Capacity and Entropy.

The vibrational frequency was estimated from those of BeF(g) , BeCl(g) , and the gaseous lithium halides. The ground term was assumed to be similar to that of BaCl(g) and BeF(g) , tabulated by G. Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950. A correlation of the interatomic distances for the alkali halides, BeF(g) , and BeCl(g) was employed in deriving r_e .

$$S_{298.15}^0 = [28.8 \pm 2] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$T_m = 753^\circ \text{K.}$$

Heat of Formation.

The heat of formation was estimated from the work of W. Biltz and C. Messerknecht, Z. anorg. Chem. 148, 157 (1925) and Biltz, Klatte and Rahlfs, Z. anorg. Chem. 166, 339 (1927) as reported in N.B.S. Circular 500, Washington 1952. They measured the heat of solution of BeI₂ in aq. HCl to an unknown concentration. This value was apparently adjusted and used with Be⁺⁺ and 2I⁻ to obtain ΔH_f⁰ of the crystal. However Be⁺⁺ was estimated by the Bureau and a total uncertainty of 8 kcal. is thought to be realistic.

Heat Capacity and Entropy.

The heat capacity was estimated graphically by comparison with BeCl₂ and BeF₂. The entropy was also estimated by comparing with α-BeCl₂ and BeF₂ and using additive entropy values for the halide ions. K. N. Semenov and T. N. Naumova, Zhur. Strukt. Khim. 4, 67 (1963) have reported that between 563 and 643°C BeI₂ exists in a β form and above 643°C a β form and an unknown form also exist. No allowance has been made for these modifications in the present table.

Melting Data.

The melting point was reported by O. Rahlfs and W. Fischer, Z. anorg. Chem. 211, 351 (1933). The heat of melting was estimated by comparison with the heats of transition and melting for BeCl₂ and BeF₂.

Sublimation Data.

The heat of sublimation was obtained from a third law analysis of the vapor pressure data of Rahlfs and Fischer, loc. cit. from 578-703°K. This gave ΔH_g⁰ 298 = 30.34 kcal. mole⁻¹ with a drift of 3.2 ± 1.1 cal. mole⁻¹ deg.⁻¹. A second law analysis gave ΔH_g⁰ 298 = 28.1 ± 0.7 kcal. mole⁻¹. No attempt was made to change the functions to eliminate the drift, since a correlation with BeCl₂, BeBr₂ and BeI₂ indicated that the drift was probably due to the data rather than the functions.

(LIQUID)

BERYLLIUM DIODIDE (BeI₂)

$$\Delta H_f^\circ 298.15 = [-47.45 \pm 3] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = [5] \text{ kcal. mole}^{-1}$$

$$\Delta F_v^\circ = [23] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = [32.4] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$T_m^\circ = 753^\circ \text{K.}$$

$$T_b^\circ = [755]^\circ \text{K.}$$

Heat of Formation.

The heat of formation was obtained from that of the crystal by adding ΔH_m° and the difference between $H_{755}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with the measured value for BeCl₂. A glass transition was assumed at 500°K. below which the heat capacity was that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See BeI₂(c) table for details.

Vaporization Data.

The temperature and heat of vaporization were calculated from the cross over point BeI₂(l) and (g).

Dec. 31, 1961 June 30, 1965

BeI₂

MOL. WT. = 262.821

BERYLLIUM DIODIDE (BeI₂) (IDEAL GAS)

Point Group D_{∞h}
S°_{298.15} = [70.44 ± 2] cal. mole⁻¹ deg.⁻¹
ΔH°_f 0 = -20 ± 4 kcal. mole⁻¹
ΔH°_f 298.15 = [-20.3 ± 10] kcal. mole⁻¹
Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm.⁻¹
[140](1)
[155](2)
[770](1)

Bond Distance: Be-I = 2.12 Å
Bond Angle: I-Be-I = [180°]
Rotational Constant: B₀ = 0.01478 cm.⁻¹
σ = 2

Heat of Formation.

The heat of formation was obtained from that of the crystal plus ΔH_g 298; see BeI₂ (c) table for details.

Heat Capacity and Entropy.

The linear structure was assumed by analogy with BeCl₂. The bond length was reported by P. A. Akishin, V. P. Spirodinov and G. A. Sobolev, Dokl. Akad. Nauk SSSR, 116, 1134 (1958) from electron diffraction measurements. The vibrational frequencies were estimated by assuming a set of force constants k₁ for the BeF₂, BeCl₂, BeBr₂ and BeI₂ series and also assuming k₁/k₁ = 50 as for BeF₂. The principal moment of inertia is 189.402 x 10⁻⁵⁹ g. cm.²

Beryllium Nitride (BeN)

(Ideal Gas) Mol. Wt. = 23.021

$$\Delta H_f^0 = [101] \text{ kcal mole}^{-1}$$

$$\Delta H_f^0 = [102] \text{ kcal mole}^{-1}$$

Electronic Levels and Multiplicities

$$\frac{E_i, \text{ cm}^{-1}}{0}$$

$$\omega_e = [1194] \text{ cm}^{-1}$$

$$\sigma = 1$$

$$B_e = [1.655] \text{ cm}^{-1}$$

$$r_e = [1.406] \text{ \AA}$$

Heat of Formation

The heat of formation was estimated by J. S. Gordon, Astronomical International, Livingston, New Jersey, private communication, April 26, 1963.

Molecular Constants

The molecular constants were taken from J. S. Gordon, loc. cit.

$\Delta H_f^0 = -142.3 \pm 0.1 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{298.15} = -143.1 \pm 0.1 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 0.06 \pm 1.0 \text{ kcal. mole}^{-1}$
 $T_m = 2325^\circ\text{K.}$
 $\Delta H_m^0 = 15.1 \pm 0.4 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{298.15} = 174.1 \pm 3.0 \text{ kcal. mole}^{-1}$

Heat of Formation.

L. A. Cosgrove and P. E. Snyder, J. Am. Chem. Soc. 75, 3102 (1953) have reviewed earlier determinations of the heat of formation and have made a very careful oxygen bomb calorimeter determination, their value is adopted here.

Heat Capacity and Entropy.

The high temperature enthalpy of BeO(c) has been reported by A. Magnua and H. Denz, Ann. Physik. [4] 81, 407 (1926) up to 1172°K; E. N. Rodigina and K. Z. Gornel'skii, Zhur. Fiz. Khim. 35, 1828 (1961) up to 1128°K; V. V. Kandyba, P. B. Kantor, R. M. Krasovitskaya and E. N. Ponomarev, Doklady. Akad. Nauk. S.S.S.R. 131, 566 (1960) up to 2840°K; B. E. Walker, C. T. Ewing, and R. R. Miller, private communication, U. S. Naval Research Laboratory 18th April 1963 up to 1100°K; A. C. Victor and T. B. Douglas, J. Res. Natl. Bureau Standards 67A, 325 (1963) up to 1173°K. A high temperature phase transition has been reported by S. B. Austerman, Bull. Am. Physical Soc. 117 (1), 28 (1962) and has been confirmed using high temperature X-rays by T. W. Baker and P. J. Baldock, Nature 193, 1172 (1962). K. K. Kelley, J. Am. Chem. Soc. 81, 1217 (1959) has reported the low temperature heat capacities from 55.5 to 292.4°K. The heat capacity was assumed to follow the T^3 law below 55.5°K. and this gave $S_{55.5} = 0.045 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. The high temperature enthalpy data was smoothed using both 18 and 27 point groupings and was assumed to be discontinuous at 2325°K. The heat capacity obtained from the smoothed enthalpy was itself smoothed graphically so as to fit with the low temperature heat capacity. The data of Kandyba, et al., show no effect of the transition at 2325° and a value of 0.06 kcal. mole⁻¹ was adopted simply to provide a somewhat improved fit of the data above 2700°K. The data above 2700°K. were not included because of apparent premelting effects and the heat capacity curve from 2700 to 2820°K. is extrapolated.

Transition Data.

See heat capacity and entropy.

Melting Data.

Obtained from the enthalpy measurements of Kandyba, et al., loc. cit.

Heat of Sublimation.

The gas above BeO(c) is complex and the value given is for the reaction BeO(c) → BeO(g) and simply read from the respective tables.

$$\Delta H_f^{298.15} = 8.04 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^{298.15} = -129.562 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = 15.1 \pm 0.4 \text{ kcal. mole}^{-1}$$

$$T_m = 2820^\circ\text{K.}$$

$$T_b = [4060]^\circ\text{K.}$$

Heat of Formation.

The heat of formation was obtained from that of the crystal by adding ΔH_m^0 and the difference between H_{298}^0 and H_{298}^0 for crystal and liquid.

Heat Capacity and Entropy.

The enthalpy of three points in the liquid phase was determined by V. V. Kandyba, P. B. Kantor, R. M. Krasovitskiy and E. N. Pomichov, Dokl. Akad. Nauk S.S.S.R. 131, 566 (1960). These values were used to obtain a heat capacity for the liquid which was assumed constant. At 1900°K. a glass transition was assumed below which the heat capacity was that of the solid. The entropy at 298°K. was obtained in a manner analogous to the heat of formation.

Melting Data.

See the table for BeO(c).

Vaporization Data.

The vapor composition over BeO(c) at 2300°K. is composed of Be(g), O(g), BeO(g), (BeO)₂(g), (BeO)₃(g), (BeO)₄(g), (BeO)₅(g), (BeO)₆(g) and other species and thus a boiling point becomes almost meaningless and the value given here is the point at which the total pressure reaches 1 atm.

$\sigma = 1$

Heat of Formation.

W. A. Chupko, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) obtained a value of 106 ± 3 kcal. mole⁻¹ for D_0 from the reactions $\text{BeO}(g) \rightarrow \text{Be}(g) + \text{O}(g)$ and $\text{BeO}(g) + \text{O}(g) \rightarrow \text{Be}(g) + \text{O}_2(g)$. The reactions were followed mass spectrometrically at low electron energies in order to eliminate fragmentation of higher polymers. A Lagerqvist, Arkiv. Fysik 1, 473 (1954) had previously reported a value for $D_0 = 110 \pm 10$ kcal. mole⁻¹ based on the dissociation limit of the lowest $1\bar{1}\bar{1}$ state which was assumed to dissociate to $\text{Be}(\bar{1}s)$ and $\text{O}(\bar{1}D)$. The $\Delta H^{\circ}_{f 298} \text{ BeO}(g) = 31 \pm 3 \text{ kcal. mole}^{-1}$ from $D_0 = 106 \pm 3 \text{ kcal. mole}^{-1}$ was adopted.

Heat Capacity and Entropy.

The spectroscopic constants are from O. Herzberg, "Molecular Spectra and Molecular Structure. I. Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York 1950. The ground state configuration has been confirmed by B. A. Thrush, Proc. Chem. Soc. (London), 339 (1960) using absorption spectroscopy.

BERYLLIUM SULFATE (α - BeSO₄) (CRYSTAL) $\Delta H_f^\circ = -284.4 \pm 0.8$ kcal/mol

OPW = 105.0738

$\Delta H_f^\circ = -284.4 \pm 0.8$ kcal/mol
 $\Delta H_f^\circ_{298.15} = -287.0 \pm 0.8$ kcal/mol
 $\Delta H^\circ_1 = [0.266]$ kcal/mol
 $\Delta H^\circ_2 = [4.673]$ kcal/mol

$S^\circ_{298.15} = 18.635$ gibbs/mol

$T^\circ_1 = 863^\circ\text{K}$

$T^\circ_2 = 908^\circ\text{K}$

Heat of Formation.

Bear et al. measured the heats of solution of Be(c) and BeSO₄(α) in concentrated HF and the heat of reaction of H₂SO₄ (aq) with BeSO₄ (aq HF). Combination of these yield reaction (a) below. Taylor et al. measured heats of solution of Be(c) and BeSO₄(α) in H₂SO₄ (aq) which yields reaction (b). Marchal measured the total vapor pressure of BeSO₄(c) in the temperature range 863-1103°K. Partial pressures of SO₃(g) were calculated from Marchal's data using JANAF values for the SO₃ - SO₂ equilibrium. Third law analysis of these data yields ΔH_f° for reaction (c) as given below. This was converted to ΔH_f° for α -BeSO₄ using JANAF heats of transition.

Author	Method	Reaction	T°K	ΔH_f° kcal/mol	ΔH_f° kcal/mol
1. Bear (1966)	Calorimetric	(a) Be(c) + H ₂ SO ₄ (109 H ₂ O) = H ₂ (g) + α -BeSO ₄	294	-74.47	-286.65 $\pm$ 0.5
2. Taylor (1966)	Calorimetric	(b) Be(c) + H ₂ SO ₄ (47.849 H ₂ O) = H ₂ (g) + α -BeSO ₄	298	-76.38	-287.55 $\pm$ 0.13
3. Marchal (1925)	Kp (973-1083°K)	(c) BeSO ₄ (γ)-BeO(c) + SO ₃ (g) = H ₂ (g) + α -BeSO ₄	298	+43.92	-286.55 $\pm$ 0.5

References: 1. I. J. Bear and A. G. Turnbull, J. Phys. Chem. **70**, 711-17 (1966).

2. A. R. Taylor, Jr., B. E. Lefson and D. P. Smith, U. S. Bureau of Mines, Report No. 6724, 1966.

3. G. Marchal, J. Chim. Phys. **22**, 502 (1925).

The adopted $\Delta H_f^\circ_{298.15} = -287.0 \pm 0.8$ is an average value of reactions (a) and (b). This value is for relatively finely divided crystals of BeSO₄ as was indicated by Bear et al.

Heat Capacity and Entropy.

Low temperature heat capacities (12-301°K) and high temperature enthalpies (366-864°K) were measured by A. R. Taylor, Jr., T. E. Gardner and D. P. Smith, U. S. Bureau of Mines, Report No. 6240, 1963. These data were joined smoothly at 298°K and extrapolated graphically above 864°K. The entropy was obtained from the heat capacities using $S^\circ_{12.56} = 0.034$ eu.

Transition Data.

I. I. Bosik, A. V. Novoselova and Yu. P. Simanov, Russ. J. Inorg. Chem. **5**, 1295 (1961), observed two endothermic effects at 863-863°K and 908-913°K on the heating and cooling curves of BeSO₄(c); thus we have adopted T₁($\alpha \rightarrow \beta$) = 863°K and T₂($\beta \rightarrow \gamma$) = 908°K. ΔH° ($\alpha \rightarrow \beta$) = 0.266 kcal/mol was obtained from the single enthalpy point at 863.9°K observed by Taylor, Gardner and Smith. ΔH° ($\beta \rightarrow \gamma$) = 4.673 kcal/mol was chosen in order to give good agreement with the equilibrium data of Marchal, loc. cit.

Beryllium Sulfate, Beta (β -BeSO₄)
(Crystal) GFW = 105.0738

(CRYSTAL)

BERYLLIUM SULFATE, BETA (β -BeSO₄)

$\Delta H_f^0 = \text{Unknown}$
 $\Delta H_{298.15}^0 = [-286.734] \text{ kcal/mol}$
 $\Delta H_1^0 = [0.266] \text{ kcal/mol}$
 $\Delta H_2^0 = [4.673] \text{ kcal/mol}$

$S_{298.15}^0 = [18.943] \text{ gibbs/mol}$
 $T_1 = 863^\circ\text{K}$
 $T_2 = 908^\circ\text{K}$

Heat of Formation.

The heat of formation was calculated from that of the alpha phase by adding ΔH_1^0 , since the heat capacities of both phases are assumed the same.

Heat Capacity and Entropy.

The heat capacity was assumed to be the same as that of alpha phase. The entropy was obtained in a manner analogous to that of the heat of formation.

Transition Data.

See alpha phase.

Heat of Formation.

The heat of formation was calculated from that of the beta phase by adding ΔH°_2 , since the heat capacities of both phases are assumed the same.

Heat Capacity and Entropy.

The heat capacity was assumed to be the same as that of alpha phase. The entropy was obtained in a manner analogous to that of the heat of formation.

Transition Data.

See alpha phase.

BERYLLIUM TUNGSTATE (BeWO₄)

(CRYSTAL)

OPW = 256.8598

ΔH° = Unknown

ΔH°_{298.15} = [-361.7 ± 15] kcal/mol

ΔH° = Unknown

S°_{298.15} = [21.12 ± 2] gibbs/molT_m = Unknown

Heat of Formation.

The heat of formation, ΔH°₂₉₈(BeWO₄, c) = -361.7 kcal/mol, is calculated from ΔH°₂₉₈ = -17.1 kcal/mol for BeO(c) + WO₃(c) → BeWO₄(c). The value of ΔH°₂₉₈ is assumed to be the same as that for MgO(c) + WO₃(c) → MgWO₄(c), using -143.7, -143.1, -201.5 and -362.3 kcal/mol for the heats of formation of MgO(c), BeO(c), WO₃(c) and MgWO₄(c), respectively.

Heat Capacity and Entropy.

Heat capacities are estimated by comparison with those of CaWO₄(c)¹, BeO(c)², and CaO(c)³.

The entropy, S°₂₉₈ = 21.12 eu, is calculated from ΔS°₂₉₈ = -0.4 eu for BeO(c) + WO₃(c) → BeWO₄(c). The value of ΔS°₂₉₈ is assumed to be the same as that for MgO(c) + WO₃(c) → MgWO₄(c), using 6.44, 3.38, 18.14 and 24.18 eu for MgO(c), BeO(c), WO₃(c) and MgWO₄(c), respectively.

Bond Length: Be-Cl = [1.71] Å
Bond Angle: Cl'-Be-Cl' (in ring) = [89°]
Product of the Moments of Inertia: I_AI_BI_C = 2.62616 x 10⁻¹¹² g.³ cm.⁶
Be-Cl' (in ring) = [1.8] Å
Cl'-Be-Cl = [136°]
σ = 4

Heat of Formation.

The heat of formation was estimated by assuming that the concentration of dimer in equilibrium with the monomer was ~5% at 500°K. as reported by D. L. Hildenbrand, L. P. Theard, E. Murel and P. Ju, Aeronutronic Div. of Philco Corp., Report U-3068, April 1965 under contract AF 04(611)-8523, giving an effective K_p = 5.5 x 10⁻⁴ for 2BeCl₂(g) → Be₂Cl₄ at 500°K.

Heat Capacity and Entropy.

The structure was assumed planar with a D_{2h} symmetry, the bond lengths were estimated from the values for BeCl₂ (g), a lengthening being assumed in the ring. The frequencies were estimated using K₂Cl₂ as a basis for the ring vibrations. Two polymeric frequencies had been observed by A. Shelson, IIT Research Institute, Report No. IITRI-C6013-4, May 1964, under Contract No. DA-31-124-AHQ(D)-111. These were observed in matrix isolated BeCl₂ gas and were ascribed to polymeric species on account of their warm up behavior. They are here assigned to the B_{2u} asymmetric stretching mode and the B_{1u} asymmetric out of plane wag of the non ring chlorines. The order of the frequencies listed above is arbitrary and not related to their specie types. The individual moments of inertia are: I_A = 18.396 x 10⁻³⁵ g. cm.², I_B = 110.638 x 10⁻³⁵ g. cm.² and I_C = 129.034 g. cm.²

(Ideal Gas) GFW = 72.0206

OPF = 72.0206

Bond Distance: Be-O = [1.33] Å Be-F = [1.43] Å

Bond Angle: O-Be-F = [180]° Be-O-Be = [150]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.554374] \times 10^{-114}$ g³ cm⁶

$\sigma = [2]$

Heat of Formation

J. Sfilenko, NBS Report 8186, Jan. 1984, has studied mass spectrometrically the reaction $\text{BeO}(c) + \text{BeF}_2(g) \rightarrow \text{Be}_2\text{O}_2\text{F}_2(g)$ and also reported two sets of equilibrium constants. Using JANAF thermodynamic functions, the heat of reaction has been calculated from those reported equilibrium constants by the second law and the third law methods.

Number of Measurements	Temperature Range (°K)	$\Delta H^{\circ}_{f,298}$ kcal/mol	2nd law value	3rd law value	3rd law drift (kcal)
1st Set	13	1570-1891	41.448 ± 3.04	41.981	0.408 ± 1.726
2nd Set	21*	1872-2195	42.553 ± 0.70	42.714	0.015 ± 0.359

*Four points are rejected due to failure of statistical test.

A weighted average value, $\Delta H^{\circ}_{f,298} = 42.70$ kcal/mol, was chosen for the heat of reaction. The heat of formation, $\Delta H^{\circ}_{f,298}(\text{Be}_2\text{O}_2\text{F}_2, g) = -287.9 \pm 5$ kcal/mol, was calculated from the selected heat of reaction, using $\Delta H^{\circ}_{f,298}(\text{BeO}, c) = 143.1$ kcal/mol and $\Delta H^{\circ}_{f,298}(\text{BeF}_2, g) = -187.5$ kcal/mol.

Heat Capacity and Entropy

The adopted "v" shape molecular structure with nine fundamental vibrational frequencies was obtained from an estimation by D. E. Mann, NBS Report 8186, Jan. 1, 1984. The bond distances Be-O and Be-F were estimated to be the same as those in BeO(g) and BeF₂(g), respectively. The three principal moments of inertia are $I_A = 1.0103 \times 10^{-39}$, $I_B = 49.7805 \times 10^{-39}$ and $I_C = 50.7908 \times 10^{-39}$ g cm².

Bond distance: Be-O = [1.4] Å

Bond Angle: Be-O-Be = [180°]

 $\sigma = 2$ Moment of Inertia: $I_A = 5.8656 \times 10^{-39}$ g. cm.²

Heat of Formation.

D. L. Hildenbrand, L. P. Theard, and P. Ju, Ford Motor Co., Aeronautics Division, Third Quarterly Technical Report U-2231, April-June 1963, have reported the heat of formation. Equilibrium constants were determined in a mass spectrometer for the reactions $2BeO(c) \rightarrow Be_2O(g) + O(g) - (1)$ $2BeO(g) \rightarrow Be_2O(g) + O(g) - (2)$ and $Be_2O(g) \rightarrow Be_2O(g) + O(g) - (3)$. Using our own free energy functions we obtain $\Delta H_f^\circ 298$ Be₂O(g) = -13.1, -14.5, and -16.7 kcal. mole⁻¹, all ± 10 ; the 2nd law treatment of reaction 1 gives -18.3 ± 10 kcal. mole⁻¹. We adopt a median value -15 ± 10 kcal. mole⁻¹.

Heat Capacity and Entropy.

A. Buchler, J. L. Stauffer, W. Klemperer and C. Wharton, A. D. Little, Inc., Interim Technical Report No. 5, 1963, have shown Li₂O to be linear. Also A. D. Walsh, J. Chem. Soc. London 2269 (1953) predicted that AP₂ molecules with less than 16 bonding electrons would be linear. Thus Be₂O was taken to be linear and symmetrical, with a Be-O bond length of 1.4 Å, which is a little longer than in BeO(g). The vibrational frequencies were estimated by taking ω_3 to be larger than the stretch in BeO(g) and then calculating ω_4 from the valence force field assumption. The bending force constant was estimated as 1/20th of the stretching force constant. The two outermost electrons were considered unpaired and so gave a $\sum$ ground state.

Vibrotional Frequencies and Degeneracies

Bond Distance: Be-O = [1.63] Å $\sigma = 4$

Bond Angle: Be-O-Be = $[90^\circ]$ O-Be-O = $[90^\circ]$

Product of the Moments of Inertia: $I_{L_1 L_2} = \{3.0957\} \times 10^{-115} \text{ g. cm.}^6$

Heat of Formation.

W. A. Chupke, J. Berkowitz, and C. P. Glase, *J. Chem. Phys.* **30**, 827 (1959) studied the temperature dependence of the $(\text{BeO})_2$ ion in a mass spectrometer and obtained a second law heat of vaporization of 172 ± 8 kcal. per mole $^{-1}$ at 2150°K. No correction was made for fragmentation of higher polymers and this is reflected in the uncertainty. We adopted a heat of sublimation of 178 kcal. mole $^{-1}$ in order to match more closely the equilibrium constant found by Chupke, et al. However, it was not possible to alter either the heat or entropy sufficiently to obtain exact agreement, the predicted pressure being too high by a factor of 20.

Heat Capacity and Entropy.

A planer ring configuration was assumed which has six vibrational frequencies of the type $2\nu_{2a}$, ν_{2b} , ν_{2c} , ν_{2d} , ν_{2e} , and ν_{2f} . These were estimated by comparison with $(110)_2$ for which values have been calculated by D. White, ν_{2a} , ν_{2b} , D. F. Dever, D. E. Mann, and M. J. Linevsky, prepublication communication, July, 1963. It seems unlikely that any other structure than that of a ring is possible, so, in order to approach the observed equilibrium constant even lower entropy is needed. A non-linear chain would have a higher entropy due to the change in symmetry number and the two odd electrons. A linear chain would have approximately the same entropy due to the change in symmetry number and the two odd electrons. The vibrational frequencies were also made as high as possible by normalizing them using B_{20} equal to the BeO stretch in BeO(g) . The bond length was taken as the sum of the covalent radii of O and Be, which is in general agreement with other polymeric structures which generally increase in bond length by 10–20% in going from monomer to polymer. The bond angle was chosen arbitrarily, however, changes in the angle would change the entropy less than 1 eu.

The individual moments of inertia were $I_A = 7.057$, $I_B = 3.976$, and $I_C = 11.033 \times 10^{-39}$ g. cm.²

BERYLLIUM ORTHOSILICATE (Be_2SiO_4) (CRYSTAL)

MOL. WT. = 110.108

$\Delta H^\circ_f = -503.1 \pm 7$ kcal. mole⁻¹
 $\Delta F^\circ_f = -506.0 \pm 7$ kcal. mole⁻¹
 $S^\circ_{298.15} = 15.342 \pm 0.1$ cal. deg.⁻¹ mole⁻¹
 $T_m = 1833^\circ\text{K}.$

Heat of Formation.

The ΔH°_f 298.15 was estimated from the ΔH°_f 298.15 of Mg, Ca and Be oxides with SiO_2 given by K. K. Kelley in the report of investigations 5801, U. S. Department of the Interior, Bureau of Mines 1962, and from the ΔH°_f 298.15 of $\text{BeO}(c)$ (Sept. 30, 1963) and $\text{SiO}_2(c)$ (Dec. 31, 1962) in JANAP tables. The ΔH°_f 298.15 = 0 ± 7 kcal. mole⁻¹ was estimated for the reaction $2\text{BeO}(c) + \text{SiO}_2(c) \rightarrow \text{Be}_2\text{SiO}_4(c)$.

Heat Capacity and Entropy.

At low temperatures C_p was used from K. K. Kelley, J. Am. Chem. Soc., 61, 1217 (1939). Above 298.15°K. C_p values were estimated by summation of the component oxides using JANAP tables, BaO (Sept. 30, 1963) and SiO_2 (Dec. 31, 1962). The entropy was calculated at 54.7°K. using the Debye and Planck-Einstein Functions $D(\frac{422}{T}) + 25(\frac{227}{T})$ given by K. K. Kelley, J. Am. Chem. Soc., 61, 1217 (1939). The value of $S^\circ_{54.7} = 13.59$ cal. deg.⁻¹ mole⁻¹.

Melting Data.

The incongruent melting point was taken from Kubaschewski and Evans, "Metallurgical Thermochemistry" 3rd edition, Pergamon Press., New York 1958.

*Points rejected due to failure of statistical test.

**Calculated from 3rd law ΔH°₂₉₈.

The data of Yates et al. are seen to be in good agreement with the adopted ΔH°₂₉₈.

Heat Capacity and Entropy.

The low temperature heat capacity of α-Be₃N₂ has been measured, from 25° - 310°K, by B. H. Justice, The Dow Chemical Co., last Quarterly Report under Contract AF04611-67-C-0009, April 1967. These measurements are joined smoothly with the high temperature enthalpies reported by T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report 7587, July 1962. Above 1200°K the values were smoothly extrapolated to a limiting value of 6.2 gibbs/g-atom. The entropy at 298° was calculated by integration of the low temperature data based on S°₂₅ = 0.002 eu.

Melting Data.

See Be₃N₂(1) for details.

BERYLLIUM NITRIDE, ALPHA (α-Be₃N₂)

(CRYSTAL)

OPW = 55.050

$$\Delta H_f^\circ = -136.8 \pm 0.3 \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = -140.6 \pm 0.3 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [30.9] \text{ kcal/mol}$$

$$S_{298.15}^\circ = 6.157 \text{ gibbs/mol}$$

$$T_m = 2473^\circ\text{K}$$

Heat of Formation.

P. Orsso, C. Hayman, F. D. Oreene and J. T. Bingham, Trans. Faraday Soc. 52, 2719 (1956), have measured the heat of chlorination of α-Be₃N₂ to α-BeCl₂, and the heat of reaction of Be with ammonia. The chlorination reaction (A) α-Be₃N₂(c) + 3Cl₂(g) → 3 α-BeCl₂(c) + N₂(g) had a ΔH°₂₉₈ = -210.3 ± 1.1 kcal/mol, which, combined with the value of -117.1 ± 0.4 kcal/mol for α-BeCl₂ reported in the same paper, yields ΔH°₂₉₈(α-Be₃N₂,c) = -141.0 ± 1.6 kcal/mol. Reaction (B) 3 Be(c) + 2 NH₃(g) = α-Be₃N₂(c) + 3 H₂(g) had a ΔH°₂₉₈ = -214.6 ± 0.3 kcal/mol, which, combined with the JANAP value for NH₃(g), yields ΔH°₂₉₈(α-Be₃N₂,c) = -140.3 ± 0.3 kcal/mol. A weighted mean value of the above two determinations is adopted.

The decomposition Be₃N₂(c) = 3 Be(g) + N₂(g) has been studied by R. E. Yates, M. A. Greenbaum and M. Parber, J. Phys. Chem. 69, 2682 (1964), using the torsion effusion technique. The same decomposition has also been investigated by C. L. Hoenig, UCRL-7521, April 1964, using the Knudsen technique. An analysis of these data sets by 2nd and 3rd law methods is given below.

Reference	Range	Points	ΔH° ₂₉₈ kcal/mol	Drift	**ΔH° _{298.15} Be ₃ N ₂ kcal/mol

*Points rejected due to failure of statistical test.

**Calculated from 3rd law ΔH°₂₉₈.

The data of Yates et al. are seen to be in good agreement with the adopted ΔH°₂₉₈.

$$\Delta H_f^{298.15} = [-116.4] \text{ kcal/mol}$$

$$\Delta H_m^\circ = [30.9] \text{ kcal/mol}$$

$$S_{298.15}^\circ = [9.425] \text{ gibbs/mol}$$

$$T_m = 2473^\circ \text{K}$$

Heat of Formation.

The heat of formation of Be₃N₂(l) is calculated from $\Delta H_f^{298} \text{ Be}_2\text{N}_2(\text{c})$ by adding ΔH_m° and the difference between $H_{2473}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is estimated to be constant and slightly greater than the maximum for Be₃N₂(c). The entropy at 298°K is estimated in a manner analogous to that of the heat of formation.

Melting Data.

The melting point was reported by P. Fichter and E. Brunner, Z. Anorg. Allgem. Chem. 93, 84 (1915). The heat of melting was calculated on the assumption that each g-atom contributed 2.5 gibbs to ΔS_m° .

Bond Distances: Be-O = [1.63] Å $\sigma = [6]$

Bond Angle: Be-O-Be = [120°] O-Be-O = [120°]

Product of the Moments of Inertia: $I_A I_B I_C = [9.0658] \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

W. A. Chupka, J. Barkowitz, and C. P. Glease, J. Chem. Phys. **30**, 827 (1959) measured the change in the intensity of the $(\text{BeO})_3^+$ ion with temperature and obtained a second law heat of vaporization of $161 \pm 6 \text{ kcal. mole}^{-1}$ at 2150° K. The uncertainty is large because of an approximate correction of $8 \text{ kcal. mole}^{-1}$ and the neglect of fragmentation effects. We adopted a heat of sublimation at 2150° K. of $163 \text{ kcal. mole}^{-1}$ in order to bring the equilibrium vapor pressure into agreement with that measured by Chupka, at al.

Heat Capacity and Entropy.

The assumed D_{3h} symmetry implies eight vibrational frequencies of the types $2A_1$, A_2 , A_2' , $3E'$, and E_2' . The frequencies were estimated by comparison with the values for the $\text{Be}_2\text{O}(0^-)$ skeleton as given by J. L. Parsons, J. Chem. Phys. **33**, 1860 (1960) and the partial assignment of Borokina by S. K. Gupta and R. P. Porter, J. Phys. Chem. **67**, 1286 (1963). The bond length was taken as that in $\text{Be}_2\text{O}_2(\text{g})$, while the bond angle was arbitrarily taken as 120° . The individual moments of inertia were $I_A = I_B = 16.550$, $I_C = 33.010 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) measured the variation of intensity of the (BaO)₄ ion with temperature in a mass spectrometer. They reported a second law heat of vaporization of 177 ± 8 kcal. mole⁻¹ at 2150°K., which included an approximate correction of 9 kcal. mole⁻¹, and this value was adopted here.

Heat Capacity and Entropy

The assumed D_{4h} structure has 14 vibrational frequencies of the type 2A_{1g}, A_{2g}, 2B_{1g}, 2B_{2g}, E_g, A_{2u}, B_{2u}, E_{2u}, and 3E_u. The frequencies were estimated by comparison with (BaO)₃ and cyclobutane from G. W. Rathjens, N. K. Freeman, W. D. Olinn, and K. S. Fitzer, J. Am. Chem. Soc. 75, 5634 (1953). The estimated structure and frequencies gave an entropy which was in excellent agreement with the experimental heat and equilibrium constant determined by Chupka, et al.

The bond lengths were taken equal to those in Be₂O₂(g) and the angles were chosen so that O-Be-O was almost linear. The individual moments of inertia were calculated to be I_A = I_B = 38.219, I_C = 76.438 X 10⁻³⁹ g. cm.²

Bond Distances: Be-O = [1.63] Å $\sigma = [10]$

Bond Angle: Be-O-Be = [110°] O-Be-O = [178°]

Product of the Moment of Inertia: $I_A I_B I_C = [6.9653] \times 10^{-112}$ g.³ cm.⁶

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, *J. Chem. Phys.* **30**, 827 (1959) measured the variation in intensity of the $(\text{BeO})_5^+$ ion with temperature in a mass spectrometer. They calculated a second law heat of vaporization of 193 ± 12 kcal. mole⁻¹ at 2150°K., the uncertainty reflects the inclusion of an approximate correction of 10 kcal. mole⁻¹. This value was adopted here.

Heat Capacity and Entropy.

The assumed D_{5h} structure has 14 vibrations of the type $2A_1$, A_2 , $3E_1$, $4E_2$, E_1' , and $2E_2'$. These were estimated by comparison with similar motions in other ring structures including $(\text{BaO})_3$ and $(\text{BeO})_4$. The estimated structure and frequencies gave an entropy in good agreement with the experimental heat and equilibrium constant determined by Chupka, et al.

The bond length was assumed to be the same as in Be_2O_3 (g) and the angles were chosen so as to make O-Be-O almost linear. The individual moments of inertia are calculated to be $I_A = I_B = 70.356$, $I_C = 140.713 \times 10^{-39}$ g.² cm.²

(Ideal Gas) Mol. Wt. = 150.078

BERYLLIUM OXIDE HEXAMERIC (Be₆O)₆ (IDEAL GAS)

Bond Distance: Be-O = [1.63] Å

Bond Angle: Be-O-Be = [110°] O-Be-O = [190°]

Product of the Moments of Inertia: $I_A I_B I_C = [3.1266] \times 10^{-111}$ g.³ cm.⁶

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. **30**, 827 (1959) measured the temperature dependence of the (BeO)₆⁺ ion in a mass spectrometer. They calculated a second law heat of vaporization of 203 ± 15 kcal. mole⁻¹ which was adopted here. The uncertainty reflects in part an approximate correction of 10 kcal. mole⁻¹ and the small observed intensities.

Heat Capacity and Entropy.

The assumed symmetry D_{6h} has 20 vibrational frequencies of the type 2A_{1g}, A_{2g}, B_{1g}, B_{2g}, E_{1g}, 4E_{2g}, 2E_{1u}, 2E_{2u}, 3A_{1u}, and 2E_{2u}. The frequencies were estimated by comparison with similar motions in other ring molecules including benzene, (BeO)₃ and (BeO)₄. The assumed structure and vibrational frequencies gave an entropy in good agreement with the heat and equilibrium constant determined by Chupka, et al. The bond length was taken equal to that in BeO₂(s) the angles were chosen so that the O-Be-O angle was almost linear but with the Be-O-Be angle less than 120°. The individual moments of inertia were calculated to be I_A = I_B = 116.089, I_C = 232.118 X 10⁻³⁹ g. cm.²

Thermodynamic Functions.

Thermodynamic functions were calculated using electronic levels and multiplicities listed by C. E. Moore [Nat'l. Bur. Standards Circ. 467 (1949)]. Higher levels were averaged. The results are in good agreement with W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Nat'l. Bur. Standards 55, 147 (1955)], who used essentially the same data.

Heat of Formation.

The heat of formation is calculated from the dissociation energy of bromine selected by Evans, Munson, and Wagman (loc. cit.) and the heat of sublimation derived for diatomic bromine. Evans, Munson, and Wagman list experimental vapor density measurements from the literature which agree with the spectroscopic value within their estimated uncertainty.

Sept. 30, 1962; Sept. 30, 1965

Ground State Configuration $1\Sigma^+$
 $S_{298.15}^{\circ} = 57.337 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} 0 = 5.28 \pm 0.30 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = 3.50 \pm 0.3 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

ϵ , cm.⁻¹ g_i
0 1
 $\omega_e x_e = 1.8 \text{ cm.}^{-1}$
 $\omega_e = 443.1 \text{ cm.}^{-1}$
 $\alpha_e = 0.000757 \text{ cm.}^{-1}$
 $r_e = 2.136 \text{ \AA}$
 $\sigma = 1$

Heat of Formation.

The average $\Delta H_f^{\circ} 298.15 = -0.406 \text{ kcal. mole}^{-1}$ for the reaction $\text{Br}_2(\text{g}) + \text{Cl}_2(\text{g}) = 2\text{BrCl}(\text{g})$ and the $\Delta H_f^{\circ} 298.15 = -3.694 \text{ kcal. mole}^{-1}$ for $1/2 \text{ Br}_2(\text{g})$ from JANAP tables were used to calculate the $\Delta H_f^{\circ} 298.15 = 3.5 \pm 0.3 \text{ kcal. mole}^{-1}$. Other equilibrium measurements not included below have been summarized by Beeson and Yost, loc. cit.

Third Law $\Delta H_f^{\circ} 298.15$

Heat Capacity and Entropy.

All spectroscopic and molecular constants were obtained from W. H. Evans, T. R. Munson and D. D. Wagman, J. Res. Natl. Bur. of Standards, 55, 147 (1955) except r_e which was calculated from B_e. The value of r_e was reported to be 2.13 Å by C. M. Beeson and D. M. Yost, J. Am. Chem. Soc. 61, 1432 (1939) and L. O. Cole and G. W. Elverum Jr., J. Chem. Phys., 20, 1543 (1952), respectively. Ground state configuration was taken from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

BROMINE MONOFLUORIDE (BrF)

(IDEAL GAS)

MOL. WT. = 98.9074

Ground State Configuration $1\sum^+$ $\Delta H_f^o = -12.1 \pm 0.4$ kcal. mole⁻¹

$S_{298.15}^o = 54.700$ cal. deg.⁻¹ mole⁻¹ $\Delta H_f^o 298.15 = -14.0 \pm 0.4$ kcal. mole⁻¹

Electronic Levels and Quantum Weight

ϵ , cm.⁻¹ g_i

0 1

$\omega_e x_e = 4$ cm.⁻¹

$\omega_e = 0.005206$ cm.⁻¹

$\sigma = 1$

$r_e = 1.7555$ Å

Heat of Formation.

The equilibrium constant for the reaction $\text{Br}_2(\text{g}) + \text{BrF}_3(\text{g}) = 3\text{BrF}(\text{g})$ has been measured over the temperature range 328-380°K. by R. K. Steunenberg, R. C. Vogel and J. Fischer, J. Am. Chem. Soc. **79**, 1320 (1957). Third law analysis of the data yields a $\Delta H_f^o 298 = 11.785 \pm 0.2$ kcal. mole⁻¹, with a drift of -0.6 ± 1.2 cal. mole⁻¹ deg.⁻¹. Second law analysis yields $\Delta H_f^o 298 = 11.98 \pm 0.45$ kcal. mole⁻¹, thus it is obvious that the data is thermodynamically self consistent. There is uncertainty in the entropy of $\text{BrF}_3(\text{g})$ of ± 1 cal. mole⁻¹ deg.⁻¹ but this corresponds only to ± 0.35 kcal. mole⁻¹ in $\Delta H_f^o 298$, thus a best value of $\Delta H_f^o 298 = 11.78 \pm 0.5$ kcal. mole⁻¹ is adopted. This yields $\Delta H_f^o 298 \text{ BrF} = -13.973 \pm 0.4$ kcal. mole⁻¹, the uncertainty in the heat of formation being a maximum value comprising the sum of the uncertainties in Br_2 , BrF_3 and ΔH_f^o .

Attempts have been made to analyze the spectra of BrF to obtain a D^o value. P. H. Broderick and J. E. Sicra, Z. Physik **141**, 515 (1955) obtained two dissociation limits for BrF of 66.52 kcal. mole⁻¹ and 54.98 kcal. mole⁻¹. The difference corresponds to the $\text{Br}(^2P_{1/2}) - \text{Br}(^2P_{3/2})$ excitation energy, indicating that the upper state goes to $\text{F}(^2P_{3/2})$ and $\text{Br}(^2P_{3/2})$. This yields a heat of formation of BrF of -10.23 kcal. mole⁻¹. Since this value is well outside the possible uncertainty limits of the equilibrium data we must conclude that the extrapolation is in error. W. H. Evans, T. R. Munson and D. D. Wagman, J. Res. Natl. Bur. Std. **55**, 147 (1955) have also analyzed the spectra and conclude that a heat of formation of -14.4 kcal. mole⁻¹ is possible. However M. H. Evans, private communication Nov. 1965, now believes that the dissociating state was too strongly perturbed for meaningful extrapolation.

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. of Standards **55**, 147 (1955) except r_e and ground state configuration which were taken from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

Heat of Formation.

The ΔH_f° 298.15 = -61.087 $\pm$ 0.7 kcal. mole⁻¹ is from L. Stein, J. Phys. Chem. 66, 288 (1962) and was derived from heats of reaction of F₂ with Br₂ which were measured in an adiabatic calorimeter. Stein's value for the ΔH_f° 298.15 = -64.78 kcal. mole⁻¹ was based upon gaseous Br₂, which has been adjusted to the liquid Br₂ reference state at 298.15°K.

Heat Capacity and Entropy.

D. W. Magnuson, Report No. K-1173, Carbide and Carbon Chemicals Co., K-25 plant, Oak Ridge, Tennessee (December, 1954) determined the moments of inertia and quadrupole coupling coefficients of both Br⁷⁹F₃ and Br⁸¹F₃ from a number of microwave transitions. From the moment of inertia of the bromine trifluoride molecule was found to have a distorted -T_h structure with one short, 1.721 Å, and two long, 1.810 Å Br-F bonds. The FBrF angle was found to be 86° 12.6'.

H. H. Claassen, B. Weinatock, and J. G. Malm, J. Chem. Phys. 28, 285 (1958), observed two of the six vibrational levels in the vapor, and calculated the other four levels from a normal coordinate treatment of the molecule. They also obtained a measured entropy of BrF₃(g), from low temperature data combined with vapor pressure data and an approximate correction for dimerization. This value is 71.9 e.u. at 316.27°K. compared with a value of 70.82 e.u. from this table, the difference is probably within the uncertainty of the data. The three principal moments of inertia are: I_A = 7.7514 $\times$ 10⁻³⁹, I_B = 2.05791 $\times$ 10⁻³⁸ and I_C = 2.83308 $\times$ 10⁻³⁸ g. cm.²

Heat of Formation.
The ΔH_f^{298.15} = -102.466 ± 0.5 kcal. mole⁻¹ is from L. Stein J. Phys. Chem. 66, 289 (1962) and was derived from heats of reaction of F₂ with Br₂ which were measured in an adiabatic calorimeter. Stein's value for the ΔH_f^{298.15} = -106.16 kcal. mole⁻¹ was based upon gaseous Br₂ which has been adjusted to the liquid Br₂ reference state at 298.15°K.

Heat Capacity and Entropy.

O. M. Begun, W. H. Fletcher and D. P. Smith, J. Chem. Phys. 42, 2235 (1965) report the infrared (gas phase) and Raman (liquid phase) spectra and correlate the observations by means of normal coordinate calculations for the similar molecules BrF₃, IF₃, ClF₃ and XeOF₄. The fundamental frequencies are taken from Begun, et al., except for ν₂ which was beyond the range of their infrared measurements. The value ν₂ = 245 cm.⁻¹ for the gas has been observed by R. S. McDevell and L. B. Asprey, J. Chem. Phys. 37, 165 (1962) and is confirmed by 237 cm.⁻¹ found in the Raman spectra of the liquid. Raman values from the liquid were used for the infrared inactive fundamentals ν₄ and ν₅. One Raman active frequency, presumably ν₆, is not observed in any of the four molecules. The value ν₆ = 261 cm.⁻¹ was obtained from the normal coordinate calculation. Previous Raman studies were reported by C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 1830 (1952).

A tetragonal pyramidal structure (C_{4v} symmetry) with the above parameters was used by Begun, et al., in the analysis of the spectra. This symmetry is consistent with the NMR spectra of H. S. Outowsky and C. J. Hoffman, J. Chem. Phys. 19, 1259 (1951), with the dipole moment determined by M. T. Rogers, R. D. Pruett, H. B. Thompson and J. L. Speiser, J. Am. Chem. Soc. 78, 44 (1956), and with the X-ray crystal structure obtained by R. D. Burbank and F. N. Benesey, Jr., J. Chem. Phys. 27, 982 (1957). Bond distances were based on those in the crystal and the bond angle was assumed to be 90°, slightly larger than those in the crystal (90.5-86.5°). Begun, et al., indicate that the angle in the gaseous molecule is probably not exactly 90° but that the normal coordinate calculations are not sensitive to this angle. The three principal moments of inertia are: I_A = 2.61497 X 10⁻³⁸, I_B = 2.61497 X 10⁻³⁸ and I_C = 4.04277 X 10⁻³⁸ g. cm.²

Sept. 30, 1961; Sept. 30, 1965

HYDROGEN BROMIDE (HBr)

(IDEAL GAS)

MOL. WT. = 80.91697

$\Delta H_f^{\circ} 0 = -6.84 \pm 0.13 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = -8.71 \pm 0.10 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{E}{\text{cm}^{-1}} = \frac{g_1}{0} - \frac{g_2}{1}$$

$\omega_e = 2649.218 \pm 0.016 \text{ cm}^{-1}$
 $\omega_e^* = 45.246 \pm 0.008 \text{ cm}^{-1}$
 $\alpha_e = 0.23248 \pm 7 \times 10^{-5} \text{ cm}^{-1}$

Heat of Formation

The enthalpy change, $\Delta H_f^{\circ} 376.2 = -12.47 \pm 0.13 \text{ kcal. mole}^{-1}$, for the reaction $(1) 1/2 \text{ H}_2(\text{g}) + 1/2 \text{ Br}_2(\text{g}) = \text{HBr}(\text{g})$ was reported by J. R. Lacher, L. Casali, and J. D. Park, J. Phys. Chem. **50**, 608 (1956). Using $\Delta H_f^{\circ} 298.15$ (Br_2, g) = $7.59 \text{ kcal. mole}^{-1}$, the $\Delta H_f^{\circ} 298.15$ (HBr, g) was derived as $-8.71 \pm 0.13 \text{ kcal. mole}^{-1}$.

The heat of oxidation of aqueous sulfur dioxide with gaseous chlorine and liquid bromine were determined by calorimetric methods by W. H. Johnson and J. R. Ambrose, J. Res. Natl. Bur. Std. **67A**, 427 (1963) and W. H. Johnson and S. Sumner, Acta Chem. Scand., **11**, 1917 (1957), respectively. The results were given as $\Delta H_f^{\circ} 298.15 = -77.28 \pm 0.14 \text{ kcal. mole}^{-1}$ ($\text{X}_2 = \text{Cl}_2(\text{g})$) and $-55.47 \pm 0.11 \text{ kcal. mole}^{-1}$ ($\text{X}_2 = \text{Br}_2(\text{l})$) for the reaction $\text{X}_2 + \text{SO}_2 \rightarrow \text{H}_2\text{SO}_4 + 2 \text{ H}_2\text{O}(\text{l}) = \text{H}_2\text{SO}_4 + 2 \text{ H}_2\text{O}(\text{l}) = \text{H}_2\text{SO}_4 + 2 \text{ H}_2\text{O}(\text{l})$. The enthalpy change for the reaction $\text{Cl}_2(\text{g}) + 2 (\text{HBr} \cdot \infty \text{H}_2\text{O}) = \text{Br}_2(\text{l}) + 2 \text{ H}_2\text{O}(\text{l}) = \text{H}_2\text{SO}_4 + 2 \text{ H}_2\text{O}(\text{l})$ was calculated to be $-21.82 \pm 0.18 \text{ kcal. mole}^{-1}$. Using $\Delta H_f^{\circ} 298.15$ ($\text{HCl} \cdot 1250 \text{ H}_2\text{O}$) = $-39.93 \pm 0.05 \text{ kcal. mole}^{-1}$, the heat of formation for $\text{HBr} \cdot 1250 \text{ H}_2\text{O}$ was derived to be $-28.53 \pm 0.10 \text{ kcal. mole}^{-1}$. Employing $\Delta H_f^{\circ} (\text{HBr} \cdot 1250 \text{ H}_2\text{O}) = -20.350 \pm 0.012 \text{ kcal. mole}^{-1}$, leads to $\Delta H_f^{\circ} 298.15$ ($\text{HBr} \cdot \infty \text{H}_2\text{O}$) = $-29.016 \pm 0.10 \text{ kcal. mole}^{-1}$. Based on the value, $\Delta H_f^{\circ} 298.15 = -20.350 \pm 0.012 \text{ kcal. mole}^{-1}$ for the reaction $\text{HBr}(\text{g}) = \text{HBr}(\infty \text{H}_2\text{O})$ reported by C. E. Vandervee and J. D. Mitter, J. Phys. Chem. **67**, 2521 (1963), the heat of formation ($\Delta H_f^{\circ} 298.15$) for $\text{HBr}(\text{g})$ was evaluated as $-8.67 \pm 0.10 \text{ kcal. mole}^{-1}$.

The heats of oxidation of As_2O_3 to As_2O_5 in aqueous solution with $\text{Br}_2(\text{l})$ and $\text{Cl}_2(\text{g})$ were measured by L. Bjellerup, S. Sumner and I. Wedberg, Acta Chem. Scand., **11**, 1761 (1957) and S. Thoren, Symposium on Thermodynamics and Thermochemistry, Lund, Sweden, July, 1963. Using the values $\Delta H_f^{\circ} = -56.61 \pm 0.11 \text{ kcal. mole}^{-1}$ ($\text{X}_2 = \text{Br}_2(\text{l})$) and $-100.09 \pm 0.08 \text{ kcal. mole}^{-1}$ ($\text{X}_2 = \text{Cl}_2(\text{g})$) for the reaction $\text{As}_2\text{O}_3(\text{aq.}) + 2 \text{X}_2 + 2 \text{ H}_2\text{O}(\text{aq.}) \rightarrow \text{As}_2\text{O}_5(\text{aq.}) + 4 \text{ HX}(\text{aq.})$ obtained from H. A. Skinner, Pure Appl. Chem. **9**, 95 (1964), the enthalpy change for the reaction $2\text{HBr}_2(\text{l}) + 4\text{HCl}(\text{aq.}) = 2\text{Cl}_2 + 4\text{HBr}(\text{aq.})$ was calculated to be $+43.48 \pm 0.14 \text{ kcal. mole}^{-1}$. Based on ΔH_f° reaction $2\text{HBr}_2(\text{l}) + 4\text{HCl}(\text{aq.}) = 2\text{Cl}_2 + 4\text{HBr}(\text{aq.})$ was calculated to be $+43.48 \pm 0.14 \text{ kcal. mole}^{-1}$. Based on ΔH_f° ($\text{HCl} \cdot \infty \text{H}_2\text{O}$) = $-39.93 \pm 0.05 \text{ kcal. mole}^{-1}$, the value of $\Delta H_f^{\circ} 298.15$ ($\text{HBr} \cdot \infty \text{H}_2\text{O}$) was derived to be $-29.06 \pm 0.06 \text{ kcal. mole}^{-1}$, yielding $\Delta H_f^{\circ} 298.15$ (HBr, g) = $-8.71 \pm 0.06 \text{ kcal. mole}^{-1}$.

The value of $\Delta H_f^{\circ} 298.15$ (HBr, g) adopted is $-8.71 \pm 0.10 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy

The values of ω_e , ω_e^* , B_e and α_e were taken from T. C. James and R. J. Thibault, J. Chem. Phys. **42**, 1450 (1965), and corrected to the average isotopic species. Submillimeter-wave spectra of HBr were measured by G. Jones and W. Gordy, Phys. Rev. **135**, A 1223 (1964). The molecular constants derived were close to the values adopted. The ground state configuration was obtained from G. Herzberg, Spectra of Diatomic Molecules, D. Van Nostrand Company, Inc., New York, 1950, in which molecular constants for $\text{HBr}(\text{g})$ were also given. A precise measurement of the infrared fundamental bands of HBr has been made by E. K. Plyler, J. Res. Natl. Bur. Std., **64**, 377 (1960). The corresponding rotational and vibrational constants have been calculated from the observed data. The moment of inertia is $3.30514 \times 10^{-40} \text{ g. cm}^2$.

MOL. WT. = 97.94758

(CRYSTAL)

AMMONIUM BROMIDE (NH₄Br)

ΔH_f^o 0 = -60.9 ± 0.3 kcal. mole⁻¹
 ΔH_f^o 298.15 = -84.9 ± 0.3 kcal. mole⁻¹
 ΔH_f^o = 0.77 kcal. mole⁻¹
 ΔH_m^o = Unknown

S_{298.15} = 26.97 cal. deg.⁻¹ mole⁻¹

T_c = 411°K.

T_m = 815.2°K.

T_d = 670°K.

Heat of Formation.

The equilibrium pressures for the reaction NH₄Br(c) → NH₃(g) + HBr(g) have been measured by several investigators. Using the densi-tensimeter, A. Smith and R. Purcell, J. Chem. Soc. 2944 (1928), determined both the equilibrium pressures and vapor densities of the decomposition products, simultaneously, at several temperatures. In order to check the density values obtained, the authors applied the "extrapolation method", from which it was calculated that the corresponding vapor density agreed with complete dissociation. Based on this conclusion, the reported equilibrium pressures were employed to evaluate the enthalpy changes (ΔH_f^o) of the decomposition reaction by both the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	Equipment Used
Smith and Calvert (1)	576.40-676.02	45.12 ± 0.13	44.93	Isotenoscope
Smith and Purcell (2)	604.95-668.15	45.50 ± 0.17	45.08	Densi-tensimeter
Johnson (3)	573.15-667.75	45.41 ± 0.44	44.85	Spiral Manometer
(1) A. Smith and R. P. Calvert, J. Am. Chem. Soc. 56, 1363 (1934).				
(2) A. Smith and R. Purcell, J. Chem. Soc. 2944 (1928).				
(3) F. M. G. Johnson, Z. Physik. Chem. 65, 38 (1909).				

The value of ΔH_f^o 298.15 adopted is 45.2 ± 0.2 kcal. mole⁻¹. Using ΔH_f^o 298.15 = -10.97 and -8.71 kcal. mole⁻¹ for NH₃(g) and HBr(g), respectively, the value of ΔH_f^o 298.15 for NH₄Br(c) is evaluated as -64.9 ± 0.3 kcal. mole⁻¹. The corresponding ΔH_f^o 298.15 value evaluated from solution data, selected by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NBS-RS-NBS2, National Bureau of Standards, April 1, 1965, is 45.5 ± 0.2 kcal. mole⁻¹.

The vapor densities (573-661°K.) of dissociation products of NH₄Br(c) were also measured by A. Smith and R. H. Lombard, J. Am. Chem. Soc. 57, 38 (1935). Using the equilibrium pressures reported by A. Smith and R. P. Calvert, loc. cit., they derived the corresponding degrees of dissociation of NH₄Br(c) at different temperatures. The calculated results indicated that only 46% of NH₄Br(c) decomposed at 573°K. and as reaction temperatures increased to 661°K. the degree of dissociation decreased to 10%. This conclusion was stated to be erroneous by Smith and Purcell, loc. cit., probably because of incorrect density determinations.

Heat Capacity and Entropy.

The low temperatures (13-305°K.) heat capacities and S_{298.15} were obtained from M. Sorri, H. Suga and S. Seki, Bull. Chem. Soc. Japan, 38, 1125 (1965). The C_p values above 305°K. were estimated by comparison with those for NaCl(c), NaBr(c) and NH₄Cl(c). The low temperature heat capacities were also measured by R. Enald, Ann. Physik, 44, 1213 (1914), 139-301°K., and P. Simon, C. V. Simon and M. Ruhemann, Z. phys. Chem. 129, 339 (1927), 201.2-277.1°K.

Transition Data.

The temperature (T_c) and heat of transition (ΔH_f^o) were given by P. W. Bridgman, Proc. Am. Acad. Arts Sci. 52, 91 (1916-17). T_c = 419.5 ± 0.6°K. was reported by M. M. Markowitz and D. A. Boryta, J. Phys. Chem. 66, 1477 (1962), which was determined by differential thermal analysis. According to Sorri, Suga and Seki, loc. cit., there are 3 solid phase transitions, namely Phase IV (CaCl) → Phase III (tetragonal) at 108°K., Phase III (tetragonal) → Phase II (CaCl) at 235°K. and Phase II (CaCl) → Phase I (NaCl) at 411°K.

Melting Temperature.

The value of T_m was taken from H. Rasmus, Z. anorg. Chem. 114, 117 (1920), determined under pressure.

Mar. 31, 1962; Sept. 30, 1965

Temperatures of Decomposition.

The temperature of decomposition (T_d) was calculated as the temperature at which the total pressure of the decomposition products for the reaction NH₄Br(c) → NH₃(g) + HBr(g) equals 1 atm. T_d = 674 and 688.4°K. were reported by N. W. Laft. Ind. Chemist, 31, 502 (1955) and M. M. Markowitz and D. A. Boryta, loc. cit., respectively.

$$r_e = 2.485 \text{ \AA}$$

Heat of Formation

The equilibrium constants for the reaction (A) $I_2(g) + Br_2(g) = 2 IBr(g)$ were determined to be 0.0124 and 0.01303 at 547.7 and 578°K, respectively, by W. Müller, Z. Physik. Chem. 123, 1 (1926), who studied the rate of reaction between $H_2(g)$ and $Br_2(g)$ in the presence of $I_2(g)$. M. Bodenstein and A. Schmidt, Z. Physik. Chem. 123, 28 (1926), derived two values of the equilibrium constants at 1495°K for the same reaction by vapor density studies on the system I_2 , I , Br_2 , Br and BrI . The equilibrium between $CuBr_2(c)$, $I_2(g)$, $CuBr(c)$ and $IBr(g)$ was investigated by J. Morris and D. M. Yost, J. Am. Chem. Soc. 53, 2625 (1931), and the equilibrium constants at 115.0, 151.2 and 176.0°C for reaction (A) were evaluated. Based on these reported equilibrium constants, the corresponding enthalpy changes for reaction (A) are calculated by both the second and third law methods.

R. M. Badger and D. M. Yost, Phys. Rev. 37, 1548 (1931), observed the infrared bands of IBr and classified them as the $A''\pi_2 - X\Sigma^+$ transition. They have shown that the dissociation products of the upper state are normal atoms. M. O. Brown, Phys. Rev. 42, 355 (1932), assigned a faint set of bands in the red as the $B''\pi_0 - X\Sigma^+$ system. By means of a vibrational analysis he found that the absorption spectrum of IBr is analogous to that of ICl . The heat of dissociation for IBr was evaluated to be $14,560 \pm 5 \text{ cm}^{-1}$ or 1.817 eV . Hence the enthalpy change for the reaction (B) $IBr(g) = I(g) + Br(g)$ is calculated as 41.92 kcal/mol .

The heats of formation for $BrI(g)$ derived from the enthalpy changes for reaction (A) and (B) are presented in the following table. The value of $\Delta H_{298.15}^\circ (IBr, g)$ adopted is $9.77 \pm 0.02 \text{ kcal/mol}$.

Investigator	Reaction	Temperature °K	No. of Points	$\Delta H_{298.15}^\circ$, kcal/mol	Drift eu	$\Delta H_{298.15}^\circ$, kcal/mol
Müller (1926)	(A)	547.7, 578	2	-3.07	-0.55	9.47
Bodenstein and Schmidt (1926)	"	1495	1	-2.92	-	9.70
McMorris and Yost (1931)	(B)	388.2-449.2	14	-2.46	-0.9 $\pm$ 0.4	9.73
Brown (1932)	"	298	-	-	41.92**	9.77**

*Calculation based on third law $\Delta H_{298.15}^\circ$ value.

**The value is derived from $D_0^0(I-Br)$.

Heat Capacity and Entropy

The ground state configuration, electronic levels, quantum weights, w_e and w_e^x are obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand, Inc., New York, 1950. The values of B_e , α_e (corrected to the average isotopic species) and r_e were reported by T. S. Jaseja, J. Mol. Spectry. 5, 445 (1960), who analyzed the microwave spectrum of IBr , corresponding to the transitions $J = 4-5$ and $J = 5-6$, for the two isotopic species, $^{127}\text{Br}^{79}\text{I}$ and $^{127}\text{Br}^{81}\text{I}$. The moment of inertia is $5.007 \times 10^{-38} \text{ g cm}^2$.

The infrared absorption spectrum of IBr at 8000 - 6800 $\text{\AA}$, associated with a ${}^3\Pi_1 - {}^1\Sigma^+$ transition, was observed by L. E. Selin, Arkiv Fysik 21, 479 (1962). The derived rotational constants are different from those reported by Jaseja, loc. cit.

$$\Delta H_f^\circ = -92.42 \pm 0.1 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = -94.12 \pm 0.1 \text{ kcal/mol}$$

$$\Delta G_m^\circ = 8.1 \text{ kcal/mol}$$

$$\Delta H_a^\circ_{298.15} \text{ (to monomer)} = 51.08 \text{ kcal/mol}$$

$$\Delta H_a^\circ_{298.15} \text{ (to dimer)} = 59.04 \text{ kcal/mol}$$

Heat of Formation.

The heat of solution (ΔH_{sol}) of KBr(c) in $H_2O(l)$ has been measured by many investigators. The results were reviewed in detail by V. B. Parker, U. S. Natl. Bur. Std. NBS-NSR-2, 1955. Eight pertinent ΔH_{sol}° values are reproduced in the table below. Adopting the best value, $\Delta H_{sol}^\circ = 4.75 \pm 0.02 \text{ kcal/mol}$, for the reaction $KBr(c) + K^+(\infty H_2O) + Br^-(\infty H_2O) = -94.12 \text{ kcal/mol}$ for KBr(c). The auxiliary values $\Delta H_{sol}^\circ = -60.32$ and -29.05 kcal/mol for $K^+(\infty H_2O)$ and $Br^-(\infty H_2O)$, respectively, are obtained from U. S. Natl. Bur. Std. Tech. Note 270-1, 1955.

*Values are adjusted to 298.15°K and to infinite dilution.

**Lowest experimental molelity.

Heat Capacity and Entropy.

The low temperature heat capacities, 2.9 - 272.2°K, were measured by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A 242, 467 (1957), using an adiabatic calorimeter. The high temperature heat capacities, 325.25 - 711.75°K, are taken from A. Mustajoki, Ann. Acad. Sci. Fennicae, Ser. A I, 98, 7 (1951). These two sets of Cp data are joined smoothly at 298°K. The Cp values at temperatures, 720 - 1007°K, are extrapolated graphically, so that the derived antherly change ($H^\circ_{1007} - H^\circ_{298}$) = 9.9 kcal/mol agrees with that determined by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tennessee, Dec. 1, 1964. The derived enthalpies at 700, 800 and 900°K are also in good agreement with those measured by S. M. Skuratov and S. A. Lapushkin, J. On. Chem. USSR (Eng. Transl.) 21, 2485 (1951). The Cp values above 1007°K are obtained by graphical extrapolation.

The S°_{298} is calculated from the adopted low temperature Cp, based on $S^\circ_{2.9} = 0.0015 \text{ eu}$.

The heat capacities of KBr(s) were also measured by W. Nernst and F. A. Lindemann, Z. Elektrochem. 17, 817 (1911), 78.7 - 89.2°K; F. Korf, Ann. Physik 4, 49 (1911), 137 - 234°K; and K. Clausen, J. Goldmann, and A. Parlick, Z. Naturforsch. 4b, 424 (1949). The enthalpies of KBr(c) were determined by A. Magnus, Phys. Z. 14, 5 (1913), and C. B. Cooper, J. Chem. Phys. 21, 777 (1953). The results are in reasonable agreement with the adopted functions except for those reported by Cooper.

Melting Data.

See KBr(1) table for details.

Heat of Sublimation.

The heat of sublimation to monomer and dimer are calculated as the enthalpy changes for the following two reactions: $KBr(c) = KBr(g)$ and $2 KBr(c) = K_2Br_2(g)$.

POTASSIUM BROMIDE (KBr)

(LIQUID)

GFW = 119.011

 $S_{298.15}^{\circ} = 25.225$ gibbs/mol $\Delta H_f^{\circ} = -89.984$ kcal/mol $T_m = 1007^{\circ}\text{K}$ $\Delta H_m^{\circ} = 6.1$ kcal/mol $T_b = 1671^{\circ}\text{K}$ $\Delta H_v^{\circ} = 35.65$ kcal/mol

Heat of Formation.

The heat of formation (ΔH_f°) for KBr(l) is obtained from ΔH_f° (KBr, c) by adding ΔH_m° and the difference between $H_{1007}^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

J. Togruri, H. Flood and T. Forland, Acta Chem. Scand. **17**, 1502 (1963), studied the chemical equilibrium for the reaction $\text{KBr(l)} + \text{HCl(g)} = \text{KCl(l)} + \text{HBr(g)}$. They obtained $\Delta H_{1073}^{\circ} = 3.50 \pm 0.08$ and 3.54 kcal/mol from partial pressure data and emf data, respectively. The corresponding value calculated from these tables is 3.78 kcal/mol. Combination of the experimental results with JANAF auxiliary data leads to -89.70 and -89.74 kcal/mol for ΔH_f° .

Heat Capacity and Entropy.

The heat capacity of 16.7 gibbs/mol was derived by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tennessee, Dec. 1, 1964, from enthalpy data in the range $1010 - 1100^{\circ}\text{K}$. This Cp value is adopted here for the temperature range $298 - 2500^{\circ}\text{K}$.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data.

The adopted T_m and ΔH_m° were determined by J. W. Johnson and M. A. Bredig, J. Phys. Chem. **62**, 604 (1958), and A. S. Dworkin and M. A. Bredig, J. Phys. Chem. **64**, 269 (1960), respectively.

Heats of melting of 6.2 kcal/mol from phase diagram studies and 6.7 kcal/mol from calorimetric measurements were obtained by E. Aukrust, B. Bjorge, H. Flood, and T. Forland, Annals of the New York Academy of Sciences **79**, Art. 11, 830 (1960).

Vaporization Data.

The boiling point, $T_b = 1671^{\circ}\text{K}$, is calculated as the temperature at which the sum of the partial pressures of KBr(g) and $\text{K}_2\text{Br}_2(\text{g})$ over KBr(l) equals one atmosphere. The value of ΔH_v° is calculated as the heat required to produce one mole of vapor mixture, which contains 19.5% dimer (K_2Br_2) and 80.5% monomer (KBr).

T_b was reported to be 1648 and 1668°K by H. von Wartenberg and P. Albrecht, Z. Elektrochem. **27**, 162 (1921), and O. Ruff and S. Mugdan, Z. Anorg. Chem. **117**, 147 (1921), respectively.

GFW = 119.011

Ground State Configuration $1^1\Sigma^+$ $\Delta H_f^\circ = -40.83 \pm 0.5 \text{ kcal/mol}$ $\Delta H_f^{298.15} = -43.04 \pm 0.5 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

ϵ , cm ⁻¹	$\frac{g_i}{1}$
0	1
$w_e = 218.47 \text{ cm}^{-1}$	$w_{x_e} = 0.7533 \text{ cm}^{-1}$
$w_e = 0.0807 \text{ cm}^{-1}$	$w_{e_e} = 0.000401 \text{ cm}^{-1}$
	$\tau_e = 2.821 \text{ Å}$

Heat of Formation.

The heat of formation is derived from the sublimation and vaporization data analyzed below. Numerous investigators have obtained total pressures by static methods or "apparent" pressures by effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see $K_{2Br}(g)$ table] which are consistent with the dimer-monomer equilibrium data of Hagemark et al.(6). Second and third law analyses of the monomer pressures show remarkable consistency over temperatures from 637 to 1668°K. The selected value of $\Delta H_f^{298} = -43.0 \pm 0.5 \text{ kcal/mol}$ may be compared with -43.8 kcal/mol derived from $D_0 = 3.95 \text{ eV}$ which is reported by Gaydon(14) based on atomic fluorescence data.

*Based on the third law ΔH_f^{298} value. (A) KBr(1) = KBr(g), (B) KBr(c) = KBr(g).

Heat Capacity and Entropy.

Rusk and Gordy(10) have investigated the pure rotational spectra of KBr in the 1.5 to 5.0 mm range of the microwave region by millimeter wave molecular beam spectroscopy. The reported values of w_e , w_{x_e} , B_e and r_e are adopted here and corrected to the average isotopic species. The value of a_e is obtained from Fabre and et al.(11). Molecular constants for KBr(g) have also been reported by Herzberg(12) and Rice and Klemperer(13). They are in good agreement with the values adopted. Herzberg(12) also lists an A state at 31770 cm⁻¹ based on observed electronic spectra. The moment of inertia is $3.4604 \times 10^{-38} \text{ g cm}^2$.

BrLi

LITHIUM BROMIDE (LiBr)

(CRYSTAL)

OPW = 86.848

 $\Delta H^\circ_f = \text{Unknown}$ $\Delta H^\circ_{298,15} = -83.87 \pm 0.1 \text{ kcal/mol}$ $\Delta H^\circ = -4.22 \text{ kcal/mol}$ $S^\circ_{298,15} = [17.7] \text{ gibbs/mol}$ $T_m = 823^\circ\text{K}$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298}(\text{LiBr}, c) = -83.87 \text{ kcal/mol}$, was calculated from the heat of solution of lithium bromide (c) at infinite dilution and the ionic heats of formation of $\text{Li}^+(\text{aq}, \text{H}_2\text{O})$ and $\text{Br}^-(\text{aq}, \text{H}_2\text{O})$.

V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-RS-NBS 2, April 1, 1955, reviewed the heat of solution data in the literature and gave the "best" value, $\Delta H^\circ_{\text{sol}} = -11.670 \pm 50 \text{ cal/mol}$ for $\text{LiBr}(c) \rightarrow \text{LiBr}(\text{aq}, \text{H}_2\text{O})$ at 298.15°K . The ionic heat of formation, $\Delta H^\circ_{298}(\text{Li}^+, \text{aq}, \text{H}_2\text{O}) = -66.49 \text{ kcal/mol}$, was calculated from $\Delta H^\circ_{298}(\text{LiOH} \cdot \text{aq}, \text{H}_2\text{O}) = -121.46 \text{ kcal/mol}$ (see JANAF LiOH(c) table, Mar. 31, 1956) with $\Delta H^\circ_{298}(\text{OH}^-, \text{aq}, \text{H}_2\text{O}) = -54.97 \text{ kcal/mol}$ from NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Oct. 1, 1955. The value $\Delta H^\circ_{298}(\text{Br}^-, \text{aq}, \text{H}_2\text{O}) = -29.05 \text{ kcal/mol}$ was also obtained from NBS Technical Note 270-1. Combination of the ionic heats of formation of $\text{Li}^+(\text{aq}, \text{H}_2\text{O})$ and $\text{Br}^-(\text{aq}, \text{H}_2\text{O})$ gives the heat of formation of $\text{LiBr}(\text{aq}, \text{H}_2\text{O})$, $\Delta H^\circ_{298} = -95.54 \text{ kcal/mol}$.

Heat Capacity and Entropy.

A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has measured the enthalpy changes by the drop method ($723\text{--}883^\circ\text{K}$), yielding $H_{298} - H_{298} = 7.0 \text{ kcal/mol}$ for the crystal at the melting point. Heat capacities derived from his data were $C_p 773^\circ = 15.1$ and $C_p 853^\circ = 15.6 \text{ gibbs/mol}$ for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of $\text{LiCl}(c)$, $\text{NaCl}(c)$ and $\text{NaBr}(c)$.

The entropy, $S^\circ_{298,15} = 17.7 \text{ eu}$, was estimated by adding the entropy difference between $\text{NaBr}(c)$ and $\text{NaCl}(c)$ to the entropy of lithium chloride (c) at 298.15°K . Comparisons with other alkali halides give results within $\pm 0.5 \text{ eu}$ of this value. K. K. Kelley, U. S. Bur. Min. Bull. 584 (1960) and 592 (1961), has estimated the heat capacities ($C_p = 11.50 + 3.02 \times 10^{-5} T$ gibbs/mol) and the entropy ($S^\circ_{298} = 16.0 \pm 0.5 \text{ eu}$)

Melting Data.

The selected heat of fusion ($\Delta H^\circ_{298} = 4.22 \text{ kcal/mol}$) was obtained from enthalpy measurements in a drop calorimeter by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 54, 269 (1960).

K. K. Kelley, U. S. Bur. Min. Bull. 393 (1936), reviewed some phase diagram studies of the lithium bromide system in the literature, and gave the heat of fusion $\Delta H^\circ_{298} = 2.90 \text{ kcal/mol}$. M. Blanc, Compt. rend. 246, 570 (1958), reported the heat of fusion $\Delta H^\circ_{298} = 3.095 \text{ kcal/mol}$ by a cryoscopic method. Both values are too low.

$S_{298.15}^{\circ} = [20.220]$ gibbs/mol
 $T_m = 823^{\circ}\text{K}$
 $T_b(\text{to equilibrium mixture}) = 1562^{\circ}\text{K}$
 $T_b(\text{to monomer only}) = [1811]^{\circ}\text{K}$

Heat of Formation.
 The heat of formation was calculated from that of the crystal by adding the heat of fusion and the difference between H_{823}° - H_{298}° for crystal and liquid.

Heat Capacity and Entropy.
 A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has derived the heat capacity ($C_p = 15.6$ gibbs/mol) from enthalpy measurements ($823^{\circ} - 803^{\circ}\text{K}$) by the drop method. The liquid heat capacity was assumed to be a constant, 15.6 gibbs/mol. The entropy ($S_{298}^{\circ} = 20.220$ eu) was obtained in a manner analogous to that of the heat of formation.

Melting Data.
 See LiBr(c) table for detail.

Vaporization Data.
 T_b (to monomer only) is taken as the temperature at which the calculated Gibbs energy change is zero for $\text{LiBr(l)} \rightarrow \text{LiBr(g)}$, while ΔH_v° (to monomer only) is the corresponding heat of reaction.

T_b (to equilibrium mixture) is taken as the temperature at which the sum of the calculated partial vapor pressures of LiBr(g) and $\text{Li}_2\text{Br}_2(\text{g})$ reaches one atmosphere (trimer and higher polymers have been neglected in calculation). This value (1562°K) is in good agreement with the boiling point of 1563°K obtained from total vapor pressure measurements by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 588 (1921), and also the boiling point of 1538°K by O. Ruff and S. Migdan, Z. anorg. Chem. 117, 147 (1921). ΔH_v° (to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 29.23 mole percent of dimer. For detailed information see LiBr(g) and $\text{Li}_2\text{Br}_2(\text{g})$ tables.

Heat of Formation.

The heat of formation (ΔH_f²⁹⁸ (LiBr, g) = -36.8 ± 3 kcal/mol) was calculated from the selected heat of vaporization and the heat of formation for lithium bromide (1). Lithium bromide vaporizes to a mixture of monomeric and diatomic gases. (Higher polymers have been neglected in the calculation.) The heats of vaporization to monomer and to dimer were chosen to satisfy (1) the total vapor pressure data measured by H. von Wartenberg and H. Schulz, Z. Elektrochem. 21, 568 (1921), and O. Ruff and S. Mugdan, Z. anorg. Chem. 117, 147 (1921); (2) the partial vapor pressures of monomer and dimer derived from R. C. Muller and P. Kuch, J. Chem. Phys. 25, 860 (1956), 28, 981 (1958), in an analysis of the velocity distribution of molecules in alkali halide vapor. The selected heats of vaporization are ΔH_v²⁹⁸ (to monomer) = 44.0 ± 3 kcal/mol and ΔH_v²⁹⁸ (to dimer) = 42.0 ± 5 kcal/mol which combine with the heat of formation of lithium bromide (1) (ΔH_f²⁹⁸ = -80.84 kcal/mol) to give the standard heats of formation of LiBr(g) and Li₂Br₂(g) = -36.8 and -119.7 kcal/mol, respectively. The derived heat of dissociation is ΔH₂₉₈⁰ = 46.0 kcal/mol for Li₂Br₂(g) → 2LiBr(g).

J. Berkowitz, H. A. Tassan and W. A. Chupka, J. Chem. Phys. 36, 2170 (1962), have measured mass-spectrometrically the heat of dissociation ΔH₂₉₈⁰ = 45.9 kcal/mol (ΔH₂₉₈⁰ = 46.9 kcal/mol) for Li₂Br₂(g) → 2LiBr(g) in a double open apparatus by the second law method. D. L. Hildenbrand, L. F. Theard, W. F. Hall and N. D. Potter, Philco Report U-2289, under Contract N061-0905-C, Sept. 15, 1963, have determined mass-spectrometrically the heats of sublimation of lithium bromide by the second law method as ΔH_{sub}⁰ (to monomer) = 46.9 and ΔH_{sub}⁰ (to dimer) = 45.0 kcal/mol (equivalent to ΔH_v²⁹⁸ (to monomer) = 45.82 kcal/mol and ΔH_v²⁹⁸ (to dimer) = 41.93 kcal/mol). These values are in reasonable agreement with those selected in the tabulation.

Heat Capacity and Entropy.

The bond distance (r_e) was obtained from the microwave studies by A. Honig, M. Mandel, M. L. Stich and C. H. Townes, Phys. Rev. 95, 623 (1954). The vibrational constants (ω_e and ω_ex_e) were determined from the infrared spectrum by W. Klempner, W. G. Morris, A. Bichler, and A. G. Emile, J. Chem. Phys. 33, 1534 (1960). The rotational constants which have been corrected to the average isotopic species were obtained by A. J. Herbert, P. W. Breivogel, Jr., and K. Street, Jr., J. Chem. Phys. 41, 2368 (1964), using microwave spectra. Their data are in good agreement with those reported by Honig et al., loc. cit., and J. R. Runk and W. Gordy, Phys. Rev. 127, 817 (1962).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by R. L. Wilkins, J. Chem. Eng. Data 5, 337 (1960), who used slightly different molecular constants.

 $\alpha_e = [0.000809] \text{ cm}^{-1}$
 $\sigma = 1$
 $r_e = [2.34] \text{ \AA}$

Heat of Formation.

The heat of formation was calculated from that of $\text{MgBr}_2(g)$ using the relation $D(\text{MgBr})/\Delta H_{\text{atom}}(\text{MgBr}_2) = 0.46 \pm 0.04$ which has been shown to apply to several dihalides. This results in $\Delta H_f^o = -13 \pm 7$ and $D_0 = 74.4 \pm 7$ kcal/mol. The selected value is in good agreement with $D_0 \leq 77$ kcal/mol obtained from predissociation by O. Herzberg, "Spectre of Diatomic Molecules," second edition, D. van Nostrand Co., Inc., New York, 1950, and with the linear Birge-Sponner extrapolation of $D_0 = 74$ kcal/mol given by A. O. Aylton, "Dissociation Energies," second edition, Chapman and Hall Ltd. London, 1953. Aylton's selected value of $D_0 = 88 \pm 23$ kcal/mol was discounted since it would require the unlikely ratio $D(\text{MgBr})/\Delta H_{\text{atom}}(\text{MgBr}_2) = 0.28$.

Heat Capacity and Entropy.

The molecular constants ω_e , $\omega_e x_e$ and ground state configuration ($2\sum$) were taken from O. Herzberg, loc. cit., while α_e was calculated from the above constants. The bond distance was estimated to be the same as in $\text{MgBr}_2(g)$.

Heat of Formation

E. R. V. Miller and H. B. Dunford, J. Chem. Phys. 35, 1202 (1961) have extrapolated the ground state vibrational levels and obtain $D_0^0 = 67 \pm 5 \text{ kcal. mole}^{-1}$ or $\Delta H_f^0 = 73.7 \pm 5 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy

Miller and Dunford loc. cit. give all the vibrational and rotational constants, which have been adjusted to the normally occurring isotopic mixture for bromine.

Heat of Formation

The chemical equilibrium of the reaction $2NO(g) + Br_2(g) = 2NOBr(g)$ has been studied by Trautz and Dala¹, Blair, Brea and Yoal², and Kraus³, respectively. Using the reported equilibrium constants, the enthalpy changes ($\Delta H^{\circ}_{298.15}$) of this reaction are evaluated by both the second and third law methods. Based on the third law $\Delta H^{\circ}_{298.15}$ values, the heats of formation for NOBr(g) are derived. The results obtained are presented in the table below. The value of $\Delta H^{\circ}_{298.15}$ (NOBr,g) adopted is 19.63 ± 0.2 kcal/mol.

Investigator	No. of Points	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H^{\circ}_{298.15}$ kcal/mol
1. Trautz and Dala ¹	•	258.2 - 603.2	-11.11	-11.30	-0.4	19.62
2. Blair et al.	30	296.9 - 502.9	-11.74 ± 0.07	-11.26	1.3 ± 0.2	19.64
3. Kraus ³	23	264.0 - 290.1	-13.46 ± 0.50	-9.62	-13.7 ± 1.1	20.46

Heat Capacity and Entropy

The molecular structure of NOBr(g) has been determined by electron diffraction by J. A. A. Ketelaar and K. J. Palmer, J. Am. Chem. Soc. **59**, 2829 (1937). The results were confirmed later by T. L. Weatherly and Q. Williams, J. Chem. Phys. **25**, 717 (1956), who studied the microwave spectrum of NOBr(g) in the region 20,000 - 40,000 Mc/sec and analyzed the J = 2-3 transition. The values of bond length and angle adopted are obtained from Ketelaar and Palmer, loc. cit. The infrared absorption spectrum of NOBr(g) has been examined from 400 to 5303 cm⁻¹ by W. O. Burns and H. J. Bernalein, J. Chem. Phys. **18**, 1689 (1950). The authors observed the first two fundamental vibrational frequencies and obtained the third from combination and overtone. These assignments are adopted. The three principal moments of inertia are: $I_A = 9.404 \times 10^{-40}$, $I_B = 2.2985 \times 10^{-38}$ and $I_C = 2.3906 \times 10^{-38}$ g cm².

BrNa

MOL. WT. = 102.907

(CRYSTAL)

SODIUM BROMIDE (NaBr)

$\Delta H_f^0 = -84.68 \pm 0.10 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{298.15} = -86.38 \pm 0.10 \text{ kcal. mole}^{-1}$
 $\Delta H_m^0 = 6.24 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{298.15} = 51.98 \text{ kcal. mole}^{-1} \text{ to monomer gas}$
 $T_m = 1020^\circ \text{K.}$

Heat of Formation.

The heat of solution of NaBr(c) in water has been measured by F. A. Askew, E. Bullock, H. T. Smith, R. K. Tinkler, O. Gatty and J. R. Wolfenden, *J. Chem. Soc.* 1368 (1934) and W. E. Wallace, *J. Am. Chem. Soc.* 71, 2485 (1949) to be +0.01 and -0.14 kcal. mole⁻¹, respectively. Using $\Delta H_f^{298.15}(\text{Na}^+, \text{aq.}) = -57.39$ and $\Delta H_f^{298.15}(\text{Br}^-, \text{aq.}) = -29.05 \text{ kcal. mole}^{-1}$, obtained from D. D. Wagman, National Bureau of Standards, private communication, July 2, 1964, the respective value of $\Delta H_f^{298.15}$ for NaBr(c) was found to be -86.3 and -86.45 kcal. mole⁻¹. The adopted value is the average of these two.

Heat Capacity and Entropy.

The low temperature heat capacities (7.21 - 301.63°K.) were measured by T. E. Gardner and A. R. Taylor, Jr., U. S. Bur. Mines RI 6435 (1964). The high temperature enthalpy changes (280 - 645, 290 - 916°K.) were determined by A. Wagnua, *Phys. Z.* 14, 5 (1913). Based upon the latter data the high temperature heat capacities were derived. The two sets of C_p data were joined smoothly at 298°K. by graphical method. $S_{298.15}^{298.15}$ was obtained from T. E. Gardner and A. R. Taylor, Jr., loc. cit., using $S_{10}^0 = 0.034 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m and ΔH_m^0 were reported by A. S. Dworkin and M. A. Bredig, *J. Phys. Chem.* 54, 269 (1960). The values, $T_m = 1014^\circ \text{K.}$ and $\Delta H_m^0 = 5.52 \text{ kcal. mole}^{-1}$, reported by M. Blanc, *Compt. Rend.*, 246, 570 (1958), were not used.

Heat of Sublimation.

The value of ΔH_m^0 is 298.15 was derived from six sets of vapor pressure data by both the second and third law methods. See NaBr(g) table for detail.

S_{298.15} = [24.940] cal. deg.⁻¹ mole⁻¹

ΔH_f^o 298.15 = [-81.105] kcal. mole⁻¹

ΔH_m^o = 6.24 kcal. mole⁻¹

T_m = 1020°K.

T_b = [1720]°K. to monomer gas

ΔH_v^o = 39.42 kcal. mole⁻¹ to monomer gas

Heat of Formation.

ΔH_f^o 298.15(l) was obtained from ΔH_f^o 298.15(c) by adding ΔH_m^o and the difference between H° - H°_{298.15} for crystal and liquid. The equilibrium constant of the reaction NaBr(l) + HCl(g) = NaCl(l) + HBr(g) has been determined by J. Toguri, H. Flood and T. Forland, *Acta Chem. Scand.* 17, 1502 (1963). From the reported data, lnK_{900°K} = -1.19 ± 0.01, the heat of reaction (ΔH_r^o 298.15) was derived to be 2.11 kcal. mole⁻¹. Using ΔH_f^o 298.15 (HCl, g) = -22.062, ΔH_f^o 298.15 (NaCl, l) = -92.24 and ΔH_f^o 298.15 (HBr, g) = -8.70 kcal. mole⁻¹, the value of ΔH_f^o 298.15 for NaBr(l) was evaluated to be -81.0 ± 0.5 kcal. mole⁻¹ which is in reasonable agreement with the value adopted. The values of ΔH_f^o 298.15 for HCl(g) and HBr(g) were obtained from D. D. Wagman, National Bureau of Standards, private communication, July 2, 1964.

Heat Capacity and Entropy.

Heat capacity for NaBr(l) was estimated by comparison with those for NaCl(c), AgCl(c) and AgCl(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH_m^o were reported by A. S. Dworkin and M. A. Bredig, *J. Phys. Chem.* 64, 269 (1960). The values, T_m = 1014°K. and ΔH_m^o = 5.52 kcal. mole⁻¹, reported by M. Blanc, *Compt. Rend.*, 246, 570 (1958), were not used.

Vaporization Data.

The boiling point, T_b, was calculated as the temperature at which the value of ΔH_f^o becomes zero for the reaction NaBr(l) → NaBr(g). The difference between ΔH_f^o for NaBr(l) and NaBr(g) at T_b is the heat of vaporization, ΔH_v^o.

Sept. 30, 1964

SODIUM BROMIDE (NaBr)

(IDEAL GAS)

MOL. WT. = 102.907

Ground State Configuration $1\sum^+ +$ $S^{\circ}_{298.15} = 57.628 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H^{\circ}_f 0 = -32.27 \pm 0.50 \text{ kcal. mole}^{-1}$ $\Delta H^{\circ}_f 298.15 = -34.40 \pm 0.50 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

 $\frac{g_1}{0} \text{ cm.}^{-1}$ $\omega_e x_e = 1.50 \text{ cm.}^{-1}$ $\sigma = 1$ $\alpha_e = 0.000959 \text{ cm.}^{-1}$ $r_e = 2.5020 \pm 0.0001 \text{ \AA}$

Heat of Formation.

The heat of formation ($\Delta H^{\circ}_f 298.15$) was calculated from $\Delta H^{\circ}_f 298.15$ and $\Delta H^{\circ}_f 298.15$ for NaBr(c). The latter was derived from six sets of corrected vapor pressure data, due to the presence of dimeric species in the vapor, by both the second and third law methods. The results are listed as follows.

Investigator	Reaction	Third Law Value	Second Law Value	$\Delta H^{\circ}_f 298.15$, kcal. mole ⁻¹	$\Delta H^{\circ}_f 298.15$, kcal. mole ⁻¹
Niwe ¹	NaBr(c) → NaBr(g)	51.97	50.31	-35.24	-35.24
Cogin and Kimball ²	NaBr(c) → NaBr(g)	52.26	52.14	-34.18	-34.18
Meyer and Wintner ³	NaBr(c) → NaBr(g)	52.59	52.59	-33.79**	-33.79**
Ruff and Muggen ⁴	NaBr(l) → NaBr(g)	46.43	47.48	-34.15	-34.15
Wertheberg and Albrecht ⁵	NaBr(l) → NaBr(g)	46.38	47.54	-34.15	-34.15
Bloom et al. ⁶	NaBr(l) → NaBr(g)	46.23	51.53	-34.88**	-34.88**

*Based on the average of the second and third law values.

**Only the third law value being used.

1 K. Niwe, J. Rec. Sci., Hokkaido Univ., Ser. III, 2, 201 (1938).

2 O. E. Cogin and O. E. Kimball, J. Chem. Phys. 16, 1035 (1948).

3 J. E. Meyer and I. H. Wintner, J. Chem. Phys. 6, 301 (1938).

4 O. Ruff and S. Muggen, Z. anorg. allgem. Chem., 117, 147 (1921).

5 H. von Wertheberg and P. Albrecht, Z. Electrochem., 27, 162 (1921).

6 H. Bloom, J. O. M. Bockris, N. E. Richards and R. O. Taylor, J. Am. Chem. Soc. 80, 2044 (1958).

The value of $\Delta H^{\circ}_f 298.15$ for NaBr(g) adopted is the average value of the six $\Delta H^{\circ}_f 298.15$ values listed in the above table. The dissociation energy (D°_0) was calculated to be 86.28 kcal. mole⁻¹ or 3.74 e.v. which is in good agreement with the value, $D^{\circ}_0 = 3.84 \pm 1$ and 3.65 e.v., reported by A. G. Oeydon, "Disociation Energies", Chapman and Hall Ltd., London, 1953 and O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, New York, 1950, respectively. According to L. Brewer, private communication, October 23, 1964, Oeydon's original reported value, $D^{\circ}_0 = 3.8$, is an average of the value of 3.84 e.v. from atomic fluorescence and the value of 3.75 e.v. calculated for Oeydon by Brewer from pressure data available at that time.

Heat Capacity and Entropy.

The values of ω_e , $\omega_e x_e$, B_e and α_e were taken from S. A. Rice and W. Klemperer, J. Chem. Phys. 27, 573 (1957). The adopted bond distance (r_e) was reported by A. Honig, M. Mendel, M. L. Sticht and C. H. Townes, Phys. Rev. 96, 629 (1954), which was derived from microwave spectrum. By electron-diffraction method, the Na-Br bond distance was determined as $2.64 \pm 0.01 \text{ \AA}$ by L. R. Maxwell, S. B. Hendricks and V. M. Moaley, Phys. Rev. 52, 968 (1937). The discrepancy may be due to the presence of a large proportion of dimer at the higher pressures used in the electron-diffraction determination. The ground state configuration was reported by O. Herzberg, loc. cit.

June 30, 1963; Dec. 31, 1963

Ground State Configuration [$\sum$]
S^{298.15} = [59.5] cal. deg.⁻¹ mole⁻¹
ΔH_f^o = [45] kcal. mole⁻¹
ΔH_f^{298.15} = [43] kcal. mole⁻¹

Electronic Levels and Multiplicities

$$\frac{\epsilon_f, \text{cm.}^{-1}}{0} \frac{g_f}{(3)}$$

$$\omega_e x_e = [1.5] \text{ cm.}^{-1} \quad \sigma = 1 \quad r_e = [2.23] \text{ \AA}$$

$$\omega_e = [400] \text{ cm.}^{-1} \quad \alpha_e = [0.0008] \text{ cm.}^{-1}$$

$$B_e = [0.1519] \text{ cm.}^{-1}$$

Heat of Formation.

ΔH_f^o 0 was estimated as 40.8 kcal. mole⁻¹ by J. S. Gordon, Astronautics International, Livingston, New Jersey, private communication, August 25, 1961. This ΔH_f^{298.15} was changed from the white (α) to red (V) phosphorus reference state.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit.

σ = 1

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbBr(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and ω_ex_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950). B_e and α_e were estimated by J. S. Gordon, AstroSystems, Inc., private communication, May, 1962. Electronic levels and multiplicities were estimated from those for Pb(g).

 $r_e = [2.5]$ Å

Heat of Formation

The heat of formation, ΔH°_f of TiBr (g) is calculated from the dissociation energy, D°₀ which is estimated as 104 kcal/mol. This estimate is obtained from the relation D(TiBr₂) < D°(TiBr₂) < D°(TiBr₃), where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF₂(g) by Zubov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interaction distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti⁺ (3). α_e is estimated from the Morse potential function.

TUNGSTEN MONOBROMIDE (WBr)

(IDEAL GAS)

GFW = 263.759

Ground State Configuration [Δ] $\Delta H^o_f = [141.9 \pm 20] \text{ kcal/mol}$ $S^o_{298.15} = [65.1] \text{ gibbs/mol}$ $\Delta H^o_{298.15} = [140.1 \pm 20] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

E_e, cm^{-1}	g_e
0	[4]
[5000]	[2]
[15000]	[20]

 $\omega_e X_e = [0.80] \text{ cm}^{-1}$ $\sigma = 1$ $B_e = [0.05254] \text{ cm}^{-1}$ $r_e = [2.40] \text{ \AA}$

Heat of Formation

The heat of formation, $\Delta H^o_{298}(\text{WBr}, g) = 140.1 \text{ kcal/mol}$, is calculated from the bond dissociation energy. $D^o_{298}(\text{W-Br}) = 90 \pm 20 \text{ kcal/mol}$. This value of D^o_{298} is estimated to be slightly higher than the average bond dissociation energy of $\text{WBr}_2(g)$, by analogy with the WCl_4 system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $\text{WBr}_2(g)$. This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency, ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 486 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D^o + 0.5 \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of a_e is calculated from the Morse potential function. The moment of inertia is $53.27 \times 10^{-39} \text{ g cm}^2$.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for $\text{WF}_6(g)$. See $\text{WF}_6(g)$ table (March 31, 1967) for details.

(IDEAL GAS) $\Delta H_f^\circ = 171.129$
Ground State Configuration $[^4Z]$
 $S_{298.15}^\circ = [63.4 \pm 2] \text{ gibbs/mol}$
 $\Delta H_f^\circ = [73.9 \pm 10] \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = [72 \pm 10] \text{ kcal/mol}$

Sept. 30, 1984; June 30, 1970

Heat Capacity and Entropy
The bond distance is assumed to be the same as that in ZrBr₄(g), which was estimated as 2.47 Å by Godnev, Aleksandrova and Rigina, Optics and Spectroscopy, 1, 172 (1959). The estimated bond distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental frequency ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 416 (1946)). The anharmonicity correction x_e is estimated roughly by assuming x_e = ω_e/4 (0.5 ω_e) = 0.0021. The rotational constant B_e is calculated from the estimated bond distance. The value of a_e is calculated from the Morse potential function. The moment of inertia is 42.148 x 10⁻³⁹ g cm².
The ground state configuration is taken from the ground state multiplet of Zr²⁺ reported by C. E. Moore, "Atomic Energy Levels," Vol. II, Natl. Bur. Std. Circ. 467, 1952. The electronic levels and quantum weights are estimated to be the same as those of Zr²⁺(g).

Heat of Formation
The heat of formation, ΔH₂₉₈^o(ZrBr₂, g) = 72 kcal/mol, is derived from the estimated bond dissociation energy, D₂₉₈^o(Zr-Br) = 103.5 ± 10 kcal/mol. The value of D₂₉₈^o(Zr-Br) is calculated from the relation D₂₉₈^o(Zr-Br)/n₂₉₈^o(Ti-Br) = D₂₉₈^o(Zr-Br₄)^o/n₂₉₈^o(Ti-Br₄)^o where the average bond dissociation energies, D₂₉₈^o(Zr-Br₄) = 102.2 kcal/mol, D₂₉₈^o(Ti-Br₄) = 87.9 kcal/mol and D₂₉₈^o(Ti-Cl) = 89.0 kcal/mol, all calculated from JANAF ΔH₂₉₈^o for ZrBr₄(g), TiBr₄(g), TiCl₄(g), Zr(g), Ti(g) and Br(g).

TUNGSTEN MONOBROMIDE (WBr)

(IDEAL GAS)

GFW = 263.759

Ground State Configuration [2Δ]

 $\Delta H_f^\circ = [141.9 \pm 20] \text{ kcal/mol}$ $S_{298.15}^\circ = [65.1] \text{ gibbs/mol}$ $\Delta H_f^\circ = [140.1 \pm 20] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$\epsilon_i, \text{cm}^{-1}$	g_i
0	[4]
[9000]	[2]
[15000]	[20]

 $\omega_e = [321.4] \text{ cm}^{-1}$ $\omega_e x_e = [0.80] \text{ cm}^{-1}$ $\sigma = 1$ $\alpha_e = [0.00015] \text{ cm}^{-1}$ $r_e = [2.40] \text{ Å}$

Heat of Formation

The heat of formation, $\Delta H_f^\circ(\text{WBr}, g) = 140.1 \text{ kcal/mol}$, is calculated from the bond dissociation energy, $D_{298}^\circ(\text{W-Br}) = 90 \pm 20 \text{ kcal/mol}$. This value of D_{298}° is estimated to be slightly higher than the average bond dissociation energy of $\text{WBr}_2(g)$, by analogy with the WCl_2 system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $\text{WBr}_2(g)$. This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency, ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D_0 + 0.5 \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is $53.27 \times 10^{-39} \text{ g cm}^2$.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for $\text{WF}_2(g)$. See WF(g) table (March 31, 1967) for details.

ZIRCONIUM MONOBROMIDE (ZrBr)

(IDEAL GAS)

GFW = 171.129

Zirconium Monobromide (ZrBr)

(Ideal Gas) GFW = 171.129

Ground State Configuration $[4f]$ $\Delta H_f^\circ = [73.9 \pm 10] \text{ kcal/mol}$ $S_{298.15}^\circ = [63.4 \pm 2] \text{ gibbs/mol}$ $\Delta H_{298.15}^\circ = [72 \pm 10] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

0	[4]
[3000]	[4]
[6000]	[4]
[12000]	[4]
[18000]	[4]
[24000]	[4]
[30000]	[4]

 $\omega_e = [317] \text{ cm}^{-1}$ $\omega_e x_e = [0.69] \text{ cm}^{-1}$ $\sigma = 1$ $B_e = [0.065] \text{ cm}^{-1}$ $\alpha_e = [0.00018] \text{ cm}^{-1}$ $r = [2.47] \text{ \AA}$

Heat of Formation

The heat of formation, $\Delta H_f^\circ(\text{ZrBr}, g) = 72 \text{ kcal/mol}$ is derived from the estimated bond dissociation energy, $D_0^\circ(\text{Zr-Br}) = 103.5 \pm 10 \text{ kcal/mol}$. The value of $D_{298}^\circ(\text{Zr-Br})$ is calculated from the relation $D_{298}^\circ(\text{Zr-Br})/D_{298}^\circ(\text{Ti-Br}) = D_{298}^\circ(\text{Zr-Br}_4)/D_{298}^\circ(\text{Ti-Br}_4)$ where the average bond dissociation energies, $D_{298}^\circ(\text{Zr-Br}_4) = 102.2 \text{ kcal/mol}$, $D_{298}^\circ(\text{Ti-Br}_4) = 87.9 \text{ kcal/mol}$ and $D_{298}^\circ(\text{Ti-Cl}) = 89.0 \text{ kcal/mol}$, all calculated from JANAF ΔH_f° for $\text{ZrBr}_4(g)$, $\text{TiBr}_4(g)$, $\text{TiCl}_4(g)$, $\text{Zr}(g)$, $\text{Ti}(g)$ and $\text{Br}(g)$.

Heat Capacity and Entropy

The bond distance is assumed to be the same as that in $\text{ZrBr}_4(g)$, which was estimated as $2.47 \text{ \AA}$ by Godnev, Aleksandrovskaya and Pignia, Optics and Spectroscopy, **2**, 172 (1959). The estimated bond distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental frequency ω_0 (K. M. Guggenheimer, Proc. Phys. Soc. (London) **58**, 416 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4 (D_0 + 0.5 \omega_e) = 0.0021$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is $42.1488 \times 10^{-39} \text{ g cm}^2$.

The ground state configuration is taken from the ground state multiplet of Zr^+ reported by C. E. Moore, "Atomic Energy Levels," Vol. II, Natl. Bur. Std. Circ. 467, 1952. The electronic levels and quantum weights are estimated to be the same as those of $\text{ZrF}(g)$.

September 30, 1961

Br₂

MOL. WT. = 159.832

(REFERENCE STATE)

0°K to 285.90°K Crystal
 285.90°K to 332.62°K Liquid
 332.62°K to 6000°K Ideal Diatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal and Liquid.

Low temperature thermal data have been adopted from the work of D. L. Hildenbrand, W. R. Kramer, R. A. McDonald, and D. R. Stull [J. Am. Chem. Soc. **80**, 4129 (1958)]. References to older work are given by Hildenbrand, et al., and are not given any weight here.

Heat of Melting and Melting Point.

Hildenbrand, et al., (loc. cit.) report $T_m = 285.90^\circ\text{K}$ and $\Delta H_m = 2.527 \text{ kcal. mole}^{-1}$.

Heat of Sublimation, Ideal Gas Functions.

See ideal gas tables for details.

BROMINE (Br₂)

(LIQUID)

MOL. WT. = 159.832

ΔH_f° 298 = 0

ΔH_m° = 2.527 kcal. mole⁻¹

ΔH_v° = 7.084 kcal. mole⁻¹

T_m = 265.90°K.

T_b = 332.62°K.

Heat of Formation.

The heat of formation at 298.15°K is zero by definition.

Heat Capacity.

The liquid heat capacity data of D. L. Hildenbrand, W. R. Kramer, R. A. McDonald, and D. R. Stull [J. Am. Chem. Soc. 80, 4129 (1958)] were extrapolated to a constant value of 18.0 cal. mole⁻¹ deg.⁻¹

Entropy.

The entropy is that given by Hildenbrand, et al., (loc. cit.) for liquid bromine at 298.15°K.

Vaporization.

See ideal gas tables for details.

$\Delta H^\circ_{298.15} = 33.62 \pm 0.3$ gibbs/mol
 $T_f = 650^\circ\text{K}$
 $T_m = 964^\circ\text{K}$
 $\Delta H^\circ_{298.15} = -59.5 \pm 0.5$ kcal/mol
 $\Delta H^\circ = 0.1$ kcal/mol
 $\Delta H^\circ_m = [12 \pm 3]$ kcal/mol
 $\Delta H^\circ_{298.15}$ (to monomer) = $[49.6]$ kcal/mol
 $\Delta H^\circ_{298.15}$ (to dimer) = $[58.5]$ kcal/mol

$\Delta H^\circ_{298.15}$ = Unknown

Heat of Formation.

The heats of solution of Fe(c), Br₂(l) and FeBr₂(c) in Br₂-KBr aqueous solution were measured by use of ice calorimeter by (1) W. Hieber and A. Woerner, Z. Elektrochem. 40, 287 (1934). From the results obtained the heat of formation for FeBr₂(c) was reported to be -59.87 kcal/mol.

The heats of solution of FeBr₂(c) in water were determined by (2) J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. 74, 4670 (1952) and (3) P. Paoletti, Trans. Faraday Soc. 61, 219 (1965), to be -20.1 ± 0.4 and -20.06 ± 0.08 kcal/mol, respectively. Using $\Delta H^\circ_{298.15} = -29.05$ and -21.3 kcal/mol for Br⁻(aq) and Fe²⁺(aq), the corresponding heats of formation for FeBr₂(c) were calculated as -59.3 and -59.34 kcal/mol. The value of $\Delta H^\circ_{298.15}$ (Br⁻, aq) was taken from "Selected Values of Chemical Thermodynamic Properties," Part I, Technical Note 270-1, by D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, National Bureau of Standards, 1965. The value of $\Delta H^\circ_{298.15}$ (Fe²⁺, aq) was derived from heats of solution and formation for FeCl₂(c) using $\Delta H^\circ_{298.15}(\text{Cl}^-, \text{aq}) = -39.552$ kcal/mol from the same source as $\Delta H^\circ_{298.15}$ (Br⁻, aq). The value of $\Delta H^\circ_{298.15}$ (FeBr₂, c) adopted is -59.5 ± 0.5 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 323-633°K, were measured by N. W. Gregory and H. E. O'Neal, J. Am. Chem. Soc. 81, 2649 (1959). Those for temperatures below 323°K and above 633°K were estimated by linear extrapolation. Low temperature heat capacities, 12-110°K, were reported by G. Miljutin and N. Nachimowitch, Phys. Trans. Ukrain. Acad. Sci. 7, 71 (1940). However, these data are inadequate for obtaining an accurate entropy at 298°K. The adopted $S^\circ_{298.15}$ value was reported by N. W. Gregory and R. O. MacLaren, J. Phys. Chem. 59, 110 (1955). It was obtained from E. F. Westrum, Jr., University of Michigan, Ann Arbor, Michigan, by private communication. A magnetic transition at 11°K was reported by H. Bizette, C. Terrier, and B. Tsai, Compt. rend. 245, 507 (1957).

Transition Data.

T_f and ΔH°_f were taken from N. W. Gregory and H. E. O'Neal, loc. cit.

Melting Data.

T_m adopted was reported by R. O. MacLaren and N. W. Gregory, J. Phys. Chem. 59, 184 (1955). The value was calculated from the vapor pressure equations and is slightly above the previously reported value, 684°C (957°K), by A. Ferreri, A. Celeri and F. Giorgi, Atti accad. Nazl. Lincei 9, 782, 1134 (1929). However, it agrees well with 982 ± 2°K obtained by the differential thermocouple cooling curve analysis by the same authors. The ΔH°_m value was estimated from the vapor pressure data in order to obtain good agreement between the second and third law heats of vaporization. See the FeBr₂(g) table for details.

Heat of Sublimation.

$\Delta H^\circ_{298.15}$ (to monomer) is calculated as the difference between $\Delta H^\circ_{298.15}$ for FeBr₂(g) and FeBr₂(c). $\Delta H^\circ_{298.15}$ (to dimer) is calculated as the difference between those for Fe₂Br₄(g) and 2 FeBr₂(c).

Sept. 30, 1966

IRON DIBROMIDE (FeBr₂) (LIQUID) GFW = 215.665

$S_{298.15}^{\circ} = [40.483] \text{ gibbs/mol}$

$\Delta H_{298.15}^{\circ} = [-50.431] \text{ kcal/mol}$

$\Delta H_m^{\circ} = [12 + 3] \text{ kcal/mol}$

$\Delta H_v^{\circ} = [29.4] \text{ kcal/mol}$

$T_m = 964^{\circ}\text{K}$

$T_b = [1207] ^{\circ}\text{K}$

Heat of Formation.

The value of $\Delta H_{298.15}^{\circ} (l)$ was obtained from $\Delta H_{298.15}^{\circ} (c)$ by adding ΔH_m° and the difference between $H_m^{\circ} - H_m^{\circ}$ for FeBr₂(c) and FeBr₂(l).

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K and was estimated on the basis of 8.5 gibbs/g-atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See FeBr₂(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the total pressure of FeBr₂(g) and Fe₂Br₃(g) over FeBr₂(l) equals one atmosphere. Based on the vapor composition and the value of ΔH_v° for both the monomer and dimer at T_b , the heat of vaporization is derived.

Rotational Constant: B₀ = [0.02102] cm⁻¹

Heat of Formation.

The vapor pressures of FeBr₂(c) and FeBr₂(l) have been measured in the temperature range from 823.15 to 982.15°K by several investigators. Using the reported data the corresponding enthalpy changes (ΔH^o) for the reactions (A) FeBr₂(c) = FeBr₂(g) and (B) FeBr₂(l) = FeBr₂(g) were evaluated by both the second and third law methods. The results obtained are presented in the following table. The values of ΔH_{f298.15}° for FeBr₂(c) are calculated based on the third law values for ΔH_{f298.15}° for FeBr₂(g) adopted in -9.9 ± 0.5 kcal/mol.

Reference	Reaction	Temperature, °K	Method	ΔH _{f298.15} °, kcal/mol	Drift	ΔH _{f298.15} °, kcal/mol

1. R. O. MacLaren and N. W. Gregory, J. Phys. Chem. **59**, 184 (1955).
2. R. J. Sime and N. W. Gregory, J. Phys. Chem. **84**, 86 (1980).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The electronic levels and quantum weights were estimated by comparison with those for FeCl₂(g) reported by C. W. Dekock and D. M. Gruen, J. Chem. Phys. **43**, 4387 (1966). The bond distance was estimated by L. Brewer, O. R. Somayajulu and E. Brackett, Chem. Rev. **93**, 111 (1983). The vibrational frequencies were estimated in order to obtain good agreement between the second and third law heats of sublimation and vaporization. The moment of inertia is 1.33146 x 10⁻³⁷ g cm².

 $S_{298.15}^\circ$ = [40.706] ± 1.5 cal. deg. ⁻¹ mole⁻¹
 T_m = 514°K
 ΔH_m = 4.280 ± 0.08 kcal. mole⁻¹

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952).

Heat Capacity and Entropy. C_p was assumed to be a linear function of temperature and was fitted to the data of M. Guinchant, Comp. Rend. 145, 320 (1907) and G. J. Janz and J. Goodkin, J. Phys. Chem. 63, 1975 (1959). The entropy was estimated by adjusting its value until the melting, sublimation and vaporization data were in agreement.

Melting. T_m was taken from National Bureau of Standards (U.S.) Circular 500 (loc. cit.). ΔH_m was given by G. J. Janz and J. Goodkin (loc. cit.).

MERCURY DIBROMIDE (HgBr₂)

(Liquid)

Mol. Wt. = 360.442

ΔH°_f 298.15 = -37.158 ± 0.58 kcal. mole⁻¹S° 298.15 = [46.797] ± 1.5 cal. deg.⁻¹ mole⁻¹T_m = 514°KΔH°_m = 4.280 ± 0.08 kcal. mole⁻¹T_b = 592°KΔH°_v = 14.148 ± 0.25 kcal. mole⁻¹Heat of Formation. Calculated from ΔH°_f(c).Heat Capacity and Entropy. C_p obtained from the data of O. J.

Janz and J. Goodkin, J. Phys. Chem. 63, 1975 (1959) in the range 507-544°K, it was assumed constant above and below this value.

A glassy type transition was assumed at 343°K below which the heat capacity was equal to that of the crystal. The entropy was obtained from S°(c), the entropy of fusion and the estimated heat capacity.

Melting and Vaporization. T_m and T_b were taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952). ΔH°_m was given by O. J. Janz and J. Goodkin (loc. cit.) and ΔH°_v was obtained from the data of E. B. R. Prideaux, J. Chem. Soc. (London) 57, 2032 (1936) and F. M. G. Johnson, J. Amer. Chem. Soc. 53, 777 (1931).

41 { 2 }
233 { 1 }

Hg-Br distance = 2.41 Å

Moment of Inertia = 154.12 X 10⁻³⁹ g. cm.²

σ = 2

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952, was combined with the 3rd law heat of sublimation at 298°K from the data of K. Naka and Z. Shibata, J. Fac. Sci. Hokkaido Imp. Univ. Ser. III 2, 193 (1938) and P. M. G. Johnson, J. Amer. Chem. Soc. 53, 777 (1931).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The bond length is an average of the values given by H. Braune and S. Knöke, Zeits. phys. Chemie B23, 163 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton, Trans. Farad. Soc. 33, 852 (1937) and P. A. Akshin, V. P. Spiridinov and A. N. Khodchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

MERCURY MONOBROMIDE, DIMERIC (Hg₂Br₂) (crystal)

Mol. Wt. = 561.052

ΔH_f 298.15 = -48.800 ± 0.2 kcal. mole⁻¹

S° 298.15 = 52.283 ± 0.75 cal. deg. ⁻¹ mole⁻¹

T_{sub} = 666°K (decomp.)

Heat of Formation. The average of the values obtained from the cell measurements of T. W. Dakin and D. T. Ewing, J. Am. Chem. Soc. 62, 2280 (1940) and those of F. Iahikawa and Y. Ueda, J. Chem. Soc. Japan 51, 59 (1930) was adopted.

Heat Capacity and Entropy. The heat capacity was estimated by analogy with mercurous chloride. The entropy of formation was obtained from the free energy and heat of formation data listed under heat of formation.

Sublimation. The vapor pressure over mercurous bromide reaches one atmosphere at 666°K according to G. Jung and W. Ziegler Zalta. f. physik. Chem. A150, 139 (1930). At this point the vapor is dissociated into Hg(g) and HgBr₂(g).

Potassium Bromide, Dimeric (K₂Br₂)

Bond Distances: K-Br = [3.07] Å

Bond Angles: Br-K-Br = [102]°

Product of the Moments of Inertia: I_AI_BI_C = [1.473 x 10⁻¹¹] g³ cm⁶

Heat of Formation

Vapor densities and vapor pressures of KBr were measured, using a liquid gold isothermometer, by K. I. Hagemark, M. Blander, and E. B. Luchinger, J. Phys. Chem. 70, 276 (1966), and K. I. Hagemark, private communication, 3M Company, St. Paul, Minn., Feb. 6, 1967. Based on the equilibrium constants for the reaction 2KBr(g) = K₂Br₂(g) in the temperature range 1267-1434°K, the enthalpy change (ΔH_f^o₂₉₈) of this reaction is evaluated by the second and third law methods to be -42.80 ± 4.26 and -43.12 kcal/mol, respectively. The heat of formation for K₂Br₂(g) is calculated to be -129.2 ± 4 kcal/mol, using the third law ΔH_f^o₂₉₈ value and ΔH_f^o₂₉₈(KBr,g) = -43.04 kcal/mol. The drift in the third law ΔH_f^o₂₉₈ values is 0.01 ± 3.2 eu.

Heat Capacity and Entropy

The molecular structure and bond distances were estimated by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958), and are tentatively adopted. J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), has calculated vibrational frequencies on the basis of the potential function for an ionic model. These values are adjusted so that the third law ΔH_f^o₂₉₈ value for the reaction 2KBr(g) = K₂Br₂(g) agrees with the second law value. The three principal moments of inertia are: I_A = 4.867 x 10⁻³⁸, I_B = 1.513 x 10⁻³⁷, I_C = 2.000 x 10⁻³⁷ g cm².

Product of the Moments of Inertia: $I_A I_B I_C = 4.220745 \times 10^{-113} \text{ g}^3 \text{ cm}^6$

Heat of Formation

This was obtained from the heat of formation of the liquid and the selected heat of vaporization to the dimer, which derivation has been given in the LiBr(g) table.

Heat Capacity and Entropy

J. Berkowitz, J. Chem. Phys. 29, 1386 (1958), 32, 1519 (1960), has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure for dimeric lithium bromide, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 85, 4544 (1964). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by P. A. Kikichin and N. G. Rambidi, Z. Physik Chem. 213, 111 (1960). The bond distances ($r_{\text{Br-Br}} = 4.20 \text{ Å}$ and $r_{\text{Li-Li}} = 2.60 \text{ Å}$) calculated by Berkowitz are in reasonable agreement with those selected. The three principal moments of inertia are $I_A = 4.1866 \times 10^{-39}$, $I_B = 98.3352 \times 10^{-39}$ and $I_C = 102.5218 \times 10^{-39} \text{ g cm}^2$.

S. H. Bauer, T. Ino and R. P. Porter, J. Chem. Phys. 33, 685 (1960), have estimated six vibrational frequencies (576, 576, 202, 230, 329 and 365 cm⁻¹) for Li₂Br₂(g) in the electron diffraction studies of Li₂Cl₂(g). W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), have observed two fundamental vibrational frequencies (413 and 295 cm⁻¹) in the infrared spectrum and tentatively assigned them as B_{2u} and B_{3u} modes and these have been adopted in the tabulation. The remaining four vibrational frequencies were obtained from J. Berkowitz, loc. cit., because his model and derivation are self-consistent.

(CRYSTAL)

MAGNESIUM DIBROMIDE (MgBr₂)

ΔH_f⁰ = Unknown

ΔH_f⁰298.15 = -124.0 ± 1 kcal/mol

ΔH_m⁰ = 8.3 ± 2 kcal/mol

S_{298.15} = [28.5 ± 2] gibbs/mol

T_m = 984°K

Heat of Formation

The heat of formation was calculated from ΔH_f⁰ values for Mg⁺⁺(H₂O) and Br⁻(H₂O) and ΔHsol⁰(H₂O) for MgBr₂(c). The value for Br⁻ was obtained from D. D. Wagman et al., NBS Tech. Note 270-1, Natl. Bur. of Std., Washington, D.C., 1965. Values for Mg⁺⁺ and ΔHsol⁰ were taken from F. D. Rossini et al., NBS Circ. 500, Natl. Bur. of Std., Washington, D.C., 1952, since a survey of the literature revealed no new data which would significantly change these values. ΔHsol⁰ is based on measurements of Beketoff, Bull. acad. sci. Russ. 34, 291 (1892), while Mg⁺⁺ is presumably based on data for MgCl₂.

The selected heat of formation is confirmed by ΔH_f⁰073 = -0.287 kcal/mol for MgBr₂(l) + HCl(g) = MgCl₂(l) + HBr(g) observed by J. Toguri, H. Flood and T. Forland, Acta Chem. Scand. 17, 1502 (1963). Based on JANAP functions, this leads to ΔH_f⁰298 = -124.9 kcal/mol for MgBr₂(c).

Heat Capacity and Entropy

The entropy and heat capacity were estimated by comparison with the corresponding values for MgCl₂, NaCl and NaBr. W. M. Latimer, "Oxidation Potentials," 2nd Edition, Prentice-Hall, Inc., New York, 1952, has estimated S₂₉₈ = 29.4 eu which is also a reasonable value. Use of 29.4 eu would give almost exact agreement between the selected ΔH_f⁰ and the equilibrium data of Toguri et al., but this may be fortuitous because of uncertainties in the enthalpy and heat of melting for MgBr₂.

Melting Data

T_m and ΔH_m⁰ are the values obtained by K. K. Kelley, USNM Bulletin 393, 1956, from phase diagrams for the systems MgBr₂ - NaBr and MgBr₂ - KBr studied by G. Kellner, Z. Anorg. Chem. 99, 137 (1912), and for MgBr₂ - LiBr studied by A. Ferrati and C. Colla, Atti accad. Lincei, ser. 6, 13, 78 (1931).

MAGNESIUM DIBROMIDE (MgBr₂)

OPW = 184.130

(LIQUID)

S° _{298.15} = [31.968] gibbs/mol	ΔHf° _{298.15} = [-118.337] kcal/mol
Tm = 984°K	ΔHm° = 8.3 kcal/mol
Tb = [1557]*K	ΔHv° = [32.9] kcal/mol

Heat of Formation.

The ΔHf°_{298.15} was obtained from ΔHf°_{298.15(c)} by adding ΔHm° and the difference between H°_m - H°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed constant and estimated as 23.25 gibbs/mol using 7.75 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See MgBr₂(c) table.

Vaporization Data.

Tb was calculated as the temperature at which ΔGr° = 0 for MgBr₂(c) → MgBr₂(g). ΔHv° is the corresponding enthalpy change.

Bond Angle: Br-Mg-Br = 180°

Rotational Constant: B = 0.019264 cm⁻¹

σ = 2

Heat of Formation.

The ΔHf°_{298.15} was calculated from the ΔHf°_{298.15} = 49.4 kcal/mol for the reaction MgBr₂(c) = MgBr₂(g), based on third law analysis of pressures at 758 and 842°K determined from Knudsen effusion - mass spectrometric studies by J. Berkowitz and J. R. Marquert, J. Chem. Phys. **37**, 1853 (1962). Second law analysis of ion intensities (635 - 850°K) gave ΔHf° = 50.3 kcal/mol at 727°K, corresponding to ΔHf° = 52.2 kcal/mol at 298.15°K. The absolute pressure at 842°K was calibrated by integrating the ion current during complete volatilization of the sample. Data for (MgBr₂)₂ indicate that the dimer mole fraction (about 0.04 at 842°K) over the crystal increases with increasing temperature; this behavior is similar to that of the alkali halides.

Heat Capacity and Entropy.

Bond distance and bond angle were taken from the electron diffraction studies of P. A. Akishin, V. P. Spiridonov, G. A. Sobolev and V. A. Naumov, Zhur. Fiz. Khim. **31**, 461 (1957). Electric deflection experiments of A. Bichler, J. L. Stauffer and W. Klumperer, J. Am. Chem. Soc. **86**, 4544 (1964), also suggest a linear structure for MgBr₂ within the sensitivity of the measurements. The antisymmetric stretching vibration ν₃ is that observed in the infrared spectra of the vapor by S. P. Rendell, P. T. Greene and J. L. Margrave, J. Phys. Chem. **63**, 758 (1959). The other frequencies were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. **63**, 111 (1963), from a valence force model using K = 1.5 and kδ/12 = 0.15 md/Å.

Bond Distances: Na-Br = [2.75] Å

Bond Angle: Na-Br-Na = [71]°

Product of the Moments of Inertia: I_AI_BI_C = [3.9701 X 10⁻¹¹²] g³ cm.⁶

Heat of Formation.

The temperature dependence of the equilibrium constants (1293-1434°K.) for the reaction (NaBr)₂(g) ⇌ 2NaBr(g) has been studied by S. Smith, W. T. Smith, Jr. and E. H. Taylor, J. Chem. Phys. **24**, 558 (1956). The dissociation energy (ΔE_{300°K.}) was evaluated to be 42.9 ± 1.3 kcal. mole⁻¹. The vapor mixture contains 37 to 17% of dimers in the temperature range of 1293 to 1434°K. Hence the vapor pressure data on NaBr(g) reported by the previous investigators were reexamined. In other words, the reported vapor pressure of NaBr(g) is the sum of the partial pressures of both the monomer (NaBr) and the dimer (Na₂Br₂). The partial pressures of Na₂Br₂(g) thus obtained were used to evaluate the heats of vaporization by both the second and third law methods. The values of ΔH_f^{298.15} for Na₂Br₂(g) were then calculated. The results are presented as follows.

Investigator	Reaction	Third Law Value	Second Law Value	ΔH _f ^{298.15} , kcal. mole ⁻¹
Niwa ¹	2NaBr(c) → Na ₂ Br ₂ (g)	56.51	54.84	-117.08
Cogin and Kimball ²	2NaBr(c) → Na ₂ Br ₂ (g)	56.80	56.69	-116.01
Mayer and Wintner ³	2NaBr(c) → Na ₂ Br ₂ (g)	57.13	68.78	-115.63**
Ruff and Muggan ⁴	2NaBr(l) → Na ₂ Br ₂ (g)	45.70	46.71	-116.00
Wartenberg and Albrecht ⁵	2NaBr(l) → Na ₂ Br ₂ (g)	45.84	46.77	-116.00
Bloom et al. ⁶	2NaBr(l) → Na ₂ Br ₂ (g)	45.49	53.17	-116.72**

*Based on the average of the second and third law values.

**Only the third law value being used.

1 K. Niwa, J. Fac. Sci., Hokkaido Univ., Ser. III, **2**, 201 (1938).

2 G. E. Cogin and O. E. Kimball, J. Chem. Phys. **16**, 1035 (1948).

3 J. E. Mayer and I. H. Wintner, J. Chem. Phys., **5**, 301 (1938).

4 O. Ruff and S. Muggan, Z. anorg. allgem. Chem., **117**, 147 (1921).

5 H. von Wartenberg and P. Albrecht, Z. Electrochem., **27**, 162 (1921).

6 H. Bloom, J. O.W. Bockris, N. E. Richards and R. O. Taylor, J. Am. Chem. Soc. **80**, 2044 (1958).

The value of ΔH_f^{298.15} for Na₂Br₂(g) adopted is the average of the six ΔH_f^{298.15} values listed in the above table.

Heat Capacity and Entropy.

Bond distance and angles were calculated based on the related data reported by J. Berkowitz, J. Chem. Phys. **29**, 1386 (1958). The vibrational frequencies were calculated by J. Berkowitz, J. Chem. Phys., **32**, 1519 (1960), from an assumed model. The ground state quantum weight was estimated. The three principal moments of inertia are I_A = 1.94452 X 10⁻³⁸, I_B = 1.33619 X 10⁻³⁷ and I_C = 1.53065 X 10⁻³⁷ g. cm.²

Lead Dibromide (PbBr₂) (crystal)

Mol. Wt. = 367.04

ΔH_f^o 298.15 = -66.07 ± 0.20 kcal. mole⁻¹

S_{298.15}^o = 38.66 ± 0.5 cal. deg.⁻¹ mole⁻¹

ΔH_f^o 298.15 = 41.90 ± 0.17 kcal. mole⁻¹

T_m = 640°K.

ΔH_m^o = 4.96 kcal. mole⁻¹

Heat of Formation. Recalculated from the data reported by H. Braune and P. Koref, Z. anorg. Chem., 87, 175 (1914) and C. Kramer, Z. Elektrochem., 26, 97 (1920).

Heat Capacity, Entropy, and Melting Data. C_p (18.4° to 297.0°K.) reported by W. M. Latimer and H. D. Hoenel, J. Am. Chem. Soc., 49, 19 (1926). Above 298.15°K., C_p given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. T_m and ΔH_m^o obtained from M. Blanc and G. Petit, Compt. rend., 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of H. Bloom, J. O'M. Bockris, R. E. Richards and R. G. Taylor, J. Am. Chem. Soc., 80, 2044 (1958), H. von Wartenberg and O. Boase, Z. Elektrochem., 28, 384 (1922), F. Volmer, Phys. Z., 30, 590 (1929), and B. Greiner and K. Jellinek, Z. physik. Chem., 165, 97 (1933) which are in good agreement.

Br₂Pb

Lead Dibromide (PbBr₂) (Liquid)

Mol. Wt. = 367.04
 ΔH_f° 298.15 = [-63.00 ± 0.20] kcal. mole⁻¹
 $S_{298.15}^\circ$ = [42.699] cal. deg.⁻¹ mole⁻¹
 T_m = 640°K.
 ΔH_m° = 4.96 kcal. mole⁻¹
 T_b = 1187°K.
 ΔH_v° = 27.44 ± 0.17 kcal. mole⁻¹

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). T_m and ΔH_m reported by M. Blanc and G. Petit, Compt. rend. 248, 1305-6 (1959). A glass transition temperature of 400°K. is assumed.

Vaporization Phenomena. T_b and ΔH_v calculated from ΔH_f 298.15 and free energy functions for condensed and gaseous states.

Br₂Pb

Lead Dibromide (PbBr₂)

(Ideal Gas) Mol. Wt. = 367.04

Heat of Formation

The heat of formation of TiBr₂ crystal is derived from the data of Hall and Blocher (1) for the reaction 2TiBr₃(c) = TiBr₄(g) + TiBr₂(c). Second and third law analyses of these data are not useful because of the formation of solid solutions in the above process. Hall and Blocher obtained a value of ΔH_f^o₂₉₈ of 31.3 kcal/mol for the reaction by integrating the incremental free energy changes over varying compositions of the solid solutions. The corresponding ΔH_f^o₂₉₈ and ΔH_f^o₂₉₈ are calculated as 34.6 kcal/mol and -96.9 kcal/mol, respectively, using auxiliary JANAF heats of formation and enthalpy data.

Heat Capacity and Entropy

The heat capacity of TiBr₂(c) was estimated by Kelley (2). The value of S_{298.15}^o is estimated from that of TiCl₂(c) and the difference between ionic entropy contributions of Cl⁻ and Br⁻.

Heat of Sublimation

The heat of sublimation of TiBr₂(c) is taken as the difference in the heats of formation of TiBr₂(c) and TiBr₂(g) at the sublimation temperature. The sublimation temperature is taken as the point at which ΔG^o = 0 for the reaction TiBr₂(c) = TiBr₂(g). The heat of formation of TiBr₂(g), upon which these quantities depend, is an estimated quantity.

Bond Distance: Ti-Br = [2.4] Å

Bond Angle: Br-Ti-Br = [180°]

Rotational Constant: B₀ = [0.0183] cm⁻¹

Heat of Formation

The heat of formation of TiBr₂(g) is calculated from the estimated Ti-Br bond energy. The bond energy is estimated as being the same as the average Ti-Cl bond energy of TiCl₂(g). This estimate is used because the measured average bond energies of TiBr₃(g) and TiCl₃(g) and those of TiBr₄(g) and TiCl₄(g) are very nearly equal.

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiCl₂(g), TiCl₄(g) and TiBr₄(g). The vibrational frequencies are estimated from a valence force field model. The force constant k is estimated as 1.2 millidynes Å⁻¹, and the constant k_f/l² is assumed to be 0.06 millidynes Å⁻¹. These values are derived by a correlation with other dihalides.

The electronic levels are assumed to be the same as TiCl₂(g). The levels of TiCl₂(g) are estimated by assuming that they correspond to the inverted states of NiCl₂(g) (1). The linear configuration is adopted since experimental evidence indicates that other transition metal dihalides are linear (2, 3, 4, 5).

ZIRCONIUM DIBROMIDE (ZrBr₂)

(CRYSTAL)

ZIRCONIUM DIBROMIDE (ZrBr₂)Zirconium Dibromide (ZrBr₂)
(Crystal)

GFW = 251.038

GFW = 251.038

 ΔH_f° = Unknown $\Delta H_f^\circ_{298.15} = [-96.7 \pm 10] \text{ kcal/mol}$ $\Delta H_m^\circ = [15.0 \pm 10] \text{ kcal/mol}$ $\Delta H_{298.15}^\circ = [55.0 \pm 5] \text{ kcal/mol}$ $S_{298.15}^\circ = [27.7 \pm 3] \text{ gibbs/mol}$ $T_m = [900]^\circ\text{K}$ Heat of Formation

The value of $\Delta H_f^\circ(\text{ZrBr}_2, c) = -96.7 \text{ kcal/mol}$ is calculated from the estimated $\Delta H_{298}^\circ = 55 \pm 5 \text{ kcal/mol}$ for $\text{ZrBr}_2(c) \rightarrow \text{ZrBr}_2(g)$, using $\Delta H_{298}^\circ(\text{ZrBr}_2, g) = -41.7 \text{ kcal/mol}$ (1). The estimated ΔH_{298}° is obtained as an average of the heats of sublimation at 298°K for CrBr_2 , MnBr_2 , CoBr_2 , NiBr_2 , SbBr_2 given by Brewer, Somayajulu and Brackett (2) and TiBr_2 and FeBr_2 listed in JANAF tables (3).

Heat Capacity and Entropy

The heat capacities of $\text{ZrBr}_2(c)$ are estimated from $\text{TiBr}_2(c)$ (3), based on the assumption $\text{Cp}(\text{ZrBr}_2) = \text{Cp}(\text{TiBr}_2) + 3/2 R \ln(\text{at. wt. of Zr}/(\text{at. wt. of Ti}))$. The entropy, S_{298}° - 27.7 eu, is estimated in a similar manner based on $\text{TiCl}_2(c)$ (4) and $\text{TiBr}_2(c)$ (3).

Melting Data

The heat of fusion is roughly estimated, so that the entropy of vaporization is about 20 eu. The melting point was estimated by Brewer (5).

Heat of Formation

The ΔH_f° (ZrBr₂, l) is calculated from ΔH_f° (ZrBr₂, c) by adding ΔH_m° and the difference between $H_{900}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

See ZrBr₂(c) table for details.

Vaporization Data

T_b is the temperature at which the Gibbs energy change approaches zero for the process ZrBr₂(l) + ZrBr₂(g). The difference between ΔH_f° for ZrBr₂(l) and ZrBr₂(g) at T_b is ΔH_v° .

Bond Distance: Zr-Br = [2.47] Å
Bond Angle: Br-Zr-Br = [180°]
Rotational Constant: B₀ = [0.01729] cm⁻¹
σ = [2]

Heat of Formation

The heat of formation, $\Delta H_f^\circ(\text{ZrBr}_2, g) = -41.7 \text{ kcal/mol}$, is derived from the estimated $\Delta H_f^\circ(\text{Zr-Br}_2) = 243.5 \pm 10 \text{ kcal/mol}$ for $\text{ZrBr}_2(g) + \text{Zr}(g) + 2\text{Br}(g)$. The value of ΔH_f° is twice the average bond dissociation energy, $D_{298}^\circ(\text{Zr-Br}_2) = 121.75 \text{ kcal/mol}$, which is calculated from the relation $D_{298}^\circ(\text{Zr-Br}_2) = D_{298}^\circ(\text{Zr-Br}) + D_{298}^\circ(\text{Ti-Br})$. The average bond dissociation energies, $D_{298}^\circ(\text{Zr-Br}) = 102.2 \text{ kcal/mol}$, $D_{298}^\circ(\text{Ti-Br}) = 87.9 \text{ kcal/mol}$ and $D_{298}^\circ(\text{Ti-Br}_2) = 104.6 \text{ kcal/mol}$, are all calculated from JANAF $\Delta H_f^\circ_{298}$ for $\text{ZrBr}_4(g)$, $\text{TiBr}_4(g)$, $\text{TiBr}_3(g)$, $\text{TiBr}_2(g)$, $\text{TiBr}(g)$ and $\text{Br}(g)$.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the transition metal dihalides are generally linear ($\bar{A}$, $\bar{B}$, $\bar{C}$, $\bar{D}$, $\bar{E}$) even though a few fluorides are bent ($\bar{G}$). The bond distance is assumed to be the same as that in $\text{ZrBr}_4(g)$ which was estimated as 2.47 Å by Godnev et al. ($\bar{Z}$). The moment of inertia is $161.8979 \times 10^{-39} \text{ g cm}^2$.

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 1.2 millidyne/Å and the bending force constant 0.06 millidyne/Å . These values are derived from force constants of transition metal dihalides listed by Brewer, Somayajulu and Brackett ($\bar{B}$). The electronic levels and quantum weights are estimated to be the same as those of gaseous TiCl_2 ($\bar{Z}$).

Bond Distances: P-O = 1.41 ± 0.07 Å P-Br = 2.06 ± 0.03 Å

Bond Angle: Br-P-Br = 108° ± 3°

Product of the Moments of Inertia: I_AI_BI_C = 2.2602 × 10⁻¹¹² g.³ cm.⁶

Heat of Formation.

The ΔH_f⁰ 298.15 of POBr₃(g) was calculated from the heat of formation of the crystal and the heat of sublimation. The heat of sublimation was obtained by combining the ΔH_f⁰ and an estimated ΔH_{sub}⁰. The heat of formation of the crystal was derived from the heat observed for the reaction: POBr₃(c) + (n+3)H₂O(l) → [H₃PO₄·3HBr] in nH₂O(l). The data used in these calculations may be summarized as follows:

Data	Source
ΔH _f ⁰ 298.15 (water solutions) H ₃ PO ₄	Obtained graphically from W. S. Holmes, Trans. Faraday Soc. 59, 1916 (1962).
ΔH _f ⁰ 298.15 (water solutions) HBr	Obtained graphically from "Selected Values of Chemical Thermodynamic Properties," Natl. Bur. Stds. Circular 500.
ΔH _f ⁰ 298.15 (liquid) H ₂ O = -58.3174 kcal. mole ⁻¹	"Selected Values of Chemical Thermodynamic Properties," National Bureau of Standards Circular 500.
ΔH _f ⁰ 298.15 (crystal) POBr ₃ = -109.1 kcal. mole ⁻¹	Recalculated from heats observed by T. Charnley and H. A. Skinner, J. Chem. Soc. 450 (1953).
ΔH _f ⁰ 298.15 = [3.7] kcal. mole ⁻¹	Estimated from comparison with POCl ₃ .
ΔH _f ⁰ 298.15 = [12.1] kcal. mole ⁻¹	Estimated from the ΔH _f ⁰ at T _m (10.6 kcal. mole ⁻¹ at 464.9°K). ΔH _f ⁰ was calculated from a least squares treatment of the v.p. data of M. Van Driel, Rec. Trav. Chim. 61, 748 (1942).

Heat Capacity and Entropy.

The molecular constants used were calculated from electron diffraction measurements by J. H. Searles and L. O. Brockway, J. Am. Chem. Soc. 85, 1941 (1944). The calculated moments are I_A = I_B = 8.69174 × 10⁻⁸⁶ g.² cm.² and I_C = 1.474471 × 10⁻⁵⁷ g.² cm.²

From the Raman spectra of POBr₃ the vibrational frequencies were measured and assigned by H. Garding and M. van Driel, Rec. Trav. Chim. 61, 419 (1942). The Raman spectra was studied and the vibrational frequencies were listed by M. L. Delvaule and P. Francois, Compt. Rend. 220, 817 (1945). The frequencies may also be found in Compt. Rend. 222, 550 (1946) and J. Chim. Phys. 45, 87 (1948) by Delvaule and Francois.

Dec. 31, 1963

PHOSPHORUS TRIBROMIDE (PBr₃)
(IDEAL GAS)

Point Group C_{3v}
S°_{298.15} = 83.206 cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight = [1]
ΔH_f⁰ = -25.3 ± 1.5 kcal. mole⁻¹
ΔF_f⁰ = -30.7 ± 1.5 kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	ω, cm. ⁻¹
392 (1)	392.2 (2)
161.3 (1)	115.7 (2)

Bond Distance: P-Br = 2.20 ± 0.03 Å

Bond Angle: Br-P-Br = 106° ± 3°

Product of the Moments of Inertia: I_AI_BI_C = 1.1897 X 10⁻¹¹ g. cm.⁶

Heat of Formation.

The heat of formation of PBr₃ gas from white (α) phosphorus, -34.9 kcal. mole⁻¹, was obtained by T. Charnley and H. A. Skinner, J. Chem. Soc. 450 (1953). This was changed from white (α) to the red (V) phosphorus reference state to give the value used in this table (-30.7 kcal. mole⁻¹). To obtain their value (-34.9 kcal. mole⁻¹), Charnley and Skinner measured the heat of formation of the liquid, and combined it and their estimate of the liquid enthalpy with the heat of vaporization (9.5 kcal. mole⁻¹) calculated by M. Van Driel and H. Oardings, Rec. Trav. Chem. 50, 943 (1941). For the liquid heat of formation Charnley and Skinner observed the ΔH_f⁰ = -67.2 ± 0.6 kcal. mole⁻¹ for PBr₃(l) + (n+3)H₂O(l) → [H₃PO₃ + 3HBr] in nH₂O(l). Van Driel and Oardings measured the vapor pressure over PBr₃(l) and calculated the heat of vaporization with the aid of a modified Clapeyron equation. The uncertainties on the heats of formation are estimates.

Heat Capacity and Entropy.

Q. Williams and W. Oordy, Phys. Rev. 79, 225 (1950) have reported moments of inertia from the microwave spectrum of PBr₃. From this data D. H. Whiffen in "Tables of Interatomic Distances and Configuration in Molecules and Ions", Scientific Editor, L. E. Sutton, Special Publication No. 11, The Chemical Society (London) 1958, has calculated the selected molecular constants. From these constants the principal moments of inertia were calculated as I_A = I_B = 8.5214 X 10⁻³⁸ g. cm.² and I_C = 1.6363 X 10⁻³⁷ g. cm.²

M. Liatera and L. E. Sutton, Trans. Faraday Soc. 37, 393 (1941) have reported P-Br = 2.23 ± 0.04 Å and the angle P-Br-P = 100° ± 2°. S. M. Swingle has measured P-Br = 2.18 ± 0.03 Å and the angle P-Br-P = 101.5° ± 1.5°. The work of Swingle was reported in a private communication from L. Pauling and V. Schomaker, California Institute of Technology to P. W. Allen and L. E. Sutton, Acta. Cryst. 3, 48 (1950). Swingle's data as well as that of Liatera and Sutton was obtained by electron diffraction. The 106° angle was selected since 101.5° and 100° give imaginary force constants with the ranges allowed for the type A, 392 cm.⁻¹ frequency and the form of the potential function assumed by P. W. Davis and R. A. Oetjen, J. Molecular Spec. 2, 253 (1958).

The vibrational frequencies were measured and assigned in the infrared by Davis and Oetjen. Raman measurements and assignments by J. Cabannes and A. Rausset, Ann. Phys. (Paris) 19, 229 (1953) were also listed by M. L. Delaunay, Compt. Rend. 222, 1391 (1946) and Compt. Rend. 224, 389 (1947). The Raman assignments were as follows: type A, 380 cm.⁻¹ and 162 cm.⁻¹ and type E, 400 cm.⁻¹ and 116 cm.⁻¹.

Br₃P

Thiophosphoryl Bromide (PSBr₃)

Bond Distance: P-Br = $2.13 \pm 0.03 \text{ \AA}$ P-S = $1.89 \pm 0.06 \text{ \AA}$
 Bond Angle: Br-P-Br = $106^\circ \pm 3^\circ$ $\sigma = 3$
 Product of the Moments of Inertia: $I_A I_B I_C = 1.8780 \times 10^{-111} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The $\Delta H_f^0 \text{ 298.15}$ of PSBr₃(g) was calculated from the $\Delta H_f^0 \text{ 298.15}$ of POBr₃(g) and estimated strengths for P-S and P-O bonds.

The difference in the P-S and P-O bond strengths was assumed to be the same for POBr₃ - PSF₃ and POBr₃ - PSBr₃. For the P-S bond strength in PSF₃, C. B. Henderson and R. S. Scheffer, "Survey of Thermochemical Data," January 1960, Atlantic Research Corp., Alexandria, Virginia, estimated 91 kcal., from a consideration of unpublished data. The P-O bond was estimated to be 115 kcal. by E. Neale and L. T. D. Williams, J. Chem. Soc. 2485 (1955) and E. Neale, L. T. D. Williams, and V. T. Moores, J. Chem. Soc., 422 (1956).

The $\Delta H_f^0 \text{ 298.15}$ of POBr₃(g), [-93] kcal. mole⁻¹, was taken from the March 31, 1963, JANAP Table. The $\Delta H_f^0 \text{ 298.15}$ of O(g) and S(g) were taken from June 30, 1952, and March 31, 1961, JANAP Tables.

Heat Capacity and Entropy.

The molecular constants were determined from electron diffraction data by J. H. Secriast and L. O. Brockway, J. Am. Chem. Soc. 66, 1941 (1944). The principal moments of inertia calculated from these constants were $I_A = 1.105941 \times 10^{-37} \text{ g. cm.}^2$, and $I_C = 1.535429 \times 10^{-37} \text{ g. cm.}^2$.

The vibrational frequencies obtained from the Raman spectra of PSBr₃ were reported by M. L. Delvaux and P. Francois, Compt. Rend. 224, 1422 (1947).

TITANIUM TRIBROMIDE (TiBr₃)

(CRYSTAL)

GFW = 287.627

$\Delta H_f^\circ = -127.0 \pm 2.0$ kcal/mol
 $\Delta H_f^\circ = -127.050$
 $\Delta H_f^\circ = -131.5 \pm 2.0$ kcal/mol
 $\Delta H_f^\circ = 0$ kcal/mol
 $\Delta H_s^\circ = 33.165$ kcal/mol

$S_{298.15}^\circ = 42.2 \pm 0.8$ gibbs/mol

$T_t = 179.9^\circ\text{K}$

$T_s = 1067.2^\circ\text{K}$

Heat of Formation

The heat of formation of TiBr₃(c) is based on the vapor pressure data reported by Hall and Blocher (1) for the process 1/2Hg₂Br₂(c) + TiBr₃(c) = TiBr₄(g) + Hg(l) over the temperature range 430 to 546°K. Second and third law analyses of these data give values for the heat of reaction of 24.2 ± 0.3 and 24.4 kcal/mol, respectively, for seventy three points, with ten points rejected due to failure of a statistical test. The third law drift in the data is calculated as 0.6 ± 0.6 eu. The third law value of 24.4 kcal/mol is combined with the JANAF heats of formation of TiBr₄(g) and Hg₂Br₂(c) to obtain the adopted heat of formation.

Heat Capacity and Entropy

The heat capacity and entropy of TiBr₃(c) have been measured over the temperature range 51° to 800°K by King et al. (2). Heat capacities above 800°K are estimated from graphical extrapolation. The value of S_{298}° is derived from these data, based on $S_{51}^\circ = 8.60$ eu. The value of S_{51}° is estimated from a Debye-Einstein extrapolation of the measured heat capacities, the equation being $C_p = D(70.0/T) + E(120/T) + 2E(306/T)$. It is assumed that all electronic entropy is contained within the measured and extrapolated heat capacities.

Transition Data

A second order transition at 179.9°K was observed by King et al. (2). The heat capacity at this temperature is in excess of 56.1 gibbs/mol. King et al. measured the value of $H_{160}^\circ - H_{160}^\circ$ as 0.773 kcal/mol.

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of TiBr₃(c) and TiBr₃(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta G_r = 0$ for the process TiBr₃(c) = TiBr₃(g).

σ = 3

Heat of Formation

The heat of formation of TiBr₃(g) is calculated from the heat of sublimation of TiBr₃(c). A tentative equation for the vapor pressure of TiBr₃(c) was reported by Hall and Blocher (1). Second and third law analyses of the equation over the temperature range 700° to 900°K give values of ΔH_f^o of 45.2 and 41.9 kcal/mol, respectively, with a third law drift of -4.2 eu. The chosen value of ΔH_f^o is based on the third law ΔH_f^o298.

Heat Capacity and Entropy

The interatomic distance is estimated from those of TiCl₄, TiCl₃ and TiBr₄. The pyramidal bond angle is estimated by assuming that TiBr₃(g) is similar to the group V trihalides. The principal moments of inertia are I_A = 9.76 × 10⁻³⁶ g cm² and I_C = 1.78 cm². The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti³⁺ (2).

$\Delta F_f^o = [-147] \text{ kcal. mole}^{-1}$
 $\Delta F_f^o \text{ 298.15} = [-152] \text{ kcal. mole}^{-1}$
 $\Delta F_g^o \text{ 298.15} = [49] \text{ kcal. mole}^{-1}$

$S^o \text{ 298.15} = [41.12] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$
 $T_g = [1100]^{\circ}\text{K.}$

Heat of Formation.

E. M. Larsen and J. J. Leddy, J. Am. Chem. Soc. 78, 5983 (1956), studied the reaction $\text{Zr(c)} + 3\text{ZrBr}_4(\text{g}) = 4\text{ZrBr}_3(\text{c})$ in the temperature range 473 to 973°K. and pressure range 5 to 15 atm. They present a plot of the fractional reaction, for a series of temperatures, as a function of the reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The free energy function change for this reaction was calculated at 100° intervals from 500 to 1100°K. At each temperature, the equilibrium constant was assumed to be 1, and ΔF_f^o 298 accordingly calculated. These values and the heat of formation of $\text{ZrBr}_4(\text{g})$ [see ZrBr₄ table] were used to compute a series of values for the standard heat of formation of $\text{ZrBr}_3(\text{c})$. The following table gives representative values at four temperatures.

T(°K.)	K _p	ΔF _f ^o 298	ΔF _f ^o 298.15 [ZrBr ₃ (c)]
500	1	-70.26 kcal. mole ⁻¹	-132.8 kcal. mole ⁻¹
700	1	-96.48 kcal. mole ⁻¹	-139.3 kcal. mole ⁻¹
900	1	-121.75 kcal. mole ⁻¹	-145.6 kcal. mole ⁻¹
1100	1	-146.28 kcal. mole ⁻¹	-151.8 kcal. mole ⁻¹

If one assumes an initial pressure of from 5 to 10 atm. for ZrBr_4 and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of ZrBr_4 to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larsen and Leddy indicate about 82% reaction at 973°K. It was assumed that around 1100°K. the equilibrium constant attains a value of 1 giving -152 kcal. mole⁻¹ for the heat of formation of $\text{ZrBr}_3(\text{c})$ at 298.15°K. The limits of error were taken to be ±16 kcal. mole⁻¹ which corresponds to a ±500° temperature spread in the above table.

A second law calculation of their data was carried out but the results are of doubtful value in view of the uncertainty in the attainment of equilibrium at the lower temperatures.

Heat Capacity and Entropy.

The heat capacity was estimated in the same manner as for $\text{ZrBr}_4(\text{c})$ [see ZrBr₄(c) table]. The values for Q_p and Q_g were taken to be the same as those estimated for $\text{ZrBr}_4(\text{c})$. The internal contribution was obtained from the estimated ZrBr_3 vibrational frequencies and the anharmonicity factor " θ " was taken to be 2.5×10^{-3} . The specific heat above 300°K. was obtained by graphical extrapolation.

It was assumed, in the above estimation, that the crystalline lattice is made up of ZrBr_3 molecules. However, E. Holze [see R. P. Rolsten, "Iodide Metals and Metal Iodides", John Wiley & Sons, Inc., New York, 1961, page 46] concluded that crystalline ZrI_3 was composed of a chain lattice of $(\text{Zr}_2\text{I}_6)_n$ units. A chain lattice of $(\text{Zr}_2\text{Br}_6)_n$ units is probably a better representation of the solid state structure of ZrBr_3 . Until more quantitative data become available, however, it is felt that the above analysis gives a fair approximation to the heat capacity of ZrBr_3 .

Temperature of Disproportionation.

As detailed in the "Heat of Formation" section, this was assumed to be 1100 ± 500°K.

Liquid Phase.

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data.

The heat of sublimation at 298.15°K. was obtained from the difference in the heats of formation of the gas and solid at 298.15°K. The sublimation point was obtained from the free energy crossover between gas and solid.

Heat of Formation

The heats of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this heat of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal. mole⁻¹ greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium tribromide, the heat of formation from the gaseous atoms was -329 kcal. mole⁻¹ and from the elements in their standard state, -103 kcal. mole⁻¹.

Heat Capacity and Entropy

The measured internuclear distances for the tribromides of P, As, and Sb were plotted as a function of the atomic weight of these atoms and a smooth curve was drawn through the points. The internuclear distance for ZrBr₃ was taken from this plot. The bond angle was assumed to be intermediate between the bond angles of AsBr₃ and SbBr₃; it was taken to be 98°. The individual moments of inertia are I_A = I_B = 101.408 X 10⁻³⁹ gm. cm.², I_C = 172.669 gm. cm.².

The measured vibrational frequencies for the tribromides of phosphorus, arsenic, and antimony were plotted as a function of internuclear distance. Smooth curves through these points were obtained for ω₁, ω₂, and ω₄; these curves and the estimated ZrBr₃ bond distance were used to obtain correlation values of ω₁, ω₂, and ω₄ for ZrBr₃. Force constants, assuming a valence force field and a Br-Zr-Br angle of 98°, were derived from the above values for ω₁ and ω₂. These force constants were then used to derive values for ω₃ and ω₄. By a process of successive approximation, a set of force constants was obtained which gave frequencies in good agreement with the three correlation values. The three correlation frequencies and the derived frequency were used in this table.

Bond Distance: Fe-Br = [2.24] Å

Bond Angles: Fe-Br₂-bridge - Fe = [90]^o Br₂-bridge - Fe-Br₂-bridge = [90]^o

Br-Fe-Br₂-bridge = [135]^o σ = [4]

Product of the Moments of Inertia: I_AI_BI_C = [1.4498 x 10⁻¹¹⁰] g³ cm⁶

Heat of Formation

The chemical equilibria, 622-665°K, for the reaction Fe₂Br₄(g) = 2 FeBr₂(g) were studied by R. P. Porter and R. C. Schoonmaker, J. Phys. Chem. 63, 626 (1959), using a mass spectrometer. Based on the reported partial pressures for the two species, the enthalpy change (ΔH_{298.15}^o) for the reaction was evaluated by both the second and third law methods to be 40.36 ± 2.0 and 40.75 ± 0.2 kcal/mol, respectively. Using the third law ΔH^o value and ΔH_{298.15}^o (FeBr₂,g) = -9.9 ± 0.5 kcal/mol, the heat of formation (ΔH_{298.15}^o) for Fe₂Br₄(g) was calculated as -60.5 ± 2.0 kcal/mol and was adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be planar. The two Fe atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two Br atoms. The two remaining Br atoms are situated outside the square on a straight line joining the two Fe atoms. The Fe-Br bond distance was estimated to be the same as that in the FeBr₂(g) molecule. The first six vibrational frequencies were estimated by comparison with those for FeBr₂(g) calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The last three degenerate frequencies were assigned arbitrarily in order to give good second and third law agreement for the heats of dissociation of dimer to monomer. The order of the frequencies listed above is arbitrary and not related to their species types.

The electronic levels and quantum weights were estimated by comparison with those for FeBr₂(g). The three principal moments of inertia are: I_A = 6.6576 x 10⁻³⁸, I_B = 4.3456 x 10⁻³⁷ and I_C = 5.0113 x 10⁻³⁷ g cm².

Dec. 31, 1961; June 30, 1964; June 30, 1968

TITANIUM TETRABROMIDE (TiBr₄)

(CRYSTAL)

GFW = 367.536

ΔHf° = -141.7 ± 1.1 kcal/mol
ΔHf°_{298.15} = -147.7 ± 1.0 kcal/mol
ΔHm° = 3.08 kcal/mol

S°_{298.15} = 56.2 ± 1.6 kcal/mol
Tm = 311.4°K

Heat of Formation

The heat of formation, ΔHf°₂₉₈, of TiBr₄(c) has been determined calorimetrically by several investigators as follows.

Investigators	Reaction	ΔHf° _{298.15} kcal/mol
Nelson, Johnson and Prosen (1)	Ti(c) + 2Br ₂ (g) = TiBr ₄ (c)	-147.3 ± 1.1
Johnson, Gilliland and Prosen (2)	TiCl ₄ (l) + 2Br ₂ (l) = TiBr ₄ (c) + 2Cl ₂ (g)	-147.6 ± 1.3
Schlafer and Schmidtke (3)	Ti(c) + 2Br ₂ (l) = TiBr ₄ (c)	-147.7 ± 0.3
Gross, Hayman and Levi (4)	Ti(c) + 2Br ₂ (l) = TiBr ₄ (c)	-146.1 ± 0.3

The chosen value of ΔHf°₂₉₈ is the average of these determinations. The value from the work of Nelson et al. (1) is obtained from their heat of reaction and the JANAF value for the heat of vaporization of bromine. The value obtained from Johnson et al. (2) is a combination of their heat of reaction and the JANAF value for the heat of formation of TiCl₄(l).

Heat Capacity and Entropy

The heat capacity of TiBr₄(c) has been measured over the temperature range 51° to 298°K by King et al. (5). They reported a value of 42.74 eu for S°₂₉₈ - S°₅₁ based on their measurements. The value of S°₅₁ is estimated as 15.46 eu. King et al. (5) reported an estimate of 14.75 ± 1.60 for the same quantity. The former estimate is used so that the values of ΔHf°₂₉₈ obtained by both second and third law methods are in agreement. See TiBr₄(g) table for details. The value of H°₅₁ - H°₀ is estimated as 0.372 kcal/mol. This estimate is based on a Debye-Einstein extrapolation of the measured heat capacity with vibrational contributions removed.

Melting Data

The melting temperature and heat of melting were reported by King et al. (5).

TITANIUM TETRABROMIDE (TiBr₄)

(LIQUID)

GFW = 367.536

$$S_{298.15}^\circ = 67.918 \pm 1.6 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^\circ = -144.681 \pm 1.0 \text{ kcal/mol}$$

$$T_m = 311.4^\circ\text{K}$$

$$\Delta H_m^\circ = 3.08 \text{ kcal/mol}$$

$$T_b = 504.1^\circ\text{K}$$

$$\Delta H_v^\circ = 10.80 \text{ kcal/mol}$$

Heat of Formation

The heat of formation of TiBr₄(l) is calculated from the heat of melting, ΔH_m° , the heat of formation of TiBr₄(c), and the values of $H_{311.4}^\circ - H_{298.15}^\circ$ for both crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the heat capacity of TiBr₄(l) between the melting point and normal boiling point. The entropy, S_{298}° , of TiBr₄(l) is calculated from $\Delta S_{311.4}^\circ$, the values of $S_{311.4}^\circ - S_{298.15}^\circ$ of both crystal and liquid and the value of $S_{298.15}^\circ$ of TiBr₄(c).

Melting Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, T_b , is taken as the point at which $K_p = 1$ for the reaction $\text{TiBr}_4(l) = \text{TiBr}_4(g)$. The heat of vaporization is calculated as the difference between ΔH_f° of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for TiBr₄(g).

Heat of Formation

The heat of formation of TiBr₄(g) is calculated from those of TiBr₄(c) and TiBr₄(l) and the heats of reaction for the processes (A) TiBr₄(c) = TiBr₄(g) and (B) TiBr₄(l) = TiBr₄(g). Second and third law analyses of the vapor pressure data for these processes yield the following results. The first four investigations employed the spoon gauge method, the last investigation being a manometric determination.

Source	Reaction	No. Pts.	Range T°K	ΔH° ₂₉₈ , kcal/mol	Drift, kcal/mol
Boni, 1966 (1)	A	13	275 - 311	16.4 ± 0.2	16.19
Funaki et al., 1961 (2)	B	14	385 - 493	12.2 ± 0.3	12.92
Seki, 1941 (3)	A	12	286 - 306	15.4 ± 0.5	1.6 ± 0.3
Hall et al., 1958 (4)	B	69*	341 - 499	13.2 ± 0.1	13.14
Keavney & Smith, 1960 (5)	A	14	287 - 310	16.1 ± 0.3	16.14

* Four points rejected due to failure of a statistical test.

** Calculation based on third law ΔH°₂₉₈.

The adopted value of 131.5 kcal/mol is that obtained from the data of Hall et al. (4), whose third law drift was adjusted to zero by changing the entropy of the crystal within its uncertainty.

Heat Capacity and Entropy

The interatomic distance was reported by Lister and Sutton (6). The tetrahedral configuration is confirmed by spectroscopic studies (7,8). The individual moments of inertia are I_A = I_B = I_C = 1.89 × 10⁻³⁷ g cm².

The vibrational frequencies have been reported by Delvaux and Francois (7) and by Miller and Carlson (8). These values are based primarily on the Raman and infrared spectra of TiBr₄(l), the value of ν₃ being the only frequency measured for TiBr₄(g).

The electronic spectra of TiBr₄ in solution have been measured by Dijkgraaf (9). Di Sipio et al. (10) have reported the near ultraviolet spectra of TiBr₄(g). Both of these studies indicate that TiBr₄ has no low lying electronic levels which would contribute significantly to the entropy.

ZIRCONIUM TETRABROMIDE (ZrBr₄)

(CRYSTAL)

Br₄Zr

MOL. WT. = 410.884

S_{298.15} = [53.70] cal. deg.⁻¹ mole⁻¹
T_m = 723°K.
T_g = 630°K.
ΔH_f⁰ = -175.3 ± 0.8 kcal. mole⁻¹
ΔH_f⁰ 298.15 = -181.6 ± 0.6 kcal. mole⁻¹
ΔH_g⁰ 298.15 = 28.0 ± 1.0 kcal. mole⁻¹

Heat of Formation.

A. G. Turnbull, J. Phys. Chem. 65, 1852 (1961), measured the heat effect accompanying the following reactions:

Turnbull also measured the chlorine analogue of the above reactions. He used the measured heat of formation of zirconium tetrachloride, reported by Gross, Hyman and Levi [see ZrCl₄ table], to calculate the heats of formation of ZrO₂(hyd.) and ZrO₂(aq.). The heat of formation of solid zirconium tetrabromide from reaction (1) was -182.2 ± 0.7 kcal. mole⁻¹ and from reaction (2) was -181.0 ± 0.6 kcal. mole⁻¹. An average of the two was taken to represent the heat of formation of the tetrabromide.

Heat Capacity and Entropy.

The heat capacity from 0 to 300°K. was calculated by means of the relationship $C_p = C_{vib}(e_D = 85°K.) + C_{tr}(e_D = 155°K.) + C_{vib} + a_2 C_{vib}$, where C_{vib} represents the hindered translational, C_{tr} the librational, and C_{vib} the internal vibrational contributions to the heat capacity of the solid. $C_v = C_{vib} + C_{tr} + C_{vib}$ represents the constant volume heat capacity to which $a_2 C_{vib}$, the anharmonic contribution, is added to convert to a heat capacity at constant pressure. The internal contribution, C_{vib} , was obtained from the estimated vibrational frequencies [see gas table]. The values for q_p and q_r were obtained from an elaborate correlation with the corresponding values for ZrCl₄ [see ZrCl₄ crystal table]. C_p was computed using a number of values for the constant term "a". The value, $a = 2.5 \times 10^{-3}$, was chosen from a consideration of the sublimation calculations [see below]. The heat capacity above 300°K. was obtained by a graphical extrapolation.

Melting Point.

This was reported by O. Rahlfs and M. Fischer, Z. anorg. allgem. Chem. 211, 349 (1933).

Sublimation Data.

Vapor pressure measurements have been reported by Rahlfs and Fischer (loc. cit.) and by H. L. Schlafer and H. Skoludek, Z. Elektrochem. 55, 367 (1952). The heat of sublimation results, for two values of "a", are given in the following table.

Reference	"a"	ΔH _g (298) [3rd Law]	ΔH _g (298) [2nd Law]
	A		B
Schlaf	3.0 X 10 ⁻³	27.43	28.82
Schlaf	2.5 X 10 ⁻³	27.73	28.68
Rahlfs	3.0 X 10 ⁻³	27.52	28.15
Rahlfs	2.5 X 10 ⁻³	27.85	27.99

All heat values are in kcal. mole⁻¹. Two sets of second law heat values are given; set "A" was obtained from the slope reported by the authors and set "B" from a least squares fit performed at The Dow Thermal Laboratory. Various high temperature extrapolations were carried out for a particular value of "a" but only insignificant changes in the heat of sublimation resulted. The data of Schlafer and Skoludek showed a considerable temperature dependent third law heat of sublimation at 298°K. when "a" was taken as 3.0 X 10⁻³, and a moderate temperature dependence when "a" was taken as 2.5 X 10⁻³. The data of Rahlfs and Fischer showed a very slight temperature dependence for a = 3.0 X 10⁻³ and no temperature dependence for a = 2.5 X 10⁻³.

In both sets of data there are large differences between 2nd and 3rd law values for a = 3.0 X 10⁻³, good 2nd and 3rd law agreement for the data of Rahlfs and Fischer and a = 2.5 X 10⁻³, and only fair agreement for the data of Schlafer and Skoludek and a = 2.5 X 10⁻³. Extrapolation of the data of Schlafer and Skoludek for a = 2.0 X 10⁻³ indicated a continuing temperature dependent third law heat of sublimation and disagreement between 2nd and 3rd law values. The heat of sublimation was taken as the average of the third law and two second law values calculated from the data of Rahlfs and Fischer using "a" = 2.5 X 10⁻³. The results of this analysis should not be considered conclusive since all of the data is estimated.

The sublimation point reported by Rahlfs and Fischer (loc. cit.) was 630°K., that calculated from the data of Schlafer and Skoludek was 624°K. and that obtained from the free energy crossover between solid and gas was 630°K. The sublimation point was taken as 630°K.

Since the sublimation point is lower than the melting point, the liquid phase is thermodynamically unstable under ordinary conditions.

Product of the Moments of Inertia: I_AI_BI_C = [9.5782 × 10⁻¹¹¹] gm.³ cm.⁶O⁻ = [12]

Heat of Formation.

Calculated from the heats of formation and sublimation for the crystal at 298.15°K. (see crystal table for details).

Heat Capacity and Entropy.

The interatomic distance was obtained from an involved correlation of the interatomic distances and covalent radii of the tetrahalides of Pb, Si, Ti, Ge, and Sn. I. N. Odnev, A. M. Aleksandrovskaya, and I. V. Regins, Optics and Spectroscopy 7, 172 (1959), estimated the interatomic distance and report 2.47 Å as the Zr-Br distance. The bond angle was taken to be the tetrahedral angle. The three principal moments of inertia are: I_A = I_B = I_C = 2.1237 × 10⁻¹¹¹ gm. cm.².

The fundamental vibrational frequencies are all estimated. The product of ω₁ and ω₂ versus internuclear distance for these molecules gave nearly linear smooth curves. Values of ω₁ and ω₂ obtained from these plots were 216 cm.⁻¹ and 58 cm.⁻¹ respectively. These values for ω₁ and ω₂ were used in a valence force field calculation to derive values for ω₃ and ω₄. Central and valence force field calculations, using estimated force constants were carried out but the results proved to be inconsistent. Therefore, ω₁ was taken as the average of the two empirically derived values, ω₂ as its empirically derived value, and ω₃ and ω₄ as those derived from the empirical values and the valence force field calculation. Odnev, Aleksandrovskaya, and Regins (loc. cit.) estimated the vibrational frequencies; they obtained ω₁ = 224 cm.⁻¹, ω₂ = 65 cm.⁻¹, ω₃ = 309 cm.⁻¹, and ω₄ = 78 cm.⁻¹.

TUNGSTEN PENTABROMIDE (WBr₅) (CRYSTAL)

GFW = 583.395

Br₅W

$\Delta H_f^\circ = \text{Unknown}$

$\Delta H_f^\circ_{298.15} = -74.5 \pm 3 \text{ kcal/mol}$

$\Delta H_m^\circ = 4.10 \text{ kcal/mol}$

$S^\circ_{298.15} = [65 \pm 5] \text{ gibbs/mol}$

$T_m = 559^\circ \pm 10^\circ \text{K}$

Heat of Formation

S. A. Shchukarev and G. A. Kokovin (1) have measured calorimetrically the heat of reaction $\Delta H_{298}^\circ = -187.475 \pm 0.9 \text{ kcal/mol}$ for $\text{WBr}_5(\text{c}) + 1/2\text{Br}_2(\text{l}) + 8\text{NaOH}(77.4\text{H}_2\text{O}) + \text{Na}_2\text{WO}_4(\text{c}) + 6\text{NaBr}(\text{c}) + \text{H}_2\text{O}(\text{l})$. This leads to $\Delta H_{298}^\circ(\text{WBr}_5, \text{c}) = -74.5 \pm 3 \text{ kcal/mol}$, using $\Delta H_{298}^\circ(\text{NaOH}(77.4\text{H}_2\text{O})) = -112.348 \text{ kcal/mol}$ (2), $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c}) = -369.2 \text{ kcal/mol}$ (3), $\Delta H_{298}^\circ(\text{NaBr}, \text{c}) = -86.38 \text{ kcal/mol}$ (4) and $\Delta H_{298}^\circ(\text{H}_2\text{O}, \text{l}) = -68.315 \text{ kcal/mol}$ (5).

Heat Capacity and Entropy

$C_{p00} = 6.2 \text{ gibbs/g-atom}$ and $C_{p559} = 7.25 \text{ gibbs/g-atom}$ are estimated using the method described by O. Kubaschewski and E. L. Evans (6). Between 300°K and 559°K , which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S_{298}^\circ = 65 \text{ eu}$, is estimated from that of $\text{WCl}_5(\text{c})$ (7) and the entropy difference between bromides and chlorides. The latter is estimated to be 13 eu based on an extrapolation to pentavalent compounds of the entropy values of bromides and chlorides given by W. M. Latimer (8). Both WBr_5 and WCl_5 are paramagnetic with an effective moment of about 1.1 Bohr magnetons as indicated by B. N. Figgis and J. L. Lewis, "Progress in Inorg. Chem.," Vol. 6, page 121, Interscience Publishers, New York, 1964.

Melting Data

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin (8) have found the melting point, 559°K , by the thermographic method and 568°K by the tensimetric method. The value of 559°K is adopted in the tabulation.

The heat of melting is calculated from the difference between the heats of sublimation and vaporization at the melting point. The heats are both calculated from a second law analysis of the vapor pressure data reported by Shchukarev et al. (8), who gave the uncorrected heat of fusion, 5 kcal/mol . This value, when corrected for ΔC_p of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

TUNGSTEN PENTABROMIDE (WBr₅)
S_{298.15} = [70.113] gibbs/mol

T_m = 559° ± 10°K

T_b = 633.5°K

Heat of Formation

The heat of formation, ΔH_{f298}^o (WBr₅, l) = -71.236 kcal/mol, is calculated from that of WBr₅(c) by adding the heat of melting and the difference between H_{f559} - H_{f298} for the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be a constant, 7.25 gibbs/g-atom.

The entropy, S₂₉₈ = 70.113 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data

See WBr₅(c) table (June 30, 1967) for details.

Vaporization Data

T_b is calculated as the temperatures at which the Gibbs energy of reaction WBr₅(l) → WBr₅(g) approaches zero. The differences between the heats of formation for liquid and gas at the boiling point is ΔH_v^o.

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin, Zh. Neorg. Khim. 1, 2185 (1959), derived the boiling point 665°K and the heat of vaporization 14.5 ± 0.5 kcal/mol from vapor pressure data. Our second law values, corrected for ΔC_p, are T_b = 666°K and ΔH_v^o = 13.8 kcal/mol. The adopted values are significantly different because the second law value of ΔS_v is not adopted in the table.

(LIQUID)

GFW = 583.395

ΔH_{f298.15} = [-71.236] kcal/mol

ΔH_m^o = 4.10 kcal/mol

ΔH_v^o = 13.48 kcal/mol

Heat of Formation

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin, Zh. Neorg. Khim. 4, 2185 (1959), measured the vapor pressure of WBr₅(c, l) using a null manometer. Their results are given as below. The adopted heat of formation is -47.6 kcal/mol.

Reactions	No. of Exptl.	Temp. Range (°K)	ΔH _f ²⁹⁸ (kcal/mol)	Drift (kcal)
WBr ₅ (l) + WBr ₅ (g)	13	18.37	24.11	573.3-657.5
WBr ₅ (c) + WBr ₅ (g)	6	21.61	26.46	443.5-496.5

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of MoCl₅ determined by electron diffraction (1). The bond distance is estimated to be the same as that in WBr₅(g). The three principal moments of inertia are $I_A = I_B = 267.5 \times 10^{-39}$ and $I_C = 229.3 \times 10^{-39} \text{ g cm}^2$.

All vibrational frequencies are estimated from those of WCl₅(g) (2), using the average value of $\nu(\text{WBr}_5)/\nu(\text{WCl}_5) = 0.62$ for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of ReX₅, SnX₅ and PtX₅ summarized by H. Siebert (3) and K. Nakamoto (4).

The electronic levels and quantum weights are estimated to be the same as those in WCl₅(g) (2).

TUNGSTEN HEXABROMIDE (WBr₆)

(CRYSTAL)

GFW = 663.304

ΔHf° = Unknown

ΔHf°_{298.15} = -82.0 ± 3 kcal/mol

S°_{298.15} = [75 ± 5] gibbs/mol

ΔHm° = Unknown

Tm = 582°K

Heat of Formation

S. A. Shchukarev and G. A. Kokovin (1) have measured calorimetrically the heat of reaction ΔHr°₂₉₈ = -180.0 ± 0.8 kcal/mol for WBr₆(c) + 8NaOH(77.4H₂O) → Na₂WO₄(c) + 6NaBr(c) + 4H₂O(l). This leads to ΔHf°₂₉₈(WBr₆, c) = -82.0 ± 3 kcal/mol, using ΔHf°₂₉₈(NaOH·77.4H₂O) = -112.348 kcal/mol (2), ΔHf°₂₉₈(Na₂WO₄, c) = -369.2 kcal/mol (3), ΔHf°₂₉₈(NaBr, c) = -86.38 kcal/mol (4) and ΔHf°₂₉₈(H₂O, l) = -68.315 kcal/mol (5).

Heat Capacity and Entropy

Cp₃₀₀ = 6.2 gibbs/g-atom and Cp₅₈₂ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans (6). Between 300° and 582°K, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, S°₂₉₈(WBr₆, c) = 75 eu, is estimated by assuming S°₂₉₈(WBr₆) = S°₂₉₈(WCl₆) + 6[S°₂₉₈(Br⁻) - S°₂₉₈(Cl⁻)]. The value, S°₂₉₈(WCl₆, c) = 57 eu, is obtained from the JANAF WCl₆(a) table (Dec. 31, 1966); and the value, S°₂₉₈(Br⁻) - S°₂₉₈(Cl⁻) = 3 gibbs/mol, is obtained from the average entropy values for Br⁻ and Cl⁻ ions given by W. M. Latimer (7) and K. K. Kelley (8).

Melting Data

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin (9) have found the melting point, 582°K, under 50 atm pressure of Br₂(g) by the thermographic method. The heat of fusion is unknown.

Heat of Formation

The heat of formation, $\Delta H_f^\circ(\text{WBr}_6, \text{g}) = -56.1 \text{ kcal/mol}$, is calculated from that of the crystal plus the estimated heat of sublimation $\Delta H_{\text{sub}}^\circ = 73.9 \text{ kcal/mol}$ for $\text{WBr}_6(\text{c}) + \text{WBr}_6(\text{g})$. The value of $\Delta H_{\text{sub}}^\circ$ is assumed to be the same as that for $\text{WCl}_6(\text{c}) + \text{WCl}_6(\text{g})$. See WCl_6 table (Dec. 31, 1966) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be an octahedron similar to those of $\text{WF}_6(\text{g})$, and $\text{WCl}_6(\text{g})$ determined by electron diffraction. The bond distance is estimated to be $2.40 \text{ \AA}$ by assuming $r_{\text{W-Br}} = r_{\text{W-Cl}} + (r_{\text{Na-Br}} - r_{\text{Na-Cl}})$. The bond distances, W-Cl , Na-Br and Na-Cl , are given in JANAF $\text{WCl}_6(\text{g})$ and $\text{NaBr}(\text{g})$ tables, as $2.26 \text{ \AA}$, $2.50 \text{ \AA}$ and $2.36 \text{ \AA}$, respectively. The three principal moments of inertia are: $I_A = I_B = I_C = 305.7 \times 10^{-39} \text{ g cm}^2$. All vibrational frequencies are estimated from those of $\text{WCl}_6(\text{g})$ (1), using the average value of $\nu(\text{WBr}_6)/\nu(\text{WCl}_6) = 0.62$ for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of ReX_6 , SnX_6 and PtX_6 summarized by H. Siebert (2), and K. Nakamoto (3).

 $\Delta H_f^{\circ} 298.15 = 0$ $\Delta S^{\circ} 298.15 = 1.359 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^{\circ} 298.15 = 170.89 \pm 0.5 \text{ kcal. mole}^{-1}$ Heat of Formation

Zero by definition.

Heat Capacity and Extrapolation

The low temperature C_p measurements of F. H. Keesom and N. Pearson (1° to 4°K. and 10° to 20°K.), Phys. Rev. 99, 1119 (1955), and of W. Dasorbo and G. E. Nichols (1° to 20°K.), The Phys. and Chem. of Solids 6, 352 (1956), were joined smoothly with the C_p measurements of W. Desorbo and W. W. Tyler (13° to 300°K.), J. Chem. Phys. 21, 1660 (1953). C_p values above 300°K were taken from National Bureau of Standards Report 6928, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element Compounds", July, 1960. Heat capacity values above 1000°K were adjusted to give smooth results. Above 4000°K. the C_p values are estimated.

S_{15}° and H_{15}° were calculated to be 0.00265 cal. deg.⁻¹ mole⁻¹ and 0.03982 cal. mole⁻¹ respectively from smooth C_p values using Meddle's rule.

33,735	5	85,000	401

Heat of Formation

The ΔH_f^o is given by the following cycle at 0°K.

(I) C(c) + 1/2 O ₂ (g) = CO(g)	-27.195 kcal. mole ⁻¹
(II) CO(g) = C(g) + O(g)	255.764
(III) O(g) = 1/2 O ₂ (g)	-58.989

For details concerning (I), (II), and (III) see the CO(g) and O₂(g) sheets. A definitive review of the heat of sublimation of carbon is given by L. Brewer and A. W. Searcy, Ann. Rev. Phys. Chem., 7, 259 (1956).

Heat Capacities and Entropies

The electronic energy levels are those listed by C. E. Moore, Nat. Bur. Standards (U. S.) Circ. 467, (1949). Levels above 50,000 cm.⁻¹ have been averaged.

Heat of Formation.

The heat of formation was calculated from the equation: C(g) + e⁻ → C⁻(g) with the JANAP auxiliary value for C(g); using an electron affinity = 1.25 e.v. (28.83 kcal/mole) obtained from M. Senan and L. M. Branscomb, Phys. Rev. 125, 1602 (1962). Other values for the electron affinity are: 1.17 e.v. reported by E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 1.12 e.v. reported by E. Clementi, A. D. McLean, D. L. Raimondi and M. Yoshimine, Phys. Rev. 133, A1274 (1964); and 1.24 e.v. reported by B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, U. S. National Bureau of Standards Circular 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case nitrogen. The electronic levels above 1 X 10⁵ cm⁻¹ were omitted because their contribution is negligible below 5000°K. The H₂₉₈ value at 0°K. is -1.481 kcal/mole.

$$B = 1$$

Heat of Formation.

ΔH_f^0 was calculated from D_0 , 83.0 kcal. mole⁻¹, estimated by J. S. Gordon, AstroSystems International, Livingston, N. J., private communication, June 6, 1963. $\Delta H_f^0 298.15$ was then calculated. P. Zeeman, Can. J. Phys. 32, 9 (1954) reported a $D_0 = 1.6 \pm 0.2 \text{ e.v.}$, 36.9 kcal. mole⁻¹, for a molecule that was apparently AlC(g) . However, H. Wooley, Nat'l Bur. Std. Report No. 6928, July 1, 1960, surmised that this D_0 and the reported molecular constants were for the $\text{Al}_2(\text{g})$ molecule. His judgment was accepted.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit.

Heat of Formation.

The heat of formation at 298.15°K. was calculated from $\Delta H_f^o = 105 \pm 10 \text{ kcal. mole}^{-1}$ for the reaction $\text{BC(g)} = \text{B(g)} + \text{C(g)}$ reported by G. Verhaegen, P. E. Stafford, M. Ackerman, and J. Drowart, *Nature*, **193**, 1280 (1962).

Heat Capacity and Entropy.

All spectroscopic constants were obtained from J. S. Gordon, Astroaystema, International, West Caldwell, New Jersey, private communication, November 2, 1962.

MOL. WT. = 55.25515

(CRYSTAL)

TETRABORON MONOCARBIDE (B₄C)

$$\Delta H_f^0 = -9.2 \pm 2.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -9.3 \pm 2.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = [25] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 6.483 \pm 0.03 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 2743 \pm 20^\circ \text{K.}$$

Heat of Formation.

The ΔH_f^0 298.15 was calculated from ΔH_f^0 298.15 = -683.3 ± 2.2 kcal. mole⁻¹ for the reaction B₄C(c) + 4O₂(g) → 2B₂O₃(amorph) + CO₂(g) measured by D. Smith, A. S. Dworkin and E. R. Van Artsdalen, J. Am. Chem. Soc. **71**, 2654-6 (1955) and the heat of formation for B₂O₃(amorph) (Dec. 31, 1964) and for CO₂(g) (March 31, 1961) in JANAF Tables.

Heat Capacity and Entropy.

The low temperature heat capacities, 54-294°K., were taken from K. K. Kelley, J. Am. Chem. Soc. **63**, 1137 (1941). Above 298°K., C_p was calculated using the equation C_p = 22.89 + 5.40 X 10⁻³T - 10.72 X 10⁻⁶T² obtained from the enthalpy data in the range 298 to 1726°K. reported by E. G. King, Ind. Eng. Chem. **41**, 1298 (1949). The values from the two sources join smoothly at 298°K. The S_{298.15} was calculated based on the low temperature heat capacities measured by K. K. Kelley, loc. cit., using S_{53.1} = 0.047 cal. deg.⁻¹ mole⁻¹.

Melting Data.

T_m was determined by Dolloff, WADD Tech. Rept. 60-143, 1960 and ΔH_m⁰ was estimated.

CB₄

CB₄

(Liquid) Mol. Wt. = 55.25515

MOL. WT. = 55.25515

(LIQUID)

TETRABORON MONOCARBIDE (B₄C)

$$\Delta H_f^\circ 298.15 = 16.592 \text{ cal. deg.}^{-1} \text{ mole}^{-1} \quad \Delta H_f^\circ 298.15 = 16.1 \pm 2.5 \text{ kcal. mole}^{-1}$$

$$T_m = 2743 \pm 20^\circ \text{K.} \quad \Delta H_m^\circ = [25] \text{ kcal. mole}^{-1}$$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ was obtained from $\Delta H_f^\circ 298.15(c)$ by adding ΔH_m° and the difference between H_m° and $H_{298.15}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 1750°K. The heat capacity below 1750°K. was obtained from the heat capacity of the crystal. Above 1750°K. the heat capacity was assumed constant and estimated as 32.50 cal. deg.⁻¹ mole⁻¹ or 8.5 cal. deg.⁻¹ per g.-atom.

The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See B₄C(c) table.

CBe_2

DIBERYLLIUM MONOCARBIDE (Be_2C) (CRYSTAL) MOL. WT. = 30.037

$\Delta F_f^\circ 0 = \text{Unknown}$
 $\Delta H_f^\circ 298.15 = 21.7 \pm 2.5 \text{ kcal. mole}^{-1}$
 $\Delta F_f^\circ = [16] \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = [3.9 \pm 1.0] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = [2400]^\circ \text{K.}$

Heat of Formation.

The selected $\Delta H_f^\circ 298.15$ was calculated by the 3rd law method using vapor pressures reported by B. D. Pollock, J. Phys. Chem. 63, 587 (1959). Pressures for the reaction $\text{Be}_2\text{C}(c) \rightarrow 2\text{Be}(g) + \text{C}(\text{graphite})$ were measured by Pollock in the temperature range 1430-1669°K. by Knudsen technique. Vapor pressure data for this decomposition reaction have also been reported by J. Baboin, French Patents 1,193,790 (1959), J. Quirk, Reactor Handbook 3, 88 (1955) and P. Muratov and A. Novoselova, Dokl. Akad. Nauk SSSR 123, 334 (1959). The calculated $\Delta H_f^\circ 298.15$ values are summarized as follows:

Calc. Method	Number of Pressures	T, °K.	$\Delta H_f^\circ 298.15$ kcal. mole ⁻¹	$\Delta F_f^\circ 298.15$ kcal. mole ⁻¹	References
3rd law	14	1430-1669	89.117	-21.7	B. D. Pollock
2nd law	14	1430-1669	90.8	-25.1	Least squares fit of Pollock's v.p. to the equation: $\log P (\text{atm.}) = 6.946 - 19.593/T$
3rd law	6	1675-1953	71.411	+13.7	P. Muratov and A. Novoselova
3rd law	8	1900-2600	81.278	- 6.1	J. Quirk
3rd law	8	1800-2300	96.266	-36.0	J. Baboin

H. L. Schick, D. F. Anthrop, P. L. Hanst, R. E. Dreikorn, and M. B. Panish, "Thermodynamics of Certain Refractory Compounds, Part II", 1 March 1963 to 31 May 1963 have listed the measured vapor pressures. The vapor pressures reported by J. Baboin (loc. cit.) used in the 3rd law calculation were those listed by H. L. Schick, et al.

Heat Capacity and Entropy.

The heat capacity values, from 298.15 to 1200°K., were derived from the mean C_p data measured by J. J. Neely, E. Teeter, Jr., and J. B. Trice, J. Am. Ceramic Soc. 33, 363 (1950). Neely, et al., estimated an overall error of 15% in their mean heat capacity data. The powdered Be_2C material which was used analyzed 80 to 74% Be_2C . The impurities were mainly oxide and nitride of Be. No corrections were made for the effect of these impurities.

From 1200-2400°K. the C_p was extrapolated so as to approach the value, 22 cal. deg.⁻¹ mole⁻¹ calculated from O. H. Krikorian, "Estimation of High-Temperature Heat Capacities of Carbides," University of California, UCL 6785, February 6, 1962. The $S_{298.15}^\circ$, 3.9 cal. deg.⁻¹ mole⁻¹, was estimated by Krikorian (loc. cit.).

Melting Data.

H. L. Schick, et al., (loc. cit.) have summarized the available melting data i.e.: Y. Oishi and Y. Hamons, Osaka Kogyo Gijyuu Shikenjo Kiko 8, 89 (1957) have reported decomposition upon heating as low as 1873°K. L. Brewer, L. Bromley, P. Gilles, and N. Lofgren, "The Chemistry and Metallurgy of Miscellaneous Materials," in "Thermodynamics", McGraw-Hill, New York (1950) and I. S. Gev, AEC TR 3036 Transl. from Zh. Neorg. Khim. 1, 196 (1956) reported melting or dissociation between 2373° and 2423°K.

The melting point is assumed to be 2400°K. as estimated by T. B. Douglas and A. C. Victor, National Bureau of Standards Preliminary Report 6645, 1 January 1960 and H. L. Schick, et al. (loc. cit.). From the estimated melting point, 2400°K., and an estimated 2.5 cal. g. atom⁻¹ deg.⁻¹ for the entropy of melting, the heat of melting was calculated.

Dec. 31, 1950; Mar. 31, 1962; June 30, 1963

 $S_{298.15}^{\circ} = [11.345] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^{\circ} 298.15 = [3.798 \pm 10] \text{ kcal. mole}^{-1}$ $T_m = [2400]^{\circ}\text{K.}$ $\Delta H_m^{\circ} = [18] \text{ kcal. mole}^{-1}$

Heat of Formation.

The $\Delta H_f^{\circ} 298.15$ was calculated from the heat of formation of the crystal and the estimated heat of melting.

Heat Capacity and Entropy.

The heat capacity was assumed constant and equal to the heat capacity of the solid Be₂C at the estimated melting point.

Melting Data.

The National Bureau of Standards Report 6645, January, 1960, states that Be₂C seems to decompose easily only at temperatures above its reported melting point. For this reason they extended their Be₂C table into the liquid region. For detailed melting data see the Be₂C (c) table.CBe₂

Vibrational Frequencies and Degeneracies

 $\frac{\omega_e}{\text{cm}^{-1}}$ $\frac{\omega_e}{\text{cm}^{-1}}$

Bond Distance: C-F = 1.328 Å C-Br = 1.909 Å

Bond Angle: F-C-F = 108.6 ± 1° F-C-Br = 110.33°

Product of the Moments of Inertia: $I_{ABC} = 2.3403 \times 10^{-113}$ g cm⁶ σ = 3

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₄. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2, 3, 4) have determined equilibrium data for CClF₃(g) + BrCl(g) = CBrF₃(g) + Cl₂(g) and for CF₃X(g) + Br₂(g) = CF₃Br(g) + BrX(g) where X = H, Cl, and CF₃. Equilibrium data for CF₃I(g) + BrI(g) = CBrF₃(g) + I₂(g) were obtained by Lord et al. (5). These data link CBrF₃ with C₂F₆, CHF₃, CClF₃ and CF₃I.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Sharbaugh et al. (6), Bowen (7), and Anderson (8) and from microwave data by Sheridan and Gordy (9). The adopted parameters are an average of those reported by (6, 7). Infrared spectra of the gas were observed by several investigators (10, 11, 12) and Raman spectra of the liquid were obtained by Edgell and May (12). The vibrational assignments of (11, 12) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. The value for ν₆ is taken as 300 cm⁻¹ which is between the values of 305 and 297 ± 3 cm⁻¹ derived from Raman spectra and IR (combination and overtone) spectra, respectively.

The thermodynamic functions of this table are essentially the same as those calculated by (11). Uncertainty in the entropy is estimated to vary from 0.12 to 0.5 gibbs/mol over the range from 300 to 1000°K. Uncertainty in ν₆ and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for CClF₃(g) and CF₄(g). The principal moments of inertia are I_A = 14.68 × 10⁻³⁹ and I_B = I_C = 39.93 × 10⁻³⁹ g cm².

Heat of Formation

The heat of formation is calculated from $\Delta H_f^\circ(\text{BrCN}, \text{c}) = 33.58$ kcal/mol (1) and $\Delta H_f^\circ = 10.92 \pm 0.1$ kcal/mol.

This latter is obtained from an analysis of the vapor pressure data of Lord and Woolf (2) and Baxter et al. (3).

The heat of formation of the crystal is calculated from $\Delta H_f^\circ = -56.0$ kcal/mol obtained by Lord and Woolf (2)for the reaction $\text{BrCN(c)} + 2\text{NaOH(56 H}_2\text{O)} = \text{NaCNO(2800 H}_2\text{O)} + \text{NaBr(2800 H}_2\text{O)} + \text{H}_2\text{O(l)}$.The auxiliary data used were $\Delta H_f^\circ(\text{NaOH-56 H}_2\text{O)} = -112.26$ kcal/mol (1, 4), $\Delta H_f^\circ(\text{NaCNO-2800 H}_2\text{O)} = -92.25$ kcal/mol (1, 4) and $\Delta H_f^\circ(\text{NaBr-2800 H}_2\text{O)} = -70.54$ kcal/mol (1, 4). The uncertainty in the final value reflects the uncertainty in $\Delta H_f^\circ(\text{NaCNO-2800 H}_2\text{O})$ which was determined by Lord and Woolf (2) to be -93.6 kcal/mol in excess $\text{NaOH-56 H}_2\text{O}$.

Heat Capacity and Entropy

J. S. Gordon (5) used the constants given above to calculate the adopted table, using the method of Pennington and

Kobe (6) for anharmonicity, vibration rotation interaction, and centrifugal stretching corrections.

The bond lengths and angle were reported by Tyler and Sheridan (7).

Heat of Formation.

The heat of formation, ΔH_f^o 298.15, was calculated and reported by P. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and I. Jaffe, "Selected Values of Chemical Thermodynamic Properties", National Bureau of Standards Circular 500, 1952.

Heat Capacity and Entropy.

The molecular constants, bond distance, and bond angle were determined by electron diffraction by C. Finbak, O. Haase, and B. Ottar, Arch. Math. Naturv B44, No. 13 (1941) and C. Finbak, O. Haase, and O. Olsson, Tidsskr. Kjemi Bergv. 3, 13 (1943). The constants reported by C. Finbak, et al., in 1943 were selected. These constants are listed in, "Tables of Interatomic Distances and Configuration in Molecules and Ions," Special Publication No. 11, The Chemical Society (London), 1958. The principal moments of inertia calculated from these constants were I_A = I_B = I_C = 1.3343 X 10⁻³⁷ g. cm.²

The vibrational frequencies used were assigned by A. O. Meister, S. E. Rosser, and F. P. Cleveland, J. Chem. Phys. 18, 346 (1950). They measured the infrared and Raman spectrum, considered the previous literature, calculated force constants and made most probable value assignments for the frequencies. A more recent paper by B. Morzynska and J. P. Mathieu, Compt. Rend 255, 2820 (1963) made assignments from Raman and Infrared spectra which agreed with all of Meister, et al.'s assignments except ν₂ which they found was 126 cm.⁻¹ rather than 122 cm.⁻¹.

Heat of Formation

The data of Miller and Palmer (1) provide a value of $D_0\text{-Cl} = 80 \pm 5 \text{ kcal/mol}$, which appears to be reasonably substantiated. They studied the chemiluminescence from flames of CHCl_3 and CCl_4 burning in potassium vapor. These flames exhibit C_2 Swan band radiation with major departures from vibrational and rotational equilibrium. The spectra are interpreted as due to the reaction $\text{C} + \text{CCl} + C_2^* + \text{Cl}$ where the carbon atom is either 3D ground state or 1D first excited state. The separation between the ground and first excited state of the carbon atom is matched closely by the difference in preferential population of the excited C_2 levels. The assumption is made that all the exothermicity of the reaction is retained as vibrational excitation of the C_2 , thus the populated levels are measures of the heat of reaction. In this manner we obtain a heat of reaction of $67 \pm 2.5 \text{ kcal}$ for the reaction $\text{C} + \text{CCl} + C_2 + \text{Cl}$ which, using JANAF auxiliary data, gives $\Delta H_f^\circ(\text{CCl}, g) = 124 \pm 2.5 \text{ kcal/mol}$; however, this represents the initial state of the CCl which in the flame is presumed to have about 4 kcal of vibrational energy at roughly 2000°K. Thus, we obtain $\Delta H_{298}^\circ(\text{CCl}, g) = 120 \pm 5 \text{ kcal/mol}$, which is adopted.

The heat of formation can also be estimated from the dissociation energy calculated from the linear Birge-Sponer extrapolation of the ground state vibrational constants. This yields $D_0 = 89 \text{ kcal}$ or $\Delta H_{298}^\circ = 111 \text{ kcal/mol}$. There are several indications that this dissociation energy is probably a maximum value, for example, Hildenbrand (3) has applied an ionic-covalent correction to the linear extrapolation which gives $D_0 = 72 \text{ kcal}$. We would expect this heat of formation to be a minimum value. A real minimum for the dissociation energy can be obtained from the knowledge that the first vibrational level of the $^2\Delta$ state is occupied and so the dissociation energy of this state must be greater than 850 cm^{-1} . This yields a minimum dissociation energy of the ground state of 76 kcal, assuming the dissociation products are $C(^3P)$ and $Cl(^2P)$, and $\Delta H_{298}^\circ(\text{CCl}, g) = 124 \text{ kcal/mol}$ which is the maximum value of the heat of formation.

Heat Capacity and Entropy

The rotational and electronic constants are those of Verma and Mulliken (2). The vibrational constants are those derived by Oucharenko et al. (3) from the data of Gordon and King (4). The anharmonicity constants listed by Verma and Mulliken are not used, since these are based only on the 0,0 and 0,1 transitions. The u_2 level is estimated by analogy with $\text{CF}(g)$. The value for a_e was obtained from the other constants assuming a Morse potential function.

Bond Distance: C-F = 1.328 Å C-Cl = 1.751 Å

Bond Angle: F-C-F = 108.6 ± 0.5° F-C-Cl = 110.33°

Product of the Moments of Inertia: $I_A I_B I_C = 9.4425 \times 10^{-114}$ g⁶ cm⁶

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₄. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2) have determined equilibrium data for CClF₃(g) + BrF₃(g) = CBrF₃(g) + ClF₃(g) where X = Cl and Br. Lord et al. (3) studied the analogous equilibria CF₃I(g) + ClI(g) = CClF₃(g) + I₂(g). These data link CClF₃ with CBrF₃ and CF₃I.

Other data which were omitted from the adjustment include those of Baibuz (4, 5), Mears (6), Kolesov (7), Kiribridge (8), and von Wartenberg (9). Baibuz (4, 5) derived $\Delta H_f^\circ = -166.2 \pm 2.2$ kcal/mol by applying the method of estimate in a spherical bomb to mixtures of H₂, O₂ and CClF₃. By comparison with similar data for CF₄ and CCl₄, we estimate the bias in Baibuz' value to be about +2 kcal/mol. Mears (6) gave a preliminary report of values of ΔH_f° for reactions involving HF, HCl and CCl₃F_n (n = 1, 2, 3, 4). We derive $\Delta H_f^\circ = -177$ and -173 kcal/mol from two different combinations of reactions; however, no detailed account of the data has been published. The other authors (7, 8, 9) measured ΔH_f° for reaction of CClF₃ with an alkali metal (Na or K) to form amorphous carbon and mixtures of the fluoride and chloride. Discrepancies of many kcal/mol exist in these studies, presumably due to inadequate characterization of the thermochemical reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (10) and Bartell (11). Results from Bartell are adopted. These parameters are consistent with the microwave data of Coles (12). Principal moments of inertia are $I_A = 14.58 \times 10^{-39}$ and $I_B = I_C = 23.37 \times 10^{-39}$ g cm². Vibrational assignments are based on the work of Claassen (13) and the gas-phase Raman spectra observed by Holzer and Moser (14).

The largest uncertainty in Cp and S° probably results from the neglect of anharmonicity. Barbo (15) and Albright (16) have given estimates for the anharmonic contributions. These vary from 0.1 to 0.3 gibbs/mol in both Cp° and S° over the range from 300 to 1000°K, respectively. Somewhat larger contributions are possible based on the anharmonic functions calculated by McBride (17) for CF₄(g). We estimate the overall uncertainty in the entropy of this JANAF table to be 0.1 eu at 300°K and 0.4 eu at 1000°K. Cp° is consistent with Cv° measured at 300°K by the wire-ribbon method (18).

C-N = 1.162 Å

Bond Angle: Cl-C-N = 180°

Rotational constants: B₀ = 0.19817 cm⁻¹D₀ = 5.503 X 10⁻⁸ cm⁻¹Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm⁻¹): $\alpha_1 = 8.25 \times 10^{-4}$ $\alpha_2 = -5.46 \times 10^{-4}$ $\alpha_3 = 1.06 \times 10^{-3}$ $x_{11} = [-4]$ $x_{22} = -0.85$ $x_{33} = [-7]$ $x_{12} = [-6.8]$ $x_{23} = -7.236$ $x_{13} = -2.8$ $\epsilon_{22} = 0.95$ $\epsilon_{23} = -2.8$

Heat of Formation:

The heat of formation was taken from D. D. Wagman, W. H. Evans, I. Helow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties" NBS Technical Note 270-1, Washington, 1965.

Heat Capacity and Entropy:

J. S. Gordon, AstroSystems International Inc., Fairfield, N. J., (private communication, Feb., 1966), has used the constants listed above to calculate C from 298.15 to 6000°K using the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants B₀ and D₀ were taken from C. A. Burrus and W. Gordy, Phys. Rev. 101, 599 (1956); ω_1 , α_1 , α_2 , α_3 , x_{11} , x_{22} , x_{13} and ϵ_{22} were obtained from W. J. Lafferty, D. R. Lide and R. A. Toth, J. Chem. Phys. 43, 2083 (1965); α_2 has been taken from C. H. Townes, A. N. Holden and P. R. Merritt, Phys. Rev. 74, 1113 (1948) and x_{11} , x_{33} and x_{12} were estimated by Gordon, loc. cit. The bond distances and bond angle were taken from Lafferty et al., loc. cit.

CARBONYL MONOCHLORIDE (COCl₂)

(IDEAL GAS)

MOL. WT. = 63.46355

Point Group C_{2v}

S_{298.15} = [64] cal. deg.⁻¹ mole⁻¹

Ground State Quantum Weight = 2

Vibrational Frequencies and Degeneracies

(ω, cm.⁻¹)

570 (1)

281 (1)

1880 (1)

C-Cl = [1.75] Å

C-Cl-C = [120] °

Product of the Moments of Inertia: I_AI_BI_C = [1.27603 x 10⁻¹¹⁵] g.³ cm.⁶

Heat of Formation.

The enthalpy change (ΔH_f⁰) for the reaction COCl₂(g) = CO(g) + 2Cl(g) is calculated to be 82 kcal. mole⁻¹, which is the sum of two bond energies, i.e. D(Cl-COCl) + D(Cl-CO). By comparison with the values, D(H₃C-COCH₃)/D(H₃C-CO) = 72/18 = 4.0 for CH₃COC(=O)Cl/D(Cl-CO) = 4.3 for CH₃COCl(g), the ratio of D(Cl-COCl)/D(Cl-CO) is estimated to be 4.0 for COCl₂(g). Hence the enthalpy change for the reaction COCl₂(g) = COCl(g) + Cl(g) is calculated as 82 x (4/5) = 65.6 kcal. mole⁻¹. Using the ΔH_f⁰ value obtained, the heat of formation for COCl(g) is derived to be -15 ± 10 kcal. mole⁻¹.

Heat Capacity and Entropy.

The vibrational frequencies were reported by M. E. Jécox and D. E. Milligan, J. Chem. Phys. 43, 866 (1965).

The bond distances and angle were estimated by Jécox and Milligan, loc. cit. Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The three principal moments of inertia are: I_A = 1.29987 x 10⁻³⁶, I_B = 7.1580 x 10⁻⁴⁰, and I_C = 1.37145 x 10⁻³⁸ g. cm.²

CARBON DICHLORIDE (CCl₂)

(IDEAL GAS)

GFW = 82.91715

Heat of Formation

Shapiro and Jacox (1) have measured mass-spectrometrically the appearance potentials 12.2 and 14.7 eV for the processes CHCl₃(g) + e⁻ → CCl₂(g) + HCl(g) + 2e⁻ and C₂Cl₄(g) + e⁻ → CCl₂(g) + CCl₂(g) + 2e⁻, respectively. The difference in these two processes gives ΔHf° = 2.5 eV (57.65 kcal/mol) for the reaction C₂Cl₄(g) + HCl(g) → CCl₂(g) + CHCl₃(g) which leads to ΔHf°₂₉₈ (CCl₂, g) = 57.32 kcal/mol, using JANAF ΔHf°₂₉₈ = -2.97, -22.063 and -24.7 kcal/mol for C₂Cl₄(g), HCl(g) and CHCl₃(g), respectively. Since the authors claimed that the experimental error was probably 5 kcal/mol, the value, 57 ± 5 kcal/mol, is adopted for the heat of formation.

Heat Capacity and Entropy

Milligan and Jacox (2) have found two stretching fundamentals (721 and 748 cm⁻¹) for the CCl₂ radical in the infrared and ultraviolet spectra by matrix-isolation, and proposed a bent molecular structure (the valence angle = 100 ± 10°) with a ground singlet state which was based on the analogy with the electronic absorption spectrum of CF₂. L. Andrews (3) has confirmed all these observations in his infrared spectrometric studies of dichlorocarbene in solid argon, and made vibrational assignment to the fundamentals and also eliminated the possibility of a linear molecular structure for CCl₂. The bending frequency (350 cm⁻¹) is estimated by the valence force method (4), using the same ratio of bending over stretching force constants from CF₂(g) (5). The bond distance is estimated to be the same as that of CCl₄(g) measured by Bartell et al (6). The three principal moments of inertia are I_A = 2.1028 × 10⁻³⁹, I_B = 21.4013 × 10⁻³⁹, and I_C = 23.5840 × 10⁻³⁹ g cm².

The triplet low lying electronic level of 4000 cm⁻¹ is estimated by analogy with that of CF₂(g). The other level of 17,500 cm⁻¹ is also estimated based on a weak band appearing between 4400 and 5600 Å in the spectra of CCl₂ observed by Milligan and Jacox (2).

Bond Distance: C-Cl = 1.77 ± 0.02 Å C-F = 1.33 ± 0.02 Å			
Bond Angle: F-C-F = 109.5 ± 3° Cl-C-Cl = 108.5 ± 2°			
Product of the Moments of Inertia: I _A I _B I _C = 2.5841 × 10 ⁻¹¹³ g ³ cm ⁻⁶			
Heat of Formation			

Mears and Stahl (1) investigated several heats of reaction involving CF₄, CF₃Cl, CF₂Cl₂, CFCI₃, CCl₄, HF and HCl. Using JANAF values for all compounds except CF₂Cl₂ and CFCI₃ we obtain the following observations:

- ΔHf^o (CCl₃F, g) = -70.12 ± 1.1 kcal/mol
- ΔHf^o (CCl₂F₂, g) = -116.53 ± 1.5 kcal/mol
- ΔHf^o (CCl₃F, g) - ΔHf^o (CCl₂F₂, g) = -49.39 ± 1.0 kcal/mol
- ΔHf^o (CCl₂F₂, g) - 2ΔHf^o (CCl₃F, g) = 20.34 ± 1.0 kcal/mol
- ΔHf^o (CCl₃F, g) - 2ΔHf^o (CCl₂F₂, g) = 165.47 ± 1.0 kcal/mol

The sum of the squares of the deviations is smallest when ΔHf^o (CCl₂F₂, g) = -117.5 kcal/mol and ΔHf^o (CCl₃F, g) = -69 kcal/mol, and all the values are within their uncertainty ranges.

Petersen and Pitzer (2) obtained an approximate equilibrium constant for the reaction 2CCl₃F(g) + CCl₄(g) = 3CCl₂F₂(g) of log K₄₀₀ = -3.0. This on 3rd law reduction gives ΔH^o = 7.64 kcal and with ΔHf^o (CCl₂F₂, g) = -117.9 kcal/mol. ΔHf^o (CCl₄, g) = -22.94 kcal/mol this yields ΔHf^o (CCl₃F, g) = 20.34 ± 1.0 kcal/mol.

Kirkbride and Davidson (3) investigated the reaction of potassium with the chlorofluoromethanes and obtained

ΔHf^o (CCl₂F₂, g) = -115.1 ± 2 kcal/mol and ΔHf^o (CCl₃F, g) = -72.9 ± 4 kcal/mol after correction with JANAF auxiliary data. Wartenberg and Schiefer (4) investigated the same reaction and we obtain, after correction with JANAF auxiliary data, ΔHf^o (CCl₂F₂, g) = -112.7 kcal/mol and ΔHf^o (CCl₃F, g) = -63.1 kcal/mol. Kolesov et al. (4) have reported analogous data for the reaction with sodium which, after correction with JANAF auxiliary data, yields

ΔHf^o (CCl₂F₂, g) = -114.4 ± 3.5 kcal/mol.

We adopt the values calculated above from Mears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF₄ to CCl₄. With the adopted heats of formation, the successive replacement of F by Cl changes the atomization heats by 43.8, 41.6, 38.5 and 36.0 kcal.

Heat Capacity and Entropy

Classen (5) chose the frequencies given above from his own gas-phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6). Masi (7) has measured the gas phase heat capacities at 243, 273, 318 and 363°K, within this range our adopted heat capacities are from .3 to .7% high. The entropies agree to within 0.05% and further adjustment to obtain better fits was not considered necessary. The molecular structure was determined from the microwave measurements of Long et al. (7). The individual moments of inertia were: I_A = 31.928 × 10⁻³⁹ g cm², I_B = 21.216 × 10⁻³⁹ g cm², and I_C = 38.148 × 10⁻³⁹ g cm².

Moments of inertia: I_A = 1.0690 X 10⁻³⁸ g. cm.² I_B = 2.4489 X 10⁻³⁸ I_C = 3.5291 X 10⁻³⁸ σ = 2

Heat of Formation

J. Thomsen, Thermochemische Untersuchungen, Barth, Leipzig, 1882, Vol. 2, p. 361, reports the heat of alkali line hydrolysis of COCl₂, from which ΔH°_f 298.15 is calculated to be -54.4 ± 0.3 kcal. mole⁻¹. From the heat of combustion of COCl₂ in O₂ and H₂, reported by Thomsen, op. cit., p. 363, ΔH°_f 298.15 is calculated to be -51.73 ± 0.43 kcal. mole⁻¹. M. Bodenstein and H. Plaut, Z. Phys. Chem. 110, 399 (1924), J. A. Christiansen, ibid. 103, 99 (1923), and M. Bodenstein and O. Duanat, ibid. 61, 437 (1908), report 10 values of K_p from 647° to 876°K for the reaction CO + Cl₂ ⇌ COCl₂. These yield -25.91 ± 0.04 kcal. for ΔH°_f 298.15, whence ΔH°_f 298.15 for COCl₂ is -52.33 ± 0.62 kcal. mole⁻¹. The average of the 5 foregoing values of ΔH°_f 298.15, weighted for the uncertainties, is adopted here. Values calculated from the degrees of dissociation of COCl₂ from 374° to 778°K, reported by R. H. Atkinson, C. T. Heycock, and W. J. Pope, J. Chem. Soc. 117, 1410 (1920), range from -47.06 to -53.11 kcal. mole⁻¹ and are ignored.

Heat Capacity and Entropy

The vibrational frequencies were assigned by E. Catalano and K. S. Pitzer, J. Am. Chem. Soc. 80, 1054 (1958), on the basis of their own infra-red spectra and other data. The molecular dimensions listed above were deduced from microwave spectra by G. W. Robinson, J. Chem. Phys. 21, 1741 (1953), and are confirmed by electron-diffraction values compiled by P. W. Allen and L. E. Sutton, Acta Cryst. 2, 46 (1950). The moments of inertia are weighted for the isotopes and were calculated from Robinson's dimensions by M. F. Olafson and J. B. Ott, J. Am. Chem. Soc. 82, 2689 (1960). Olafson and Ott, loc. cit., determined S°_{298.15} experimentally to be 67.81 cal. deg⁻¹ mole⁻¹, with which the value calculated here agrees.

Heat of Formation

Benson (1) has reanalysed the kinetic data of Sullivan and Davidson (2) for the reaction $\text{Br}_2(\text{g}) + \text{CHCl}_3(\text{g}) = \text{HBr}(\text{g}) + \text{CH}_2\text{Cl}_2(\text{g})$ and has obtained from it the heat of the initial step, $\text{Br}(\text{g}) + \text{CHCl}_3(\text{g}) = \text{CCl}_3(\text{g}) + \text{HBr}(\text{g})$, as $8.2 \pm 1 \text{ kcal/mol}$. Substituting this value and $\Delta H_f^\circ(298) (\text{Br}) = 26.74 \text{ kcal/mol}$, $\Delta H_f^\circ(298) (\text{CHCl}_3) = -24.66 \text{ kcal/mol}$ and $\Delta H_f^\circ(298) (\text{HBr}) = -8.71 \text{ kcal/mol}$, we obtain $\Delta H_f^\circ(298) (\text{CCl}_3, \text{g}) = 19 \pm 2 \text{ kcal/mol}$, which is adopted here.

Heat Capacity and Entropy

Walsh (3) has predicted that CCl_3 is non-planar on the basis of his orbital correlation diagram. Andrews (4) indicates that his matrix infrared observations of the symmetric and antisymmetric stretches are consistent with a non-planar C_3v structure and a near tetrahedral angle. The antisymmetric stretch has been confirmed by Current and Burdett (5). They rationalize the absence of the symmetric stretch and claim support of the C_3v structure. Rogers et al. (6) have made a thorough search for the symmetric stretch and did not find it in the region where it was reported by Andrews (4). Thus, they conclude that since only the antisymmetric stretch has been confirmed, the possibility of a planar D_3h molecule cannot be excluded. Hagat et al. (7) have observed the NMR spectrum of trapped CCl_3 and find it consistent with a planar molecule. The absence of the symmetric stretch strongly implies a planar configuration, and we adopt such a configuration until more definitive proof of the non-planarity can be obtained. The remaining vibrational frequencies are estimated by comparison with those of BCl_3 . The bond length was estimated as 1.74 Å by Andrews (4) from a correlation with related molecules. The individual moments of inertia are $I_A = I_B = 2.6734 \times 10^{-38} \text{ g cm}^2$ and $I_C = 5.3468 \times 10^{-38} \text{ g cm}^2$.

Dec. 31, 1960; June 30, 1961; Mar. 31, 1964; June 30, 1970

Point Group C_{3v}

$S_{298.15}^{\circ} = 74.00 \pm 0.05$ gibbs/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω_1, cm^{-1} ω_2, cm^{-1}

349.5 (1) 241 (2)

535.3 (1) 398 (2)

1085 (1) 847 (2)

Bond Distance: C-Cl = 1.76 Å C-F = 1.33 Å

Bond Angle: Cl-C-Cl = $109^{\circ}40'$ F-C-Cl = $109^{\circ}28'$

Product of the Moments of Inertia: $I_{AB}I_C = 5.73499 \times 10^{-113} \text{ g cm}^{-6}$ $\sigma = 3$

Heat of Formation

Wears and Stahl (1) investigated several heats of reaction involving CF_4 , CF_3Cl , CF_2Cl_2 , CFCl_3 , CCl_4 , HF and HCl.

Using JANAF values for all compounds except CF_2Cl_2 and CFCl_3 , we obtain the following observations:

1. $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -70.12 \pm 1.1$ kcal/mol
2. $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) = -116.53 \pm 1.5$ kcal/mol
3. $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) - \Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -49.39 \pm 1.0$ kcal/mol
4. $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) - 2\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = 20.34 \pm 1.0$ kcal/mol
5. $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) - 2\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) = 165.47 \pm 1.0$ kcal/mol

The sum of the squares of the deviations is smallest when $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) = -117.5$ kcal/mol and $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -69$ kcal/mol, and all the values are within their uncertainty ranges.

Petersen and Pitzer (2) obtained an approximate equilibrium constant for the reaction $\text{CClF}_3(g) + 2\text{CCl}_4(g) = 3\text{CCl}_3\text{F}(g)$ of $\log K_{1400} = -4.5$. This on 3rd law reduction gives $\Delta H_{298}^{\circ} = 10.56$ kcal and with $\Delta H_{298}^{\circ}(\text{CClF}_3, g) = -169.2$ kcal/mol and $\Delta H_{298}^{\circ}(\text{CCl}_4, g) = -22.94$ kcal/mol this yields $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -68.2$ kcal/mol.

Kirkbridge and Davidson (2) investigated the reaction of potassium with the chlorofluoromethanes and obtained $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) = -115.1 \pm 2$ kcal/mol and $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -72.9 \pm 4$ kcal/mol after correction with JANAF auxiliary data. Wartenberg and Schiefer (3) investigated the same reaction and we obtain, after correction with JANAF

auxiliary data, $\Delta H_{298}^{\circ}(\text{CCl}_2\text{F}_2, g) = -112.7$ kcal/mol and $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -63.1$ kcal/mol. Baibuz (4) has reported $\Delta H_{298}^{\circ}(\text{CCl}_3\text{F}, g) = -66.4 \pm 2.1$ from heat of explosion measurements. A correlation of his other results would indicate that this value is not negative enough, possibly by as much as 3 kcal.

We adopt the values calculated above from Wears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF_4 to CCl_4 . With the adopted heats of formation, the successive replacement of F by Cl changes the atomization heats by 43.8, 41.6, 38.5 and 36.0 kcal.

Heat Capacity and Entropy

Claassen (5) chose the frequencies given above from his own gas phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6), and the matrix studies of King (7). The molecular structure was determined from the microwave measurements of Long et al. (8). The individual moments of inertia were: $I_A = I_C = 34.301 \times 10^{-39} \text{ g cm}^2$ and $I_B = 40.744 \times 10^{-39} \text{ g cm}^2$.

Heat of Formation
 Hu and Sinks (1) have measured the heat of combustion of CCl₄(l) in the rotating platinum bomb calorimeter, using As₂O₃ solution as the reducing agent. They reported ΔH_{c,298}⁰ = -86.02 kcal/mol for CCl₄(l) + 2H₂O(l) + CO₂(g) + 4HCl(600H₂O, aq) which leads to ΔH_{f,298}⁰(CCl₄, l) = -30.69 kcal/mol, using ΔH_{f,298}⁰ = -94.051, -39.823 and -88.315 kcal/mol for CO₂(g), HCl(600H₂O, aq) and H₂O(l), respectively (2). The standard deviation of five combustion runs was 10.074 kcal/mol. Employing the heat of vaporization of CCl₄(l) at 298°K as 7.75 kcal/mol (3), we obtain ΔH_{f,298}⁰(CCl₄, g) = -22.94 kcal/mol which is adopted in the tabulation.

L. Smith et al. (5), based on the combustion data of E. Efring (2), re-evaluated the heat of combustion of carbon tetrachloride at 18.7°C as ΔH_{c,18.7}⁰ = -567.5 cal/g for CCl₄(l) + 2H₂O(l) + CO₂(g) + 4HCl(600H₂O). This value needs to be further corrected for a change in the heat of oxidation of As₂O₃(s) and calculated to 25°C to give ΔH_{c,298}⁰ = -88.105 kcal/mol, ΔH_{c,298}⁰ = -87.513 kcal/mol, ΔH_{f,298}⁰(CCl₄, l) = -29.20 kcal/mol and ΔH_{f,298}⁰(CCl₄, g) = -21.45 kcal/mol.

C. A. Neugebauer (7) has measured the heat of reaction of CCl₄ with Hg in presence of hydrogen in the stationary bomb calorimeter and then derived the heat of formation, ΔH_{f,298}⁰(CCl₄, l) = -32.3 ± 2 kcal/mol which yields ΔH_{f,298}⁰(CCl₄, g) = -24.55 ± 2 kcal/mol. V. F. Baibuz (8), using an explosion technique, obtained ΔH_{f,298}⁰(CCl₄, g) = -24.6 ± 1.9 kcal/mol. Bodenstern and Gunther (9) have measured calorimetrically ΔH_{f,293}⁰ = -62.57 ± 0.35 kcal/mole for CCl₄(g) + 2H₂(g) + C(c) + 4HCl(g). They calibrated their calorimeter by means of the reaction H₂(g) + Cl₂(g) + 2HCl(g) for which they took ΔH_{f,293}⁰ = -44 kcal/mol. Their data have been re-evaluated to give ΔH_{f,298}⁰(CCl₄, g) = -25.68 kcal/mol, but no correction is applied for the heat of formation of carbon which was not the reference state "graphite" formed in the reaction. Domalski and Armstrong (10) reviewed several cases of active carbon formed in similar reactions and quoted a heat of formation of carbon from 1.9 to 3.95 kcal/mol. If this correction is applied to the data of Bodenstern, their heat of formation of CCl₄(g) should be 2 to 4 kcal/mol less negative than -25.68 kcal/mol.

Heat Capacity and Entropy

Bartell, Brockway and Schwendeman (11) have measured the bond distance as 1.760 ± 0.004 Å by the electron diffraction measurement. The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (12) in which they are essentially the same as those frequencies determined from Raman and infrared spectra by Glasen (13). The three principal moments of inertia are I_A = I_B = I_C = 48.627 × 10⁻³⁹ g cm².

Heat of Formation

M. Farber et al. (1) have studied the weight change of graphite in CF_4 at high temperatures. Our reanalysis of their data uses the equilibrium constants for CF_4 , CF_3 and CF_2 from the JANAF Tables (2); the only other C-F species considered is assumed to be CF. This treatment yields negative values for the CF pressure except at the highest temperature, where 3rd law analysis of the equilibrium constant yields $\Delta H_{298}^\circ(CF, g) = 59.4 \text{ kcal/mol}$. Farber et al. also investigated mass-spectrometrically the vapor species present at equilibrium and followed the intensities of CF^+ and F^+ . From a second law treatment of the intensities they report $\Delta H_{2300}^\circ(CF, g) = 62.0 \text{ kcal/mol}$, or $\Delta H_{298}^\circ(CF, g) = 64 \text{ kcal/mol}$.

Porter et al. (3) have investigated the A-X band system under high dispersion. From an analytical extrapolation of the 10 observed levels they reported a dissociation energy of $126.9 \pm 2.9 \text{ kcal/mol}$, which yields $\Delta H_{298}^\circ(CF, g) = 61.9 \pm 2.9 \text{ kcal/mol}$. The predissociation limit of $CF(g)$ has been reported by Thrush and Zwolnick (4) as $\leq 132 \text{ kcal/mol}$; Kuzakov and Tatiievsky (5) determined the same quantity as $\leq 133 \text{ kcal/mol}$. These results yield $\Delta H_{298}^\circ(CF, g) \geq 55 \text{ kcal/mol}$. Thrush and Zwolnick (4) also report a predissociation limit for the reaction $CF_2 \rightarrow CF + F$ which is $\leq 140 \text{ kcal/mol}$. This value has now been shown to be erroneous (see the CF_2 table for details).

Modica (6) has studied the equilibrium $CF_2 \rightarrow CF + F$ in a shock tube in the range 2880° to $3400^\circ K$. Since functions for CF_2 , CF and F are well established, the data were analyzed using 2nd and 3rd law treatments. The 2nd law analysis gives $\Delta H_{298}^\circ = 107.2 \pm 7.6 \text{ kcal/mol}$, in agreement with the value reported by Modica. The 3rd law analysis yields $\Delta H_{298}^\circ = 134.9 \pm 7.2 \text{ kcal/mol}$ and a drift of $9.7 \pm 2.5 \text{ eu}$. The excessive drift indicates that the reported equilibrium constants do not represent the stated reaction.

Andrews and Barrow (7) report a dissociation energy of 114 kcal from an extrapolation of four B state levels. This extrapolation is considered unreliable by Porter et al. (3) since this state is formed from an avoided crossing and is likely to be perturbed.

The adopted value of $\Delta H_{298}^\circ(CF, g)$ is $61 \pm 2 \text{ kcal/mol}$, which is within the uncertainties and ranges of the acceptable investigations.

Heat Capacity and Entropy

The vibrational and rotational constants are from Porter et al. (3); the higher electronic levels are those reported by Andrews and Barrow (7), except that the B state is now considered to be $^2\Sigma$. The estimated level at 25000 cm^{-1} is proposed in order to explain the low bond dissociation energy of C_2F_2 by analogy with the reasoning used by Simons (8) for C_2F_4 . This level would be a $^2\Sigma$ level and could correlate with the ground state atoms.

Heat of Formation

Davis and Okabe (1) have determined the dissociation energy of FCN to F(g) and CN(g) by measuring the threshold energies of incident photon radiation to produce F^2CN which is monitored by its fluorescence. The dissociation energy determined by this technique is ≤ 111 kcal/mol with an uncertainty of about 1 kcal in the determination of the limit.

Dibeler and Liston (2) have reported a dissociation energy of ≤ 115.6 kcal/mol from the threshold of the CN^+ ion as determined by photoionization.

We adopt a median value of 113.1 ± 2.5 kcal/mol which leads to $\Delta H_f^\circ(\text{FCN}, g) = 8.6 \pm 4$ kcal/mol with auxiliary JANAF values for F(g) and CN(g).

Heat Capacity and Entropy

The molecular structure and bond lengths and angle were determined using microwave spectroscopy by Tyler and Sheridan (3). The vibrational frequencies were reported by Aynsley et. al. (4) from the infra-red spectrum, except for the bending frequency which is estimated from the values for ClCN, BrCN and ICN, by comparison of bending force constants. The reasonable limits for this value as calculated from generous limits on the bending force constant are 405-450 cm^{-1} .

C-O = [1.18] Å

C-O = [1.34] Å

P-C-O = [135] °

Product of the Moments of Inertia: I_AI_BI_C = [2.1986 x 10⁻¹¹⁶] g.³ cm.⁶

Bond Distance: C-P = [1.34] Å

Bond Angle: P-C-O = [135] °

Heat of Formation.

The enthalpy change (ΔH_f°) for the reaction COF₂(g) = CO(g) + 2F(g) was calculated as 180.5 kcal. mole⁻¹. By analogy with D(Cl-COCl)/D(Cl-CO), the value of D(F-COF)/D(F-CO) was taken to be 4. Based on ΔH_f° = 180.5 x (4/5) = 128.4 kcal. mole⁻¹ for the reaction COF₂(g) = CO(g) + F(g), the heat of formation for COF(g) was derived as -41 ± 15 kcal. mole⁻¹.

Heat Capacity and Entropy.

The vibrational frequencies were reported by D. E. Milligen, M. E. Jacob, A. M. Bass, J. J. Comeford and D. E. Mann, J. Chem. Phys. 42, 3187 (1965). The bond distances and angle were estimated by comparison with those for HFCO (g). Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The three principal moments of inertia are: I_A = 7.8757 x 10⁻³⁹, I_B = 3.3980 x 10⁻⁴⁰, and I_C = 8.2155 x 10⁻³⁹ g. cm.²

Point Group C_{2v}S_{298,15} = 57.53 ± 0.01 gibbs/molΔH_{f,0}⁰ = -43.6 ± 1.5 kcal/molΔH_{f,298,15} = -43.5 ± 1.5 kcal/molCarbon Difluoride (CF₂)

1222 (1)	665 (1)	1110 (1)

Bond Distance: C-F = 1.300 Å Bond Angle: F-C-F = 104.9°

Product of the Moments of Inertia: I_AI_BI_C = 4.87886 × 10⁻¹¹⁶ g³ cm⁶

Heat of Formation

Thrush and Zwoelenik (1) reported a predissociation limit for CF₂ + CF + F; however, Harsigny et al. (2) have since observed in emission the assumed predissociated level, and others above it, which invalidates the reported limit.

Walter et al. (3) have obtained the photoionization threshold at 0°K for onset of the reaction C₂F₄ + e⁻ → CF₂⁺ + CF₂ + 2e⁻, as 14.63 ± 0.04 eV (337.37 Kcal). The ionization potential of CF₂ has been reported as 11.7 eV (4), 11.8 ± 0.3 eV (5) and 11.86 ± 0.1 eV (6). Since these values were obtained by electron impact methods, there may be excess energy involved. Thus, adopting the lowest value as 11.7 ± 0.2 eV, we obtain ΔH_{f,298}⁰(CF₂, g) = -44.4 ± 2.5 Kcal/mol (2). All previous electron impact methods are considered superseded by this photoionization result.

Modica and LaGraff (8) determined equilibrium constants for the reaction (A) C₂F₄ + 2CF₂ by use of a shock tube to achieve high temperatures and ultra violet absorption to detect the CF₂ concentration. Carlson (9) has studied the same reaction using a similar technique, and also Zmbov et al. (5) have investigated this equilibrium in a mass spectrometer. A 2nd and 3rd law analysis of all three sets of data is given below along with our recalculated equilibrium data of Farber et al. (10) for the reaction (B) C + 2F + CF₂ from weight loss experiments in the system C + CF₄.

Kinetic methods were used by Edwards and Small (11) to study the equilibrium (C) CHF₃Cl(g) ⇌ CF₂(g) + HCl(g). They analysed their data by assuming that the only other equilibrium occurring was 2CF₂(g) ⇌ C₂F₄(g), and fit their kinetic data by 6.21 ± 3.0 Kcal, thus ΔE = 49.6 ± 3.0 and ΔH₃₀₀ = 51.4 ± 3 Kcal, which yields ΔH_{f,298}⁰(CF₂) = -42 ± 4 Kcal/mol (2). They also obtained the activation energy of reaction (A) as 70.36 ± 1.3 Kcal. Dalby (12) has reported the activation energy of the reverse of (A) as 1.2 ± 0.2 Kcal, thus, ΔE_a = 69.2 ± 1.3 and ΔH₃₀₀ = 71.0 ± 1.3 Kcal, which yields ΔH_{f,298}⁰(CF₂) = -42.6 ± 1.0 Kcal/mol (2). Gozzo and Patrick (13) also investigated the kinetics of reaction C and obtained activation energies of 51.4 ± 2.5 and 14.4 ± 5 Kcal, the latter value being corrected for the activation energy of CF₂ recombination (12). Thus, we obtain ΔE_a = 37 ± 7 and ΔH₁₀₀₀ = 39 ± 7 Kcal, which yields ΔH_{f,298}⁰(CF₂) = -54 ± 9 Kcal/mol (2).

Modica and LaGraff (14) investigated the kinetics of CHF₃ decomposition by a mass spectrometer coupled to a shock tube. They investigated the pressure dependence of the rate and concluded that at the high pressure limit P₀ = 58.4 ± 2.2 Kcal. Taking this value as ΔH_f⁰ for the reaction (D) CHF₃(g) + CF₂(g) + HF(g) ⇌ HF(g) + CF₂(g) we obtain ΔH_{f,298}⁰(CF₂) = -41.3 ± 2.5 Kcal/mol (2). However, any activation energy of the reverse reaction (D) will make this value more negative. Since values of the reverse activation energy of analogous reaction (C) range from 6.2 to 14.4 Kcal, it appears likely that reverse reaction (D) will have a significant activation energy; thus, ΔH_{f,298}⁰(CF₂) < -41.3 ± 2.5 Kcal. Tschukow-Roux (15) has investigated the same reaction in a shock tube, but was unable to obtain sufficient variation of rate with pressure to calculate the high pressure limit.

**ΔH_{f,298}⁰(CF₂, g)

Reference	Points	Range, °K	2nd Law	3rd Law	Drift
9. A	35*	1165-1940	0.5727	0.5727	-0.320
10. B	11	1127-1244	77.3 ± 2.1	75.13 ± 0.72	-0.350
10. B	11	2023-2474	-73.8 ± 1.4	-80.04 ± 1.0	-41.15 ± 1.5
					-42.3 ± 1.0

*Points omitted due to failure of a statistical test **Calculated from the 3rd law heat of reaction.

A median value of ΔH_{f,298}⁰(CF₂, g) covering the area of maximum probability is adopted as -43.5 ± 1.5 Kcal/mol.

Heat Capacity and Entropy

The structure of CF₂ has been reported by Powell and Lide (16) from microwave measurements and has been confirmed by Mathews (17) from the fine structure of the 2500Å absorption band. Mathews also reported ω₂ and Herr and Pimentel (18) reported ω₃, both from gas phase studies. Milligan et al. (19) have observed all three vibrations in matrix-isolated CF₂ as 1222, 665 and 1102 cm⁻¹. The electronic levels are from Mathews (17) with the triplet level estimated by Simons (20) to explain the low C-C bond energy of 70 Kcal in C₂F₄. The individual moments of inertia are I_A = 0.9512 × 10⁻³⁹ g cm², I_B = 6.7020 × 10⁻³⁹ g cm², and I_C = 7.6532 × 10⁻³⁹ g cm².

Heat of Formation

Ruff and Li (1) measured equilibrium constants for the reaction

in the temperature range 573-1273°K. These equilibrium data were recently analyzed by Stull, Westrum, and Sinke (2).

Their third law analysis of the data clearly indicates that the three low temperature points are in error and should not be used in calculating ΔH₂₉₈°. They reported, ΔH₂₉₈° = -12 ± 3 kcal/mol, based upon an average of the five high temperature points. Combining this result with the heat of formation of carbon dioxide and carbon tetrafluoride (3), we derive,

$$\Delta H_f^\circ(\text{COF}_2, \text{g}) = -152.5 \pm 3.3 \text{ kcal/mol.}$$

Wartenberg and Ritaris (4) measured the heat of hydrolysis of CF₂O. They reported, ΔH_r = -26.7 ± 0.2 kcal/mol, for the reactionCombining this result with heat of formation data for carbon dioxide and HF(ΔH_f°(HF·300 H₂O) = -76.84 kcal/mol (5)), we derive,

$$\Delta H_f^\circ(\text{CF}_2\text{O}, \text{g}) = -152.7 \pm 0.4 \text{ kcal/mol.}$$

Armstrong, Coyle, and Krieger (6) measured the heats of combustion of CH₄ in O₂-F₂ mixtures and found ΔH₂₉₈°(CF₂O, g) = -154.8 kcal/mol. The value calculated from Wartenberg's data is adopted here.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Hopper et al. (7) and are in good agreement with the results of Lovall et al. (8) and Nielsen et al. (9). The molecular constants are from the microwave studies of Laurie et al. (10) and are in reasonable agreement with the electron-diffraction work of Brown and Livingston (11). Individual moments of inertia calculated from the rotational constants of Laurie et al. (10) are I_A = 7.105 × 10⁻³⁹ g cm², I_B = 7.144 × 10⁻³⁹ g cm², and I_C = 14.27 × 10⁻³⁹ g cm².

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃). Details of the input data and the adjustment are given in (1). Kinetic data provide the most consistent paths to ΔH_f⁰ of CF₃(g). Forward and reverse activation energies for the reactions CHF₃(g) + X(g) → CF₃(g) + HX(g) have been reported for X = Cl by Coomber (2), for X = Br by Amphlett (3), and for X = I by Goy (4). Increases of about 0.3 kcal/mol in the reverse activation energies for X = Cl and Br were proposed by Arthur (5) on the basis of additional data. Combining these values and reducing to 298.15°K, we get ΔH_r⁰ = 2.93 ± 0.7 (X = Cl), 18.89 ± 0.7 (X = Br), and 35.5 ± 3 kcal/mol at 298.15°K for X = I. Coomber (2) reviewed data for the analogous reactions with X = CH₃ and CD₃; these yield ΔH_r⁰ = 0.6 ± 2 kcal/mol at 298.15°K for X = CH₃. Activation energies have also been reported (6) for CF₃I(g) + I(g) → CF₃(g) + I₂(g) from which we derive the average value ΔH_r⁰ = 17.1 ± 2 kcal/mol. The data of Tschuikow-Roux (7) for C₂F₆(g) + 2CF₃(g), recalculated as suggested by Coomber (8) but with JANAF functions, yield ΔH_r⁰ = 97.6 ± 6 kcal/mol. Differences between the calculated and observed values of ΔH_r⁰ are all less than half of the uncertainties assigned to the observed values.

The thorough discussion of photoionization data by Noutary (9) emphasized that CF₃⁺ is formed with large amounts of excess energy both during ionization of CF₃ and during fragmentation of other fluorides. The amount of excess energy varies with the parent molecule. This may also be involved in electron-impact studies and could account for some of the discrepancies in bond-dissociation energies derived from appearance potentials and ionization potentials. Such data have been summarized by Coomber (10). Ionization data were omitted from the simultaneous adjustment due to uncertainty in the amounts of excess energy. Also omitted was the mass-spectrometric study of 3C₂F₄(g) + 4CF₃(g) → 2C₂F₆(g) + 2C(CF₃)₂(g) by Ehler (11) which gave ΔH_f⁰ = -102 ± 3 kcal/mol. The discrepancy of 10 kcal/mol suggests that the data may not represent equilibrium for the above reaction. This reaction was one of many which resulted from heating MnF₃ in an effusion cell made of graphite.

Heat Capacity and Entropy

The bond length is assumed to be 1.33 Å by comparison with the molecules CF₃X, and the bond angle is estimated from molecular-orbital calculations of Morokuma (12) and Pople and coworkers (13). The nonplanar structure is consistent with electron-spin-resonance spectra (14) of CF₃ in krypton and xenon matrices, with infrared spectra of CF₃ in various matrices (15) and in the gaseous phase (16), and with photoionization spectra (17). The observed vibrational fundamentals of Carlson (18) are confirmed by the matrix spectra of Milligan (19). The latter estimated ν₄ to be in the range of 500 to 600 cm⁻¹. We choose the lower value by comparison with CF₃H, SiF₃H and SiF₃ (18).

The uncertainty in ν₄ corresponds to an uncertainty in the entropy of 0.4 eu at 300°K and 0.7 eu at 1000°K. Coomber (2) and Amphlett (13) used kinetic data to derive entropies of 63.2 eu at 350°K and 71.5 eu at 600°K. The calculated entropies from this table are higher by 2.0 and 1.7 eu, respectively. These differences are only slightly larger than our estimate of the uncertainty in the kinetic results. We estimate the overall uncertainty in the calculated entropies as 1.0 eu at 298°K and 1.6 eu at 1000°K.

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₆. Details of the input data and the adjustment are given in (1). Lord, Goy and Fritchard (2, 3) report equilibrium data for the reactions CF₃X(g) + I₂(g) = CF₃I(g) + XI(g) where X = H, Cl, and Br. In addition to these prime links, there is a weak link to CF₃ through kinetic studies of CF₃I(g) + I(g) = CF₃(g) + I₂(g). Data for this reaction (3, 12) yield the average value $\Delta H_f^\circ = 17.1 \pm 2 \text{ kcal/mol}$ at 298.15°K.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (4), Anderson (5), and Mong and Schomaker (6). Differences among the data are small. The results of Anderson are adopted since they are intermediate between the others. Microwave data (7) are consistent with the adopted parameters. Infrared spectra of the gas were observed by several investigators (8, 9, 10) and Raman spectra of the liquid were obtained by Edgell and May (10). The vibrational assignments of (9, 10) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. In particular, ν_6 is taken as 260 cm⁻¹ (from overtone and combination bands of the gas) rather than 265 cm⁻¹ (from the Raman spectra of the liquid). The approximate values of ν_2 , ν_3 and ν_6 have been confirmed by analysis (11) of absorption spectra in the UV.

The thermodynamic functions of this table are essentially the same as those calculated by (9). Uncertainty in the entropy is estimated to vary from 0.15 to 0.6 gibbs/mol over the range from 300 to 1000°K. Uncertainty in ν_6 and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for CClF₃(g) and CF₄(g). The principal moments of inertia are $I_A = 14.71 \times 10^{-39}$ and $I_B = I_C = 54.75 \times 10^{-39} \text{ g cm}^2$.

CF 4

Vibrational Frequencies and Degeneracies

 $\frac{\omega}{\text{cm}^{-1}}$ $\frac{\omega}{\text{cm}^{-1}}$

908.5 (1)

1783.0 (3)

435.0 (2)

631.5 (3)

 $\sigma = 12$ $I_A I_B I_C = 3.1489 \times 10^{-114} \text{ g cm}^2$

Bond Angle: F-C-F = 109.47°

Bond Distance: C-F = 1.320 Å

Product of the Moments of Inertia: $I_A I_B I_C = 3.1489 \times 10^{-114} \text{ g cm}^2$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of HF(g), HF(50 H₂O) and five closely related fluorides. Adjustment of 73 selected observations relating the 7 variables gives the following heats of formation in kcal/mol at 298.15°K: HF(g), -65.14 ± 0.2; HF(50 H₂O), -76.78 ± 0.1; NaF(s), -137.52 ± 0.2; BF₃(g), -271.42 ± 0.4; CF₄(g), -223.04 ± 0.3; NF₃(g), -31.43 ± 0.3; and C₂F₄(polymer), -198.2 ± 0.7. The ± values are estimates of the overall uncertainty including systematic error. Further details of the simultaneous adjustment are given in (1).

The selected value is essentially the same as that obtained by Greenberg and Hubbard (2) in their thorough calorimetric study of the combustion in fluorine of natural and synthetic graphite. Their result is confirmed by the data of Domalski and Armstrong (3) for combustion of graphite-Teflon mixtures. Reliable data (1) also link CF₄(g) with HF(n H₂O), NF₃(g) and C₂F₄(polymer). Armstrong (1, 3) critically reviewed the more uncertain data which were omitted from the adjustment.

Heat Capacity and Entropy

The fundamental vibrations are those observed in the gas-phase Raman spectra by Monostori and Weber (3) and the gas-phase infrared spectra by Haki et al. (5) and Chalmers and McKean (7). The frequencies are essentially the same as those selected by Shimanouchi (8) who also lists earlier spectral studies. Electron-diffraction studies of the gas were reported by Thornton (9) and Hoffman and Livingston (10). The adopted bond length is the average of these two results which differ by only 0.006 Å. The principal moments of inertia are $I_A = I_B = I_C = 14.657 \times 10^{-39} \text{ g cm}^2$.

The most significant uncertainty in the calculated thermodynamic functions is due to neglect of anharmonic contributions. Estimates for these contributions were given by Barho (11) and Albright et al. (12), and functions calculated with anharmonic terms were given by McBride et al. (13). Differences between McBride and this JANAF table vary from 0.1 to 0.75 gibbs/mol in Cp° and 0.05 to 0.49 gibbs/mol in S° over the range from 300 to 1000°K. Measurements (14) of Cp° (303-473°K) suggest that anharmonic contributions are significant, but the data are not sufficiently accurate to test the calculations of McBride (13). Heat capacity data (15) for the condensed phases were reviewed by Kelley and King (16) who derived S°_{298.15} = 62.8 ± 0.5 gibbs/mol for CF₄(g).

947.3 (1)	433.7 (1)	250.0 (1)
882.1 (1)	227.5 (1)	Internal rotation

Bond Distances: C-F = $1.331 \text{ \AA}$ F-O = $1.42 \text{ \AA}$ C-O = $1.431 \text{ \AA}$ Bond Angles: C-O-F = (103.2°) F-C-F = (109.5°) Product of Moments of Inertia: $I_A I_B I_C = 1.138 \times 10^{-113} \text{ g}^3 \text{ cm}^6$

Heat of Formation

Porter and Cady (1) measured equilibrium constants for the reaction

 $\text{CF}_3\text{OF(g)} \rightleftharpoons \text{COF}_2\text{(g)} + \text{F}_2\text{(g)}$

in the temperature range 630-750°K. Equilibrium constants were also determined with excess fluorine added to the system.

Second and third law analyses of these data yield the following heats of reaction:

	ΔH_{298}° 2nd law	ΔH_{298}° 3rd law	Drift
Set 1	27.65 ± 0.2	30.10	3.6 ± 0.3
Set added fluorine	25.11 ± 0.3	30.09	7.2 ± 0.5

The third law analyses indicate significant trends within each set of equilibrium data. If the entire error is assigned to the free energy functions, then the drifts in the third law analysis imply that the free energy functions for CF₃OF should be increased by 3.6 or 7.2 gibbs/mol. However, the real error in these free energy functions is probably no larger than 1 gibbs/mol in the temperature range of the experimental data. Apparently, the equilibrium reaction investigated by Porter and Cady (1) was affected by side reactions possibly involving perfluorodimethyl peroxide. However, since the only other approach to the heat of formation of CF₃OF involves bond energies, we adopt the third law value, $\Delta H_f^\circ = 30.1 \text{ kcal/mol}$, and derive $\Delta H_{298}^\circ(\text{CF}_3\text{OF, g}) = -182.8 \pm 3 \text{ kcal/mol}$ with $\Delta H_{298}^\circ(\text{COF}_2, \text{g}) = -152.7 \pm 0.4 \text{ kcal/mol}$ (2).

Czarnowski et al. (3) recently determined the O-F bond energy in CF₃OF from kinetic studies on the thermal decomposition of CF₃OF in the presence of SO₃. They reported the value $D(\text{O-F}) = 43.5 \pm 0.5 \text{ kcal/mol}$. Combining this result with the following data,

 $\Delta H_{298}^\circ(\text{C, g}) = 170.89 \pm 0.45 \text{ kcal/mol}$ (4) $\Delta H_{298}^\circ(\text{F, g}) = 18.96 \pm 0.40 \text{ kcal/mol}$ (5) $\Delta H_{298}^\circ(\text{O, g}) = 59.559 \pm 0.03 \text{ kcal/mol}$ (6) $D(\text{C-O}) = 117.4 \text{ kcal/mol}$ (from $\Delta H_{298}^\circ(\text{CF}_4, \text{g}) = -223.04 \pm 0.3 \text{ kcal/mol}$ (7))we derive $\Delta H_{298}^\circ(\text{CF}_3\text{OF, g}) = -173.8 \text{ kcal/mol}$.

The value determined from Porter and Cady's equilibrium data is adopted here. H_{298}° is determined to be -4.086 kcal/mol .

Heat Capacity and Entropy

The vibrational frequencies are from the infrared and Raman studies of Wilt and Jones (9) and are in reasonable agreement with nine of the twelve expected fundamentals observed by Lagemann et al. (10). Bond lengths and angles are estimated quantities chosen by Wilt and Jones (9). Individual moments of inertia calculated from these estimated molecular constants are $I_A = 14.723 \times 10^{-39} \text{ g cm}^2$, $I_B = 27.796 \times 10^{-39} \text{ g cm}^2$, and $I_C = 27.801 \times 10^{-39} \text{ g cm}^2$. The contributions of hindered internal rotation to the thermodynamic properties of CF₃OF are from the tables of Pitzer and Gwinn (11). The reduced moment of inertia, I_r , and the potential barrier, V_0 , are from the work of Wilt and Jones (9) and are:

$$I_r = 2.939 \times 10^{-39} \text{ g cm}^2$$

$$V_0 = 1130 \text{ cal/mol } (V_{12} = 56 \text{ cm}^{-1})$$

Heat of Formation

G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950, reanalyzed the rotational predissociation reported by T. Shidei, Japan J. Phys. 11, 23 (1936), and concluded that $D_0^\circ = 80.0$ kcal/mol (3.47 eV). This yields $\Delta H_f^\circ(298.15^\circ\text{K}, g) = 142.0$ kcal/mol and is the adopted value.

R. G. Brewer and F. L. Kester, J. Chem. Phys. 40, 812 (1964), have confirmed the value as 142 ± 5 kcal/mol, from an equilibrium study of the temperature variation of the intensity of the $\lambda_{2,2}^1\Pi$ emission band.

M. Linevsky, J. Chem. Phys. 47, 1495 (1967), determined the concentration of CH radicals in equilibrium with 1 atm. of hydrogen gas, by application of a high resolution spectro-photographic technique to three electronic transitions in absorption.

A third law analysis, using the present functions, of 27 determinations in the temperature range 3065 - 3155°K yielded $\Delta H_f^\circ(298.15^\circ\text{K}, g) = 142.01 \pm 1.28$ kcal/mol with a negligible drift. This value is in excellent agreement with the spectroscopic predissociation value.

Heat Capacity and Entropy

The vibrational and rotational constants and electronic levels are from Herzberg, loc. cit., with the exception of the estimated $\frac{1}{2}\epsilon$ level. All the constants have been adjusted to the normal isotopic abundances for both carbon and hydrogen. The $\frac{1}{2}\epsilon$ level is estimated from the ab initio calculations of A. C. Hurley, Proc. Roy. Soc. (London), 249A, 402 (1959), which include electron correlation effects. Earlier LCAO calculations had predicted the $\frac{1}{2}\epsilon$ level to be the ground state, but J. Higuchi, J. Chem. Phys. 22, 1339 (1954), used LCAO-SCF calculations and obtained the $\frac{1}{2}\epsilon$ level at 800 cm⁻¹. M. Krauss and J. F. Wöhner, J. Chem. Phys. 23, 1287 (1955), using essentially the same technique as Hurley, obtained $\frac{1}{2}\epsilon$ at 3000 cm⁻¹.

Monochloromethylene (CHCl)

(Ideal Gas) GFW = 48.47212

Point Group C_s $\Delta H_f^\circ = [79.9 \pm 10] \text{ kcal/mol}$ $S_{298.15}^\circ = 56.12 \pm 0.05 \text{ gibbs/mol}$ $\Delta H_f^\circ = [80 \pm 10] \text{ kcal/mol}$

Bond Distance: C-H = 1.12 Å C-Cl = 1.889 Å

Bond Angle: H-C-Cl = 103.4°

Product of the Moments of Inertia: $I_A I_B I_C = 3.9877 \times 10^{-117} \text{ g}^3 \text{ cm}^6$

Heat of Formation

The heat of formation can be estimated as the average of those of the CH₂ and CCl₂ radicals, which gives $\Delta H_f^\circ(\text{CHCl}, g) = 74.5 \pm 15 \text{ kcal/mol}$. A better value for the heat of formation can be obtained by considering the reactions $\text{CHCl} + \text{CH} + \text{Cl}$ and $\text{CHCl} + \text{CCl} + \text{H}$. When $\Delta H_f^\circ(\text{CCl}, g) = 74.5 \text{ kcal/mol}$ is substituted into the above equations it gives $D_{\text{C-Cl}} = 98 \text{ kcal}$ and $D_{\text{C-H}} = 98 \text{ kcal}$. Although these values are not unreasonable the $D_{\text{C-H}}$ value appears to be too high compared to that in CFH. Thus, we adopt $\Delta H_f^\circ(\text{CHCl}, g) = 80 \text{ kcal/mol}$ which gives $D_{\text{C-Cl}} = 91 \text{ kcal}$ and $D_{\text{C-H}} = 92 \text{ kcal}$.

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absorption bands. The estimated triplet state is based on the electronic levels of CCl₂ and CH₂ as given in these tables. The vibrational levels are from Iacox and Milligan (2) who investigated the infrared spectrum of matrix-isolated CHCl, and also estimated the missing frequency.

² The individual moments of inertia are $I_A = 4.6455 \times 10^{-39} \text{ g cm}^2$, $I_B = 1.780 \times 10^{-40} \text{ g cm}^2$, and $I_C = 4.8235 \times 10^{-39} \text{ g cm}^2$.

Heat of Formation
Edwards and Small (1) determined a single equilibrium constant at 600°C for the reaction 2CHClF₂(g) + C₂F₆(g) + 2HCl(g). The value was not obtained directly but was obtained by extrapolation to eliminate the effects of side reactions. The equilibrium constant was used with JANAF free energy functions (2) to obtain ΔH_f⁰ = -115.1 kcal/mol, which yields ΔH_f⁰ (CHClF₂, g) = -115.1 kcal/mol. An uncertainty of ±3 kcal/mol corresponds to an uncertainty of about ±50% in the equilibrium constant.

Heat Capacity and Entropy

The gas phase vibrational frequencies have been observed in the Raman by Holzer and Moser (3); they do not see anything in the 1350 cm⁻¹ region as reported in the liquid by Glockler and Edgell (4). Plyler and Benedict (5) in their assignment replaced an 831 cm⁻¹ frequency by 1178 cm⁻¹. We essentially adopt Glockler and Edgell's assignment with updated gas phase values for the observed frequencies. The microwave spectrum has been analysed by McLay and Mann (6) and Beeson et al. (7), who derive bond lengths and angles in excellent agreement with each other. The values given by Beeson et al. are adopted here.

Neelson and White (8) have measured the low temperature heat capacity and heat of vaporization and have reported an entropy in the gas phase at 232.5°C of 63.919 ± 0.28 gibbs/mol. This compares with 63.959 gibbs/mol calculated from our adopted functions.

The individual moments of inertia are I_A = 8.203 × 10⁻³⁹ g cm², I_B = 17.402 × 10⁻³⁹ g cm² and I_C = 24.060 × 10⁻³⁹ g cm².

Vibrational Frequencies and Degeneracies

ω_1, cm^{-1}	ω_2, cm^{-1}	ω_3, cm^{-1}
3023 (1)	741 (1)	1242 (1)
1313 (1)	455 (1)	806 (1)
1079 (1)	270 (1)	368 (1)
Bond Distance: C-H = 1.09 Å C-Cl = 1.75 Å C-F = 1.367 Å		
Bond Angle: Cl-C-Cl = 112°12' F-C-Cl = 109° H-C-Cl = 109°45'		
Product of the Moments of Inertia: $I_A I_B I_C = 1.11593 \times 10^{-113} \text{ g}^3 \text{ cm}^6$		
$\sigma = 1$		

Heat of Formation

The change in heat of atomization by successive replacement of F by Cl in the CF₄ to CCl₄ series follows a regular pattern (see CCl₂F₂ table). A similar pattern is to be expected in the CHCl₃ series. The first replacement of the series is, in fact, 4 kcal higher than the mean versus 3.8 kcal higher in the CF₃-CCl₄ series. Thus, we have selected the atomization energy of the second and third replacements to continue this pattern. In this manner we have selected the atomization energy of CHCl₂F as 367.4 kcal which corresponds to ΔH_f° (CHCl₂F, g) = -57.7 kcal/mol. With this adopted value, the successive replacement of F by Cl changes the heat of atomization by 41.4, 37.3 and 33.0 kcal.

Heat Capacity and Entropy

Holzer (1) has reported the gas phase Raman spectrum which is in excellent agreement with the assignments of Plyler and Benedict (2). The only discrepancy is in ν_7 , which Plyler and Benedict assign at 1242 cm⁻¹, and Holzer (1) does not report a band in this region. Holzer does, however, report a band at 728 cm⁻¹ which has not been reported in the earlier liquid studies. There is strong evidence from correlations with CHCl₃ and CHF₃ that two frequencies should occur between 1220 and 1376 cm⁻¹. On this basis we adopt the assignment of Plyler and Benedict for ν_7 , while accepting the gas phase values of Holzer for the other frequencies. The extra band at 728 cm⁻¹ is not used. It is probable that the bands at 741 and 728 cm⁻¹ are due to Fermi resonance of ν_4 with $2\nu_9$; the unperturbed level would lie at 735 cm⁻¹. The symmetry classes of ν_4 and $2\nu_9$ are identical and thus Fermi resonance is allowed.

Nclay (3) has reported the molecular structure from his microwave investigations. The individual principal moments of inertia are $I_A = 12.053 \times 10^{-39} \text{ g cm}^2$, $I_B = 25.684 \times 10^{-39} \text{ g cm}^2$ and $I_C = 36.047 \times 10^{-39} \text{ g cm}^2$.

Heat of Formation
Hu and Sinke (1) have measured the heat of combustion of CHCl₃(l) in the rotating bomb calorimeter, using As₂O₃ solution as the reducing agent. The reported $\Delta H_{298}^\circ = -113.10 \text{ kcal/mol}$ for CHCl₃(l) + 0.5O₂ + H₂O(l) + CO₂(g) + 3HCl(600H₂O, aq) which leads to $\Delta H_{298}^\circ(\text{CHCl}_3, l) = -32.10 \text{ kcal/mol}$, using $\Delta H_{298}^\circ = -94.051, -39.873, -68.315 \text{ kcal/mol}$ for CO₂(g), HCl(600H₂O, aq) and H₂O(l), respectively (2). The standard deviation of six combustion runs was 0.09 kcal/mol. Employing the heat of vaporization of chloroform at 298°K as 7.44 kcal/mol (3), we obtain $\Delta H_{298}^\circ(\text{CHCl}_3, g) = -24.66 \text{ kcal/mol}$ which is adopted in the tabulation.

L. Smith et al. (4), based on the combustion data of E. Efring (5), re-evaluated the heat of combustion of chloroform at 18.7°C as $\Delta C_p^\circ/M = -347.7 \text{ cal/g}$ for CHCl₃(l) + 0.5O₂(g) + H₂O(l) + CO₂(g) + 3HCl(600H₂O, aq). This value needs to be further corrected for a change in the heat of oxidation of As₂O₃ (6) and calculated to 25°C to give $\Delta H_{298}^\circ = -113.44 \text{ kcal/mol}$, $\Delta H_{298}^\circ(\text{CHCl}_3, l) = -31.76 \text{ kcal/mol}$ and $\Delta H_{298}^\circ(\text{CHCl}_3, g) = -24.32 \text{ kcal/mol}$.

Heat Capacity and Entropy

The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (7), based on infrared and Raman spectra measured by Nielsen and Ward (8), Madigan and Cleveland (9), Gibian and McKinney (10) and Stanevich and Yaroslavskii (11).

The bond distances and angles were obtained from the microwave spectra by Jen and Lide (12). The three principal moments of inertia are $I_A = I_B = 25.719 \times 10^{-39}$ and $I_C = 49.603 \times 10^{-39} \text{ g cm}^2$.

Monofluoromethylene (CHF)

(Ideal Gas)

GFW = 32.01752

Point Group C_s $\Delta H_f^\circ = [29.9 \pm 7] \text{ kcal/mol}$ $S_{298.15}^\circ = 53.35 \pm 0.05 \text{ gibbs/mol}$ $\Delta H_f^{298.15} = [30 \pm 7] \text{ kcal/mol}$

Bond Distance: C-H = 1.121 Å C-F = 1.314 Å

Bond Angle: H-C-F = 101.6°

Product of the Moments of Inertia: $I_A I_B I_C = 1.0217 \times 10^{-117} \text{ g}^3 \text{ cm}^6$ $\sigma = 1$

Heat of Formation

The heat of formation can be estimated as the average of those of the CH₂ and CF₂ radicals, which gives $\Delta H_f^\circ(\text{CHF}, g) = 25 \pm 20 \text{ kcal/mol}$. A better value for the heat of formation can be obtained by considering the bond energies CHF = CH + F and CHF = CF + H. When $\Delta H_f^\circ(\text{CHF}, g) = 25 \text{ kcal/mol}$ is substituted into the above equations it gives D_{C-F} = 136 kcal and D_{C-H} = 86 kcal. These are not unreasonable values but are probably close to the upper and lower limits respectively. A value of $\Delta H_f^\circ(\text{CHF}, g) = 30 \text{ kcal/mol}$ gives D_{C-F} = 131 kcal and D_{C-H} = 81 kcal which are more probable since both fall within the bounds of normal bond strengths. The strongest established C-F bond is 135 kcal in CF₃ and the weakest established C-H bond is 80 kcal in CH. We adopt $\Delta H_f^\circ(\text{CHF}, g) = 30 \pm 7 \text{ kcal/mol}$.

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absorption bands. The estimated triplet state is based on the electronic levels of CF₂ and CH₂ as given in these tables. The vibrational levels are from Merer and Travis (1) and Jacox and Milligan (2), the latter investigated the infrared spectrum of matrix-isolated HCF and also estimated the missing frequency.

The individual moments of inertia are $I_A = 2.2979 \times 10^{-39} \text{ g cm}^2$, $I_B = 1.795 \times 10^{-40} \text{ g cm}^2$, and $I_C = 2.4774 \times 10^{-39} \text{ g cm}^2$.

 $\chi_{\text{HCO}} = 109 \pm 3^\circ$ $\chi_{\text{HCO}} = 129 \pm 3^\circ$ Moments of Inertia $I_A = 0.92052 \times 10^{-39} \text{ g. cm}^2$ $I_B = 7.13510 \times 10^{-39} \text{ g. cm}^2$ $I_C = 8.07064 \times 10^{-39} \text{ g. cm}^2$ $r = 1$

Heat of Formation

 ΔH_f for III was estimated to be the average of the ΔH_f 's of I and II.(I) $\text{CH}_2\text{O(g)} = \text{CO(g)} + 2\text{H(g)}$ 106 kcal.(II) $\text{CF}_2\text{O(g)} = \text{CO(g)} + 2\text{F(g)}$ 162 kcal.(III) $\text{CHFO(g)} = \text{CO(g)} + \text{F(g)} + \text{H(g)}$ [134] kcal.The auxiliary ΔH_f 298.15 of $\text{CH}_2\text{O} = -28$, $\text{H} = 52$, $\text{F} = 19$, $\text{CO} = -26$, $\text{CF}_2\text{O} = -150$ kcal. mole⁻¹ was used. See the respective sheets for details. The estimated heat of formation is consistent with the instability of CHFO(g) at room temperature.

Heat Capacities and Entropies

The molecular structural parameters were obtained by O. H. LeBlanc, V. W. Laurie and W. D. Ormrod, J. Chem. Phys. 33, 598 (1960), from combining the results of microwave measurements with those of electron diffraction determined by M. E. Jones, K. Hedberg, and V. Schomaker, J. Am. Chem. Soc. 77, 5278 (1955). Agreement within the assigned uncertainties was obtained by R. P. Stratton and A. H. Nielsen, J. Mol. Spect. 3, 373 (1960), on the basis of infrared measurements.

Five of the fundamental were observed by Stratton and Nielsen, loc. cit. in agreement with those obtained by H. W. Morgan, P. A. Staats and J. H. Goldstein, J. Chem. Phys. 25, 337 (1956). The estimated frequency was based upon the observed value of 857.4 cm.⁻¹ for the fundamental in the infrared spectrum of the deuterated compound and the application of the Teller-Redlich isotope rule.

Bond Distance: C-F = 1.333 Å C-H = 1.098 Å

Bond Angle: F-C-F = 108.6 ± 0.5° F-C-H = 110.33°

Product of the Moments of Inertia: $I_A I_B I_C = 9.7204 \times 10^{-115} \text{ g}^3 \text{ cm}^6$ $\sigma = 3$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₆. Details of the input data and the adjustment are given in (1). Trifluoromethane is linked to HF(21.5 H₂O) by calorimetric data, to CHF₃(g) and CF₃I(g) by equilibrium data, and to CF₃(g) by kinetic data. Heugebauer (2) reported calorimetric data for CHF₃(g) + 0.5 O₂(g) + CO₂(g) + 3 HF(21.5 H₂O), where CF₃(g) was also formed in a competing reaction. Recalculation of the original data with $\Delta H_f^\circ(298.15 \text{ CF}_4, \text{g}) = -223.0 \text{ kcal/mol}$ yields the mean value of $\Delta H_f^\circ(298.15) = -90.35 \pm 0.7 \text{ kcal/mol}$, but the individual values of ΔH_f° show a disturbing trend with the amount of competing reaction. Possible causes for the trend include corrosion and error in the analysis of the reaction products. Calibration was done in the presence of HF in an attempt to eliminate the heat due to corrosion. Because of this unexplained trend, we increase the uncertainty to ± 1.0 kcal/mol. Goy (3) and Coomber (4) determined equilibrium data for CHF₃(g) + X₂(g) = CF₃X(g) + HX(g) where X = I and Br. Kinetic data pertinent to CHF₃ are noted on the table for CF₃(g).

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Thornton (5) and from microwave data by Ghosh (6). The results are in close agreement and average values are adopted. Vibrational frequencies are from the assignment of Long (7) who reviewed the spectral data and gave force-constant calculations. Preference has been given to the gas-phase spectra, particularly the Raman data of Claassen (8). Shimanouchi (9) assigned $\nu_2 = 1117$ rather than 1137 cm^{-1} , but he apparently did not consider the gas-phase data of (8, 10). Principal moments of inertia are $I_A = 14.786 \times 10^{-39}$ and $I_B = I_C = 8.108 \times 10^{-39} \text{ g cm}^2$.

Valentine (11) used low-temperature calorimetric data to derive the ideal gas entropy at the normal boiling point of 190.97°K. The experimental value of 57.18 gibbs/mol is in good agreement with 57.216 gibbs/mol obtained from this table. Schwing (12) measured C_p for CHF₃ vapor (25-100°C) and confirmed that the vibrational assignment is adequate. Uncertainty in C_p and S° increases at higher temperatures due to neglect of anharmonicity in the calculations. Discussions of anharmonic contributions are given on the tables for CF₄(g) and CClF₃(g). The error probably does not exceed 0.3 gibbs/mol in S° at 1000°K. C_p° is consistent with C_p° measured at 300°K by the wire-ribbon method (13).

HC bond length = $1.08 \pm 0.005 \text{ \AA}$ CO bond length = $1.198 \pm 0.005 \text{ \AA}$ HCO angle = $119^\circ 30' \pm 1^\circ$

Product of Moments of Inertia = $I_A I_B I_C = 4.73 \times 10^{-118} \text{ g.}^3 \text{ cm.}^6$ $\sigma = 1$

Heat of Formation

Calculated from $\Delta H_0^\circ = 75.1 \pm 2.3 \text{ kcal.}$ for the reaction $\text{H}_2\text{CO(g)} \rightarrow \text{HCO(g)} + \text{H(g)}$, reported by J. C. D. Brand and R. T. Reed, J. Chem. Soc. 2386 (1957).

Heat Capacity and Entropy

The vibrational levels and multiplicities are from G. E. Ewing, W. E. Thompson, and G. C. Pimentel, J. Chem. Phys. 32, 927 (1960), while the ground state multiplicity and structural data are from G. Herzberg and D. A. Ramsay, Proc. Roy. Soc. A233, 34 (1955).

Heat of Formation.

The selected heat of formation, ΔH_{298}° (HCO⁺, g) = 203 kcal/mol was obtained from electron impact studies on cis- and trans-HCOOH by F. M. Field and J. L. Franklin, "Electron Impact Phenomena," Academic Press, New York, 1957. A higher value, $\Delta H_{298}^{\circ} = 220$ kcal/mol, has also been reported from appearance potential measurements on CH₃CHO by J. R. Major, C. R. Patrick and J. C. Robb, Trans-Paraday Soc. 57, 14 (1961). Generally, errors in the heat of formation derived from electron impact studies are such as to cause the quantities to be high because of unaccounted excitations or residual kinetic energy in the fragments; therefore, the value of 203 kcal/mol is preferable, assuming the same reliability of the experiments.

Heat Capacity and Entropy.

Since the molecule HCO⁺(g) has the same number of valence electrons as HCN(g), a linear molecular configuration is assumed for HCO⁺(g) in the tabulation. The bond distances H-C and C-O were estimated by comparison with those in similar molecules by D. G. Clifton, J. Chem. Phys. 41, 3656 (1964). The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton. The principal moment of inertia is 1.7941 X 10⁻³⁹ g cm².

Spectroscopic constants used in calculating corrections to the rigid-rotor harmonic oscillator model (cm^{-1}):

$$\begin{aligned}\sigma_1 &= 3.4 \times 10^{-3} & -\chi_{11} &= \{3.7\} & -\chi_{12} &= \{1.9\} \\ \sigma_2 &= -3.4 \times 10^{-4} & -\chi_{22} &= \{2.4\} & -\chi_{23} &= \{18.0\} \\ \sigma_3 &= 3.1 \times 10^{-3} & -\chi_{23} &= \{51.0\} & -\chi_{13} &= \{6.0\}\end{aligned}$$

Bond Distances: C-H = 1.0667 Å C-P = 1.5421 Å

Bond Angle: H-C-P = 180°

Rotational Constant: $B_0 = 0.56633 \text{ cm}^{-1}$ $\sigma = 1$

Heat of Formation

The bonding in HCP and HCN is very similar, as evidenced by the bond lengths and vibrational frequencies. We assume that the C-H bond strength is thus the same in these two molecules. For the reaction $\text{HCN} \rightarrow \text{H} + \text{CN}$ we derive $\Delta H^\circ = 123.8 \text{ kcal}$ from $\Delta H_f^\circ(\text{HCN}) = 32.3$, $\Delta H_f^\circ(\text{H}) = 52.1$ and $\Delta H_f^\circ(\text{CN}) = 104 \text{ kcal/mol}$. Applying this to the reaction $\text{HCP} \rightarrow \text{H} + \text{CP}$, we obtain $\Delta H_f^\circ(\text{HCP}) = 40 \pm 15 \text{ kcal/mol}$, from $\Delta H_f^\circ(\text{CP}) = 111.7 \text{ kcal/mol}$.

Heat Capacity and Entropy

The molecular configuration was first reported by Gier (1), and later the bond lengths were determined by Tyler (2) using microwave spectroscopy. The vibrational frequencies and electronic levels were obtained from an analysis of the ultraviolet spectrum by Johns et al. (3). Since the first excited state is above 24000 cm^{-1} and the first nonlinear state at $34,000 \text{ cm}^{-1}$, there is negligible error introduced by assuming ground state molecular constants for all excited states. The anharmonic constants were estimated from those of HCN by Gordon (4) and the adopted table includes these corrections and the electronic contributions.

Heat of Formation

Chupka and Livshitz (1) have recently obtained the photoionization threshold for the production of CH₂⁺ from CH₃ as 15.09 ± 0.03 eV. In conjunction with the spectroscopic ionization potential determined by Herzberg (2), they report D₀(CH₃-H) = 4.694 ± 0.033 eV (108.25 ± 0.77 kcal). Use of ΔH₀⁰(CH₃, g) = 35.62 kcal/mol from these tables yields ΔH₀⁰(CH₂, g) = 92.25 ± 1.0 kcal/mol, which is adopted.

Chupka (3) and Dibeler et al. (4) have determined the photoionization threshold for the production of CH₂⁺ from CH₄. If the latter value is corrected for rotational energy effects as suggested by Chupka the two values are identical and yield ΔH₀⁰(CH₂, g) = 94.6 kcal/mol. However, Chupka indicates that this is a maximum value since the process of H₂ elimination is likely to occur with excess energy in the products at the threshold. Chupka et al. (14) have obtained the appearance threshold of CH₂⁺ from C₂H₄(g) by photoionization and obtained a maximum value of ΔH₀⁰(CH₂, g) = 95.5 kcal/mol.

Dibeler and Liston (5) have also reported the photoionization threshold for the process CH₃CH + CH₂⁺ + HCN as 14.94 eV (344.55 kcal). Using auxiliary data from (2) and (13) we obtain ΔH₀⁰(CH₂, g) = 95 kcal/mol, however the above process is also likely to occur with excess energy and so this is a maximum value.

The older electron impact data of Langer et al. (6) contained several inconsistencies with presently accepted values and was reanalysed by Prophet (7) to give ΔH₀⁰(CH₂, g) = 95 ± 5 kcal/mol. Chupka et al. (8) have also reported a heat of formation, from chemical equilibria measured in a mass spectrometer, as 86.8 ± 6 kcal/mol.

Heat Capacity and Entropy

The ground state configuration, bond length and angle are from Herzberg (9). The excited electronic states are from the calculations of Goldberg and Riter (10) who have tried to allow for correlation energy effects in the different states. The separation between the a₁ and b₁ states is established as 7100 cm⁻¹. The degenerate bending frequency was listed as a possible fundamental of CH₂ by Milligan and Pimentel (11). There is considerable uncertainty that it is in fact the ground state bending frequency, excited state bending frequencies of 1363 and 557 cm⁻¹ have been reported. The symmetric stretch was estimated to be that listed by Herzberg (12) for a bent molecule. The asymmetric stretch was estimated using the valence force field approximation.

The uncertainty in the entropy reflects the possible errors in the vibrational frequencies and the uncertain position of the low lying electronic levels and their varying geometries.

σ = 1

Product of the Moments of Inertia: I_AI_BI_C = 4.8154 × 10⁻¹¹⁵ g³ cm⁶

Heat of Formation

The change in heat of atomization by successive replacement of F by Cl, in the CF₄ to CCl₄ series and CHF₃ to CHCl₃ series, follows a regular pattern (see CCl₂F₂ and CHCl₂F Tables). We make the assumption that this same regular variation occurs also in the CH₂F₂ to CH₂Cl₂ series. Thus, the difference between the atomization energies of CH₂F₂ and CH₂Cl₂ is divided into two unequal parts which fall into the pattern established in the CF₄ and CHF₃ sequences. We adopt a heat of atomization of 385.5 kcal which corresponds to a ΔH_f°₂₉₈(CH₂ClF, g) = -62.6 kcal/mol. The changes, in kcal, in the heat of atomization by successive replacement of F by Cl are tabulated, below for all three series.

CF ₄	43.8	CHF ₃	33.0	CH ₂ F ₂	35.0
CF ₃ Cl	41.4	CHCl ₃	29.7	CH ₂ Cl ₂	33.0

CCl ₄	33.0	CHCl ₂ F	33.0	CHCl ₂ F	33.0

Heat Capacity and Entropy

Plyler and Benedict (1) assigned the vibrational frequencies from the infrared and Raman data for the liquid. The molecular structure was obtained from the microwave measurements of Muller (2). The individual moments of inertia are I_A = 2.008 × 10⁻³⁹ g cm², I_B = 16.241 × 10⁻³⁹ g cm², and I_C = 14.766 × 10⁻³⁹ g cm².

Heat of Formation

Hu and Sinks (1) have measured the heat of combustion of CH₂Cl₂(l) in the rotating bomb calorimeter, using As₂O₃ solution as the reducing agent. They reported $\Delta H_c^\circ = -144.00$ kcal/mole for CH₂Cl₂(l) + O₂(g) → CO₂(g) + 2HCl(600H₂O, aq) which leads to $\Delta H_f^\circ(\text{CH}_2\text{Cl}_2, l) = -79.70$ kcal/mol, using $\Delta H_f^\circ = -94.051$ and -39.823 kcal/mol for CO₂(g) and HCl(600H₂O, aq), respectively (2). The standard deviation of five combustion runs was 0.12 kcal/mol. Employing the heat of vaporization of CH₂Cl₂(l) at 298°K as 6.87 kcal/mol (3), we obtain $\Delta H_f^\circ(\text{CH}_2\text{Cl}_2, g) = -22.83$ kcal/mol which is adopted in the tabulation.

L. Smith et al. (4), based on the combustion data of E. Efring (5), re-evaluated the heat of combustion of dichloromethane at 18.7°C as $\Delta H_c^\circ = -1701.4$ cal/g for CH₂Cl₂(l) + O₂(g) + 2HCl(600H₂O, aq). This value needs to be further corrected for a change in the heat of oxidation of As₂O₃(g) and calculated to 25°C to give $\Delta H_c^\circ = \Delta H_c^\circ - 144.89$ kcal/mol, $\Delta H_f^\circ(\text{CH}_2\text{Cl}_2, l) = -28.80$ kcal/mol and $\Delta H_f^\circ(\text{CH}_2\text{Cl}_2, g) = -21.93$ kcal/mol.

J. Lacher et al. (7) have measured the heat of hydrogenation of dichloromethane to methane and hydrogen chloride at 250°C as -40.07 kcal/mol. Correction to 298°K gives $\Delta H_f^\circ(\text{CH}_2\text{Cl}_2, g) = -23.05$ kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy

The bond distances and angles have been determined from the microwave spectra by R. J. Myers and W. D. Gwinn (6). The three principal moments of inertia are $I_A = 2.630 \times 10^{-39}$, $I_B = 2.5623 \times 10^{-38}$ and $I_C = 2.7727 \times 10^{-38}$ g cm².

The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (9), based on infrared and Raman spectra by Shimanouchi and Suzuki (10), Palma et al. (11), and Welsh et al. (12).

Bond Distances: C-F = 1.358 ± 0.001 Å C-H = 1.092 ± 0.003 Å

Bond Angles: F-C-F = 108° 17' ± 6' H-C-H = 111° 52' ± 25' σ = 2

Product of the Moments of Inertia: I_AI_BI_C = 1.2272 × 10⁻¹¹⁵ g³ cm⁶

Heat of Formation

Nugebauer and Margrave (1) measured the enthalpy of combustion of CH₂F₂. Their result for the combustion reaction

was $\Delta H_{298}^\circ = -139.84 \pm 0.22$ kcal/mole. Using ΔH_{298}° (HF-21.5 H₂O) = -76.75 ± 0.1 kcal/mol (2), obtained with dilution data compiled by Parker (3), we derive,

ΔH_{298}° (CH₂F₂, g) = -107.7 ± 0.4 kcal/mol,

from Margrave's data.

Heat Capacity and Entropy

The vibrational frequencies are average values from the infrared studies of Stewart and Nielsen (4) and Plyler and Benedict (5). Individual moments of inertia are calculated from the rotational constants reported by Lide (6) with the result I_A = 1.7082 × 10⁻³⁹ g cm², I_B = 7.9160 × 10⁻³⁹ g cm², and I_C = 9.0794 × 10⁻³⁹ g cm². The molecular structure data are from the microwave studies of Lide (6) and are in excellent agreement with electron-diffraction studies of Brockway, Thornton, and Bartell whose results are reported in the Annual Review of Physical Chemistry (7).

Heats of Formation

M. Delepine and M. Badoche, Compt. rend. 214, 777 (1942), measured the heat of combustion of a formaldehyde polymer. Their value is revised to ΔH_f 298.15 = -25.0 kcal. mole⁻¹ based on the following thermochemical cycle:

I C_(c) + 1/2 O₂(g) + H₂O(l) = 1/2 (CH₂O)_n(c) -42.3 kcal.

2.4

14.9

III CH₂O(g) = CH₂O(aq)

Equation I and II are based upon data listed by Delepine and Badoche. For reaction III Delepine and Badoche obtained 15 kcal. mole⁻¹. Whereas, P. Walker, J. Am. Chem. Soc. 55, 2821 (1933) obtained 14.8 kcal. mole⁻¹. A value of -27.7 kcal. mole⁻¹ is obtained from the combustion experiments of H. von Wartenberg and B. Lerner-Steinberg, Z. anorg. Chem. 39, 591 (1925). Corrections of -0.6 and 0.1 kcal. mole⁻¹ were applied to obtain a heat of reaction at constant pressure and at 298.15°K.

Equilibrium constant determinations of reaction (IV) by R. H. Newton and B. F. Dodge, J. Am. Chem. Soc. 55, 4747 (1933), lead to a ΔH_f 298.15 = -29.0 kcal. mole⁻¹.

IV H₂(g) + CO(g) = H₂CO(g)

The value obtained from the measurements of Wartenberg and Lerner-Steinberg is believed to be the most reliable.

Heat Capacities and Entropies

Frequencies were measured by H. H. Blau and H. H. Nielsen, J. Molec. Spect. 1, 124 (1957) in the I. R. Microwave determinations of R. B. Lawrence and M. F. W. Strandberg, Phys. Rev. 82, 365 (1951), and those of G. Eriandson, J. Chem. Phys. 25, 579 (1956) are in essential agreement.

$$\sigma = 3$$

Heat of Formation

The heat of formation was measured using hydrogenation to give methane and hydrogen chloride, by J. R. Lacher, E. Emery, E. Bohmalk and J. D. Park, J. Phys. Chem. **60**, 492 (1956). The value adopted was recalculated using JANAF auxiliary data for methane and HCl.

Heat Capacity and Entropy

The vibrational frequencies were tabulated by E. K. Plyler and W. S. Benedict, J. Research Natl. Bur. Standards **47**, 202 (1951). C. C. Costain, J. Chem. Phys. **29**, 864 (1958) has calculated the bond distances and angles based on an isotopic substitution method. From these the individual moments of inertia were calculated to be $I_A = 0.5262 \times 10^{-39} \text{ g. cm.}^2$ and $I_B = I_C = 6.3863 \times 10^{-39} \text{ g. cm.}^2$.

Heat of Formation.

Appearance potentials for CH₃⁺ from CH₄⁺ and CH₃P reported by P. P. Lossing, K. V. Ingold, and I. H. S. Henderson, J. Chem. Phys. 22, 1489 (1954), the heats of dissociation of hydrogen (104.20 kcal.) and fluorine (37.72 kcal.), and the heat of formation of Methane (-17.90 kcal.) were used to calculate the heat of formation of gaseous CH₃P. These authors measured an appearance potential for CH₃⁺ from CH₃P of 14.6 ± 0.6 e.v., which would give an uncertainty of about ±15 kcal. mole⁻¹ in the heat of formation of methyl fluoride. However, a correlation of the heats of formation from the atoms of the methyl fluorides and methyl chlorides indicates that the uncertainty can be reduced to ± 7 kcal. mole⁻¹.

Heat Capacity and Entropy.

Fundamental vibrational frequencies were taken from the summary reported by W. L. Smith and I. M. Mills, J. Mol. Spect. 11, 11 (1963). Moments of inertia from the microwave results of O. R. Gilliam, H. D. Edwards, and W. Gordy, Phys. Rev. 75, 1014 (1949) are: $I_A = 5.52 \times 10^{-40}$ g. cm.², $I_B = I_C = 32.854 \times 10^{-40}$ g. cm.². Bond parameters are the values of L. O. Brockway, C. O. Thornton, and L. S. Bartell, whose electron diffraction results are given in the Annual Review of Physical Chemistry 5, 397 (1954). These values are in close agreement with the microwave parameters reported by Gilliam, Edwards, and Gordy (loc. cit.).

Heat of Formation

P. D. Rossini, J. Research Nat. Bur. Standards 5, 37 (1951) measured the heat of combustion of methane gas. His value at 298.15°K was corrected to the presently accepted molecular weight of water. The heat of formation was calculated using -68.3174 and -94.0540 kcal. mole⁻¹ for the heat of formation of H₂O(l) and CO₂(g) respectively.

Heat Capacities and Entropies

D. P. Stevenson and J. A. Ibers, J. Chem. Phys. 33, 762 (1960), calculated the bond distance from an analysis of available spectroscopic data. Vibrational frequencies listed by L. H. Jones and R. S. McDowell, J. Mol. Spect. 3, 632 (1959), are consistent with their results of a force constant calculation.

$\Delta H_f^0 = 30.54 \pm 0.25$ cal. deg.⁻¹ mole⁻¹
 $T_f = 168.3 \pm 0.1^\circ\text{K.}$
 $T_m = 895 \pm 2^\circ\text{K.}$
 $\Delta H_f^0 = -28.28 \pm 0.2$ kcal. mole⁻¹
 $\Delta H_f^0 = -27.12 \pm 0.2$ kcal. mole⁻¹
 $\Delta H_f^0 = 0.279$ kcal. mole⁻¹
 $\Delta H_m^0 = 3.5$ kcal. mole⁻¹
 $\Delta H_g^0 = 298.15$ (to dimer) = 52 ± 10 kcal. mole⁻¹
 $\Delta H_g^0 = 298.15$ (to monomer) = 46 ± 5 kcal. mole⁻¹

Heat of Formation.

The enthalpy change, $\Delta H_f^0 = 2.80 \pm 0.10$ kcal. mole⁻¹, for the reaction $\text{KCN(c)} \rightarrow \text{KCN(g)}$ was reported by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, National Bureau of Standards, April 1, 1965. Incorporating this data with the heat of formation for $\text{K}^+(\infty \text{H}_2\text{O})$ and $\text{CN}^-(\infty \text{H}_2\text{O})$, reported by D. D. Wagman, M. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, October 1, 1965, National Bureau of Standards, the value of $\Delta H_f^0 = 298.15$ for KCN(c) was evaluated to be -27.12 ± 0.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The heat capacity for KCN(c) has been measured with a heat conduction method by C. E. Measer and W. T. Ziegler, J. Am. Chem. Soc. 63, 2703 (1941), 101.6-345.8°K., and adiabatically by H. Suga, T. Matsumoto and S. Seki, Bull. Chem. Soc. Japan, 38, 1115 (1965), 14.23-308.5°K. The data of Suga, Matsumoto and Seki were adopted after correction for curvature. The anomalous region between 50-105°K. has been treated as second order by inclusion of the enthalpy in the heat capacity. The C_p values above 310°K. were estimated by graphical extrapolation. The value of $\Delta H_f^0 = 298.15$ was evaluated based on $S_{15}^0 = 0.193$ cal. deg.⁻¹ mole⁻¹. This extrapolated value appears more reasonable than the value, $S_{15}^0 = 0.307$ cal. deg.⁻¹ mole⁻¹ reported by Suga, Matsumoto and Seki.

Transition Data.

T_f was taken from Suga, Matsumoto and Seki, loc. cit. ΔH_f^0 was calculated as the difference between the total enthalpy change, $H_{173.80}^0 - H_{159.02}^0 = 0.533$ kcal. mole⁻¹ obtained from C_p values measured by Measer and Ziegler, loc. cit., and the enthalpy change, 0.254 kcal. mole⁻¹, calculated from the arbitrarily smoothed C_p curve. Suga, et al. reported $\Delta H_f^0 = 0.339$ kcal. mole⁻¹; however, their C_p data do not adequately define the total enthalpy change through the transition region. The values of T_f and ΔH_f^0 reported by Measer and Ziegler, loc. cit., were $168.3 \pm 0.4^\circ\text{K.}$ and 0.30 kcal. mole⁻¹, respectively. The lower transition, $T = 82.9 \pm 0.2^\circ\text{K.}$ and $\Delta H_f^0 = 0.095 \pm 0.001$ kcal. mole⁻¹ reported by Suga, et al., was treated as second order by inclusion of the enthalpy in the heat capacity.

Melting Data.

See KCN(1) table.

Heat of Sublimation.

The difference between $\Delta H_f^0 = 298.15$ for $(\text{KCN})_2(\text{g})$ and 2KCN(c) is $\Delta H_g^0 = 298.15$ (to dimer) and for KCN(g) and KCN(c) is $\Delta H_g^0 = 298.15$ (to monomer).

Heat of Formation.

The vapor pressure of KCN(g) at 870°C. was estimated to be 1-10 mm. Hg by D. S. Willars, J. Am. Chem. Soc. **53**, 405 (1931). Assuming the vapor pressure at this temperature to be 1 mm. Hg, the heat of vaporization ($\Delta H_v^o 298.15$) for KCN(l) was evaluated as 44 kcal. mole⁻¹. Based on $\Delta H_f^o 298.15 = -24.89$ kcal. mole⁻¹ for KCN(l), the value of $\Delta H_f^o 298.15$ for KCN(g) was calculated to be 19 ± 5 kcal. mole⁻¹.

Heat Capacity and Entropy.

The molecular structure of KCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was determined by N. Elliott and J. Hastings, Acta Cryst. **1**, 1018 (1961) by use of neutron diffraction measurements. The K-C bond distance was taken from G. E. Leroy, Ph. D. Thesis, Harvard University, 1961, which was estimated. The vibrational frequencies, $2/2$ and $2/3$, were obtained from O. E. Leroy and W. Klemperer, J. Chem. Phys. **35**, 774 (1961). The value of $2/1$ was calculated by valence force method described by O. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is 2.3540×10^{-38} g. cm.²

Heat of Formation.

The heat of formation was obtained from the heat of solution $\Delta H_{sol}^o = -7.6 \pm 0.5 \text{ kcal. mole}^{-1}$ and the heats of formation for $K^+(aq)$ and $CO_3^{2-}(aq)$, -60.32 and $-161.84 \text{ kcal. mole}^{-1}$, respectively. The standard heat of solution, ΔH_{sol}^o , was calculated by extrapolation to infinite dilution of the calorimetric data of L. Benjamen, *J. Chem. Eng. Data* **7**, 239-40 (1962), using the methods suggested by J. P. Rupert, H. P. Hopkins, Jr., and C. A. Wulff, *J. Phys. Chem.* **69**, 3059-62 (1965). The equilibrium constant for the hydrolysis $CO_3^{2-}(\infty H_2O) + OH^-(\infty H_2O) \rightleftharpoons HCO_3^-(\infty H_2O) + H_2O(l)$ was taken as $K = 2.1 \times 10^{-4}$ based on the selected values of D. D. Wagman, V. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties", NBS Technical Note 270-1, October 1, 1965. The resulting extrapolations were not as consistent as those of Rupert et al. (loc. cit.) for Na_2CO_3 . The ionic heats of formation were taken from Wagman et al. (loc. cit.). This procedure was adopted even though it may involve an inconsistency between the extrapolations for ΔH_{sol}^o and $CO_3^{2-}(\infty H_2O)$. The alternative evaluation of $\Delta H_f^{298.15}$ for $K_2CO_3(\sim 1900 H_2O)$ from the heats of mixing given by J. A. Muller, *Ann. chim. phys.* (6), **15**, 517 (1888) and M. Berthelot, *Ann. chim. phys.* (4) **29**, 433 (1873) may be subject to significant error if dissolved CO_2 was not excluded from the solutions. Presumably, this path was used by D. D. Wagman, NBS Report 8628, January 1965, in the selection of $\Delta H_f^{298.15} = -274.3 \text{ kcal. mole}^{-1}$. This value is $0.6 \text{ kcal. mole}^{-1}$ less negative than the value adopted here.

Heat Capacity and Entropy.

The low temperature heat capacity, $14.0-315^\circ K$, was measured by P. L. Oetting, unpublished data, Thermal Research Laboratory, Dow Chemical Company, Midland, Michigan, 1963. G. I. Janz, E. Neuenschwander and P. J. Kelly, *Trans. Faraday Soc.* **59**, 841 (1963) measured the heat content by drop calorimetry in the temperature range $650-1250^\circ K$, and gave enthalpy and heat capacity equations based on their measurements. The above information was used in a Shomate analysis in order to smooth the enthalpy and calculate heat capacity above $298^\circ K$. The values from the low and high temperature sources join smoothly at $298^\circ K$. The heat capacity was graphically extrapolated above the melting point. The entropy at $14.0^\circ K$ was calculated from the extrapolated low temperature C_p data, using the cubic law. The value of $S_{14.0}^o = 0.109 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m was obtained from A. Reisman, *J. Am. Chem. Soc.* **80**, 3558 (1958) and ΔH_m^o was taken from Janz et al. (loc. cit.).

POTASSIUM CARBONATE (K₂CO₃)

(LIQUID)

MOL. WT. = 138.21335

S°_{298.15} = 40.719 ± 0.1 cal. deg.⁻¹ mole⁻¹ΔH_f[°] 298.15 = -270.22 ± 0.5 kcal. mole⁻¹ΔG_f[°] = 0.60 ± 0.1 kcal. mole⁻¹T_m = 1174 ± 1°K.

Heat of Formation.

The ΔH_f[°] 298.15 was obtained from ΔH_f[°] 298.15(c) by adding ΔH_m[°] and the difference between H_m[°] - H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 800°K. The heat capacity below 800°K. was obtained from the heat capacity of the crystal. Above 800°K. the heat capacity was adopted as 50.0 cal. deg.⁻¹ mole⁻¹, based on the enthalpy measurements in the range 1189-1250°K. reported by O. J. Janz, E. Neuenchwander and P. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See K₂CO₃(c) table.

Heat Capacity and Entropy.

The low temperature heat capacity, $16.68\text{--}300^\circ\text{K.}$, was measured by O. L. I. Brown and W. M. Latimer, J. Am. Chem. Soc. 58, 2228 (1936). G. I. Janz, E. Nauenschwander and P. J. Kelly, Trans. Faraday Soc. 59, 841 (1963) measured the heat content by drop calorimetry in the temperature range $560\text{--}1150^\circ\text{K.}$, and gave enthalpy and heat capacity equations based on their measurement. The above information was used in a Shomate analysis in order to smoothly the enthalpy and calculate heat capacity. The values from the low and high temperature sources join smoothly at 298°K. The heat capacity was graphically extrapolated above the melting point. The entropy at 16.68°K. was calculated from the extrapolated low temperature C_p data, using the cubic law. The value of $S_{16.68}^\circ = 0.053 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

T_m were taken from A. Reisman, J. Am. Chem. Soc. 80, 3558 (1958). The enthalpies of transition were estimated from the relative areas of the transitions and the heat of fusion of the differential analysis curve reported by Reisman loc. cit.

Melting Data.

T_m was obtained from Reisman loc. cit. and ΔH_m° was taken from Janz et. al. (loc. cit.).

$S_{298.15}^o = 30.423 \pm 0.05 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 993.15 \pm 1^\circ\text{K.}$
 $\Delta H_f^{o, 298.15} = -281.63 \pm 0.04 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{o, 298.15} = 10.7 \pm 0.1 \text{ kcal. mole}^{-1}$

Heat of Formation.

The $\Delta H_f^{o, 298.15}$ was obtained from $\Delta H_f^{o, 298.15(c)}$ by adding $\Delta H_m^{o, 298.15}$ and the difference between $H_m^{o, 298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 683.15°K. The heat capacity below 683.15°K. was obtained from the heat capacity of the crystal. Above 683.15°K. the heat capacity was adopted as $44.32 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, based on the enthalpy measurements in the range $996\text{--}1150^\circ\text{K.}$ reported by G. J. Janz, E. Neuenchwander and P. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See Li₂CO₃(c) table.

Heat of Formation:
 $S_{298.15}^\circ = 15.74 \text{ gibbs/mol}$
 $T_d = 675^\circ \text{K}$
 $\Delta H_f^\circ = -263.9 \pm 2 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = -265.7 \pm 2 \text{ kcal/mol}$

The adopted $\Delta H_{298.15}^\circ = -265.7 \pm 2 \text{ kcal/mol}$ is the average value derived from the dissociation pressures of $\text{MgCO}_3(\text{c})$ in the temperature range $671\text{--}782^\circ \text{K}$ measured by Marc and from the $\Delta H_{923}^\circ = 25.9 \pm 0.6 \text{ kcal/mol}$ determined by Thomasson using a high temperature differential calorimeter. The decomposition of MgCO_3 has been studied in a bomb calorimeter by Roth; this yields $\Delta H_{293}^\circ = 23.8 \text{ kcal/mol}$ when corrected to constant pressure. The value is derived from the small difference between two large heats of combustion, so the uncertainty is probably large. Roth also reported $\Delta H_{365}^\circ = 26.15 \text{ kcal/mol}$ from calorimetric data on the heat of solution in HCl. Berthelot measured the heat of solution of $\text{MgSO}_4(\text{aq})$ with $\text{K}_2\text{CO}_3(\text{aq})$. Analyzing his data we find $\Delta H_{298.15}^\circ = -268.6 \text{ kcal/mol}$.

Discrepancies are apparent in the wide range of the calorimetric results and in the third law drift of the equilibrium data. Possible sources for the drift include lack of true equilibrium (e.g., excess surface energy for MgO) and uncertainty in the high temperature entropy of MgCO_3 (see entropy write-up). Non-standard state behavior of the crystal phases may also be a problem in the calorimetric studies. The data of Thomasson and Cunningham, based on a high temperature differential thermal analysis technique, are probably the most reliable of the calorimetric values; however, there are uncertainties in the absolute energy calibration. The first result of Roth may be dismissed as too discrepant and the remaining two calorimetric values are within $\pm 3 \text{ kcal}$ of the selected heat of formation.

Heat Capacity and Entropy.

Low temperature heat capacities ($56.3 - 291.0^\circ \text{K}$) were measured by C. T. Anderson, J. Am. Chem. Soc. 56, 849 (1934). The high temperature heat capacities are derived by a Shomate analysis of smoothed enthalpies reported by K. K. Kelley, Bulletin 584, p. 114, U.S. Bureau of Mines, Washington, D.C. 1960. Kelley obtained the smoothed values from unpublished high temperature ($400\text{--}743^\circ \text{K}$) enthalpy measurements by C. H. Shomate, Berkeley Thermodynamics Laboratory, Region II, Bureau of Mines, Berkeley, California. The data were joined smoothly at 298°K and extrapolated graphically above 743°K . The entropy was obtained from the heat capacities using $S_{56.2}^\circ = 0.57 \text{ eu}$.

Because of the drift in the decomposition pressure data, it is pertinent to assess the uncertainty in the functions. The greatest potential source for error is in the values above room temperature where the increment of entropy is about 20 eu between 298 and 700°K . Unfortunately, no evaluation of the unpublished enthalpies is possible, but an increase of 10% in the entropy increment would reduce the drift to a tolerable level.

Decomposition Data.

T_d is calculated as the temperature at which ΔG° equals zero for $\text{MgCO}_3(\text{c}) = \text{MgO}(\text{c}) + \text{CO}_2(\text{g})$.

Heat of Formation

The heat of formation of CN has been the subject of considerable uncertainty for many years. J. Berkowitz (1) has reviewed the earlier work and he concludes that $\Delta H_f^\circ(\text{CN}, g) = 109 \text{ kcal/mol}$. Since this review a considerable body of work has emerged which supports a value near 100 kcal/mol .

Tsang et al. (2) obtained $\Delta H_f^\circ(\text{CN}, g) = 100 \pm 4 \text{ kcal/mol}$ from shock tube studies of the decomposition of cyanogen. Dibeler and Liston (3, 4) have studied a series of cyanogen compounds and obtained their heats of dissociation from photoionization threshold measurements. The values below are obtained from the halogen ion threshold measurements using JANAF auxiliary data, except for HCN which is from the CN^+ threshold measurements. The value below is calculated using the ionization potential from CNCL measurements (3).

Davis and Okabe (5) employed a direct photodissociation technique to obtain dissociation energies for many of the same molecules. The method determines the disappearance threshold for fluorescence due to decay of excited molecules $\text{CN } B^2\Sigma^- - X^2\Sigma^+$. This corresponds to the energy needed to just break the bond and form excited cyanogen in the $B^2\Sigma^-$ state, whose energy above ground is well known.

Setser and Steadman (6) used metastable excited argon atoms with a maximum electronic energy of 270 kcal/mol to break the bonds in HCN and $(\text{CN})_2$. From the emission spectra of the excited $B^2\Sigma^-$ CN they were able to calculate the highest populated vibrational level and thus a maximum limit to the dissociation energy.

Berkowitz et al. (7) have recently examined the photoionization spectrum of HCN using the H^+ ion threshold. They also determined the threshold for the CN^+ ion which agrees exactly with that of Dibeler and Liston (4) when the latter is corrected for rotational energy contributions (0.7 kcal). Berkowitz et al. (7) suggest that the HCN limit of Setser and Steadman (6) should be ≤ 105 due to neglect of the significant vibrational population of the first harmonic of the bending mode. However, if the same allowance is made for the C_2N_2 data the limit is only ≤ 104 and this presumes significant occupation of the third harmonic of the bending mode of C_2N_2 .

It is apparent from the data that considerable scatter still exists and several sources of error are probable. HCN and the cyanogen halides all have significant uncertainties in their heats of formation, and the effects of rotational and vibrational contributions at 300°K are uncertain, but could be eliminated by using refrigerated gases. We choose to adopt a median value within the range of almost all determinations of $\Delta H_f^\circ(\text{CN}, g) = 103.2 \pm 2.5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The thermodynamic functions are taken from Johnston et al. (8) calculated based on the direct summation of the energy levels. All the electronic levels and molecular constants listed above are from Carroll (9). Johnston et al. used only the first two excited electronic states but the contribution of the higher levels is negligible.

Heat of Formation

Dibeler and Liston (1) have measured the photoionization thresholds for the processes:

ClCN + hv → Cl⁺ + CN + e⁻ $\Delta H_f^\circ = 399.44 \pm 0.5$ kcalClCN + hv → Cl + CN⁺ + e⁻ $\Delta H_f^\circ = 426.65 \pm 0.5$ kcal

By subtraction we obtain

Cl + CN⁺ + Cl⁺ + CN $\Delta H_f^\circ = -27.21 \pm 0.7$ kcalUsing JANAF values for Cl, Cl⁺ and CN we obtain $\Delta H_f^\circ(\text{CN}^+) = 430.6 \pm 3.0$ kcal/mol and the ionization potential of CN, g = 327.42 ± 0.7 kcal/mol.

Berkowitz et al. (2) have measured the photoionization thresholds for the processes:

HCN + hv → H⁺ + CN + e⁻ $\Delta H_f^\circ = 438.18 \pm 0.3$ kcalHCN + hv → H + CN⁺ $\Delta H_f^\circ = 448.09 \pm 0.3$ kcal

By subtraction we obtain

H + CN⁺ + H⁺ + CN $\Delta H_f^\circ = -9.91 \pm 0.4$ kcalUsing JANAF values for H, H⁺ and CN we obtain $\Delta H_f^\circ(\text{CN}^+) = 426.7 \pm 3.0$ kcal/mol, and the ionization potential of CN, g = 323.51 ± 0.4 kcal/mol.We adopt a median value for $\Delta H_f^\circ(\text{CN}^+) = 428.6 \pm 3.0$ kcal/mol and 325.4 ± 2 kcal/mol for the ionization potential of CN.

Heat Capacity and Entropy

The molecule has eight valence electrons and thus we expect that its molecular constants should fall between those for C₂ and BN. The ground electronic state is either $^1\Sigma$ or $^1\Pi$ and the two levels are likely to be very close. As a consequence the thermodynamic functions are dominated by the Π contribution and so we choose this to be the ground state. The other levels are estimated based on the values of Fougere and Nesbet (3) for C₂ and of Verhaegen et al. (4) for BN. The vibrational constants and bond length are estimated between those for the Π states of BN and C₂. The rotational constants B_e is obtained from the estimated bond length and α_e is calculated from the other constants assuming a Morse potential function. The enthalpy at 0°K is -2.076 kcal/mol.

Heat of Formation

Barkowitz et al. (1) have recently obtained 88 ± 0.5 kcal for the electron affinity of CN from the photoionization thresholds of the reactions $HCN + H^+ + CN^-$ and $HCN + H^+ + CN + e^-$.

Other values have been reported by Page (2), who reinterpreted his earlier data (3), to yield 73 ± 1 kcal/mol; Bakulina and Ionov (4) in conjunction with the data of Branscomb and Smith (5) reported 78 ± 5 kcal/mol and Inoue (6) who obtained 83 ± 7 kcal/mol.

We adopt the value given by Barkowitz et al. (1) as being the most well defined in terms of both the precision of measurements and the reactions being studied. This leads to $\Delta H_f^\circ(CN^-, g) = 15.2 \pm 3$ kcal/mol or $\Delta H_f^\circ(CN^-, g) = 16 \pm 3$ kcal/mol.

Heat Capacity and Entropy

The electronic structure and molecular constants are estimated by analogy with the isoelectronic species CO and N₂. The uncertainties in the constants are generally small since N₂ and CO are quite similar, thus the entropy has an uncertainty of only 0.5 eu. The enthalpy at 0°K is -2.072 kcal/mol.

SODIUM CYANIDE (NaCN)

(CRYSTAL)

MOL. WT. = 49.00765

$S_{298.15}^{\circ} = [28.32 \pm 0.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 835^{\circ} \text{ K.}$
 $\Delta H_f^{\circ} 0 = -23.49 \pm 0.3 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = -21.68 \pm 0.3 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{\circ} = [2.1] \text{ kcal. mole}^{-1}$
 $\Delta H_g^{\circ} 298.15 (\text{to dimer}) = [41.3] \text{ kcal. mole}^{-1}$
 $\Delta H_g^{\circ} 298.15 (\text{to monomer}) = 44.21 \text{ kcal. mole}^{-1}$

Heat of Formation.

The enthalpy change for the reaction $\text{NaCN}(c) \rightarrow \text{NaCN}(\infty \text{ H}_2\text{O})$ was reported to be $0.29 \pm 0.20 \text{ kcal. mole}^{-1}$ by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-RS-2, National Bureau of Standards, April 1, 1965. Incorporating this data with the heats of formation for $\text{Na}^+(\infty \text{ H}_2\text{O})$, -57.39 , and $\text{CN}^-(\infty \text{ H}_2\text{O})$, $36.0 \text{ kcal. mole}^{-1}$, reported by D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, October 1, 1965, National Bureau of Standards, the value of $\Delta H_f^{\circ} 298.15$ for $\text{NaCN}(c)$ was derived and adopted.

G. Lord and A. A. Woolf, J. Chem. Soc. 2546 (1954), determined the value, $\Delta H_f^{\circ} 298.15 (\text{NaCN}, c) = -21.4 \text{ kcal. mole}^{-1}$, by solution calorimetry. This value is in agreement with the adopted one.

Heat Capacity and Entropy.

The low temperature heat capacities, $101.6-345.8^{\circ} \text{ K.}$, were reported by C. E. Measer and W. T. Ziegler, J. Am. Chem. Soc. 63, 2703 (1941). The C_p values above 345.8° K. were estimated by graphical extrapolation. $S_{298.15}^{\circ}$ was derived from low temperature heat capacities, based on $S_{100}^{\circ} = 8.4 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ which was estimated by comparison with the $S_{298.15}^{\circ}$ values for NaCl, KCl, and KCN crystals.

Transition Data.

The transition temperatures, T_{t2} and T_{t1} , were determined by C. E. Measer and W. T. Ziegler, loc. cit. The corresponding enthalpies of transition were reported to be 0.15 and $0.70 \text{ kcal. mole}^{-1}$, respectively. However, these quantities were incorporated with C_p values used to evaluate $H^{\circ}-H_{298.15}^{\circ}$. Therefore ΔH_f° 's are not listed.

Citing Data.

see NaCN(1) table for details.

Heat Sublimation.

The difference between $\Delta H_f^{\circ} 298.15$ for $(\text{NaCN})_2(g)$ and $2\text{NaCN}(c)$ is $\Delta H_g^{\circ} 298.15$ (to dimer) and for $\text{NaCN}(g)$ and $\text{NaCN}(c)$ is $\Delta H_g^{\circ} 298.15$ (to monomer).

Dec. 31, 1960; Mar. 31, 1966

$$\Delta H_f^{298.15} = [29.996] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^{298.15} = [-20.160] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{298.15} = [2.1] \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{298.15} = [35.39] \text{ kcal. mole}^{-1}$$

$$T_m = 835^\circ \text{ K.}$$

$$T_b = [1803]^\circ \text{ K.}$$

Heat of Formation.

$\Delta H_f^{298.15}(l)$ was obtained from $\Delta H_f^{298.15}(c)$ by adding $\Delta H_m^{298.15}$ and the difference between $H_{835}^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with those for NaCN(c), KCN(c) and KCN(l). A glass transition temperature is assumed at 600°K. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature was reported by M. Truthe, Z. anorg. Chem. 76, 129 (1912). $\Delta H_m^{298.15}$ was estimated such that the derived third law value for $\Delta H_v^{298.15}$ (NaCN, l) agrees with the second law value. See NaCN(g) table for details.

Vaporization Data.

T_b is the temperature at which the free energy change for the reaction $\text{NaCN}(l) = \text{NaCN}(g)$ becomes zero. The difference between $\Delta H_f^{298.15}$ for NaCN(g) and NaCN(l) at T_b is $\Delta H_v^{298.15}$.

Heat of Formation

The vapor pressures of NaCN(l) at temperatures 805-1353°K. were measured by C. K. Ingold, J. Chem. Soc. 123, 865 (1923). According to the investigation reported by R. P. Porter, J. Chem. Phys. 35, 318 (1961), the vapor consists of NaCN and (NaCN)₂. Based on his data the dimer/monomer ratios at temperatures 805-1353°K. (1078.2-1626.2°K.) were calculated to be 0.29-0.09. Hence the respective partial pressures for NaCN(g) and (NaCN)₂(g) were derived. By the second and third law methods, the values of $\Delta H_f^{\circ} 298.15$ (1 → monomer) were evaluated to be 43.43 and 42.69 kcal. mole⁻¹, respectively. The heat of formation ($\Delta H_f^{\circ} 298.15$) for NaCN(g) was calculated from $\Delta H_f^{\circ} 298.15$ (NaCN, c) and the third law value for ΔH_v° .

Heat Capacity and Entropy

The molecular structure of NaCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was assumed to be the same as that in KCN(g) and the Na-C bond distance was taken from G. E. Lerol, Ph. D. Dissertation, Harvard University, 1961, which was calculated. The vibrational frequencies, ν_2 and ν_3 , were measured by G. E. Lerol and M. Klemperer, J. Chem. Phys. 35, 774 (1961) from infrared absorption spectra. The value of ν_1 was calculated by valence force method described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is $1.53187 \times 10^{-38} \text{ g. cm.}^2$.

Bond Angle: C-N-N = 180°

Rotational Constant: $B_0 = [0.450368] \text{ cm}^{-1}$ $\sigma = 1$

Heat of Formation.

The heat of formation is calculated from the estimated heat of reaction $\Delta H_f^{\circ} = 255 \pm 30 \text{ kcal/mol}$ for $\text{CN}(\text{g}) \rightarrow \text{C}(\text{g}) + 2\text{N}(\text{g})$. Since CN radical can dissociate to give C + N₂ or CN + N, the molecule must have more energy than either CN or N₂. It is assumed that the extra bond will be quite weak, for this we estimate $30 \pm 30 \text{ kcal/mol}$ which gives $\Delta H_f^{\circ} = 255 \pm 30 \text{ kcal/mol}$ for the first path and $\Delta H_f^{\circ} = 204 \pm 30 \text{ kcal/mol}$ for the second. We adopt the former value.

Heat Capacity and Entropy.

D. E. Milligan and M. E. Jacox, J. Chem. Phys. 44, 2850 (1966), have measured three fundamental vibrational frequencies for CN radical (g) in the infrared and ultraviolet spectra by matrix-isolation, and proposed a linear molecular configuration with a $\sum$ ground state which has been confirmed by E. Weisserman, L. Barash and W. A. Yager, J. Am. Chem. Soc. 81, 2075 (1959), in the electron paramagnetic resonance observations. Also Milligan and Jacox suggested a "C≡N-N" bond structure, based on the agreement between the C-N and N-N stretching force constants (calculated from observed vibrational frequencies in the CN radical) and the typical C≡N and N-N stretching force constants. In addition, they estimated the bond distances $r_{\text{C-N}} = 1.15 \text{ Å}$ and $r_{\text{N-N}} = 1.25 \text{ Å}$ from the proposed structure. The principal moment of inertia is $6.2148 \times 10^{-39} \text{ g cm}^2$.

Heat of Formation

The heat of formation of NCN radical (ΔH_f°) was calculated from the heat of reaction $\Delta H_r^\circ = 294 \pm 25 \text{ kcal/mol}$ for $\text{N} \rightarrow \text{N}(\text{g}) + \text{C}(\text{g})$ which was estimated as twice the C-N bond dissociation energy (147 kcal/mol). The value of C-N bond dissociation energy was derived from the heat of combustion for n-butyl-isobutylidene amine, determined by G. E. Costes and L. E. Sutton, J. Chem. Soc. 1187 (1948).

Heat Capacity and Entropy

G. Herzberg and D. N. Travis, Can. J. Phys. 42, 1658 (1964), have found NCN radical (g) is a linear symmetric molecule with a $\sum g$ ground state in the rotational spectra by a flash photolysis technique, and determined the bond distance $r_{\text{C-N}} = 1.232 \text{ Å}$ and rotational constant $B_0 = 0.3968 \text{ cm}^{-1}$ which have been adopted in the tabulation. Also the structure "N-C-N" has been suggested by Herzberg and Travis, based on the bond distance of 1.232 Å, which is in good agreement with the C-N bond length observed in the HNCO, HNCS and CH₃NCS. The principal moment of inertia is $7.0601 \times 10^{-39} \text{ g cm}^2$.

D. E. Milligan, M. E. Jacox and A. M. Bana, J. Chem. Phys. 43, 3149 (1965), have found two infrared-active vibrational fundamentals of NCN(g) at 423 and 1475 cm^{-1} in the infrared and ultraviolet spectra by a matrix-isolation method. They also estimated the symmetric stretching frequency ($\nu_1 = 808 \text{ cm}^{-1}$) by valence force calculation.

E. Wesserman, L. Barash and W. A. Yager, J. Am. Chem. Soc. 87, 2075 (1965), have confirmed the NCN radical (g) is a linear molecule with a triplet ground state by electron paramagnetic resonance.

Dec. 31, 1950; Mar. 31, 1966

$S_{298.15}^{\circ} = 33.17 \pm 0.2$ cal. deg.⁻¹ mole⁻¹
 $T_f = 723.15^{\circ}\text{K.}$
 $T_m = 1123.15^{\circ}\text{K.}$

 $\Delta H_f^{\circ} 0 = -268.79 \pm 0.05$ kcal. mole⁻¹
 $\Delta H_f^{\circ} 298.15 = -270.26 \pm 0.05$ kcal. mole⁻¹
 $\Delta H_f^{\circ} = 0.185$ kcal. mole⁻¹
 $\Delta H_m^{\circ} = 7.090$ kcal. mole⁻¹
Heat of Formation.

The heat of formation was obtained from the heat of solution $\Delta H_{\infty}^{\circ} = -6.35$ kcal. mole⁻¹ and the heats of formation for Na⁺(aq) and CO₃²⁻(aq), -57.59 and -161.84 kcal. mole⁻¹, respectively. The heat of solution was taken from J. P. Rupert, H. P. Hopkins, Jr., and C. A. Wulff, J. Phys. Chem. **69**, 3059-62 (1965). The ionic heats of formation were taken from D. M. Ginzburg, V. B. Parker, S. M. Bailey, and R. H. Schumm "Selected Values of Chemical Thermodynamic Properties" NES Technical Note 270-1, October 1, 1965.

A value of $\Delta H_f^{\circ} 298.15 = -270.9$ kcal. mole⁻¹ has been selected by D. D. Wagman, Natl. Bur. Std. Rept. No. 8628, 87, Jan. 1965.

Heat Capacity and Entropy.

The low temperature heat capacities, 54.6-292.1°K., were measured by C. T. Anderson, J. Am. Chem. Soc. **55**, 3621 (1933). In the temperature range 473.15-873.15°K. Popov and Galchenko (Source 1) measured the heat capacities (by heat conduction calorimetry) and observed two transformations, one at about 623°K. and the other at about 750°K. Popov and Ginzburg (Source 2) measured enthalpies in the temperature range 480-1350°K. and tabulated their data only in the range 476-872°K. Ginzburg (Source 3) has given heat capacity equations based on the data from Source 1 and 2 and has tabulated thermodynamic functions in the range 500-1500°K. There appear to be inconsistencies among the data, equations and functions. Rolin and Recapet (Source 4) also measured the enthalpy in the temperature range 645-1322°K. Janz, Neuenchwander and Kelly (Source 5) have given an enthalpy equation based on their heat content measured data in the range 707-1127°K. May (Source 6) has tabulated smoothed measured enthalpy values in the range 400-1500°K. All the above information was used in a Shomate analysis in order to smooth the enthalpies and calculate heat capacities. The values from the low and high temperature sources join smoothly at 298°K. The heat capacity was graphically extrapolated above the melting point.

The entropy was calculated at 54.60° using the Debye and Einstein function $D(\frac{138}{T}) + 2E(\frac{265}{T}) + 2D(\frac{73.7}{T})$ given by Anderson, loc. cit. The value of $S_{54.6}^{\circ} = 3.943$ cal. deg.⁻¹ mole⁻¹.

Transition Data.

T_f was taken from Ginzburg loc. cit. and ΔH_f° was obtained from the above reported enthalpy measurements by means of Shomate function analysis. The heat of transition at 593.15°K. has been incorporated in the heat capacity.

Melting Data.

T_m was taken from Ginzburg loc. cit. and ΔH_m° was obtained from the above reported enthalpy measurements by means of Shomate function analysis.

(LIQUID)

SODIUM CARBONATE (Na_2CO_3)

$$\begin{aligned} S_{298.15}^{\circ} &= 37.14 \pm 0.2 \text{ cal. deg.}^{-1} \text{ mole}^{-1} \\ \Delta H_f^{\circ} 298.15 &= -285.21 \pm 0.05 \text{ kcal. mole}^{-1} \\ \Delta H_m^{\circ} &= 7.090 \text{ kcal. mole}^{-1} \\ T_m &= 1123.15^{\circ}\text{K.} \end{aligned}$$

Heat of Formation.

The $\Delta H_f^{\circ} 298.15$ was obtained from $\Delta H_f^{\circ} 298.15(c)$ by adding ΔH_m° and the difference between H_m° and $H_m^{\circ} 298.15$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 723.15°K. The heat capacity below 723.15°K. was obtained from the heat capacity of the crystal. Above 723.15°K. the heat capacity was adopted as $45.30 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, based on the enthalpy measurements in the range $1127\text{--}1210^{\circ}\text{K.}$ reported by G. J. Janz, E. Neuenchwander and F. J. Kelly, Trans. Faraday Soc. 59, 841 (1963). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $\text{Na}_2\text{CO}_3(c)$ table.

Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm.⁻¹):
 α₁ = 0.0006044 X₁₁ = -4.0 A₀₀₀ = 0
 α₂ = 0.0003559 X₂₂ = -11.5 C₀₀₀ = 0
 α₃ = 0.001838 X₃₃ = -7.0 D₀₀₀ = 4.37 X 10⁻⁸
 ε₂₂ = 3.2 X₁₃ = -4.5

Heat of Formation

E. Ferrer and H. Wesemann, *Angew. Chem.* **45**, 795 (1932), report equilibrium constants from 823° to 873°K for the reaction COS(g) + H₂O(g) = COS(g) + H₂O(g). These yield ΔH_f⁰ 700 = 8.19 ± 0.23 kcal, whence ΔH_f⁰ 298.15 for COS is -33.08 ± 0.25 kcal. mole⁻¹. The same authors report equilibrium constants for the reaction COS(g) + H₂S(g) = CS₂(g) + H₂O(g), but regard these as less reliable than the others. The resulting value of -26.39 kcal. mole⁻¹ for ΔH_f⁰ 298.15 of COS has been disregarded.

Heat Capacity and Entropy

J. S. Gordon (private communication, February 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, *J. Chem. Phys.* **22**, 1442 (1954), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants have been taken from C. A. Burrus and W. Gordy, *Phys. Rev.* **93**, 897 (1954), H. J. Callomon, D. C. McKean, and H. W. Thompson, *Proc. Roy. Soc. (London)* **A208**, 341 (1951), **A222**, 431 (1954), M. W. P. Strandberg, T. Wentink, and R. L. Kuhl, *Phys. Rev.* **75**, 270 (1949), C. H. Townes, A. N. Holden, and P. R. Merritt, *Phys. Rev.* **74**, 1113 (1948), and T. Wentink, *J. Chem. Phys.* **30**, 105 (1959). The thermodynamic functions below 298.15°K have been calculated for the rigidly rotating harmonic oscillator.

Heat of Formation.

The enthalpy change (ΔH°_f 298.15) of the reaction C(c, graphite) + O₂(g) = CO₂(g) has been measured by P. H. Dewey and D. R. Harper, *J. Res. Natl. Bur. Std.* **21**, 457 (1956), R. S. Jessup, *ibid.* **21**, 491 (1956), and E. J. Prosen and F. D. Rosini, *ibid.*, **33**, 439 (1944). Based on these data, the heat of formation (ΔH°_f 298.15) for CO₂(g) was reported to be -94.0518 ± 0.0108 kcal. mole⁻¹, using molecular weight of CO₂ = 44.010, by E. J. Prosen, R. S. Jessup and F. D. Rosini, *J. Research Natl. Bur. Standards* **33**, 447 (1944). This value was recalculated to be -94.054 ± 0.011 kcal. mole⁻¹, based on molecular weight of CO₂ = 44.011, for internal consistency.

Heat Capacity and Entropy.

The functions adopted here were obtained from H. W. Woolley, *J. Research Nat. Bur. Standards* **52**, 289 (1954) who calculated the thermodynamic functions by means of a direct summation for the naturally occurring isotopic composition. The spectroscopic constants used are essentially those selected by T. Wentnik, Jr., *J. Chem. Phys.* **30**, 105 (1959). Slightly different sets of spectroscopic constants were obtained by C. P. Courtney, *Mem. soc. roy. Liège* **18**, 496 (1957) and V. R. Stull, P. J. Wyatt and O. N. Pless, *J. Chem. Phys.* **37**, 1442 (1962). The high-resolution infrared spectrum of O₁₈ - enriched CO₂ was examined in the region 5400-1620 cm.⁻¹, using an Ebert grating Spectrometer with spectral slit widths ranging from 0.4 to 0.2 cm.⁻¹ by G. V. Barney, Ph. D. Thesis, University of Washington, 1962.

The molecular structure was reported by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc. 1945. The rotational constant, B₀, was obtained from H. W. Woolley, loc. cit. The value of bond distance, r_e, was calculated from B₀ which was derived from B₀ using B_e-B₀ = 0.0011 cm.⁻¹ given in G. Herzberg, loc. cit. The principal moment of inertia is I = 7.1495 X 10⁻³⁹ g. cm.²

Heat capacities of CO₂(g) at high pressures were reported by M. P. Vukalovich, V. V. Altunin and A. N. Gureev, *Teploenergetika*, **12** (7), 56 (1965); K. Krueger, *Ver. Daut. Ingr. Z.*, **106** (32) 1620 (1964), and M. P. Vukalovich and A. N. Gureev, *Teploenergetika*, **11** (8), 80 (1964).

COS

CARBON OXIDE SULFIDE (COS)

MOL. WT. = 60.077

(IDEAL GAS)

$\Delta H_f^o = -33.11 \pm 0.25 \text{ kcal. mole}^{-1}$
 $\Delta H_f^o = -33.08 \pm 0.25 \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = 55.323 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

Vibrational Levels and Multiplicities

ω , cm. ⁻¹	ω , cm. ⁻¹
859 (1)	524 (2)
2064 (1)	2064 (1)

Rotational Constant, B₀₀₀ = 0.20287 cm.⁻¹

Ground State Multiplicity = 1

Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm.⁻¹):
 $\chi_1 = 0.0005044$ $\chi_2 = -6.8$ $\chi_3 = -11.5$
 $\chi_4 = -0.0003539$ $\chi_5 = -7.0$ $\chi_6 = -4.5$
 $\chi_7 = 0.001838$ $\chi_8 = 4.37 \times 10^{-6}$
 $\chi_9 = 3.2$

Heat of Formation

E. Terres and H. Wesemann, Angew. Chem. 45, 795 (1932), report equilibrium constants from 623° to 873°K for the reaction $\text{CO}_2(\text{g}) + \text{H}_2\text{S}(\text{g}) \rightleftharpoons \text{COS}(\text{g}) + \text{H}_2\text{O}(\text{g})$. These yield $\Delta H_f^o = 8.13 \pm 0.23 \text{ kcal.}$ whence $\Delta H_f^o = 298.15$ for COS is $-33.08 \pm 0.25 \text{ kcal. mole}^{-1}$. The same authors report equilibrium constants for the reaction $\text{COS}(\text{g}) + \text{H}_2\text{S}(\text{g}) \rightleftharpoons \text{CS}_2(\text{g}) + \text{H}_2\text{O}(\text{g})$, but regard these as less reliable than the others. The resulting value of $-26.39 \text{ kcal. mole}^{-1}$ for ΔH_f^o of COS has been disregarded.

Heat Capacity and Entropy

J. S. Gordan (private communication, February 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants have been taken from C. A. Burrus and W. Gordy, Phys. Rev. 93, 897 (1954), H. J. Callomon, D. C. McKean, and H. W. Thompson, Proc. Roy. Soc. (London) A208, 341 (1951), A222, 431 (1954), M. W. P. Strandberg, T. Wentink, and R. L. Kynl, Phys. Rev. 75, 270 (1949), C. H. Townes, A. N. Holden, and P. R. Merritt, Phys. Rev. 74, 1113 (1948), and T. Wentink, J. Chem. Phys. 30, 105 (1959). The thermodynamic functions below 298.15°K have been calculated for the rigidly rotating harmonic oscillator.

(Ideal Gas)

Heat of Formation.

The enthalpy change ($\Delta H_f^{298.15}$) of the reaction C(c, graphite) + O₂(g) = CO₂(g) has been measured by P. H. Dewey and D. R. Harper, *J. Res. Natl. Bur. Std.* **21**, 457 (1938), R. S. Jessup, *ibid.* **21**, 491 (1938), and E. J. Frosen and F. D. Rossini, *ibid.*, **33**, 439 (1944). Based on these data, the heat of formation ($\Delta H_f^{298.15}$) for CO₂(g) was reported to be -94.0518 ± 0.0108 kcal. mole⁻¹, using molecular weight of CO₂ = 44.010, by E. J. Frosen, R. S. Jessup and F. D. Rossini, *J. Research Natl. Bur. Standards* **33**, 447 (1944). This value was recalculated to be -94.054 ± 0.011 kcal. mole⁻¹, based on molecular weight of CO₂ = 44.011, for internal consistency.

Heat Capacity and Entropy.

The functions adopted here were obtained from H. W. Woolley, *J. Research Nat. Bur. Standards* **52**, 289 (1954) who calculated the thermodynamic functions by means of a direct summation for the naturally occurring isotopic composition.

The spectroscopic constants used are essentially those selected by T. Wentnik, Jr., *J. Chem. Phys.* **30**, 105 (1959). Slightly different sets of spectroscopic constants were obtained by C. P. Courtney, *Mem. acc. roy. Liège* **18**, 496 (1957) and V. R. Stull, P. J. Wyatt and O. N. Pless, *J. Chem. Phys.* **37**, 1442 (1962). The high-resolution infrared spectrum of O₁₈ - enriched CO₂ was examined in the region 5400-1620 cm⁻¹, using an Ebert grating Spectrometer with spectral slit widths ranging from 0.4 to 0.2 cm⁻¹ by C. V. Barney, Ph. D. Thesis, University of Washington, 1962.

The molecular structure was reported by O. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc. 1945. The rotational constant, B₀, was obtained from H. W. Woolley, loc. cit. The value of bond distance, r_e, was calculated from B₀ which was derived from B₀, using B₀-B₀ = 0.0011 cm⁻¹ given in G. Herzberg, loc. cit. The principal moment of inertia is I = 7.1495 × 10⁻³⁹ g. cm².

Heat capacities of CO₂(g) at high pressures were reported by M. P. Vukobratovich, V. V. Altunin and A. N. Gureev, *Teploenergetika*, **12** (7), 56 (1965); K. Krueger, *Ver. Daut. Ingr. Z.*, **106** (32) 1620 (1964), and M. P. Vukobratovich and A. N. Gureev, *Teploenergetika*, **11** (8), 80 (1964).

CARBON DIOXIDE UNEQUIVOCAL ION (CO₂⁻) (IDEAL GAS) GFW = 44.0105

Point group [C_{2v}]

S°_{298.15} = [57.5] gibbs/mol

Ground State Quantum Weight = [2]

ΔHf°₀ = [-104.1 ± 27] kcal/mol

ΔHf°_{298.15} = [-105.5 ± 27] kcal/mol

Vibrational Frequencies and Degeneracies

ω cm ⁻¹
[1400] (1)
[800] (1)
1671 (1)

Bond Distance: C-O = [1.25] Å

Bond Angle: O-C-O = 127° ± 8°

Product of the Moments of Inertia: I_AI_BI_C = [2.1296] × 10⁻¹¹⁶ g³ cm⁶

σ = [2]

Heat of Formation

The heat of formation, ΔHf°₂₉₈ (CO₂⁻, g) = -105.5 ± 27 kcal/mol, is estimated from ΔHf°₂₉₈ = 88.6 ± 10 kcal/mol for HCO₂⁻(g) → H(g) + CO₂⁻(g), using the ΔHf°₂₉₈ (HCO₂⁻, g) = -142 ± 17 kcal/mol and ΔHf°₂₉₈ (H, g) = 52.1 kcal/mol. The value of ΔHf°₂₉₈ is assumed to be the same as that for HCOOH(g) → H(g) + COOH(g). The values of ΔHf°₂₉₈ (HCOOH, g) and ΔHf°₂₉₈ (H, g), -90.5 and 52.1 kcal/mol, respectively, are from "Selected Values of Chemical Thermodynamic Properties," Natl. Bur. Std. Tech. Note 270-1, Washington, D. C., Oct. 1965, and the value of ΔHf°₂₉₈ (COOH, g), -54 ± 3 kcal/mol, is from S. W. Benson, J. Chem. Ed. 42, 502 (1965). The value of ΔHf°₂₉₈ (HCO₂⁻, g) is estimated from an approximate lattice energy calculation for sodium formate. The derived electron affinity of CO₂(g) is 11.5 kcal/mol (0.5 eV) with an estimated uncertainty range of 0-40 kcal/mol.

Heat Capacity and Entropy

The correlations of A. D. Walsh, J. Chem. Soc. 1953, 2266, predict a bent molecular structure for CO₂⁻ based on its 17 valence electrons. K. O. Hartman and I. C. Hisataune, J. Chem. Phys. 44, 1913 (1966), measured the asymmetric C-O stretching frequency and derived the bond angle of 127° ± 8° from the infrared spectrum of matrix-isolated CO₂⁻. They also estimated the bond distance C-O and the symmetric stretching and the bending vibrational frequencies by the valence force method. These molecular constants are adopted in the tabulation. The three principal moments of inertia are I_A = 0.4511 × 10⁻³⁵, I_B = 6.6491 × 10⁻³⁵ and I_C = 7.1002 × 10⁻³⁵ g cm².

D. W. Overall and D. H. Whiffen, Mol. Phys. 4, 135 (1961), have derived a bond angle of 134° which is in good agreement with the value selected. This result was obtained from electron spin resonance for the CO₂⁻ radical trapped in sodium formate.

CS

CARBON MONOSULPHIDE (CS) (IDEAL GAS)

MOL. WT. = 44.077

$$\Delta H_f^0 = 54.2 \pm 5 \text{ kcal. mole}^{-1}$$

$$\Delta H_{298.15}^0 = 55.0 \pm 5 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 50.3 \pm 0.01 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Ground State Configuration $\sum^+$

Electronic Level and Multiplicity

$$\epsilon, \text{ cm.}^{-1} \quad \frac{g_1}{g_0}$$

$$\omega_e x_e = 6.46 \text{ cm.}^{-1}$$

$$\alpha_e = 0.82005 \text{ cm.}^{-1}$$

$$r_e = 1.535 \text{ \AA}$$

Heat of Formation.

A. Lagerqvist, H. Westerlund, C. V. Wright and R. P. Barrow, Arkiv for Fysik **14**, 387 (1958) examined the UV band system of CS and made a new extrapolation of the ground state vibrational levels to find $D_0^0 = 7.85 \text{ e.v.}$, which leads to $\Delta H_f^0 \text{ CS} = 55 \pm 5.0 \text{ kcal. mole}^{-1}$. H. Scharfer and H. Wiedemeier, Paper presented at the XVIIIth IUPAC Congress Montreal (1961). have measured $\Delta H_f^0 \text{ CS} = 55 \pm 3 \text{ kcal. mole}^{-1}$ by an equilibrium method and found $58 \pm 3 \text{ kcal. mole}^{-1}$. E. Gallegos and R. W. Kiser, J. Phys. Chem. **65**, 1177 (1961) obtained a value of $\Delta H_f^0 \text{ CS(g)} = 55.0 \text{ kcal. mole}^{-1}$ from the heat of formation of CS^+ and the ionization potential of CS. C. J. Fincham and R. A. Bergman, J. Metals, **9**, 680 (1957) measured the equilibrium between CS_2 and sulphur containing ore. Combining these with similar experiments for H_2S the heat of formation of CS at 298 K is calculated to be $69.0 \text{ kcal. mole}^{-1}$. The gases assumed are CS_2 , CS, S, S_2 , H_2 , H_2S , and HS — because of the complex equilibria and the use of outside data for the H_2S equilibrium, the assumption of $P_{\text{H}_2} = 1 \text{ atm.}$ and the uncertainty in HS values, this value was given no weight.

Heat Capacity and Entropy.

A. Lagerqvist, et al., loc. cit., give the vibrational constants. The rotational constants are from the microwave measurements of R. C. Mockler and R. Bird, Phys. Rev. **98**, 1837 (1955).

Heat of Formation

W. Good and J. P. McCullough, private communication, September 21, 1960, report ΔH_f° 298.15 from analysis of combustion calorimetry data of CS₂.

Heat Capacity and Entropy

Functions at 100° and 200°K were calculated by the RRHO approximation using the fundamental vibrational levels of T. Wentink, Jr., J. Chem. Phys. 29, 188 (1958) calculated from zero order levels reported by B. P. Stoicheff, Can. J. Phys. 36, 218 (1958). S_{298.15} and C_p from 298.15° to 6000°K taken from J. S. Gordon, private communication, February 7, 1961. In addition to the fundamental levels listed above, Gordon, in his calculation of this function, used the anharmonic constants derived from high resolution Raman spectra by Stoicheff, and the vibration-rotation interaction constants reported by A. H. Guenther, T. A. Wiggins and D. H. Rank, J. Chem. Phys. 28, 682 (1958).

J. P. McCullough, private communication, February 17, 1961, has correlated and summarized the experimental thermodynamic data for CS₂ by a set of empirical equations. The result for C_p is

$$C_p (\pm 0.5\%) = 6.478 + 1.8931 \times 10^{-2} T - 1.3873 \times 10^{-5} T^2 \text{ cal. deg.}^{-1} \text{ mole}^{-1} \text{ (325-502°K.)}$$

The experimental values of C_p were then fit within 0.08% by a given set of molecular parameters different from that used by Gordon. However, in the temperature range given above, Gordon's calculation is within the uncertainty indicated by McCullough.

Since no method of calculating anharmonic corrections for polyatomic molecules has been programmed, Gordon's values were employed.

Dec. 31, 1960; Dec. 31, 1962; Mar. 31, 1967

$S^\circ_{298.15} = 3.94 \pm 0.03 \text{ gibbs/mol}$
 $T_d = [3245]^\circ \text{K}$
 $\Delta H^\circ_0 = -16.9 \pm 1.5 \text{ kcal/mol}$
 $\Delta H^\circ_{298.15} = -17.1 \pm 1.5 \text{ kcal/mol}$

Heat of Formation.

The heat of formation is calculated from $\Delta H^\circ_{298} = -591.9 \text{ kcal/mol}$ for $\text{SiC}(\alpha) + 4\text{F}_2(\text{g}) \rightarrow \text{SiF}_4(\text{g}) + \text{CF}_4(\text{g})$ based on the tentative value of $\Delta H^\circ_{298} = -223.1 \text{ kcal/mol}$ for $\text{CF}_4(\text{g})$. Greenberg¹ determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey² obtained by oxygen bomb calorimetry yield a ΔH° which is over 2 kcal more negative; however, this difference is probably within the uncertainty due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained mass spectrometrically by Drowart³ are in close agreement with the selected ΔH° , but Knudsen weight loss data of Orievason⁴ and solubility-activity data of Kirkwood⁵ yield values less negative by 2 and 3 kcal, respectively. The results are summarized below.

The data of Drowart show a significant drift while those of Orievason do not, but the latter should be corrected for $\text{C}_2\text{Si}(\text{g})$ and $\text{CSi}_2(\text{g})$ which are present in amounts of about 4 and 3%, respectively, at 2000°K. Silicon carbide may have a small vaporization coefficient, since rates of free evaporation reported by Voronin⁶ and Ghoastagore⁷ yield apparent pressures which are smaller by factors of 1/50 to 1/1000.

Source	Method	Reaction	Range, °K	No. of Points	ΔH°_{298} (kcal/mol)	Drift ΔH°_{298} (eu)
Greenberg (1966)	F_2 Calorimetry	A	298	1	-591.9	-17.1

Drowart (1958)	Mass Spec.	C	2149-2316	7	136.9±0.7	124.61 -5.6±0.3
Orievason (1960)	Knudsen Wt. Loss	C	1785-2004	10	122.9±0.7	122.66 -0.2±0.4
Kirkwood (1961)	Sol. in Pb	D	1693	1	25.66	-14.1
A) $\text{SiC}(\alpha) + 4\text{F}_2(\text{g}) \rightarrow \text{SiF}_4(\text{g}) + \text{CF}_4(\text{g})$						
B) $\text{SiC}(\alpha) + 2\text{O}_2(\text{g}) \rightarrow \text{SiO}_2(\text{low-qtz}) + \text{CO}_2(\text{g})$						
*Value in parentheses is based on authors' data for $\text{Si}(\text{l}) \rightarrow \text{Si}(\text{g})$ rather than JANAF value.						

Heat Capacity and Entropy.

Low temperature heat capacities are from data (54-296°K) of Humphrey² and are in good agreement with earlier data (54-295°K) of Kelley⁸. The entropy is obtained from Op° using $S^\circ_{50} = 0.038 \text{ eu}$. Op° above room temperature is based on enthalpy data of Humphrey² [389-1789°K], Walker⁹ [373-1073°K] and Magna¹⁰ [372-1172°K]. Maximum deviations of the data from the selected values are 1.4, 2 and -1.7%, respectively; these occur in the range 370-621°K. Kirklin¹¹ obtained enthalpy data (1114-2843°K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.7% iron impurity, these data deviate by -1.1-5% from the selected values. Enthalpies (793-1790°K) of Fieldhouse¹² are high by 1-8% while those of Makaimenko¹³ were not available for analysis.

Transition Data.

$\text{SiC}(\alpha)$, also called hexagonal II or 6H, is one of the more common of many hexagonal forms which arise from various possible stacking sequences of the hexagonal SiC layers¹⁴. The properties of these phases are so similar that they have not been adequately differentiated thermodynamically. It has frequently been assumed that cubic $\text{SiC}(\beta)$ transforms to α at about 2300°K, but this seems unlikely since both phases have been prepared over temperature ranges of 1700-3000°K.¹⁴ Heat of formation and equilibrium data indicate that α is less stable up to 2000°K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data.

The decomposition temperature is calculated as the value at which the total pressure reaches one atm for vapor containing of $\text{C}_2\text{Si}(44.3 \text{ mol } \%)$, $\text{Si}(32.0\%)$, $\text{CSi}_2(21.2\%)$, $\text{Si}_2(1.9\%)$, $\text{CSi}(0.7\%)$, and $\text{Si}_3(0.25\%)$. The tables predict decomposition to graphite and pure liquid silicon at about 3280°K; however, Sease¹⁵ observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103±40°K. In contrast, Dolloff¹⁶ reported the peritectic at 2813±40°K and 27 percent carbon. Badami¹⁷ has shown that decomposition in vacuum at lower temperatures (2400°K) leads to graphite.

Mar. 31, 1967

$\Delta H^\circ_{298} = -17.3 \pm 1.5$ kcal/mol
 $\Delta H^\circ_{298,15} = -17.5 \pm 1.5$ kcal/mol

$S^\circ_{298,15} = 3.97 \pm 0.03$ gibbs/mol
 $T_d = [3259]^\circ K$

Heat of Formation.

The heat of formation is calculated from $\Delta H^\circ_{298} = -591.5$ kcal/mol for $SiC(\beta) + 4P_2(g) \rightarrow SiP_4(g) + 4C(s)$, based on the tentative value of $\Delta H^\circ_{298} = -223 \pm 1$ kcal/mol for $CP_4(g)$. Greenberg¹ determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey² obtained by oxygen bomb calorimetry yield a ΔH° which is over 3 kcal more negative; however, this difference is probably within the uncertainties due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained with the Knudsen weight loss method by Davis³ are in good agreement with the selected ΔH° , but similar data of Oriveason⁴ and solubility-activity data of Rein⁵ and d'Entremont⁶ yield values less negative by 1.6 to 2.5 kcal. The results are summarized below. Other equilibrium data⁵ relating SiC and SiO₂ are not included, pending the revision of tables for SiO₂.

The data of Davis show a serious drift, while those of Oriveason do not; but the latter should be corrected for $C_2Si(g)$ and $CSi_2(g)$ which are present in amounts of about 4 and 3%, respectively, at 2000°K. Silicon carbide may have a small vaporization coefficient, since rates of free evaporation reported by Voronin⁷ and Ohoatagore⁸ yield apparent pressures which are smaller by factors of 1/30 to 1/10000.

Source	Method	Reaction	Range, T°K	No. of Points	ΔH°_{298} (kcal/mol)	Drift (eu)	ΔH°_{298} (kcal/mol)

A) $SiC(\beta) + 4P_2(g) \rightarrow SiP_4(g) + 4C(s)$							
B) $SiC(\beta) + 2O_2(g) \rightarrow SiO_2(\text{low quartz}) + CO_2(g)$							
C) $SiC(\beta) \rightarrow C(\text{graph}) + Si(g)$							
D) $SiC(\beta) \rightarrow C(\text{graph}) + Si(l)$							

*Value in parentheses is based on author's data for Si(l) $\rightarrow$ Si(g) rather than JANAF value.

Heat Capacity and Entropy.

Low temperature heat capacities are from data (54-296°K) of Humphrey². The entropy is obtained from Op° using $S^\circ_{298} = 0.041$ eu. Op° above room temperature is based on Humphrey's enthalpy data (389-1693°K), which show a maximum deviation of $\pm 1.5\%$ from the selected functions. Humphrey's sample contained about 1% of α -SiC and about 0.6% of other impurities. Kirillin⁹ obtained enthalpy data (1114-2843°K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.73% iron impurity, these data deviate by $\pm 1.2\%$ from the selected values.

Transition Data.

$SiC(\beta)$, also called cubic or 3C, has a structure of the diamond or zinc blende type¹⁰. The cubic phase differs from the many hexagonal forms only in the order of the stacking sequence of the hexagonal SiC layers. It has frequently been assumed that β transforms into α at about 2300°K, but this seems unlikely, since both phases have been prepared over temperature ranges of 1700-3000°K¹¹. Heat of formation and equilibrium data indicate that β is more stable up to 2000°K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data.

The decomposition temperature is calculated as the value at which the total pressure reaches one atm for vapor con-
sisting of $C_2Si(45.4 \text{ mol } \%)$, $Si(32.1\%)$, $CSi_2(20.1\%)$, $Si_2(1.8\%)$, $CSi(0.28\%)$ and $Si_3(0.23\%)$. The tables predict decomposition to graphite and pure liquid silicon at about 3337°K; however, Seacell¹¹ observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103-40°K. In contrast, Dolloff¹² reported the peritectic at 2813-40°K and 27 percent carbon.

Heat of Formation.

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibrium over the systems SiC-graphite¹ and boron-silicon-graphite². Third law analysis of the partial pressures of Si and C yields the results summarized below. The adopted value, $\Delta H_f^\circ = 172 \pm 8$, is the mean of the two results and the uncertainty reflects the possible effect of an error of up to 4 eu in the functions. The corresponding dissociation energy is $D_0^\circ = 106.5 \pm 8 \text{ kcal/mol}$.

*For the reaction C(graphite) + Si(g) = SiC(g)

Heat Capacity and Entropy.

The ground state is assumed to be $1^1\Sigma$, as suggested by Weltner and McLeod³. By analogy with C_2 , there should be a low-lying 3Π excited state; this would dominate the thermodynamic functions at temperatures above 2000°K if the level lies below 5000 cm^{-1} . The 3Π level is assumed to lie at 1000 cm^{-1} , intermediate between the value⁴ observed for C_2 and that estimated for Si_2 (see JANAF table). Additional excited states, 3Σ , 1Π , 1Δ and $1^3\Sigma$, are estimated by comparison with those observed or predicted⁵ for C_2 . The estimates for the electronic levels are relatively uncertain and probably yield an upper limit for the entropy at temperatures where SiC(g) is significant. A probable lower limit for the electronic contribution may be obtained by increasing the 3Π level to 7000 cm^{-1} and omitting the other excited states. This would reduce the entropy by 3.5 and 2.0 eu at 2000 and 4000°K.

The vibrational frequency is that estimated by Weltner³ from a valence bond calculation using $k = 7.44 \times 10^5 \text{ dyn/cm}$ obtained from C_2Si . The constants $w_e x_e$, α_e and r_e are estimated by interpolation between those ^{6,4} for the $1^1\Pi_u$ states of Si_2 and C_2 . Use of constants based on the 3Π state is consistent with the assumption that this state dominates the electronic partition function at high temperatures. B_e is calculated from r_e .

Heat of Formation

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the SiC-graphite¹, SiC-silicon² and boron-carbon-silicon³ systems. Third law analysis of the partial pressures of CSi₂ and Si yields the concordant values 127.4, 127.9 and 128.6 kcal/mol. Two of the drifts are rather large, but they are opposite in sign so that no consistent entropy difference is apparent between the data and the tabulated functions. The drifts may be related to the low condensation coefficient for CSi₂ suggested by Drowart¹. Rates of free evaporation reported by Voronin⁴ yield apparent pressures which are lower by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of $\Delta H_f^\circ = 128 \pm 6 \text{ kcal/mol}$ includes allowance for an error in the entropy of up to 3 eu.

A) C(graph) + 2 Si(g) = CSi ₂ (g)							
B) SiC(α) + Si(l) = CSi ₂ (g)							

Heat Capacity and Entropy

Weltner and McLeod⁵ observed a band system in absorption at 5300 Å in matrix isolation and assigned this tentatively to the transition ${}^1\Pi_u - X\Sigma_g^+$ of CSi₂. This assignment is adopted, although the evidence is not at all conclusive. A ${}^3\Pi_u$ excited state is assumed to lie at 12000 cm⁻¹, presumably arising from the same molecular orbital configuration as the ${}^1\Pi_u$ state. A linear, symmetric structure is assumed, as suggested by Weltner. The bond distance is estimated by comparison with Si₂, C₂ and C₃. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 7.46 \times 10^5$ and $k_2/k_1 = 0.11 \times 10^5 \text{ dyn/cm}$. The stretching force constant is taken from C₂Si₂, while the bending force constant is from C₂Si and the ${}^1\Pi_u$ excited state of C₃. The moment of inertia is $28.56 \times 10^{-39} \text{ g cm}^2$.

TITANIUM CARBIDE (TiC)

(CRYSTAL)

GFW = 59.91115

 $\Delta H_f^\circ = -43.7 \pm 1$ kcal/mol $\Delta H_f^\circ_{298.15} = -44.0 \pm 1$ kcal/mol $\Delta H_m^\circ = [17]$ kcal/mol $S^\circ_{298.15} = 5.79 \pm 0.05$ gibbs/mol $T_m = 3290 \pm 15^\circ K$

Heat of Formation

The adopted $\Delta H_f^\circ_{298}$ is derived from $\Delta H_f^\circ_{298} = -275.72$ kcal/mol for reaction (a) determined by Humphrey (1) who burned TiC(c) in an oxygen bomb calorimeter. The author reported that the combustion product TiO_2 was >95 per cent rutile and <5 per cent anatase, the heat of formation is calculated assuming the above distribution. The uncertainty adopted is due mainly to the uncertainty in TiO_2 (rutile).

Using atomic absorption spectroscopy Vidale (2) determined that the pressure (log $P_{Ti} = -7.269$) of Ti(g) at 1666°K was equal to the pressure of TiC(c) at 2220°K. Using this data for reaction (b) we obtain a $\Delta H_f^\circ_{298} = -43.02$ kcal/mol. Lowell and Williams (3) measured the ΔH_f° of TiC(c) directly using a high temperature calorimeter, which reduces to $\Delta H_f^\circ_{298} = -37.7 \pm 4$ kcal/mol.

Fujishiro and Gokcen (4) determined the equilibrium pressure of Ti(g) in reaction (d) in the temperature range 2383-2593°K. Third law analysis of the data yields a $\Delta H_f^\circ_{298} = -31.6$ kcal/mol. Brantley and Beckman (5) measured equilibrium pressures of CO for reaction (e) in the temperature range 1276 - 1428°K. Third law analysis of the data yields a $\Delta H_f^\circ_{298} = -61.9$ kcal/mol.

Heat Capacity and Entropy

Low temperature heat capacities (55 - 295°K) have been taken from Kelley (6). Naylor (7) measured heat contents from 360 to 1738°K and Levinson (8) from 1274 to 2799°K. High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 2799°K the heat capacity is graphically extrapolated. The entropy is based on $S^\circ_0 - S^\circ_0 = 0.065$ eu.

Melting Data

See liquid table.

TITANIUM CARBIDE (TiC)

(LIQUID)

GFW = 59.9115

$$S_{298.15}^\circ = [11.329] \text{ gibbs/mol}$$

$$\Delta H_{298.15}^\circ = [-25.892 \pm 1] \text{ kcal/mol}$$

$$\Delta H_m^\circ = [17] \text{ kcal/mol}$$

$$T_m = 3290 \pm 15^\circ \text{K}$$

Heat of Formation

The heat of formation is obtained from $\Delta H_{298}^\circ(\text{c})$ by adding ΔH_m° and the differences between H_{298}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200°K the heat capacity is obtained from that of the crystal, above 2200°K it is assumed constant and estimated as 15 gibbs/mol or 7.5 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The adopted T_m is taken from the phase diagram of the system Ti-C, at the composition 50% Ti and 50% C, reported by E. Rudy and D. P. Harmon, Aerojet-General Corporation, BSP No. 64-6699-735001, Contract AF-33(611), April 1, 1965. Earlier reports by E. Friederich and L. Sittig, Z. Anorg. Chem. 144, 171(1925) and C. Agte and K. Moers, Z. Anorg. Chem. 193, 233 (1931), gave a T_m of 3430 $\pm$ 100°K and 3410 $\pm$ 90°K, respectively. ΔH_m° is derived from an estimated $\Delta S_m = 2.5$ gibbs/g-atom, as suggested by O. Kubaschewski, E. L. Evans and C. B. Alcock, "Metallurgical Thermochemistry," Pergamon Press, New York, 1957.

MOL. WT. = 103.231

(CRYSTAL)

ZIRCONIUM CARBIDE (ZrC)

$$\Delta H_f^0 = -46.8 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = -47.0 \pm 3 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = [19] \text{ kcal. mole}^{-1}$$

$$T_m = 3805 \pm 125^\circ \text{K}$$

$$S_{298.15}^0 = 7.964 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Heat of Formation.

ΔH_f^0 298.15 = -47.16 ± 1.5 kcal. mole⁻¹ was calculated from the standard free energy of formation of -38.9 ± 1.5 kcal. mole⁻¹ at 2875°K. reported by B. D. Pollock, J. Phys. Chem. **65**, 733 (1961). Using spectrophotometric data reported by G. L. Vidale, Missile and Space Vehicle Department, General Electric R61SD147, August, 1961, we calculated ΔH_f^0 298.15 = -46.9 ± 1 kcal. mole⁻¹. These values were averaged with ΔH_f^0 298.15 = 47.0 ± 0.6 kcal. mole⁻¹ reported by A. D. Mah, U. S. Bureau of Mines RI6518 (1964). The equilibria data reported by C. H. Prescott Jr., J. Am. Chem. Soc. **49**, 2534 (1926) and V. A. Epel'baum, Doklady Akad. Nauk SSSR **104**, 567 (1955) were considered but not used.

Heat Capacity and Entropy.

Heat content data over the range 470.8° to 1,174.4°K. were taken from a preliminary report by R. Mezaki, T. P. Jambois, A. K. Gungoradhyay, and J. L. Margrave, Univ. of Wisconsin, Madison, Wisconsin, "Thermodynamic Properties of Inorganic Substances VIII. The High Temperature Heat Contents of Zirconium Carbide and Tantalum Carbide". These data were smoothed by means of the Shomate plot into low temperature data reported by E. F. Westrum Jr. and G. Peick, J. Chem. Eng. Data, **8**, 176 (1963). High temperature data reported by D. S. Neel, C. D. Peers, S. Ogleby Jr., Southern Research Institute, Birmingham, Alabama, Technical Documentary Report No. WADD 60-924, p. 134, February 1962, and R. A. McDonald, P. L. Oettinger, and H. Prophet, CPFA Publication No. 44(u), p. 213, February 1964 were then used to obtain the heat capacity above 1174°K.

Melting Data.

Melting points were measured by C. Agte and H. Alvertum, Z. tech. Physik **11**, 182 (1930) and E. Friederich and L. Sittig, Z. Anorg. Chem., **144**, 169 (1925). The value of 3805 ± 125°K. by Agte and Alvertum was chosen. Friederich and Sittig obtained a measurement of 3300°K. but estimated 3500°K. because of the clouding formation of ZrO₂. Wayne L. Worrell, J. Phys. Chem., **68**, 954 (1964) quoted a value of 3480°K. taken from E. K. Storms, Los Alamos Scientific Lab Report LAMS-2674, (1962). The heat of melting is derived from an estimated $\Delta S_m = 2.5 \text{ cal. deg.}^{-1} \text{ gm. atom}^{-1}$.

Zirconium Carbide (ZrC)

CZr

(Liquid) Mol. Wt. = 103.231

MOL. WT. = 103.231

(LIQUID)

ZIRCONIUM CARBIDE (ZrC)

$$S_{298.15}^{\circ} = [12.815] \text{ cal. deg.}^{-1} \text{ mole}^{-1} \quad \Delta H_f^{\circ} 298.15 = [-29.39] \text{ kcal. mole}^{-1}$$

$$T_m = 3805 \pm 125^{\circ}\text{K.} \quad \Delta H_m^{\circ} = [19] \text{ kcal. mole}^{-1}$$

Heat of Formation.

$\Delta H_f^{\circ} 298.15$ (1) was obtained from $\Delta H_f^{\circ} 298.15(c)$ by adding ΔH_m° and the difference between $\Delta H_{Tm}^{\circ} - H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

$C_p(1)$ at and below 2500°K. were assumed to be equal to those of $\text{ZrC}(c)$. Above 2500°K. the heat capacity was estimated to be constant. $S_{298.15}(1)$ is calculated based on $S_{298.15}(c)$ and an estimated $\Delta S_m^{\circ} = 2.5 \text{ cal. deg.}^{-1} \text{ g. atom}^{-1}$.

Melting Data.

See ZrC(c) table for details.
