Heat Capacity and Entropy.

Smoothed heat capacities between 3° and 270°K. have been presented by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) **242A**, 467 (1957). Above 270°K. the heat capacity was obtained by comparing with KI(c) on a reduced temperature plot of C_p/T versus T . The values so obtained were increased by 1.4% to bring them into line with the low temperature data.

Melting Data.

A. Dworkin and M. Bredig, J. Phys. Chem. **64**, 269 (1960) have measured both T_m and ΔH_m .

Sept. 30, 1963

 $S_{298.15}^{\circ} = 28.862 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^{\circ} 298.15 = -63.695 \text{ kcal. mole}^{-1}$ $\Delta H_m = 5.64 \text{ kcal. mole}^{-1}$ $T_m = 933^{\circ}\text{K.}$ $T_b = 1577^{\circ}\text{K. (equilibrium mixture)}$

Heat of Formation.

$\Delta H_f^{\circ} 298.15$ was calculated from the heat of formation of the crystal plus the heat of melting and the difference between $H_{933}^{\circ} - H_{293}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p was estimated assuming each atom contributed $7/5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. $S_{298.15}^{\circ}$ was calculated in a manner similar to $\Delta H_f^{\circ} 298.15$.

Melting Data.

See table for crystal.

Vaporization Data.

The boiling point is that given by K. K. Kelley, U. S. Bureau of Mines Bulletin 363, 1955 from examination of the high temperature vapor pressure.

α_e = [0.00000] cm.⁻¹

σ = 1

Heat of Formation. ΔH_f⁰ 298.15 was calculated from the dissociation energy of PbI(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and ω_ex_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by comparison with the corresponding values for the other diatomic halide molecules. Electronic levels and multiplicities were estimated from those for Pb(g).

Titanium Monoiodide (TiI)
(Ideal Gas) GFW = 174.8044

Heat of Formation

The heat of formation, $\Delta H_{f,298}^\circ$ of TiI (g) is calculated from the dissociation energy, D_0° , which is estimated as 73 kcal/mol. This estimate is obtained from the relation $D(\text{TiI}) < D^\circ(\text{TiI}) < D^\circ(\text{TiI})$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF₂(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e , and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of Ti⁺ (3). σ_e is estimated from the Morse potential function.

Sept. 30, 1964

$$\Delta H_f^0 = [141.8 \pm 10.0] \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = [141.3 \pm 10.0] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = [65.87] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

<u>Electronic Levels and Multiplicities</u>		
ϵ	cm.^{-1}	g_i

$$\omega_e x_e = [1.2] \text{ cm.}^{-1}$$

$$\alpha'_e = [0.00020] \text{ cm.}^{-1}$$

$$r_e = [2.9] \text{ \AA}$$

Heat of Formation

The dissociation energy was estimated from a correlation of the JANAF values for TiCl(g) , TiI(g) , and ZrCl(g) . The resulting value, 29.7 kcal. mole⁻¹, was employed with auxiliary JANAF heats of formation for Zr(g) and I(g) in calculating $\Delta H_f^{298.15}$.

Heat Capacity and Entropy

The vibrational frequency was estimated from those of TiI(g) , TiCl(g) , and the alkali halides. The ground state configuration was assumed to be analogous to the ground term of TiCl(g) as given by E. A. Shenoyakaya, et al., Optics and Spectroscopy, 12, 359 (1962). The internuclear distance was estimated from those of TiBr(g) , TiI(g) and ZrI(g) .

September 30, 1961

IODINE (I₂)

(REFERENCE STATE)

MOL. WT. = 253.82

0°K to 386.75°K Crystal
386.75°K to 458.59°K Liquid
458.59°K to 8000°K Ideal Diatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

The recent measurements of D. A. Shirley and W. P. Giauque [J. Am. Chem. Soc. 81, 4778 (1959)] over the temperature range 13° to 327°K are adopted, no weight being given to the earlier work of E. Lange [Z. physik. Chem. 110, 343 (1924)], which deviate by 1% or more. L. G. Carpenter and T. P. Harle [Phil. Mag. 23, 193 (1937)] measured the heat capacity of crystalline and liquid iodine by an adiabatic method. Their data are in poor agreement with Shirley and Giauque in the range 275° to 330°K and are given no weight. K. J. Frederick and J. H. Hildebrand [J. Am. Chem. Soc. 80, 1436 (1958)] measured the enthalpy of crystalline and liquid iodine relative to 298°K by the method of mixtures. For calibration they used a slug of copper. The enthalpy of copper which they used now appears to be too high [K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960)]. The results of Frederick and Hildebrand were corrected by a factor which varied linearly from zero at 300°K to 0.995 at 400°K and 0.990 at 500°K. These corrected enthalpies and the heat capacities of Shirley and Giauque above 298°K were used to derive the equations for crystalline iodine:

$$H_f - H_{298} = -12.1048 T + 0.029506 T^2 - 6.686 \times 10^{-5} T^{-1} + 3228.65$$

$$C_p = -12.1048 + 0.059012 T + 6.686 \times 10^{-5} T^{-2}$$

Heat Capacity of Liquid, Melting Point, and Heat of Melting.

For the liquid, the corrected results of Frederick and Hildebrand give:

$$H_f - H_{298} = 19.281 T - 2516.5$$

$$C_p = 19.281$$

The melting point given by Frederick and Hildebrand is 113.6°C. The difference in the heat content equations at the melting point gives the heat of melting as 3706.7 cal. mole⁻¹.

Heat of Sublimation, Ideal Gas Functions.

See tables for ideal gases for details.

ΔH_f^o 298 = +3.232 kcal. mole⁻¹
S₂₉₈^o = 35.936 cal. mole⁻¹ deg⁻¹
ΔH_m^o = 3708.7 cal. mole⁻¹
ΔH_v^o = 10025.5 cal. mole⁻¹

T_m = 386.75°K
T_b = 458.39°K

Heat of Formation.

Obtained as the heat of fusion calculated to 298.15°K by adding H_{386.75}-H_{298.15} for solid and subtracting H_{386.75}-H_{298.15} for liquid.

Heat Capacity.

The liquid heat capacity of 19.281 cal. mole⁻¹ deg⁻¹ derived from the data of Fradrick and Hildebrand (see Reference State) was extrapolated back to 298.15°K and up to 1000°K.

Entropy.

The value at 400°K calculated for the reference state was back calculated to 298.15°K by means of the constant heat capacity of 19.281 cal. mole⁻¹ deg⁻¹.

Vaporization.

See ideal gas tables for details.

IODINE, DIATOMIC (I₂) (IDEAL GAS)

MOL. WT. = 253.82

$$\Delta H_f^0 = 15.66 \pm 0.1 \text{ kcal. mole}^{-1}$$

$$\Delta F_f^0 = 14.924 \text{ kcal. mole}^{-1}$$

$$S_{298}^0 = 62.281 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$\omega_e = 214.52 \text{ cm.}^{-1}$$

$$\omega_e x_e = 0.6133 \text{ cm.}^{-1}$$

$$D_e = 0.455 \times 10^{-8} \text{ cm.}^{-1}$$

$$\alpha_e = 0.001206 \text{ cm.}^{-1}$$

$$\sigma = 2$$

Thermodynamic Functions.

The molecular constants are from the work of D. H. Rank and W. M. Baldwin [J. Chem. Phys. **19**, 1210 (1951)] with a revised value of $\omega_e = 214.52$ as given by R. D. Verma [J. Chem. Phys. **32**, 738 (1960)]. The value of $\omega_e x_e$ has been adjusted to allow for the dropping of higher order corrections not used in the computer program. The calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards **55**, 147 (1955)], who used very slightly different constants. L. Mathieson and A. L. O. Rees [J. Chem. Phys. **25**, 753 (1956)] give further refinements to the spectroscopic data which are negligible for our purpose. Their ω_e is also slightly low since it is based on Rank and Baldwin.

Heat of Formation.

The heat of sublimation of iodine was calculated from published vapor pressure data as follows, using thermodynamic functions of condensed and gaseous phases described above.

	ΔH_f^0 , kcal. mole ⁻¹
Baxter, Hickey, and Holmes ¹ (273° to 328°K)	15.657 ± .004
Baxter and Orsa ² (323° to 358°K)	15.657 ± .002
Ramsay and Young ³ (solid) (331° to 386°K)	15.871 ± .018
Ramsay and Young ³ (liquid) (386° to 454°K)	15.876 ± .007
Haber and Kerschbaum ⁴ (225° to 283°K)	15.765 ± .012
Ollieple and Fraser ⁵ (303° to 333°K)	15.655 ± .005
Skiyarenko, Markin, and Balyaeva ⁶ (293° to 303°K)	15.813
Neumann ⁷ (as given by Haber and Kerschbaum) (232° to 292°K)	15.899 ± .034
Wiedemann ⁸ (393° to 453°K)	15.635 ± .008
Breune and Stresemann ⁹ (305° to 358°K)	15.635 ± .012
Arctowski ¹⁰ (288° to 345°K)	15.623 ± .080
Wright ¹¹ (352° to 372°K)	15.659 ± .003
Dewar ¹² (273° to 303°K)	15.821 ± .103
Richter ¹³ (358° to 383°K)	15.639 ± .043

The uncertainties given are the average deviation from the mean. The data of Breune and Stresemann are as recalculated by Gerry and Ollieple¹⁴. The data of Haber and Kerschbaum appear systematically too high. The results of Skiyarenko, et al., Neumann, Arctowski, Dewar, and Richter are scattered and are not given any weight. A weighted average of the remaining data yield $\Delta H_f^0 = 15.66 \pm 0.01$ kcal. mole⁻¹, which calculates to $\Delta H_{298}^0 = 14.924$ cal. mole⁻¹.

Dec. 31, 1961 June 30, 1967

POTASSIUM IODIDE, DIMERIC (K_2I_2) (IDEAL GAS)

Point Group (D_{2h})

$S^\circ_{298.15} = [94.61 \text{ gibbs/mol}]$

Ground State Quantum Weight = [1]

$\Delta H^\circ_0 = -99.5 \pm 1 \text{ kcal/mol}$

$\Delta H^\circ_{298.15} = -100.9 \pm 1 \text{ kcal/mol}$

Vibrational Frequencies and Degeneracies

ω , cm^{-1}	ω , cm^{-1}
[90] (1)	[80] (1)
[60] (1)	[105] (1)
[110] (1)	[120] (1)

Bond Distance: K-I = [3.29] Å

Bond Angles: K-I-K = [75°] I-K-I = [105°]

Product of the Moments of Inertia: $I_{A-B-C} = [5.041 \times 10^{-11}] \text{ g}^2 \text{ cm}^6$

$\sigma = [4]$

Heat of Formation

The chemical equilibrium for the reaction $K_2I_2(g) = 2KI(g)$ has been studied by S. Datz, ORNL-2933, Oak Ridge, Tenn., 1960, and S. Datz, W. T. Smith, Jr. and E. H. Taylor, J. Chem. Phys. 34, 598 (1961). They measured the temperature dependence of the molecular weight of $KI(g)$ which was determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. Based on the reported P-V-T measurements, the enthalpy change of the reaction at 298°K is evaluated by the second and third law methods. The results are given in the table below.

R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956), determined the molecular composition of KI vapor by measurement of the velocity distribution of the molecules in the beam produced as the vapor effused through a small slit in a source. The analysis was based on an assumption that the velocity distribution within the oven is Maxwellian and that the vapor effuses through the ideal slit of kinetic theory. The velocity distributions of potassium and thallium atomic beams were found to be in excellent agreement with the theoretical distributions, so the determination of the molecular composition of KI beams was tried. Using the derived equilibrium constants, we calculate the enthalpy change of the dissociation reaction by the second and third law methods. The results are presented in the following table.

The value of $\Delta H^\circ_{298}(K_2I_2, g)$ is adopted as $-100.9 \pm 1 \text{ kcal/mol}$.

Investigator	Temperature, °K	No. of Points	ΔH°_{298} , kcal/mol	Drift, eu	ΔH°_{298} , kcal/mol
Datz	1228-1395	10	40.0840.82	40.66	-100.86
	1292-1408	6	41.3741.91	41.01	-101.01
Miller-Kusch	816-921	10	54.6222.46	36.28	-98.78

Heat Capacity

The molecular structure and bond distance and angles were estimated by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958). The vibrational frequencies are estimated by comparison with those calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), and adjusted to give good agreement between second and third law evaluations of the equilibrium data. The three principal moments of inertia are: $I_A = 5.194 \times 10^{-39}$, $I_B = 2.866 \times 10^{-37}$ and $I_C = 3.386 \times 10^{-37} \text{ g cm}^2$.

I_2K_2

Lithium Iodide, Dimeric (Li_2I_2)
(Ideal Gas) $\text{GFW} = 267.6868$

I_2Li_2

$\text{OPW} = 267.6868$

(IDEAL GAS)

LITHIUM IODIDE, DIMERIC (Li_2I_2)

Point Group D_{2h}
 $S_{298.15}^\circ = [79.0] \text{ g/bbs/mol}$
Ground State Quantum Weight = 1
 $\Delta H_f^\circ = -85.3 \pm 4 \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = -86.5 \pm 4 \text{ kcal/mol}$

Vibrational Frequencies and Degeneracies

ω , cm^{-1}	ω , cm^{-1}
[166](1)	[310](1)
[160](1)	248 (1)
[383](1)	375 (1)

Bond Distance: $\text{Li-I} = 2.54 \text{ \AA}$ $\text{Li-Li} = 2.71 \text{ \AA}$
Bond Angle: $\text{I-Li-I} = 116^\circ \pm 4^\circ$
Product of the Moments of Inertia: $I_A I_B I_C = 1.63429 \times 10^{-112} \text{ g}^3 \text{ cm}^6$

$\sigma = 4$

Heat of Formation

This was obtained from the heat of formation of the crystal and the heat of sublimation of the dimer, which derivation has been given in the LiI(g) table.

Heat Capacity and Entropy

J. Berkowitz, J. Chem. Phys. 29, 1366 (1958), 32, 1519 (1960), has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 85, 4544 (1964). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by P. A. Akishin and N. G. Rambidi, Z. Physik Chem. 213, 111 (1960). The bond distances ($\text{Li-Li} = 2.712 \text{ \AA}$ and $\text{I-I} = 4.520 \text{ \AA}$) calculated by Berkowitz are in good agreement with those from Akishin and Rambidi. The three principal moments of inertia are $I_A = 4.2152 \times 10^{-39}$, $I_B = 194.8074 \times 10^{-39}$ and $I_C = 199.0226 \times 10^{-39} \text{ g cm}^2$.

S. H. Bauer, T. Ito and R. F. Porter, J. Chem. Phys. 33, 685 (1960), have estimated six vibrational frequencies (501, 501, 148, 200, 294, 360 cm^{-1}) for $\text{Li}_2\text{I}_2(\text{g})$ in the electron diffraction studies of the $\text{Li}_2\text{Cl}_2(\text{g})$. W. Klemperer and W. O. Norris, J. Chem. Phys. 33, 1071 (1961), have observed two fundamental vibrational frequencies (248 and 375 cm^{-1}) in the infrared spectrum and tentatively assigned them as E_{2u} and E_{3u} modes; these have been adopted in the table below. The remaining four vibrational frequencies were obtained from J. Berkowitz, loc. cit., because his model and derivation are self-consistent.

Lead Diiodide (PbI₂) (crystal)

Mol. Wt. = 461.03

ΔH_f^o 298.15 = -41.86 ± 0.06 kcal. mole⁻¹

S_{298.15}^o = 41.869 cal. deg.⁻¹ mole⁻¹

ΔH_f^o 298.15 = 41.70 ± 0.10 kcal. mole⁻¹

T_m = 680°K.

ΔH_m^o = 3.87 kcal. mole⁻¹

Heat of Formation. Calculated from the data reported by H. Braune and F. Koref, Z. anorg. Chem., 87, 175 (1914) and R. H. Gerke, J. Am. Chem. Soc., 44, 1664 (1922).

Heat Capacity, Entropy, and Melting Data. Cp (10° to 298.15°K.) obtained from Edgar F. Westrum, Jr., University of Michigan, Ann Arbor, Michigan, private communication, May, 1951. Above 298.15°K., Cp given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation. T_m and ΔH_m^o reported by W. Blanc and G. Petit, Compt. rend., 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of K. Jellinek and A. Rudat, Z. Physik. Chem., A143, 55 (1929) and B. Gredner and K. Jellinek, Z. Physik. Chem., A165, 97 (1933).

Heat of Formation

The heat of formation of TiI₂(c) is calculated from the heat of reaction for the process 2TiI₂(c) = Ti(c) + TiI₄(g), and the heat of formation of TiI₄(c). Vapor pressure data for this reaction were reported by Herczog and Pidgeon (1) over the temperature range 750° to 902°K. Second and third law analyses of these data give values for ΔH°_{298} of 60.5 ± 0.8 and 60.85 kcal/mol respectively, the third law drift being $0.4 \pm 1.0 \text{ eu}$. The third law ΔH°_{298} is used to obtain the adopted value of ΔH°_{298} .

Heat Capacity and Entropy

The estimated heat capacity is that reported by Kelley (2). The value of $S^\circ_{298.15}$ is estimated from that of TiCl₂(c) and the difference between ionic entropy contributions of Cl⁻ and I⁻.

Heat of Sublimation

The heat of sublimation of TiI₂(c) is taken as the difference in the heats of formation of TiI₂(c) and TiI₂(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta G^\circ = 0$ for the reaction TiI₂(c) = TiI₂(g).

Rotational Constant: $B_0 = [0.00811] \text{ cm}^{-1}$ $\sigma = 2$

Heat of Formation

The heat of formation of $\text{TiI}_2(\text{g})$ is calculated from that of $\text{TiI}_2(\text{c})$ and the heat of vaporization. Vapor pressure data over the temperature range 750°K to 902°K have been reported by Herzog and Pidgeon (1). Second and third law analyses of these data give values for ΔH_{298}° of 51.9 and 59.9 kcal/mol, respectively. The third law drift for these data is 8.3 ± 1.1 eu, with one point rejected due to failure of a statistical test. The adopted value of ΔH_{298}° is calculated from the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $\text{TiCl}_2(\text{g})$, $\text{TiCl}_4(\text{g})$, $\text{TiBr}_2(\text{g})$, $\text{TiBr}_4(\text{g})$ and $\text{TiI}_4(\text{g})$. The vibrational frequencies are estimated from a valence force field model. The force constant k is estimated as 1.0 millidynes/Å and the constant K_0/l^2 is assumed to be 0.05 millidynes/Å.

The electronic levels are assumed to be the same as $\text{TiCl}_2(\text{g})$. The levels of TiCl_2 are estimated by assuming they correspond to the inverted states of $\text{NiCl}_2(\text{g})$ (2). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (3, 4, 5, 6).

rZr-I = [2.66 Å] Δ I-Zr-I = 120° σ = 2
 Product of Moments of Inertia I_AI_BI_C = 1.0716 X 10⁻¹¹ g.³ cm.⁶

Heat of Formation. Based upon the estimated value of the ΔH°_f for the crystal and the appropriate crystal and gas functions.

Heat Capacity and Entropy. Molecular constants were all estimated by comparison to similar molecules of zirconium and titanium.

TITANIUM TRIIODIDE (TiI₃) (CRYSTAL) GFW = 428.6132

ΔHf° = unknown

ΔHf°_{298.15} = [-77 ±5] kcal/mol

ΔHs° = [35.4] kcal/mol

S°_{298.15} = [46.0 ± 2.0] gibbs/mol

Ts = [1000]°K

Heat of Formation

The heat of formation of TiI₃(c) is calculated from the free energy of formation at 623°K combined with the increment ΔGf°₆₂₃ - ΔGf°_{298.15} of TiI₂(c), TiI₃(c) and TiI₄(g). The free energy of formation, ΔGf°_{298.15}, is estimated such that ΔGr°_{298.15} = 0 for the process 2TiI₃(c) = TiI₂(c) + TiI₄(g). This assumption is based on the observations of Herczeg and Pidgeon (1) and Fast (2).

Heat Capacity and Entropy

The heat capacities of TiI₃(c) and the value of S°_{298.15} estimated by Kelley (3) have been adopted.

Heat of Sublimation

The heat of sublimation of TiI₃(c) is taken as the difference in the heats of formation of TiI₃(c) and TiI₃(g) at the sublimation temperature. The sublimation temperature is estimated as the point at which ΔGr° = 0 for the process TiI₃(c) = TiI₃(g).

Bond Distance: Ti-I = [2.7] Å

Bond Angle: I-Ti-I = [100°]

 $\sigma = 3$ Product of the Moments of Inertia: $I_A I_B I_C = [1.3 \times 10^{-110}] \text{ g cm}^6$

Heat of Formation

The heat of formation, ΔH_f° , of TiI₃(g) is estimated from the average Ti-I bond energy. The bond energy is estimated from the corresponding quantities for TiBn₃(g), TiBn₃(g), and TiI₄(g).

Heat Capacity and Entropy

The interatomic distance is estimated from those of TiI₄, TiCl₄, and TiCl₃. The pyramidal bond angle is estimated by assuming that TiI₃(g) is similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 1.9 \times 10^{-37} \text{ g cm}^2$ and $I_C = 3.6 \times 10^{-37} \text{ g cm}^2$. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti³⁺ reported by C. E. Moore, U. S. Natl. Bur. Std., Circ. 467, 1949.

$$S_{298.15}^0 = [48.90] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$T_a = [970]^{\circ}\text{K.}$$

$$T_d = [1000]^{\circ}\text{K.}$$

Heat of Formation.

E. M. Larsen and J. J. Leddy, *J. Am. Chem. Soc.* **79**, 5983 (1956), studied the reaction $\text{Zr(c)} + 3\text{ZrI}_3(\text{g}) = 4\text{ZrI}_3(\text{c})$ in the temperature range 475 to 975°K. and pressure range 5 to 15 atm. They present a plot of the fractional reaction, at a number of temperatures, as a function of reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The free energy function change for this reaction was calculated at 100° intervals from 500 to 1100°K. At each temperature the equilibrium constant was assumed to be 1, and ΔH_f^0 298 accordingly calculated. These values and the heat of formation of $\text{ZrI}_3(\text{g})$ [see ZrI_4 table] were used to compute a series of values for the heat of formation of $\text{ZrI}_3(\text{c})$ at 298.15°K. The following table gives representative values at four temperatures.

T(°K.)	K _p	ΔH _r 298	ΔH _f 298.15 [ZrI ₃ (c)]
500	1	-86.0 kcal. mole ⁻¹	-80.2 kcal. mole ⁻¹
700	1	-90.3 kcal. mole ⁻¹	-86.2 kcal. mole ⁻¹
900	1	-113.5 kcal. mole ⁻¹	-92.1 kcal. mole ⁻¹
1100	1	-135.9 kcal. mole ⁻¹	-97.7 kcal. mole ⁻¹

If one assumes an initial pressure of from 5 to 10 atm. for ZrI_4 and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of ZrI_4 to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larsen and Leddy indicate that the reaction proceeds to the extent of 86% at 975°K. From this it was assumed that at around 1000°K. the equilibrium constant attains a value of 1 giving -95 kcal. mole⁻¹ for the heat of formation of ZrI_3 at 298.15°K.

Their data was subjected to a second law calculation but the results are of doubtful value in view of the uncertainty in the attainment of thermodynamic equilibrium at the lower temperatures. The limits of error assigned to the heat of formation are ± 15 kcal. mole⁻¹ corresponding to a temperature spread of $\pm 500^{\circ}$ in the above table.

Heat Capacity and Entropy.

The heat capacity was estimated in the same manner as for $\text{ZrBr}_3(\text{c})$ [see $\text{ZrBr}_3(\text{c})$ table]. The values $\theta_p = 60^{\circ}\text{K.}$ and $\theta_g = 115^{\circ}\text{K.}$ were taken to be the same as those estimated for $\text{ZrI}_4(\text{c})$. The internal contribution was obtained from the estimated ZrI_3 vibrational frequencies and the anharmonicity factor, "a", was taken to be 2.5×10^{-3} . The specific heat above 300°K. was obtained by graphical extrapolation.

For the above estimation, it was assumed that the crystalline lattice is made up of ZrI_3 molecules. However, E. Holze [see R. F. Rolsten, "Iodide Metals and Metal Iodides", John Wiley & Sons, Inc., New York, 1961, page 46] came to the conclusion that crystalline ZrI_3 is composed of a chain lattice of $(\text{ZrI}_3)_n$ units. The results of an analysis for a crystalline lattice composed of Zr_2I_6 units would probably not differ significantly from that for a crystalline lattice composed of ZrI_3 units since both are approaching the classical harmonic heat capacity of 12R calories per formula weight of ZrI_3 at relatively low temperatures.

Until more quantitative information becomes available, it is felt that the above analysis gives a fair approximation to the heat capacity of ZrI_3 .

Temperature of Disproportionation.

As described in the "Heat of Formation" section, this was assumed to be $1000^{\circ} \pm 500^{\circ}\text{K.}$

Liquid Phase.

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data.

The heat of sublimation at 298.15°K. was obtained from the difference in the heats of formation of the gas and solid at 298.15°K. The sublimation point was obtained from the free energy crossover between gas and solid.

Heat of Formation.

The heats of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this heat of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal. mole⁻¹ greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium triiodide, the heat of formation from the gaseous atoms was -275 kcal. mole⁻¹ and from the elements in their standard state, -53 kcal. mole⁻¹.

Heat Capacity and Entropy.

The measured internuclear distances for the triiodides of phosphorus, arsenic, and antimony were plotted as a function of the atomic weight of these elements and a smooth curve was drawn through the points. The bond distance in ZrI₃ was taken from this plot. The bond angle was assumed to be 101°. The individual moments of inertia are: I_A = I_B = 1.8520 X 10⁻⁵⁷ gm.² cm.², I_C = 3.3661 X 10⁻⁵⁷ gm.² cm.².

Force constants for ZrI₃ were estimated from those of the triiodides of phosphorus and arsenic. These were used in a valence force field calculation giving ω₁ = 195, ω₂ = 88, ω₃ = 181, and ω₄ = 65 cm.⁻¹. For the fluorides and chlorides of P, As, and Sb, ω₁ is greater than ω₃ but there appears to be a reversal as one goes to the bromides and iodides with ω₃ becoming greater than ω₁. An empirical correlation procedure for ZrI₃ gave ω₁ = 195, ω₂ = 90, ω₃ = 220, and ω₄ = 65 cm.⁻¹ in which ω₃ > ω₁. Since ω₃ > ω₁ for PI₃ and AsI₃, the correlation value for ω₃ was used to represent this frequency in ZrI₃.

$$T_t = 379^\circ\text{K}$$

$$T_m = 428^\circ\text{K}$$

Heat of Formation

The heat of formation of TiI₄(c) was measured by Johnson et al. (1), based on the heats of hydrolysis of TiBr₄(c) and TiI₄(c) in sulfuric acid. These data result in a heat of reaction of -57.88 kcal/mol for the process TiI₄(c) + 2Br₂(l) = TiBr₄(c) + 2I₂(c), when recalculated with revised values of ΔH_f° for HBr(aq) and HI(aq) (2). Combination of ΔH_f° with auxiliary JANAF data gives the adopted value of ΔH_f° .

Heat Capacity and Entropy

King et al. (3) reported the heat capacity and enthalpy of TiI₄(c) over the temperature range 51° to 428°K. The value of S°_{298} is calculated from these data based on $S^\circ_{51} = 14.62$ eu. The value of $H^\circ_{51} - H^\circ_0$ is calculated to be 0.356 kcal/mol from a Debye-Einstein extrapolation of the measured heat capacities.

Transition Data

A first order transition was observed by King et al. (2) at 379°K. They reported the measured value of 2.37 kcal/mol, noting that this value had an uncertainty of 0.15 kcal/mol due to hysteresis in the transition.

Melting Data

The melting temperature and heat of melting were reported by King et al. (2). The large uncertainty on ΔH_m° is due to the uncertainty and close proximity of the transition at 379°K.

Titanium Tetraiodide (TiI₄)

(Liquid) GFW = 555.5176

TITANIUM TETRAIODIDE (TiI₄)

(LIQUID)

GFW = 555.5176

 $\Delta H_f^\circ = \text{unknown}$ $\Delta H_f^\circ_{298.15} = -83.25 \text{ kcal/mol}$ $\Delta H_m^\circ = 4.74 \pm 0.15 \text{ kcal/mol}$ $\Delta H_v^\circ = 13.50 \pm 0.5 \text{ kcal/mol}$ $S^\circ_{298.15} = 74.532 \text{ gibbs/mol}$ $T_m = 428^\circ \text{K}$ $T_b = 652.6^\circ \text{K}$

Heat of Formation

The heat of formation of $\text{TiI}_4(l)$ is calculated from the heat of melting, ΔH_m° , the heat of formation of $\text{TiI}_4(c)$, and the values of $H_{428}^\circ - H_{298.15}^\circ$ for both crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the enthalpy of $\text{TiI}_4(l)$ above the melting temperature. The heat capacity derived from these data is constant. The entropy, S°_{298} , of $\text{TiI}_4(l)$ is calculated from ΔS_m° and the values of $S^\circ_{428} - S^\circ_{298.15}$ of both crystal and liquid.

Melting Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, T_b , is taken as the point at which $K_p = 1$ for the reaction $\text{TiI}_4(l) = \text{TiI}_4(g)$. The heat of vaporization is calculated as the difference between ΔH_f° of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $\text{TiI}_4(g)$.

Bond Angle: I-Ti-I = [109°28']

 $\sigma = 12$ Product of the Moments of Inertia: $I_A I_B I_C = [4.33 \times 10^{-110}] \text{ g cm}^6$

Heat of Formation

The heat of formation of TiI₄(g) is calculated from that of TiI₄(l) and the heat of vaporization of the liquid. Blocher and Campbell (1) reported vapor pressure data for TiI₄(l) over the temperature range 473° to 655°K. Second and third law analyses of these data give values for ΔH_f° of 17.2 ± 0.1 and 16.98 kcal/mol , respectively, the third law drift being $-0.4 \pm 0.2 \text{ eu}$. The adopted value of ΔH_f° is based on the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiBr₄(c), TiBr₄(g) and TiI₄(c) (2). The tetrahedral model is assumed by analogy with TiCl₄(g) and TiBr₄(g). The principal moments of inertia are: $I_A = I_B = I_C = 3.51 \times 10^{-37} \text{ g cm}^2$. The vibrational frequencies of TiI₄(g) have been estimated by Ushanova et al. (3). The given estimates are based on their predictions and valence force field calculations.

ZIRCONIUM TETRAIODIDE (ZrI₄)

(CRYSTAL)

MOL. WT. = 598.86

$$\Delta H_f^o = [-115.4] \pm 1.0 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^o 298.15 = -115.9 \pm 0.8 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^o 298.15 = 31.0 \pm 0.7 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = [61.4] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$T_g = 704^\circ\text{K.}$$

Heat of Formation.

A. G. Turnbull, J. Phys. Chem. **65**, 1652 (1961), measured the heat of reaction for the following reactions:

Turnbull used the same procedure to calculate the heat of formation of zirconium tetraiodide as he did for zirconium tetrabromide [see ZrBr₄ table]. The heat of formation of the solid zirconium tetraiodide from reaction (1) was -115.6 ± 0.8 kcal. mole⁻¹ and from reaction (2) was -116.3 ± 0.8 kcal. mole⁻¹. An average of these was taken as the heat of formation of the tetraiodide.

Heat Capacity and Entropy.

The heat capacity from 0 to 300°K. was calculated in the same manner as for ZrBr₄(c) [see ZrBr₄(c) table]. The values, $\bar{C}_p^o$ = 60°K. and $\bar{C}_p^o$ = 115°K. were used in the analysis. The value, $\bar{C}_p^o$ = 1.5 X 10⁻³, was obtained from a consideration of the sublimation calculations [see below]. The heat capacity above 300°K. represents a graphical extrapolation.

Melting.

T_m = 772°K. was reported by O. Rahlfs and W. Fischer, Z. anorg. allgem. Chem. **211**, 349 (1933).

Sublimation Data.

Vapor pressure measurements have been reported by Rahlfs and Fischer (loc. cit.). Four values of "a" were used to compute the thermodynamic functions of the solid. That value of "a" was chosen which gave agreement between 2nd and 3rd law values for the heat of sublimation. The sublimation results for the four values of "a" are given in the following table.

"a"	ΔH _g (298) [3rd law]	ΔH _g (298) [2nd law]
3.0 X 10 ⁻³	29.99 kcal. mole ⁻¹	31.65 kcal. mole ⁻¹
2.5 X 10 ⁻³	30.39 kcal. mole ⁻¹	31.34 kcal. mole ⁻¹
2.0 X 10 ⁻³	30.76 kcal. mole ⁻¹	31.17 kcal. mole ⁻¹
1.5 X 10 ⁻³	31.02 kcal. mole ⁻¹	31.04 kcal. mole ⁻¹

A temperature dependent third law heat of sublimation at 298°K. was obtained for "a" = 3.0 X 10⁻³; this temperature trend decreased for smaller values of "a" and there was essentially no temperature dependence for "a" = 1.5 X 10⁻³. Various high temperature extrapolations were not used since, by experience with ZrBr₄(c), they produced insignificant changes in the heat values. The heat of sublimation was taken to be 31.0 kcal. mole⁻¹ since the entire analysis was conducted to obtain 2nd and 3rd law agreement.

From experience with a number of other compounds, that were found to be amenable to the theoretical treatment used here, the value "a" = 1.5 X 10⁻³ appears to be rather low, but no further analysis was deemed practical since all parameters for the gas and solid are estimated.

The sublimation point obtained from the free energy crossover of solid and gas was 703°K. The value reported by Rahlfs and Fischer (loc. cit.), was 704°K. The sublimation point was taken as 704°K.

Since the sublimation point is lower than the melting point, the liquid phase is thermodynamically unstable under ordinary conditions.

ZIRCONIUM TETRAIODIDE (ZrI₄)
(IDEAL GAS)

MOL. WT. = 598.86

ΔH_f⁰ = [-83.6] ± 1.7 kcal. mole⁻¹
ΔH_f⁰ 298 = -84.9 ± 1.5 kcal. mole⁻¹

Point Group = D_{2d}
S₂₉₈ = [106.78] cal. mole⁻¹ deg.⁻¹
Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	(146) (1)	(45) (2)	(237) (3)	(58) (3)

Q = [12]

Bond Distance: Zr-I = [2.68] Å
Bond Angle: I-Zr-I = [109° 28']

Product of the Moments of Inertia: I_AI_BI_C = [6.5718 × 10⁻¹¹⁰] gm.³ cm.⁶

Heat of Formation

Calculated from the heats of formation and sublimation for the crystal at 298.15°K. (see crystal table for details).

Heat Capacity and Entropy

The interatomic distance was obtained from an involved correlation of the interatomic distances and covalent radii of the tetrahalides of Pb, Si, Ti, Ge, and Sn. I. N. Godnev, A. M. Aleksandrovskaya, and I. V. Regina, Optics and Spectroscopy 7, 172 (1959), estimated the interatomic distance and report 2.67 Å as the Zr-I distance. The I-Zr-I angle was taken as the tetrahedral angle. The three principal moments of inertia are: I_A = I_B = I_C = 4.0355 × 10⁻³⁷ gm. cm.².

The fundamental vibrational frequencies are estimated. The product of ω₁ and ω₂ versus internuclear distance for the tetrahalides of Pb, Ti, Ge, and Sn was found to be approximately constant. Using the estimated Zr-I interatomic distance a value of 147 cm.⁻¹ was obtained for ω₁. Plots of ω₁ and ω₂ versus internuclear distance for these molecules were constructed and smooth curves drawn through the points. Values of ω₁ and ω₂ for ZrI₄ were read off from these plots; they were 146 cm.⁻¹ and 44 cm.⁻¹ respectively. Using ω₁ = 146 cm.⁻¹ and ω₂ = 45 cm.⁻¹, ω₃ = 237 cm.⁻¹ and ω₄ = 58 cm.⁻¹ were obtained from a valence force field calculation. Godnev, Aleksandrovskaya, and Regina (loc. cit.) estimated the vibrational frequencies and reported ω₁ = 152 cm.⁻¹, ω₂ = 44 cm.⁻¹, ω₃ = 211 cm.⁻¹ and ω₄ = 55 cm.⁻¹.

336.35°K. to 1043.7°K. Liquid
1043.7°K. to 6000°K. Ideal Monatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

Low temperature heat capacity measurements have been reported by L. M. Roberts [Proc. Phys. Soc. (London) 70B, 744-52 (1957)] (1.5°-20°K.), by C. A. Krier, R. S. Craig, and W. E. Wallace [J. Phys. Chem. 61, 522 (1957)] (12°-320°K.), by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas [Proc. Roy. Soc. (London), A253, 214 (1955)] (20°-350°K.), by F. Simon and M. Zeidler [Z. physikal. Chem. 123, 383 (1926)] (15°-300°K.), and by E. D. Eastman and W. H. Rodabaugh [J. Am. Chem. Soc. 40, 489 (1918)] (70°-230°K.). A smooth curve was drawn through a large scale plot of the data, giving the most weight to the first three references. Above 300°K. the heat capacity data were adjusted to join smoothly with the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)].

Heat Capacity of Liquid and Heat of Melting.

The heat of melting and liquid heat capacity are from the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis (loc. cit.).

Heat of Sublimation, Ideal Gas Functions.

See tables for K(g) and K₂(g) for details.

$$\Delta H_m^\circ = 0.558 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^\circ = 18.38 \text{ kcal. per formula weight}$$

$$T_m = 336.35^\circ \text{K.}$$

$$T_b = 1037^\circ \text{K.}$$

Heat of Formation.

Back calculated from the heat of melting and the heat contents of solid and liquid at the melting point.

Heat of Melting and Heat Capacity.

The heat of melting, melting point, and liquid heat capacity were measured by T. B. Douglas, A. P. Ball, D. C. Ginnings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)]. The heat capacity curve was extrapolated back to 298°K. and up to 2000°K. in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Potassium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1037°K. The vapor composition at this temperature is 94.5 mole % monatomic and 5.5 mole % diatomic gas. The heat of vaporization of 39.1 grams of liquid potassium to this equilibrium mixture is 18.38 kcal. See also tables for K(g) and K₂(g).

Thermodynamic Functions.

Thermodynamic functions were calculated using electronic levels and multiplicities from P. Rieberg [Arkiv. Fysik 10, 583 (1956)] and C. E. Moore [Nat. Bur. Standards Circ. 467 (1949)]. Higher levels were averaged. The results are in excellent agreement with W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 83 (1955)].

Heat of Formation.

Evans, Munson, and Wagman (loc. cit.) have reviewed the vapor pressure data on potassium. Their calculations were revised slightly for the changes made in the functions for the condensed state. In addition, the recent data of M. M. Makansi, M. Madan, W. A. Selke, and C. P. Bonilla [J. Phys. Chem. 60, 138 (1956)] were considered in selecting the heat of sublimation of 21.31 ± 0.20 kcal. mole⁻¹. A review of the properties of potassium vapor using imperfect gas theory to establish the dimer dissociation energy has recently been published by R. J. Thorn and G. H. Minnow [J. Phys. Chem. 65, 1297 (1961)]. Although the imperfect gas treatment appears to be favored by the experimental data available, this could not be unequivocally established. Unpublished vapor pressure data cited by Thorn and Minnow are in agreement with the values selected here, assuming ideal gas behavior.

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic potassium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels", Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation $K(\text{ref. state}) - e^-(\text{ref. state}) = K^+(\text{monatomic gas})$, thus K^+ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore, loc. cit.

Dec. 31, 1962; Dec. 31, 1967

POTASSIUM MONOXIDE (KO)

(IDEAL GAS)

GFW = 55.1014

Ground State Configuration [2]
S^{298.15} = [56.9 ± 0.5] gibbs/mol

ΔH_f⁰ = [17.4 ± 10] kcal/mol

ΔH_f²⁹⁸ = [17.0 ± 10] kcal/mol

Electronic Levels and Quantum Weights

$$\frac{e_i, \text{ cm}^{-1}}{0} = \frac{g_i}{[4]}$$

ω_e = [350] cm⁻¹
ω_ex_e = [2.2] cm⁻¹
B_e = [0.3068] cm⁻¹
α_e = [0.0027] cm⁻¹

σ = 1
r_e = [2.2] Å

Heat of Formation

Brewer and Margrave (1) suggested that the ΔH_f⁰ value for KO(g) from the gaseous ions can be taken as the mean of the corresponding ΔH_f⁰ values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal/mol. We obtain the values ΔH_f⁰ = -137.84 and -117.7 kcal/mol for the reactions K⁺(g) + F⁻(g) = KF(g) and K⁺(g) + Cl⁻(g) = KCl(g), respectively. Assuming ΔH_f⁰ = -127.83 kcal/mol for the reaction K⁺(g) + O⁻(g) = KO(g), we calculate ΔH_f⁰ (KO, g) = 19.0 kcal/mol with the JANAF auxiliary values for the gaseous ions.

Based on the assumption that D₀(KO) = 1/2(D₀(K₂) + D₀(O₂)), or ΔH_f⁰ = 64.9 kcal/mol for the reaction KO(g) = K(g) + O(g), we evaluate ΔH_f⁰(KO, g) = 15.6 kcal/mol or ΔH_f²⁹⁸(KO, g) = 15.2 kcal/mol.

According to Somayajulu (2), in a sequence of similar diatomic molecules, k_rv_e/D₀ = constant, where k_r = force constant, r_e = equilibrium bond distance and D₀ = dissociation energy. Using r_e = 1.62 Å, D₀ = 77.9 kcal/mol for LiO(g), r_e = 2.2 Å and k_r(KO)/r_e(LiO) = 0.3015, we calculate D₀ = 55 kcal/mol for KO(g), yielding ΔH_f²⁹⁸(KO, g) = 26.1 kcal/mol. The value k_r is derived from the relation k_r = 4π²ν²μ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass. The value of ΔH_f²⁹⁸(KO, g) is tentatively adopted as 17 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for the OH(g) molecule, which has the same number of valence electrons. The values of ω_e and ω_ex_e are estimated by comparison with those for LiF(g) and KF(g). The bond distance is estimated from those for HO(g), HF(g) and KF(g). B_e and α_e are derived from r_e, ω_e and ω_ex_e by the method suggested by Herzberg (3).

Dec. 31, 1967

(IDEAL GAS)

GFW = 55.10195

Ground State Configuration [1²]

S_{298.15} = [54.1 ± 0.3] gibbs/mol

ΔHf^o = [-33 ± 20] kcal/mol

ΔHf^o_{298.15} = [-33 ± 20] kcal/mol

Electronic Levels and Quantum Weights

$$\frac{g_i}{o} \frac{e_i}{\text{cm}^{-1}}$$

$$\omega_e X_e = [2.3] \text{ cm}^{-1}$$

$$\omega_e = [0.0027] \text{ cm}^{-1}$$

$$\sigma = 1$$

$$r_e = [2.2] \text{ Å}$$

Heat of Formation

The electron affinity (E. A.) of K⁰⁻(g) is unavailable, therefore the value of ΔHf^o₂₉₈(K⁰⁻, g) is estimated. Assuming that the enthalpy change (ΔHf^o) of the reaction (1) K⁰⁻(g) = K(g) + O⁺(g) is approximately the average of the ΔHf^o value for the reaction (2) KO(g) = K(g) + O(g) and (3) KF(g) = K(g) + F(g), we obtain ΔHf^o = 1/2(63.5 + 117.3) = 90.4 kcal/mol for reaction (1). However, we compare the ΔHf^o values for the reactions (4) HO(g) = H(g) + O(g), (5) H⁰⁻(g) = H(g) + O⁺(g), and (6) HF(g) = H(g) + F(g), and find that ΔHf^o for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔHf^o values for reactions (4) and (6). Based on this fact we estimated ΔHf^o = 80 kcal/mol for reaction (1), yielding ΔHf^o₂₉₈(K⁰⁻, g) = -33 kcal/mol. The value of ΔHf^o₂₉₈(K⁰⁻, g) is tentatively adopted as -33 ± 20 kcal/mol. The electronic affinity of KO(g) is derived to be 2.2 ± 0.9 eV. The value of E. A. for HO(g) is determined as 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of KF(g) which is isoelectronic with K⁰⁻(g). The values of ω_e, ω_eX_e, and r_e are estimated by comparison with those for KF(g). The values of B_e and α_e are calculated from r_e, ω_e and ω_eX_e using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc. New York, 1950. The enthalpy at 0°K is -2.30 kcal/mol.

Thermodynamic Functions.

Spectroscopic data are the same as that selected by W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 63 (1955)]. The calculated functions are in excellent agreement with their results.

Heat of Formation.

The heat of dissociation selected by Evans, Munson, and Wagman (loc. cit.) was used with the previously adopted heat of sublimation of the monomer to derive the heat of formation.

K_2O

DIPOTASSIUM MONOXIDE (K_2O)
(CRYSTAL)
MOL. WT. = 94.20
 $\Delta H_f^\circ O = \text{Unknown}$
 $\Delta H_f^\circ 298.15 = -86.8 \pm 0.5 \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = [22.5 \pm 1.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_d = 1154^\circ K. (600 \text{ mm Hg})$
Heat of Formation.
 $\Delta H_f^\circ 298.15$ was reported by M. Rengada, Ann. Chim. et phys. [8] 14, 540 (1908), based on the measurements of the heats of solution of K(c) and $K_2O(c)$ in H_2O . The same value of $\Delta H_f^\circ 298.15$ was also given by R. de Forcrand, Compt. rend. 159, 991 (1914).
Heat Capacity and Entropy.
Both C_p and $S_{298.15}^\circ$ were estimated by comparison with those of the $Na_2O(c)$.

Temperature of Decomposition.

T_d was taken from, "Data on Chemicals for Ceramic Use", National Research Council Bulletin 118 (1949).

Heat of Formation.

ΔH_f⁰ 298.15 was reported by National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1962. The value was based on the measured decomposition pressure of K₂O₂(c) by M. Centner and M. Blumenthal, IX Congr. IUPAC, 3A, 201 (1955).

Heat Capacity and Entropy.

The heat capacities and S_{298.15} were estimated by comparison with those for Na₂O₂(c), Na₂O(c), and K₂O(c).

Temperature of Melting.

T_m was reported by Centner and Blumenthal, loc. cit.

$$T_m = 453.69^\circ\text{K}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacities have been reported by the following authors for the temperature ranges indicated: L. M. Roberts, Proc. Phys. Soc. **70**, 744 (1957), 1.5 to 20°K (Li 99.5% pure); F. Simon and R. C. Swain, Z. Phys. Chem. **B28**, 189 (1935), 18° to 300°K; D. L. Martin, Proc. Roy. Soc. **A251**, 444 (1960), 22° to 300°K (Li 99.95% pure); T. B. Douglas, L. F. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. **77**, 2144 (1955), 298° to 1200°K (Li 99.98% pure). Martin, in a series of determinations, found that C_p depended on the thermal history of the sample; a peak at roughly 107°K was ascribed to a martensitic transformation. There is excellent continuity between the results of Roberts and of Martin, while those of Douglas et al. differ by 1% at 300°K and have been smoothly joined. The values of Simon and Swain were not used as they were 5% lower than Martin's and did not show the peak at 107°K; also their values for Al_2O_3 , reported at the same time, are lower than recent measurements. Heat capacities between 1200°K and the normal boiling point were obtained from the heat content equation given by Douglas et al. between 420° and 300°K.

Melting.

Douglas et al. (loc. cit.) report the triple point to be 186.54°C, which is here adopted as the melting point since the densities of solid and liquid lithium at 180°C are not available for calculating dT_m/dP . The same authors give the heat of melting as 432.3 ± 2.2 abs. joule g^{-1} .

Heat of Sublimation.

Lithium vapor contains an appreciable amount of dimer, whose heat of dissociation has been selected by W. H. Evans, R. Jacobson, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bureau of Standards **55**, 83 (1955), from spectroscopic and molecular beam measurements to be $25.76 \pm 0.10 \text{ kcal. mole}^{-1}$ at 0°K. This heat of dissociation, together with the thermodynamic functions calculated in this work, has been used to find the partial pressures of Li(g) and $\text{Li}_2(\text{g})$ from the measured total vapor pressures. H. Hartmann and R. Schneider, Z. anorg. allgem. Chem. **180**, 275 (1929), report values from 1204° to 1353°K, while M. Mancherat, C. Rendus **268**, 499 (1939), reports effusion measurements from 735° to 915°K. Mancherat's pressures are calculated on the assumption of monatomic vapor and have been recalculated to find the true total pressure. Effusion measurements by L. C. Lewis, Z. Physik **69**, 786 (1931), and A. Bogros, C. Rendus **191**, 560 (1930) and Ann. Phys. **17**, 199 (1932), have been disregarded. Mancherat considers them to be inaccurate because of impurities in the lithium used, and Lewis used a doubtful calibration method. Heats of sublimation to monatomic vapor calculated from the vapor pressures of Hartmann and Schneider and of Mancherat agree to within 2% and the average value has been adopted. The heat of sublimation of the dimer was then calculated using this value.

LITHIUM (LI)

(LIQUID)

AT. WT. = 6.940

 $\Delta H_f^\circ 298.15 = 0.569 \text{ kcal. mole}^{-1}$ $S_{298.15}^\circ = 8.113 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_m^\circ = 0.7171 \pm 0.0035 \text{ kcal. mole}^{-1}$ $T_m = 453.69^\circ \text{K}$ $T_b = 1620^\circ \text{K (equilibrium mixture)}$ $T_b \text{ (monatomic gas)} = 1639^\circ \text{K}$ $\Delta H_v 1639 = 35.16 \text{ kcal. mole}^{-1}$

Heat of Formation.

Obtained from the heat of fusion by adding $H_{453.69}^\circ - H_{298.15}^\circ$ for the solid and subtracting $H_{1639}^\circ - H_{298.15}^\circ$ for the liquid.

Heat Capacity.

The data of T. B. Douglas, L. F. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. 77, 2144 (1955) were taken and extrapolated below T_m and above 1200°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K .

Vaporization.

Lithium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1620°K ; the vapor pressure of the monatomic gas reaches 1 atm. at 1639°K and the heat of vaporization to monatomic gas is $35.16 \text{ kcal. mole}^{-1}$. See also Li(crystal).

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic lithium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation $\text{Li}(\text{ref. state}) - e^-(\text{ref. state}) = \text{Li}(\text{monatomic gas})$, thus Li^+ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Dec. 31, 1960; Sept. 30, 1966; Dec. 31, 1966

Ground State Configuration [3Σ] $\Delta H^\circ_{298.15} = 80 \pm 40 \text{ kcal/mol}$ $\Delta H^\circ_{298.15} = 80 \pm 40 \text{ kcal/mol}$ $S^\circ_{298.15} = [49.7] \text{ gibbs/mol}$

Electronic Levels and Quantum Weights

$$\frac{\epsilon_i, \text{cm}^{-1}}{0} = \frac{E_i}{[3]}$$

$$\omega_{e^*e} = [7] \text{ cm}^{-1}$$

$$\sigma = 1$$

$$\alpha_e = [0.0183] \text{ cm}^{-1}$$

$$r_e = [1.71] \text{ \AA}$$

Heat of Formation.

The adopted $\Delta H^\circ_{298.15}$, $80 \pm 40 \text{ kcal/mol}$, is calculated from the following estimates:

Method	D_0° kcal/mol	$\Delta H^\circ_{298.15}$ kcal/mol
--------	-------------------------	---------------------------------------

76

75

Estimate D_0° from geometric mean for Li_2 and N_2 Estimate from D_0° for series $\text{N}_2(\text{g})$, $\text{CN}(\text{g})$, and $\text{BeN}(\text{g})$ Estimate from D_0° for series $\text{HN}(\text{g})$, $\text{HO}(\text{g})$, $\text{HF}(\text{g})$, $\text{LiF}(\text{g})$ and $\text{LiO}(\text{g})$

J. L. Margrave and P. Sthapitanonda, J. Phys. Chem. 59, 1231 (1955), report estimated dissociation energies in the range 111-178 kcal/mol, based on approximate ionic binding energies calculated from ionic radii for N^- in the range 0.70 to 1.08 $\text{\AA}$.

Heat Capacity and Entropy.

The molecular constants ω_e , r_e and ω_{e^*e} are estimated by comparison with those of CN, CO, BO and LiO. The values of α_e and B_e are calculated from the above constants. The ground state configuration is assumed to be 3Σ by analogy with NH and OH $^+$.

LiN

Point Group C_{2v}
 $S_{298.15}^{\circ} = 58.61$ gibbs/mol
 Ground State Quantum Weight = 1

$$\Delta H_f^{\circ} = [43.5 \pm 10] \text{ kcal/mol}$$

$$\Delta H_{298.15}^{\circ} = [43.0 \pm 10] \text{ kcal/mol}$$

$$\text{Product of the Moments of Inertia: } I_A I_B I_C = 2.6523 \times 10^{-116} \text{ g}^3 \text{ cm}^6$$

Heat of Formation

The heat of formation (ΔH_f°) for LiON(g) has not been determined experimentally. The ΔH_{298}° value adopted is calculated from the estimated Li-O and O-N bond energies. The value, $D(\text{Li-O}) = 88$ kcal/mol, is obtained by averaging the bonds in $\text{Li}_2\text{O(g)}$. The value, $D(\text{O-N}) = 69$ kcal/mol, is calculated on the assumption that $D(\text{ClON-O}) = D(\text{N-OH})$. The ΔH_{298}° of LiOH(g) , calculated similarly from bond energies (i.e. $D(\text{Li-O}) = 88$ kcal/mol and $D(\text{O-H}) = 111$ kcal/mol), is 10 kcal/mol more than the measured value. Therefore, we subtract 10 kcal/mol from the ΔH_{298}° of LiON, 53 kcal/mol, estimated from the above bond energies, and arrive at 43 kcal/mol for the adopted value.

Heat Capacity and Entropy

The vibrational frequencies, bond distances and bond angle were obtained from W. L. S. Andrews and G. C. Pimentel, loc. cit. The three principal moments of inertia are: $I_A = 1.2706 \times 10^{-36}$, $I_B = 3.9776 \times 10^{-39}$ and $I_C = 5.2482 \times 10^{-39} \text{ g cm}^2$.

Dec. 31, 1960; Mar. 31, 1961

LITHIUM MONOXIDE (LiO)

(IDEAL GAS)

MOL. WT. = 22.940

Ground State Configuration $[^2\Pi]$
 $\Delta H_f^\circ = 20.1 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 20.1 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 20.1 \pm 5 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{\epsilon_i, \text{ cm}^{-1}}{0} \frac{g_i}{4}$$

$\omega_e x_e = 4.835 \text{ cm}^{-1}$
 $\omega_e = 1.62 \text{ cm}^{-1}$
 $\alpha_e = 0.01288 \text{ cm}^{-1}$

Heat of Formation

D. White, K. S. Sahasrab, D. P. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. **39**, 2463 (1963) calculated the heat of formation from their mass spectral data by two different methods.

For the first calculation (a) they combined the slope of the log Π vs $1/T$ curve for LiO^+ with the slope for Li^+ and Li_2O^+ for the reaction $\text{Li}_2\text{O}^+ (\text{g}) \rightarrow \text{Li}^+ (\text{g}) + \text{LiO}^+ (\text{g})$. For the second calculation (b) they assumed a cross section $\sigma_{\text{LiO}^+/\text{Li}_2\text{O}^+} = 1$ and from this they calculated a partial pressure for $\text{LiO}^+ (\text{g})$ at 1500°K and an equilibrium constant for the reaction $\text{Li}_2\text{O}^+ (\text{g}) \rightarrow \text{Li}^+ (\text{g}) + \text{LiO}^+ (\text{g})$. They obtained (a) $\Delta H_f^\circ = 18.3 \text{ kcal. mole}^{-1}$ and (b) $\Delta H_f^\circ = 16.3 \text{ kcal. mole}^{-1}$, and used the average value from the two methods for the heat of formation of $\text{LiO}^+ (\text{g})$. The JANAF heat of formation, $20.1 \pm 5 \text{ kcal. mole}^{-1}$, was obtained in the same way using their data and the present tables i.e. (a) $\Delta H_f^\circ = 22.0 \text{ kcal. mole}^{-1}$ and (b) $\Delta H_f^\circ = 18.3 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy

The molecular constants, $\omega_e x_e$, ω_e , and α_e , were calculated from ω_e and r_e , reported by White et al. The ground state configuration, $^2\Pi$, was estimated by J. S. Gorton, Thiol Chemical Corp., Reaction Motor Division, Denville, N. J., "Thermodynamic Data for Combustion Products", January, 1960, by A. Buchler and J. L. Stauffer, J. Chem. Phys. **39**, 2299 (1963) and by White et al.

LITHIUM MONOXIDE UNINEGATIVE ION (LiO⁻) (IDEAL GAS) GFW = 22.93895

Ground State Configuration [1²s]
 $S^\circ_{298.15} = [47.6 \pm 0.3] \text{ gibbs/mol}$
 $\Delta H^\circ_0 = [-16 \pm 15] \text{ kcal/mol}$
 $\Delta H^\circ_{298.15} = [-16 \pm 15] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$\epsilon_i, \text{cm}^{-1}$	$\frac{g_i}{O}$	$\frac{g_i}{[1]}$
$\omega_e X_e = [4.5] \text{ cm}^{-1}$		
$\omega_e = [750] \text{ cm}^{-1}$		
$\sigma = 1$		
$q_e = [0.0121] \text{ cm}^{-1}$		
$r_e = [1.6] \text{ \AA}$		

Heat of Formation

Data on the electron affinity (E.A.) of LiO (g) are unavailable, therefore the value of $\Delta H^\circ_{298}(\text{LiO}^-, \text{g})$ is estimated. We first assume that the enthalpy change (ΔH°_0) of the reaction (1) $\text{LiO}^-(\text{g}) = \text{Li}(\text{g}) + \text{O}^-(\text{g})$ is close to the average of the ΔH°_0 values for the reactions (2) $\text{LiO}(\text{g}) = \text{Li}(\text{g}) + \text{O}(\text{g})$ and (3) $\text{LiF}(\text{g}) = \text{Li}(\text{g}) + \text{F}(\text{g})$. The atom F(g) is isoelectronic with O⁻(g). In other words, the ΔH°_0 for reaction (1) is approximately $1/2(76.91 + 135.84) = 106.4 \text{ kcal/mol}$. Then we compare the ΔH°_0 values for the reactions (4) $\text{HO}(\text{g}) = \text{H}(\text{g}) + \text{O}(\text{g})$, (5) $\text{HO}^-(\text{g}) = \text{H}(\text{g}) + \text{O}^-(\text{g})$, and (6) $\text{HF}(\text{g}) = \text{H}(\text{g}) + \text{F}(\text{g})$, and find that ΔH°_0 for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔH°_0 values for reactions (4) and (6). Based on this fact we estimate $\Delta H^\circ_0 = 96.4 \text{ kcal/mol}$ for reaction (1), yielding $\Delta H^\circ_{298}(\text{LiO}^-, \text{g}) = -15.5 \text{ kcal/mol}$.

Applying the difference in electron affinity between H(g) and Li(g) to OH(g) gives an approximate value, E. A. = 1.7 eV (39.2 kcal/mol) for LiO(g). The value of E. A. for H(g), Li(g) and OH(g) are taken from U. S. Bur. Std. Rept. 8628, Jan. 1, 1965. Based on $\Delta H^\circ_0 = 39.2 \text{ kcal/mol}$ for the reaction $\text{LiO}^-(\text{g}) = \text{LiO}(\text{g}) + e^-(\text{g})$, we derive $\Delta H^\circ_{298} = -19.1 \text{ kcal/mol}$ for $\text{LiO}^-(\text{g})$, which is in reasonable agreement with the above estimated value.

The value of ΔH°_{298} for $\text{LiO}^-(\text{g})$ is tentatively adopted as $-16 \pm 15 \text{ kcal/mol}$. Using this ΔH°_{298} value, we derive E. A. = $1.6 \pm 0.7 \text{ eV}$ for $\text{LiO}(\text{g})$. The electron affinity of OH(g) is $1.8 \pm 0.1 \text{ eV}$.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of LiF(g) which is isoelectronic with LiO⁻(g). The values of ω_e , $\omega_e X_e$ and r_e are estimated by comparison with the observed data for LiF(g). The values of B_e and q_e are calculated from r_e , ω_e and $\omega_e X_e$ by use of the method suggested by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.137 kcal/mol .

Li_2

MOL. WT. = 13.880

(IDEAL GAS)

LITHIUM, DIATOMIC (Li_2)

ΔH_f^0 298.15 = 50.4 $\pm$ 0.9 kcal. mole⁻¹
 $S_{298.15}^0$ = 47.050 cal. deg. mole⁻¹

ΔH_f^0 = 50.298 kcal. mole⁻¹
Ground State Configuration Σ^+

$\omega_e x_e$ = 2.625 cm.⁻¹
 ω_e = 353.59 cm.⁻¹
 α_e = 0.00718 cm.⁻¹
 r_e = 2.673 Å

ω_e = 353.59 cm.⁻¹
 B_e = 0.6812 cm.⁻¹

$\sigma = 2$

Heat of Formation.

Same as the heat of sublimation to the diatomic gas; see notes on Li (crystal).

Heat Capacity and Entropy.

The spectroscopic constants of Li_2 listed by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York (1950) have been corrected for the presence of 7.5% Li^6 in naturally occurring lithium, J. R. Stehn and E. P. Clancy, "Chart of the Nuclides", General Electric Co., Schenectady (1956).

$$\Delta H_f^\circ = -141.6 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^\circ = -143.1 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = [14] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = 9.056 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1843^\circ\text{K.}$$

Heat of Formation.

The selected heat of formation was calculated as follows:

Reaction	ΔH_f° 298.15 kcal. mole ⁻¹	Ref.
(I) $\text{Li}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{LiOH}(\infty \text{H}_2\text{O})$	-31.74 ± 0.08	(a)
(II) $\text{Li}(c) + 1/2 \text{O}_2(g) = \text{LiOH}(\infty \text{H}_2\text{O})$	-121.572 ± 0.019	(b)
(III) $\text{H}_2(g) + 1/2 \text{O}_2(g) = \text{H}_2\text{O}(l)$	-68.3174	(c)
(IV) $2\text{Li}(c) + 1/2 \text{O}_2(g) = \text{Li}_2\text{O}(c)$	-143.1 ± 0.5	(d)
(a) V. P. Kolesov, S. M. Skuratov, and I. D. Zaklin, Russian J. Inorganic Chemistry, 3 , 558 (1959).		
(b) S. R. Gunn and L. G. Green, J. Am. Chem. Soc., 80 , 4782 (1958).		
(c) F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and I. Jaffe, "Selected Values of Chemical Thermodynamic Properties" National Bureau of Standards Circular 500, 1952 (reprinted 1961).		
(d) Reaction (IV) is the sum of $-(I) + 2(II) - (III)$.		

Kolesov, et al. (loc. cit.) measured the enthalpy of the reaction of Li_2O with water at 20° in 5 experiments. The mean ΔH_f° was -31.41 ± 0.08 kcal. This was brought to 298°K by Kolesov using enthalpy data of (a) H. L. Johnston and T. W. Bauer, J. Am. Chem. Soc., **73**, 1119 (1951), for Li_2O , (b) N. S. Osborne, J. P. Stimson, and D. C. Oimings, J. Res. Natl. Bur. Stds. A, **23**, 197 (1939) for H_2O , (c) F. T. Quaker and K. N. Schminke, J. Am. Chem. Soc., **55**, 1013 (1933) for O_2 of $\text{LiOH}(\text{aq})$ and (d) Rossini, et al., (loc. cit.) for aqueous LiOH . In addition to the above, N. N. Beketov, Bull. Acad. Sci. Russ. **32**, 186 (1898) and H. R. Porrand, Compt Rend. **144**, 1403 (1907) have reported experimental heats for Li_2O . Rossini et al. and Johnston and Bauer have reported heats of formation for Li_2O recalculated from older data. L. G. Fasolino, in a Natl. Research Corp. Quarterly Report, July 1 to Sept. 30, 1962, reported a ΔH_f° 298 of -141.1 ± 4.2 kcal. He measured the heat of combustion of $\text{Li}(c)$ in $\text{O}_2(g)$ in a Parr bomb.

Heat Capacity and Entropy.

The low temperature C_p data of H. L. Johnston and T. W. Bauer, (loc. cit.) from 17° to -298°K. was joined graphically to the high temperature C_p data of C. H. Shomate and A. J. Cohen, J. Am. Chem. Soc. **77**, 285 (1955) [425° - 1045°K.] and E. N. Rodgina, and K. A. Gornolukii, Russian J. Phys. Chem. **35**, 898 (1961) [370° - 1125°K.]. The $S_{298.15}^\circ$ was reported by Johnston and Bauer using S_{16}° (extrap.) = $0.003 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

The melting point of Li_2O is uncertain. The selected melting point, 1843°K. , was measured by A. E. van Arkel, E. A. Flood, and M. P. H. Bright, Can. J. Chem. **31**, 1009 (1953). L. Brewer and J. L. Margrave, J. Phys. Chem. **59**, 421 (1955) reported the melting point 1700°K. They also stated that H. van Kester and P. Jaeger, Proc. Roy. Acad. Sci., Amsterdam **16**, 857 (1914) had reported 1700° (1973°K.) as the melting point. The heat of melting, $[14] \text{ kcal. mole}^{-1}$, was estimated by A. Glassner, "The Thermodynamic Properties of the Oxides, Fluorides, and Chlorides to 2500°K. ", Argonne National Laboratory, University of Chicago, ANL-5750, 1957.

Heat of Sublimation.

$\text{Li}_2\text{O}(c)$ vaporizes to $\text{Li}_2\text{O}(g)$, $\text{LiO}(g)$, $\text{Li}_2\text{O}_2(g)$, $\text{Li}(g)$, and $\text{O}_2(g)$ [J. Berkowitz, W. A. Chupka, G. D. Blue and J. L. Margrave, J. Phys. Chem., **63**, 644 (1959); D. White, K. S. Seshadri, D. F. Dever, D. E. Mann, and M. J. Linevsky, J. Chem. Phys. **39**, 2463 (1963); D. L. Hildenbrand, W. F. Hall, and N. D. Potter, J. Chem. Phys. **39**, 296 (1963); D. L. Hildenbrand, L. P. Theard, W. F. Hall, and N. D. Potter, Fifth Quarterly Technical Report, U-2289, Aeronautics Division of Philco Corporation, 15 September 1963; L. P. Firsova and A. N. Nesmeyanov, Russian J. Phys. Chem., **34**, 1232 (1960). The major species (0° - 1700°K.) are reported to be $\text{Li}_2\text{O}(g)$, $\text{Li}(g)$, and $\text{O}_2(g)$ with lesser amounts of $\text{LiO}(g)$ and $\text{Li}_2\text{O}_2(g)$. Hildenbrand, et al., U-2298, have reported about equal amounts of Li_2O and Li^+ (1300 to 1550°K.) and about $1/30$ th of this amount of LiO^+ . White, et al., calculated ΔH_g° from their mass spectra data. They made two different calculations (a) for $\text{Li}_2\text{O}(c) \rightarrow \text{Li}_2\text{O}(g)$, and (b) for $\text{Li}_2\text{O}(g) \rightarrow 2\text{Li}(g) + 1/2 \text{O}_2(g)$, and found: (a) 102.5 kcal. and (b) 99.0 kcal. They used a weighted average of (a) and (b) and obtained 101.6 kcal. at 0°K. The selected ΔH_g° 298 of $102.3 \pm 3 \text{ kcal.}$ was obtained in the same manner using their data and the present JANAF functions, i.e. (a) 104.2 kcal. and (b) 100.3 kcal. Knudsen-effusion data of White et al., corrected for dissociation pressure with JANAF values gives Li_2O pressures slightly different than those reported. The recalculated pressures give a 3rd law ΔH_g° 298 of 101.7 kcal. for both cells. The corresponding 2nd law values are 85 and 95.5 kcal. for cell 7 and 8. The 3rd law treatment of both sets of data show relatively large trends of ΔH_g° with T which are probably too large to be only due to errors in the functions. (Continued on Lithium Oxide $\text{Li}_2\text{O}(g)$ table)

Dec. 31, 1960; Mar. 31, 1964

Li_2O

(LIQUID) MOL. WT. = 29.880

DILITHIUM MONOXIDE (Li_2O)

$S^\circ_{298.15} = 13.160 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H^\circ_f = -132.129 \text{ kcal. mole}^{-1}$
 $\Delta H^\circ_m = [14] \text{ kcal. mole}^{-1}$
 $\Delta H^\circ_v = \text{Unknown}$

Heat of Formation.

$\Delta H^\circ_f (l)$ was obtained from $\Delta H^\circ_f (c)$ by adding ΔH_m and the difference between $H_{1843-H_{298}}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated at 8 cal. deg.⁻¹ g. atom⁻¹ from comparisons with similar compounds and from Kopp's rule. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See melting data given on the Li_2O crystal table.

Vaporization Data.

The vapor over $\text{Li}_2\text{O}(c)$ at 1700°K. is composed of $\text{Li}_2\text{O}(g)$, $\text{Li}(g)$, $\text{O}_2(g)$, $\text{LiO}(g)$, and $\text{Li}_2\text{O}_2(g)$. Thus a boiling point becomes almost meaningless. The value, 2836°K. listed above is the temperature at which the free energy of $\text{Li}_2\text{O}(g)$ and the free energy of $\text{Li}_2\text{O}(l)$ are equal. L. Brewer, Chem. Rev. 52, (1953) estimated a boiling point of 2600°K.

Heat of Formation.

The heat of formation was calculated from the heat of formation of the crystal and the heat of sublimation.

Heat Capacity and Entropy.

D. White, K. S. Seshairi, and D. F. Dever, and D. E. Mann, and M. J. Linevsky, *J. Chem. Phys.* 39, 2463 (1963) made an estimate of the bond distance Li-O = 1.59 Å based on an analysis of their vibrational spectra. They found that Li₂O was a linear molecule. A. Buchler and J. L. Stauffer, *J. Chem. Phys.* 39, 2299 (1963) have shown from electric deflection experiments that Li₂O is very probably linear. They also report from the results of an effusion experiment evidence that the electron diffraction data and Li-O bond distance, 1.82 Å reported by F. A. Akishin and N. G. Rambidi, *Dokl. Akad. Nauk. SSSR* 118, 973 (1958) [English Translation, *Proc. Acad. Sci. USSR, Phys. Chem. Sect.* 118, 83 (1958)] are for Mo-O in Li₂MoO₄ rather than for Li-O in Li₂O. Buchler and Stauffer (loc. cit.) estimate an Li-O distance of 1.55 Å. White, et al., (loc. cit.) have estimated the vibrational frequencies $\nu_1 = [760]$ cm.⁻¹ and $\nu_2 = [140]$ cm.⁻¹ and assigned $\nu_3 = 987$ cm.⁻¹ from their infrared matrix spectra. The principal moments of inertia calculated from the molecular constants are: I_A = 0, and I_B = I_C = 5.8256 × 10⁻³⁹ g. cm.².

Heat of Sublimation (continued from Li₂O(c) table).

A sample of LiAlO₂ was melted 7 times in argon in an arc-image furnace, H. Prophet, "Melting Point of Lithium Aluminate", ARPA-1-150, Dow Chemical Co., Mar. 9, 1961. The sample decomposed on fusion and successive melting points approached that of Al₂O₃. The residue was found to be 95% Al₂O₃ and 5% LiAl₂O₄. The sample and residue were characterized by X-ray diffraction. A reasonable assumption from this is that $\Delta F^o_{298}(3000^\circ\text{K}) = 0$ for 2LiAlO₂(c) = Al₂O₃(c) + Li₂O(g). From this ΔF^o , a ΔH^o_{298} for Li₂O of 50 kcal. was calculated. A vapor pressure study of the molecular species over the decomposing LiAlO₂ might help resolve the discrepancies in lithium oxide ΔH^o_f values.

ΔH_f° = Unknown

S_{298.15}° = [13.5 ± 1.0] cal. deg.⁻¹ mole⁻¹

ΔH_f° 298.15 = -151.2 ± 2.0 kcal. mole⁻¹

T_d = 468°K.

Heat of Formation.

ΔH_f° 298.15 was reported by R. de Forcrand, Compt. rend. 130, 1465 (1900), based on the measured heats of the reactions of $\text{Li}_2\text{O}_2(\text{c})$ with $\text{HCl}(\text{aq.})$ and $\text{LiOH}(\text{aq.})$ with $\text{H}_2\text{O}_2(\text{aq.})$.

Heat Capacity and Entropy.

Both C_p and S_{298.15} were estimated by comparison with those of the $\text{Na}_2\text{O}_2(\text{c})$, respectively.

Temperature of Decomposition.

T_d was reported to be about 300°C. by N. M. Wiederhorn, N. F. Surprenant, and A. J. Leffler, "Research on New Methods of Separation of Air into O₂ and N₂ Components," C-63025, First-Quarterly Progress Report, September 1961, Arthur D. Little, Inc. The value adopted was reported by Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use", June, 1949, obtained from M. Centnerzwer and M. Elmenthal, Bull. intern. acad. polonaise, Classe. sci. math. nat., A 499 (1933).

$\sigma = 4$

Heat of Formation.

The heat of formation, -58 kcal., was calculated from an equilibrium constant for the reaction $1/2 \text{ O}_2(\text{g}) + \text{Li}_2\text{O}(\text{g}) \rightarrow \text{Li}_2\text{O}_2(\text{g})$ and the current JANAP functions. The equilibrium constant, 0.39, was estimated by D. White, K. S. Seshadri, D. F. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. **39**, 2463 (1963), from their mass spectrometric data.

Heat Capacity and Entropy.

White, et al., (loc. cit.), from their spectral data have assigned two observed frequencies and estimated the remaining frequencies using the ionic model calculations of J. Berkowitz, J. Chem. Phys. **23**, 1386 (1958); **32**, 1519 (1960) as a guide. They proposed a planar rhombic structure of D_{2h} symmetry, similar to the alkali halide dimers, for the previously undetected Li_2O_2 molecule, and estimated the angle, 116°, and bond distance, 1.90 Å, from their matrix spectra. The principal moments calculated from these molecular constants are: $I_A = 13.793 \times 10^{-39} \text{ g. cm.}^2$, $I_B = 2.356 \times 10^{-39}$, and $I_C = 16.129 \times 10^{-39} \text{ g. cm.}^2$.

Heat of Formation

The heats of solution of $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{SiO}_3(\text{c})$ in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kraeck, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 89 (1953). The authors derived two values of $\Delta H^\circ_{\text{soln}}$ of $\text{Li}_2\text{O}(\text{c})$ from those of $\text{LiCl}(\text{c})$ and $\text{Li}_2\text{SO}_4(\text{c})$, presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate $\Delta H^\circ_{\text{soln}}$ of $\text{Li}_2\text{O}(\text{c})$ as -59.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent ΔH°_{298} values for $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{HCl}(\text{aq})$, $\text{H}_2\text{SO}_4(\text{aq})$, and $\text{Li}_2\text{O}(\text{c})$. The corresponding enthalpy changes, ΔH°_{298} , for the reaction $\text{Li}_2\text{O}(\text{c}) + \text{SiO}_2(\text{quartz}) = \text{Li}_2\text{SiO}_3(\text{c})$ are derived as -33.08 and -34.17 kcal/mol. Adopting the weighted average $\Delta H^\circ_{298} = -33.44$ kcal/mol with $\Delta H^\circ_{298}(\text{Li}_2\text{O}, \text{c}) = -143.1$ kcal/mol and $\Delta H^\circ_{298}(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta H^\circ_{298} = -394.24$ kcal/mol for $\text{Li}_2\text{SiO}_3(\text{c})$. This $\Delta H^\circ_{298}(\text{Li}_2\text{SiO}_3, \text{c})$ value is independent of future changes in ΔH°_{298} of $\text{Li}_2\text{O}(\text{c})$ but the values of $\Delta H^\circ_{\text{soln}}$ and ΔH° are not independent.

The heats of solution of $\text{LiOH}(\text{c})$ and $\text{Li}_2\text{SiO}_3(\text{c})$ in 20 percent $\text{HF}(\text{aq})$ at 50°C were measured by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. The Li_2SiO_3 sample was prepared from lithium carbonate and silica by fusion under vacuum at 1500°C . Analysis gave 66.74 percent SiO_2 and 15.12 percent Li . The corresponding calculated values are 66.79 and 15.43.

Also present were 0.5 percent K and 0.06 percent Na. Corrections were made for impurities in the heat of formation measurements. The results are given as follows:

	ΔH°_{298} , kcal/mol
$2\text{LiOH}(\text{c}, 25^\circ\text{C}) + 2\text{HF}(\text{sol}, 50^\circ\text{C}) + 2\text{LiF}(\text{sol}, 50^\circ\text{C}) + 2\text{H}_2\text{O}(\text{sol}, 50^\circ\text{C})$	-38.728
$\text{SiO}_2(\text{c}, 25^\circ\text{C}) + 6\text{HF}(\text{sol}, 50^\circ\text{C}) + \text{H}_2\text{SiF}_6(\text{sol}, 50^\circ\text{C}) + 2\text{H}_2\text{O}(\text{sol}, 50^\circ\text{C})$	-32.810
$3\text{H}_2\text{O}(\text{sol}, 50^\circ\text{C}) + 2\text{LiF}(\text{sol}, 50^\circ\text{C}) + \text{H}_2\text{SiF}_6(\text{sol}, 50^\circ\text{C}) - \text{Li}_2\text{SiO}_3(\text{c}, 25^\circ\text{C}) + 8\text{HF}(\text{sol}, 50^\circ\text{C})$	+58.650
$\text{H}_2\text{O}(\text{sol}, 50^\circ\text{C}) - \text{H}_2\text{O}(\text{l}, 25^\circ\text{C})$	-0.450
$2\text{LiOH}(\text{c}, 25^\circ\text{C}) + \text{SiO}_2(\text{c}, 25^\circ\text{C}) + \text{Li}_2\text{SiO}_3(\text{c}, 25^\circ\text{C}) + \text{H}_2\text{O}(\text{l}, 25^\circ\text{C})$	-13.14 $\pm$ 0.70

The ΔH°_{298} for the second reaction was determined by D. R. Torgeson and T. G. Sahana, J. Am. Chem. Soc. 70, 2156 (1948). Based on the calculated enthalpy change for the overall reaction, $\Delta H^\circ_{298} = -13.14$ kcal/mol and $\Delta H^\circ_{298} = -115.84$, -217.7 and -68.32 kcal/mol for $\text{LiOH}(\text{c})$, $\text{SiO}_2(\text{low quartz})$, and $\text{H}_2\text{O}(\text{l})$, respectively, we derived $\Delta H^\circ_{298}(\text{Li}_2\text{SiO}_3, \text{c}) = -394.21 \pm 1.0$ kcal/mol, which is in agreement with the adopted value.

C. Kroger and E. Fingas, Z. Anorg. Allgem. Chem. 213, 12 (1933), measured the equilibrium pressure of CO_2 over a mixture of $\text{Li}_2\text{CO}_3(\text{c})$, $\text{SiO}_2(\text{quartz})$, and $\text{Li}_2\text{SiO}_3(\text{c})$ from 585 to 781°K . The enthalpy change (ΔH°_{298}) of the reaction $\text{Li}_2\text{CO}_3(\text{c}) + \text{SiO}_2(\text{c}) = \text{Li}_2\text{SiO}_3(\text{c}) + \text{CO}_2(\text{g})$ is evaluated by the second and third law methods to be 30.94 and 29.47 kcal/mol, respectively. Using $\Delta H^\circ_{298} = -290.84$, -217.7 and -94.05 kcal/mol for $\text{Li}_2\text{CO}_3(\text{c})$, $\text{SiO}_2(\text{c})$ and $\text{CO}_2(\text{g})$, respectively, and third law ΔH°_{298} , we obtain $\Delta H^\circ_{298}(\text{Li}_2\text{SiO}_3, \text{c}) = -394.82 \pm 5$ kcal/mol, which is not used.

Heat Capacity and Entropy

The low temperature heat capacities, 75 - 340°K , were measured by Hatton et al., loc. cit., with an adiabatic vacuum calorimeter, using a nickel-plated copper sample container. During the filling and sealing of the calorimeter, the compound was handled in an anhydrous, CO_2 -free atmosphere so as to avoid contamination. The purity of the sample is not well established. The high temperature heat capacities are estimated by summation of the Cp's of the constituent oxides Li_2O and SiO_2 , and a subsequent correction based upon a comparison of the heat capacities of $\text{Na}_2\text{SiO}_3(\text{c})$ and its constituent oxides. These estimated Cp values are plotted, and the resulting curve is joined smoothly with the low temperature Cp curve at 298°K . The entropy, S°_{298} , is derived using the measured low temperature heat capacities, based on $S^\circ_{298} = 0.023$ eu.

Melting Data

See $\text{Li}_2\text{SiO}_3(\text{l})$ table for details.

LITHIUM METASILICATE (Li_2SiO_3)
(LIQUID)

$S^0_{298.15} = 22.958$ gibbs/mol

$T_m = 1474 \pm 1^\circ\text{K}$

$\Delta H_f^{298.15} = -385.441$ kcal/mol

$\Delta H_m^0 = 6.7 \pm 0.5$ kcal/mol

$\text{GFW} = 89.9622$

Heat of Formation

$\Delta H_f^0(t)$ is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^0 and the difference between $H^0_{1474} - H^0_{298}$ for crystal and liquid.

Tchernobaieff, Rev. Met. 21, 729 (1905), measured the heat of reaction between SiO_2 and Li_2CO_3 in a bomb calorimeter, using carbon as the auxiliary combustible material. Based on the derived $\Delta H_{298} = 24.99$ kcal/mol for the reaction $\text{Li}_2\text{CO}_3(c) + \text{SiO}_2(c) \rightarrow \text{Li}_2\text{SiO}_3(\text{gl}) + \text{CO}_2(g)$, the heat of formation for $\text{Li}_2\text{SiO}_3(\text{gl})$ is evaluated as -389.30 kcal/mol, which is in fair agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $\text{Na}_2\text{SiO}_3(l)$, $\text{Na}_2\text{O}(l)$ and $\text{Li}_2\text{O}(l)$. A glass transition is assumed at 1000°K ; i.e., the heat capacities below 1000°K are taken to be the same as those for $\text{Li}_2\text{SiO}_3(c)$.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been reported as 1474 ± 1 and 1461°K by F. C. Kracek, J. Phys. Chem. 31, 2841 (1930), and H. S. Van Klooster, Z. Anorg. Chem. 69, 135 (1911), respectively. The value reported by Kracek is adopted.

R. Schwarz and H. Sturm, Ber. 12, 1730 (1914), used a cooling-curve method to compare the heats of fusion of $\text{Li}_2\text{SiO}_3(c)$ and $\text{NaCl}(c)$. From the reported ratio, $\epsilon(\text{Li}_2\text{SiO}_3)/\epsilon(\text{NaCl}) = 0.261/0.402$, where ϵ = heat of fusion in kcal/g, and heat of fusion of $\text{NaCl}(c)$, the value $\Delta H_m^0 = 6.7$ kcal/mol is derived.

June 30, 1961; Mar. 31, 1964

$\Delta H_f^\circ 0 = -396.8 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -399.3 \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = 21.930 \pm 0.1 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_f = 1485^\circ\text{K.}$
 $T_m = 1820^\circ\text{K.}$
 $\Delta H_m^\circ = 2.75 \text{ kcal. mole}^{-1}$
 $\Delta H_m = 26.33 \text{ kcal. mole}^{-1}$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ was calculated from measurements of solution calorimetry by S. S. Todd and K. K. Kelley, "Heat and Free Energy Data for Tricalcium Dittitanate, Spinel, Lithium Metatitanate and Zinc Titanium Spinel", U. S. Bureau Mines Report Invest. 5193 (1956), according to the following equation:

The $\Delta H_f^\circ 298.15 \text{ TiO}_2(c)$ value for rutile was obtained from the JANAF Tables and the other $\Delta H_f^\circ 298.15$ values were obtained from "Selected Values of Chemical Thermodynamic Properties" NBS Circular 500 (1952).

Heat Capacity and Entropy.

The low temperature heat capacities were taken from E. G. King, J. Am. Chem. Soc. 77, 2150 (1955). These low temperature heat capacities were fit to the high temperature heat contents from A. U. Christensen, K. C. Conway, and K. K. Kelley, "High Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bur. Mines Rept. Invest. 5565 (1960).

The $S_{298.15}^\circ = 21.9$ was obtained from E. G. King, loc. cit. based on the measured $S_{298.15}^\circ \text{S}_2^\circ$ and the extrapolated $S_{51}^\circ \text{S}_0^\circ$.

Transition Data.

A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit. reported that lithium metatitanate undergoes a transition from the α to the β form at $1,485^\circ\text{K.}$ with an absorption of $2.750 \text{ kcal. mole}^{-1}$.

Melting Data.

The T_m and ΔH_m were obtained from A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit.

$S^\circ_{298.15} = 35.355$ cal. mole⁻¹ deg.⁻¹
 $\Delta H^\circ_f 298.15 = -374.374$ kcal. mole⁻¹
 $\Delta F^\circ_f 298.15 = -356.667$ kcal. mole⁻¹
 $T_m = 1820^\circ\text{K.}$

Heat of Formation.

The $\Delta H^\circ_f 298.15$ was obtained from the heat of formation of the crystal by adding ΔH_m and the difference between $H_{1820} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacities were reported by A. U. Christensen, K. C. Conway, and K. K. Kelley, "High-Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bureau Mines Report Invest. 5565 (1960). The measured heat capacity is extrapolated to an assumed glass transition temperature of 1214°K., below which the heat capacity is taken to be equal to that of the crystal.

The $S^\circ_{298.15}$ was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The T_m and ΔH_m were obtained from A. U. Christensen, K. C. Conway and K. K. Kelley, loc. cit.

Heat of Formation

The heats of solution of $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). The authors derived two values of $\Delta H^\circ_{\text{soln}}$ of $\text{Li}_2\text{O}(\text{c})$ from those of $\text{LiCl}(\text{c})$ and $\text{Li}_2\text{SO}_4(\text{c})$, presumably employing auxiliary data from U. S. Natl. Bur. Std., Circ. 500, 1952. We recalculate $\Delta H^\circ_{\text{soln}}$ of $\text{Li}_2\text{O}(\text{c})$ as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent ΔH°_{298} values for $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{HCl}(\text{aq})$, $\text{H}_2\text{SO}_4(\text{aq})$, and $\text{Li}_2\text{O}(\text{c})$. The corresponding enthalpy changes, ΔH°_{298} , for the reaction $\text{Li}_2\text{O}(\text{c}) + 2\text{SiO}_2(\text{quartz}) = \text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ are derived as -33.21 and -34.30 kcal/mol. Adopting the weighted average $\Delta H^\circ_{298} = -33.57$ kcal/mol with $\Delta H^\circ_{298}(\text{Li}_2\text{O}, \text{c}) = -143.1$ kcal/mol and $\Delta H^\circ_{298}(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta H^\circ_{298} = -612.07$ kcal/mol for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$. This $\Delta H^\circ_{298}(\text{Li}_2\text{Si}_2\text{O}_5, \text{c})$ value is independent of future changes in ΔH°_{298} of $\text{Li}_2\text{O}(\text{c})$ but the values of $\Delta H^\circ_{\text{soln}}$ and ΔH° are not independent.

The heats of solution of $\text{LiOH}(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ in 20 per cent $\text{H}^\circ(\text{aq})$ at 80°C were measured by W. E. Hatton, G. C. Sinke, D. L. Hildenbrand, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. By use of a reaction scheme similar to that described on the $\text{Li}_2\text{SiO}_3(\text{c})$ table, the enthalpy change at 298°K for the reaction $2\text{LiOH}(\text{c}) + 2\text{SiO}_2(\text{c}) = \text{Li}_2\text{Si}_2\text{O}_5(\text{c}) + \text{H}_2\text{O}(\text{l})$ was calculated to be -13.44 kcal/mol. Incorporating this value with $\Delta H^\circ_{298} = -115.84$, -217.7 and -68.315 kcal/mol for $\text{LiOH}(\text{c})$, $\text{SiO}_2(\text{c})$, and $\text{H}_2\text{O}(\text{l})$, respectively, we obtain $\Delta H^\circ_{298}(\text{Li}_2\text{Si}_2\text{O}_5, \text{c}) = -612.20 \pm 2.0$ kcal/mol, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy

Both heat capacities and S°_{298} are estimated by comparison with those for $\text{Na}_2\text{Si}_2\text{O}_5(\text{c})$, $\text{Na}_2\text{O}(\text{c})$ and $\text{Li}_2\text{O}(\text{c})$.

Transition Data

The transition temperature, $T_t = 1209^\circ\text{K}$, is taken from F. C. Kracek, J. Am. Chem. Soc. 61, 2863 (1939). This author estimated a heat of transition of 1 to 2 cal/g based on the arrest in the cooling and heating curves. The value of ΔH°_t is calculated assuming the heat of transition at 1209°K is 1.5 cal/g.

Melting Data

Incongruent melting of $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ at 1033° has been reported by F. C. Kracek, J. Phys. Chem. 34, 2841 (1930); J. Am. Chem. Soc. 61, 2863 (1939). The liquidus temperature of 1034° at the composition 19.92 per cent Li_2O and 80.08 per cent SiO_2 , reported by Kracek (1939), is adopted as T_m . The heat of melting is evaluated such that $\Delta H^\circ_m + \Delta H^\circ_{298} = 11.43$ kcal/mol, where the value 11.43 kcal/mol is the difference between ΔH°_{298} for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{l})$. The latter were determined by solution calorimetry by Kracek (see Heat of Formation sections in $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{l})$ tables).

Lithium Disilicate ($\text{Li}_2\text{Si}_2\text{O}_5$)
(Liquid) GFW = 150.047

GFW = 150.047

(LIQUID)

LITHIUM DISILICATE ($\text{Li}_2\text{Si}_2\text{O}_5$)

$\Delta H_f^{298.15} = -600.640 \pm 1.0 \text{ kcal/mol}$

$\Delta H_m^* = [12.86] \text{ kcal/mol}$

$S_{298.15}^* = [38.297] \text{ gibbs/mol}$

$T_m = 1307^\circ\text{K}$

Heat of Formation

The heats of solution of LiCl(c) , $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$ in 20 percent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). Following the same procedure as described in $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ table, we derived the enthalpy changes, ΔH_f^{298} , for the reaction $\text{Li}_2\text{O(c)} + 2\text{SiO}_2(\text{quartz}) = \text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$ as -21.78 and -22.87 kcal/mol . Adopting the weighted average $\Delta H_f^{298} = -22.14 \text{ kcal/mol}$ with $\Delta H_f^{298}(\text{Li}_2\text{O, c}) = -143.1 \text{ kcal/mol}$ and $\Delta H_f^{298}(\text{SiO}_2, \text{quartz}) = -217.7 \text{ kcal/mol}$, we obtain $\Delta H_f^{298} = -600.640 \text{ kcal/mol}$ for $\text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$. This $\Delta H_f^{298}(\text{Li}_2\text{Si}_2\text{O}_5, \text{gl})$ value is independent of future changes in ΔH_f^* of $\text{Li}_2\text{O(c)}$ but the values of ΔH_{soln} and ΔH_f^* are not independent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $\text{Na}_2\text{Si}_2\text{O}_5(\text{c})$, $\text{Na}_2\text{SiO}_3(\text{c})$ and $\text{Li}_2\text{SiO}_3(\text{c})$. A glass transition temperature at 800°K is assumed, i.e. the heat capacities below 800°K are taken from those for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and above 800°K are assumed to be constant.

The S_{298}^* value is obtained from $S_{298}^*(\text{c})$ by adding ΔS_m^* and the difference between $S_{1307}^* - S_{298}^*$ for crystal and liquid.

Melting Data

See $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ table for details.

$\Delta \text{H}^\circ_0 = \text{Unknown}$
 $\Delta \text{H}^\circ_{298.15} = -47.2 \pm 1.0 \text{ kcal/mol}$

Heat of Formation.
 The adopted $\Delta \text{H}^\circ_{298.15} = -47.2 \pm 1.0 \text{ kcal/mol}$ was determined calorimetrically by Neumann et al.¹ by heating $\text{Li}(\text{c})$ at 600°C under 5 atm N_2 pressure for 1 minute. The $\Delta \text{H}^\circ_{291} = -131.1 \text{ kcal/mol}$ of reaction $\text{Li}_3\text{N}(\text{c}) + 3 \text{H}_2\text{O}(\text{l}) = 3 \text{LiOH}(\text{aq}) + \text{NH}_3(\text{g})$ was measured by Guntz.² Based on this $\Delta \text{H}^\circ_{291}$ the heat of formation was calculated to be $-47.02 \pm 2 \text{ kcal/mol}$ which is in very good agreement with that of Neumann et al.¹. Unfortunately the author does not report the amount of water in $\text{LiOH}(\text{aq})$ and we assumed 300 H_2O as the best estimate. Heat of formation for $\text{NH}_3(\text{g}) = [-19.17] \text{ kcal/mol}$ and $\text{H}_2\text{O}(\text{l}) = [-68.315] \text{ kcal/mol}$ were taken from Wagman et al.³. The ΔH° of $\text{LiOH} + 300 \text{H}_2$ (-121.30 kcal/mol) was derived from the heats of formation and solution of $\text{LiOH}(\text{c})$ (see JANAF table) and the heat of dilution selected by Parker.⁴

Heat Capacity and Entropy.

S. Satoh, Sci. Papers Inst. Phys. Chem. Research (Tokyo) **35**, 182 (1939), has measured enthalpies (273-578°K) and derived an equation for the specific heat of Li_3N . The adopted heat capacities were obtained from this equation. Above 773°K the heat capacities were graphically extrapolated. The entropy was estimated from the contribution 3.5 eu per Li given by W. M. Latimer, "Oxidation Potentials," 2nd Edition, Prentice-Hall, Inc., New York, 1952, and a -1.5 eu contribution for N.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The following heat capacity measurements were considered in drawing a smooth curve of C_p with T : P. L. Smith (1.25-4.2°K) Phil. Mag. 45, 744 (1955); J. R. Clement and H. R. Jeffers (3-13°K) Phys. Rev. 105, 1435 (1957); K. Clausius and J. V. Vaughn (11.3-228.4°K) J. Am. Chem. Soc. 52, 4686, (1930); R. S. Craig, C. A. Krier, L. W. Coffey, E. A. Bates, and W. E. Wallace (12-320°K) J. Am. Chem. Soc. 76, 238 (1954); W. Mannchen and K. Bornkessel (190-300°K) Z. Metallkunde 51, 482-5 (1960); H. Seelkamp (291-773°K) Z. anorg. Chem. 195, 345 (1931); and D. R. Stull and R. A. McDonald (700-900°K) J. Am. Chem. Soc. 77, 5293 (1955). The following heat capacity measurements were noted but not used as the data were either not tabulated, or erratic, or inconsistent or would not have altered the C_p - T curve: D. L. Martin (0.4-1.5°K) Proc. Phys. Soc. (London) 76, 1482-8 (1961); I. Rethermann, S. A. Friedberg, and J. E. Goldman (1.6-4.2°K) Phys. Rev. 87, 562 (1952); E. P. Eastman and W. H. Rodenbush (74.9-288.5°K) J. Am. Chem. Soc. 40, 489 (1918); W. O. Saba, K. P. Sterrett, R. S. Craig, and W. E. Wallace (238-543°K) J. Am. Chem. Soc. 79, 3537 (1957); F. M. Jaeger and T. J. Poppema (273-873°K) Rec. Trav. chim. 55, 492 (1936); J. H. Averbey and E. Griffiths (323-899°K) Proc. Phys. Soc. 36, 378 (1926); E. D. Eastman, A. M. Williams and T. F. Young (373-873°K) J. Am. Chem. Soc. 46, 1178 (1926); and P. Schübel (323-773°K) Z. anorg. Chem. 87, 81 (1914). $S_{298.15}^\circ$ was obtained by numerical integration using the low temperature C_p data cited above.

Melting.

Melting point is from J. L. Houghton and R. J. M. Payne (922 ± 0.5°K) J. Inst. Met. 54, 279 (1934). Also noted but not used were: R. Chadwick (923°K) J. Inst. Met. 39, 285-300 (1928); W. R. D. Jones (920.5°K) J. Inst. Met. 46, 395-419 (1931).

The heat of melting is from D. R. Stull and R. A. McDonald (loc. cit.)

Heat of Sublimation.

Is obtained by third law calculations from the vapor pressure data on the solid by P. F. Coleman and A. E. Egerton, Phil. Trans. Roy. Soc. (London) A234, 177-204 (1935) and the value is confirmed by similar use of the vapor pressure data on the liquid by E. Scheil and P. Wolf, Z. Metallkunde 50, 229-33 (1959); A. Wejnarth, Tek. Tid. 72, 33-9, 44-8 (1942); A. Schneider and E. K. Stoll, Z. Elektrochem. 47, 513-26 (1941); E. Baur and R. Brunner, Helv. Chim. Acta, 17, 958-69 (1934); and H. Hartmann and R. Schneider, Z. anorg. Chem. 180, 275-83 (1929). Additional data noted but not used on the vapor pressure are values not tabulated or they were erratic of the solid are by J. F. Smith and R. L. Smythe, Acta Metallurgica, 7, 261-7 (1959); A. Ruckner, Metallwirtschaft, 15, 64-5 (1936); W. Leitgeb, Metallwirtschaft, 14, 269 (1935); and of the liquid by P. A. Vetter and O. Kubaschewski, Z. Elektrochem. 57, 243 (1953); W. Leitgeb, Z. anorg. Chem. 202, 312 (1931); C. Zwikker, Physica, 9, 246 (1928); O. Ruff and H. Hartmann, Z. anorg. Chem., 135, 29-45 (1924); and J. Johnston, Ind. Eng. Chem., 9, 876 (1917).

MAGNESIUM (Mg)

(LIQUID)

AT. WT. = 24.32

ΔH_f^o 298.15 = [2.158] kcal. mole⁻¹

$T_m = 922 \pm 0.5^\circ K$

$T_b = 1379^\circ K$

Heat of Formation.

ΔH_f^o 298.15 (= ΔH_m 298.15) obtained from ΔH_m 922 by adding $H_{922} - H_{298.15}$ for solid and subtracting $H_{922} - H_{298.15}$ for liquid.

Heat Capacity and Entropy.

The heat capacity measurements of D. R. Stull and R. A. McDonald (950-1100°K) J. Am. Chem. Soc. 77, 5293 (1955) were used. Outside of the observed range C_p was extrapolated linearly with temperature. Below T_m the linear extrapolation was continued until the C_p curve for the solid is encountered at 710°K. At lower temperatures the C_p of the crystal is used. $S_{298.15}^o$ was calculated from that of the solid.

Melting.

See crystal for details.

Vaporization.

The normal boiling point was calculated by the third law and ΔH_v 298.15. This compares with 1377°K computed from the general vapor pressure equation for liquid Mg given on p 221 of *Chemical Thermodynamics* of the American Chemical Society, 1952, and experimentally determined values: 1376 ± 5°K by A. Schneider and U. Eick, Z. Elektrochem. 45, 888 (1953); 1380°K by E. Baur and R. Brunner, Helv. Chim. Acta 17, 958 (1934); 1370°K by W. Leitgeb, Z. anorg. Chem. 202, 305 (1931); and 1395°K by Greenwood, Chem. News 104, 31 (1911).

The ΔH_v 1378 is based on the liquid and ideal gas tables.

Mg

AT. WT. = 24.32

Heat of Formation.

$\Delta H_f^\circ 298.15$ ($-\Delta H_s 298.15$) is calculated as described on the table for crystal.

Heat Capacity and Entropy.

Thermodynamic functions were calculated using electronic levels and multiplicities from C. E. Moore [Natl. Bur. Standards Circ. 467, Vol. 1 (1949)]. Higher levels were averaged.

Heat of Formation

We derive the heat of formation at 0°K from the reaction Mg(g) - e⁻(g) + Mg⁺(g) using the JANAF auxiliary value for Mg(g) and an ionization potential of 176.278 kcal/mol from C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, Vol. I, 1949.

Heat Capacity and Entropy

We take the electronic levels and quantum weights from C. E. Moore, loc. cit. H°₀ - H°₂₉₈ = -1.481 kcal/mol at 0°K.

 $r_e = 1$

Heat of Formation.

The ΔH_f^0 298.15 for MgN was estimated from bond strengths using MgO and comparison with analogous pairs of compounds such as, PN and PO, and also the bond strengths of C-N and C-O in organic compounds.

Heat Capacity and Entropy.

The r_e value for MgN was estimated from MgO by comparison with similar pairs PO and PN, SiO and SiN, and AlO and AlN. Using Guggenheim's Relation, Proc. Phys. Soc. (London) 58, 456 (1946), μ for MgO was found to lie between the single and multiple bonding cases. Magnesium nitride was assumed to be similar to MgO and $\mu_e = 700$ cm.⁻¹ was obtained. It was assumed that the $X_e \mu^{1/2}$ value for MgN was equal to that for MgO thus giving $\mu_e X_e = 4.8$ cm.⁻¹. B_e was calculated from r_e . The α_e value was calculated from B_e , μ_e and $\mu_e X_e$.

ΔH_f^o 0 = -142.7 ± 0.3 kcal. mole⁻¹
 ΔH_f^o 298.15 = -143.7 ± 0.3 kcal. mole⁻¹
 ΔH_m^o = [16.5 ± 1.5] kcal. mole⁻¹
 T_m = 3098 ± 20 °K.
 T_B = 3456°K.

Heat of Formation.

C. E. Holley and E. J. Huber, J. Am. Chem. Soc. 73, 5577 (1951) reported ΔH_f^o 298 (MgO, c) = -143.7 kcal. mole⁻¹ by combustion calorimetry. Heat of solution measurements by C. H. Shomate and E. H. Huffman, J. Am. Chem. Soc. 65, 1625 (1943) yielded ΔH_f^o 298 (MgO, c) = -143.84 kcal. mole⁻¹, well within the adopted ΔH_f^o 298 (MgO, c) = -143.7 ± 0.3 kcal. mole⁻¹.

Heat Capacity and Entropy.

Low temperature heat capacities have been reported by:

1. W. Lien and N. Phillips, J. Chem. Phys. 29, 1415 (1958), 1.5-4°K.
2. W. F. Glauque and R. C. Archibald, J. Am. Chem. Soc. 59, 561 (1937), 20-301°K.
3. G. S. Parks and K. K. Kelley, J. Phys. Chem. 50, 47 (1926), 94-291°K.
4. T. H. K. Barron, W. T. Berg, and J. A. Morrison, Proc. Roy. Soc. (London) A250, 70 (1959), 10-270°K.
5. P. Gunther, Ann. Physik 51, 828 (1916), 21-84°K.

High temperature heat contents have been reported by:

6. A. C. Victor and T. B. Douglas, J. Res. N.B.S. 57A, 325 (1953), 373-1173°K.
7. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6295, (1963), 400-1800°K.

The samples of (1) and (2) were finely divided magnesia and the other samples were periclase. Periclase is taken to be the standard state. The high temperature heat content data of (6) and (7) were joined by a Shomate plot with the low temperature C_p data of (4). The heat capacity was extrapolated linearly above 1800°K to a value of 14 cal. mole⁻¹ deg.⁻¹ at 3100°K. S_{298.15} = 6.44 cal. deg.⁻¹ mole⁻¹ is from (4).

Melting Data.

T_m (MgO, c) = 3098 ± 20°K by R. N. McNally, P. I. Peters, and P. H. Ribbe, J. Am. Ceram. Soc. 44, 491 (1961) was adopted. Their value is 41°K higher than the earlier measurements of C. W. Kanolt, J. Wash. Acad. Sci. 3, 315 (1913). K. K. Kelley, Bur. Mines Bull. 393 (1936) calculated ΔH_m^o (MgO, c) = 18.5 ± 1.5 kcal./mole from melting point measurements in the MgO - ZnO system.

Sublimation Data.

T_B is the temperature at which the free energy change of the reaction MgO(c) = MgO(g) approaches zero. The difference between ΔH_f^o 298.15 for MgO(c) and MgO(g) is ΔH_B^o 298.15.

MAGNESIUM OXIDE (MgO)

(LIQUID)

MOL. WT. = 40.3114

$\Delta H_f^\circ 298.15 = [12.033] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_m^\circ = [18.5 \pm 1.5] \text{ kcal. mole}^{-1}$
 $\Delta H_v^\circ = [113.4] \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = [-126.137] \text{ kcal. mole}^{-1}$
 $\Delta H_m^\circ = [18.5 \pm 1.5] \text{ kcal. mole}^{-1}$
 $\Delta H_v^\circ = [113.4] \text{ kcal. mole}^{-1}$

$S_{298.15}^\circ = [12.033] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 3098^\circ \text{K.}$
 $T_B = [3533]^\circ \text{K.}$

Heat of Formation.

$\Delta H_f^\circ 298.15(1)$ was calculated from $\Delta H_f^\circ 298.15(c)$ by adding ΔH_m° and the difference between $H_m^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2066°K. $C_p(1)$ below 2066°K. were assumed to be equal to those of $\text{MgO}(c)$. At and above 2066°K. the heat capacities were assumed to be constant at $7.25 \text{ cal. deg.}^{-1} \text{ g. atom}^{-1}$. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $\text{MgO}(c)$ table for details.

Vaporization Data.

W. R. Mott, Tran. Am. Electrochem. Soc. 34, 255 (1918) estimated the boiling point at 3873°K. by comparing crater distances of arc image deposits with reference compounds. $T_B = 3533^\circ \text{K.}$ is the temperature at which the free energy change of the reaction $\text{MgO}(l) = \text{MgO}(g)$ approaches zero. The difference between $\Delta H_f^\circ 3533$ for $\text{MgO}(g)$ and $\text{MgO}(l)$ is ΔH_v° .

Heat of Formation.

There is considerable discordance in the heat of formation results even though results were adjusted to a common 3Σ ground state where necessary. A mean $\Delta H_f^o 298$ (MgO, g) = 1.0 ± 20 kcal. mole⁻¹ was selected.

R. L. Altman, J. Phys. Chem. 67, 365 (1963) made a Knudsen effusion and oxygen transpiration study of the vaporization of MgO. The predominant vapor species over MgO(c) were shown to be Mg(g) and O₂(g). MgO transpiration results with oxygen at 1 atm yielded a 3rd law heat of sublimation $\Delta H_g^o 298$ (MgO, g) = 162.3 kcal. mole⁻¹ and $\Delta H_f^o 298$ (MgO, g) = 18.6 kcal. mole⁻¹.

J. Drowart, O. Exsteen and G. Verhaegen, Trans. Far. Soc. 60, 1920 (1964) used the Knudsen effusion-mass spectrometer technique to determine relative ion intensities and enthalpies for the reaction $MgO(g) + O(g) \rightarrow Mg(g) + O_2(g)$. After adjusting their values for a 3Σ ground state we calculated $\Delta H_f^o 298$ (MgO, g) = 11.9 kcal. mole⁻¹. Similar calculations for their data on $MgO(g) + WO_2(g) \rightarrow Mg(g) + WO_3(g)$ yielded $\Delta H_f^o 298$ = 10.5 kcal. mole⁻¹. The agreement is fortuitous, however, since uncertainties in the JANAF values for $WO_2(g)$ and $WO_3(g)$ are on the order of 7 kcal. each.

R. F. Porter, W. A. Chupka and M. O. Inghram, J. Chem. Phys. 23, 1347 (1955) mass spectrometrically determined an upper limit for the vapor pressure of MgO(g) over MgO(c) at 1950°K. Their results reduce to a lower limit of 148.6 kcal. mole⁻¹ for $\Delta H_f^o 298.15$ (MgO, c) or a lower limit of 4.9 kcal. mole⁻¹ for $\Delta H_f^o 298$ (MgO, g).

E. Bulewicz and T. Sugden, Trans. Far. Soc. 55, 720 (1959), using a flame photometric technique, reported $D_0^o = 98 \pm 2$ kcal. mole⁻¹ for MgO. $\Delta H_f^o 298$ (MgO, g) = -4.1 kcal. mole⁻¹ was calculated.

I. Veita and L. Ourvich, Optika and Spektroskopiya 1, 22 (1956) used a flame technique to obtain $D_0^o = 100$ kcal. mole⁻¹. A 4 kcal. mole⁻¹ adjustment for 1Σ to 3Σ yields $\Delta H_f^o 298$ (MgO, g) = -2.1 kcal. mole⁻¹.

The flame method data of L. Huldt and A. Lagerquist, Arkiv Fysik 2, 333 (1950) yielded a 3Σ adjusted $D_0^o = 115$ kcal. mole⁻¹. $\Delta H_f^o 298$ (MgO, g) = -21.1 kcal. mole⁻¹ was calculated.

L. Brewer and R. F. Porter, J. Chem. Phys. 22, 1876 (1954) have shown by vapor pressure measurements on MgO(c) that the solid vaporizes mainly into molecular species. They gave spectroscopic evidence that the 1Σ electronic state of MgO(g) is not the principal vaporizing species. Using their vapor pressures for the reaction $MgO(c) = MgO(g)$ and a 3Σ ground state we calculated 2nd and 3rd law heat of sublimation at 298°K. of 120.0 and 129.1 kcal. mole⁻¹. The 3rd law value yields $\Delta H_f^o 298$ (MgO, g) = -14.6 kcal. mole⁻¹.

Heat Capacity and Entropy.

The fundamental frequency and anharmonicity correction were reported by L. Brewer and R. Porter, J. Chem. Phys. 22, 1876 (1954) and are based on a 3Σ ground state. The rotational constants were estimated by H. L. Schick 51. AVCO Corp. RAD-SR-62-251, 15 Dec. 1962. Although the ground state and spectroscopic constants are

In doubt, the free energies are probably within 8T in 3 of true values.

Heat Capacity and Entropy

See liquid table.

Transition Data

T₁ = 903°K is obtained from Boyd et al. (3). The authors determined the phase diagram boundary at high pressures and extrapolated to one atmosphere. T₂ = 1258°K is taken from Atlas (10). Below 903°K the phase is known as clinonastatite. Between 903° and 1258°K it is rhombic enstatite and above 1258°K it is protoenstatite. We calculate ΔH₁^o and ΔH₂^o from dT/dP (slopes of the isotherms) = 2.6°/kbar and 84°/kbar reported by Boyd et al. (3, 13) and from the densities of clinonastatite (3.210 gm/cc) and rhombic enstatite (3.208 gm/cc) reported by Stephenson et al. (11) and the density of protoenstatite (3.110 gm/cc) reported by Smith (12).

Melting Data

See liquid table.

S_{298.15} = 16.197 ± 0.2 gibbs/molT₁ = 903 °KT₂ = 1258 °KT_m = 1850 ± 2 °K

Heat of Formation

Torgeson et al. (1) report a ΔH₂₉₈^o = -8.59 ± 0.15 kcal/mol for reaction (a). They used a hydrofluoric acid solution calorimeter and measured the heats of solution of each component. They appear to have made the water-absorption correction to the heat of solution of SiO₂(c) in the wrong direction. We reverse the correction so that the new ΔH₂₉₈^o almost overlaps the range observed by King (11). We derive ΔH₂₉₈^o (MgSiO₃, c) = -370.20 ± 1.0 kcal/mol using the ΔH₂₉₈^o of MgO(c) and SiO₂(c, low quartz) from the JANAF tables.

Reesman et al. (2) calculated a ΔG₂₉₈^o = 23.72 kcal/mol for reaction (b) using aqueous solubility data. We use the ΔG₂₉₈^o of H₂O(l) and OH⁻(aq) from sources 3, ΔG₂₉₈^o of H₂SiO₄(aq) from source 4 and ΔG₂₉₈^o of Mg⁺⁺(aq) from source 6 and we obtain a ΔG₂₉₈^o (MgSiO₃, c) = -352.534 kcal/mol. We derive a ΔH₂₉₈^o (MgSiO₃, c) = -373.723 kcal/mol using the above ΔG₂₉₈^o of MgSiO₃(c) and the entropies of MgO(c), SiO₂(c) and O₂(g) from the JANAF tables.

We choose the heat of formation derived from the result of Torgeson et al. (1) which is considered to be better since it relates directly to the oxides. Also the ΔG₂₉₈^o (MgSiO₃, c) thus calculated is in very good agreement with that derived from the activities of SiO₂ and MgO (in the SiO₂ - MgO system) measured by Rein et al. (5). The ΔH₂₉₈^o (MgSiO₃, c) derived from the work of Reesman et al. is less accurate and involves uncertainties in the auxiliary data used to calculate the value.

Source	Method	Reaction
Torgeson et al.	HF solution calorimeter	(a) MgO(c) + SiO ₂ (c) = MgSiO ₃ (c)
Reesman et al.	Aqueous solubility	(b) MgSiO ₃ (c) + 3H ₂ O(l) = Mg ⁺⁺ (aq) + H ₄ SiO ₄ (aq) + 2OH ⁻ (aq)

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53 - 295°K) of Kelley (7). Wagner (8) measured the average heat capacities in the temperature range 580 - 1570°K. Using his data we derive the high temperature heat capacities which are joined smoothly with the low temperature values by a constrained fitting technique. The Cp values at 903 - 1258°K and above 1258°K are derived as 28.762 and 79.262 gibbs/mol, respectively, by assuming that the data of Wagner (8) pertain to the stable phase in these regions. The entropy is based on S₂₉₈^o = 0.49 au.

MgO_3Si

MAGNESIUM METASILICATE (MgSiO_3)

(LIQUID)

GFW = 100.3962

$\Delta H_f^{\circ}{}_{298.15} = [-357.281 \pm 5] \text{ kcal/mol}$

$\Delta H_f^{\circ}{}_{-1} = 0.16 \text{ kcal/mol}$

$\Delta H_f^{\circ}{}_{-2} = 0.39 \text{ kcal/mol}$

$\Delta H_m^{\circ} = [18 \pm 5] \text{ kcal/mol}$

$S^{\circ}_{298.15} = [22.112] \text{ gibbs/mol}$

$T_f = 903^{\circ}\text{K}$

$T_g = 1256^{\circ}\text{K}$

$T_m = 1850 \pm 2^{\circ}\text{K}$

Heat of Formation

The heat of formation is obtained from $\Delta H_f^{\circ}{}_{298}(\text{c})$ by adding ΔH_m° and the difference between $H_m^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 900°K . Below 900°K the heat capacity is obtained from the heat capacity of the crystal. Above 900°K the heat capacity is assumed constant and estimated as 35 gibbs/mol or 7 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

See crystal table.

Melting Data

T_m is taken from N. L. Bowen and O. Andersen, Ann. J. Sci. 37, 487 (1914). $\text{MgSiO}_3(\text{c})$ melts incongruently in the temperature range 1830 - 1850°K at atmospheric pressure. ΔH_m° is estimated from the phase diagrams of the $\text{MgSiO}_3 - \text{TiO}_2$ system reported by I. D. MacGregor, Ann. Rept. Director of the Geophysical Laboratory, No. 1455, 135-9 (1965). The phase diagrams were determined at 10 and 20 kbars pressure where $\text{MgSiO}_3(\text{c})$ melts congruently.

MgO_3Si

MAGNESIUM METATITANATE (MgTiO₃) (CRYSTAL) GFW = 120.2102

$\Delta H_f^\circ = -373.63 \pm 1.5$ kcal/mol
 $\Delta H_f^\circ_{298.15} = -375.85 \pm 1.5$ kcal/mol
 $\Delta H_m^\circ = [21.6]$ kcal/mol

$S^\circ_{298.15} = 17.82 \pm 0.1$ gibbs/mol
 $T_m = 1953 \pm 20^\circ\text{K}$

Heat of Formation

The adopted heat of formation is calculated from $\Delta H_f^\circ_{298.15} = -6.35 \pm 0.25$ kcal/mol for the reaction $\text{MgO(c)} + \text{TiO}_2(\text{rutile}) \rightarrow \text{MgTiO}_3(\text{c})$ measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. For the same reaction a value of $\Delta H_f^\circ_{298.15} = -5.5 \pm 0.1$ kcal/mol was obtained with a calorimetric bomb method by B. I. Ronfilov and N. N. Teodos'ev, Russ. J. Inorg. Chem. (English Transl.) 2, 1452 (1954). These authors used the oxidation of lampblack in order to initiate the formation of the titanate from the oxides. Unfortunately the desired heat of reaction was only 1.2 to 1.5 percent of the total measured heat, and consequently this result appears to be more uncertain than that measured by the solution calorimetric method.

Heat Capacity and Entropy

Low temperature heat capacities are from the data ($52 - 796^\circ\text{K}$) of C. H. Shonate, J. Am. Chem. Soc. 67, 984 (1946). High temperature enthalpies have been measured ($1007 - 1720^\circ\text{K}$) by B. F. Naylor and O. A. Cook, J. Am. Chem. Soc. 83, 1003 (1961). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S^\circ_{298} = 0.45$ eu.

Melting Data

See liquid table.

GFW = 120.2102

(LIQUID)

MAGNESIUM METATITANATE (MgTiO₃)

$$\Delta H_f^{\circ}{}_{298.15} = [-357.942 \pm 1.5] \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = [21.6] \text{ kcal/mol}$$

$$S^{\circ}{}_{298.15} = [26.549] \text{ gibbs/mol}$$

$$T_m = 1953 \pm 20^{\circ}\text{K}$$

Heat of Formation

$\Delta H_f^{\circ}{}_{298}$ is obtained from $\Delta H_f^{\circ}{}_{298}(c)$ by adding ΔH_m° and the difference between H_m° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. The heat capacity below 1300°K is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 39 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting point at 1903°K. The ΔH_m° is estimated from those of Na₂O·2TiO₂ and Na₂O·TiO₂ observed by Naylor (3) and CaO·TiO₂·SiO₂ observed by King (4).

$\Delta H_f^0 = -288.8 \pm 5$ kcal. mole⁻¹
 ΔH_f^0 298.15 = -301.6 $\pm$ 5 kcal. mole⁻¹
 $\Delta H_m^0 = 3.5$ kcal. mole⁻¹

$S_{298.15}^0 = 21.844 \pm 0.2$ cal. deg.⁻¹ mole⁻¹
 $T_m = 1400^\circ\text{K.}$

Heat of Formation.

The adopted ΔH_f^0 298.15 = -301.6 $\pm$ 5 kcal. mole⁻¹ was calculated from the ΔH_f^0 298.15 = 63.3 $\pm$ 5 kcal. mole⁻¹ for the reaction $\text{MgO}(c) + \text{SO}_3(g) = \text{MgSO}_4(c)$. The value of ΔH_f^0 298.15 was calculated by the third law method using the equilibrium data obtained from a transpiration study by Knopf and Staudte.¹ In addition Marchal² measured the total pressure of $\text{SO}_3(g)$, $\text{SO}_2(g)$ and $\text{O}_2(g)$ above $\text{MgSO}_4(c)$ and partial pressures were obtained by application of the SO_3 - SO_2 equilibrium data. Another value of ΔH_f^0 298.15 (MgSO_4, c) may be derived from the measured heat of solution of $\text{MgSO}_4(c)$ by Thomsen^{3a} and the measured heats of mixing of $\text{MgCl}_2(200 \text{ H}_2\text{O})$ with $\text{H}_2\text{SO}_4(200 \text{ H}_2\text{O})$ and $\text{MgSO}_4(200 \text{ H}_2\text{O})$ with $2\text{HCl}(100 \text{ H}_2\text{O})$ by Thomsen^{3b}.

Heat Capacity and Entropy.

The low temperature heat capacities 53.3-295.4°K. were measured by G. E. Moore and K. K. Kelley, J. Am. Chem. Soc. **64**, 2949 (1942). The heat capacities in the temperature range 298-1400°K. were estimated from the equation $\text{MgSO}_4(c) = \text{CaSO}_4(c) + \text{MgO}(c) - \text{CaO}(c)$. $\text{CaSO}_4(c)$ and $\text{CaO}(c)$ C_p were calculated using the equations $C_p = 16.78 + 23.60 \times 10^{-3}T$ and $C_p = 11.67 + 1.08 \times 10^{-3}T - 1.56 \times 10^{-5}T^2$ respectively, K. K. Kelley, U. S. Bur. Mines Bull. **584** (1960). The heat capacity of $\text{MgO}(c)$ was calculated from the correlation of the low temperature heat capacities and high temperature heat content using the Shomate functions to back calculate the heat capacities. The values from the two sources join smoothly at 298°K. Above the melting point (1400°K.) the heat capacity was graphically extrapolated. The entropy was calculated at 50.12°K. using the Debye and Einstein function $D(\frac{298}{1400}) + 2E(\frac{298}{1400}) + 2E(\frac{298}{1400})$ given by G. E. Moore and K. K. Kelley loc. cit. The value of $S_{50.12}^0 = 1.08$ cal. deg.⁻¹ mole⁻¹.

Melting Data.

T_m and ΔH_m^0 from K. K. Kelley, U. S. Bur. Mines Bull. **393** (1956).

Magnesium Sulfate (MgSO₄)

(Liquid) Mol. Wt. = 120.3736

MgO₄S

MOL. WT. = 120.3736

MAGNESIUM SULFATE (MgSO₄) (LIQUID)

$S_{298.15}^{\circ} = 24.464 \pm 0.2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = -297.9 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{\circ} = 3.5 \text{ kcal. mole}^{-1}$
 $T_m = 1400^{\circ}\text{K.}$

Heat of Formation.
 The $\Delta H_f^{\circ} 298.15$ was obtained from $\Delta H_f^{\circ} 298.15(c)$ by adding ΔH_m° and the difference between H_m° and $H_m^{\circ} 298.15$ for crystal and liquid.

Heat Capacity and Entropy.
 A glass transition was assumed at 1000°K. The heat capacity below 1000°K. was obtained from the heat capacity of the crystal. Above 1000°K. the heat capacity was assumed constant and estimated as $39.0 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ by comparison with those for $\text{MgCl}_2(l)$, $\text{KCl}(l)$ and $\text{K}_2\text{SO}_4(l)$. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.
 See $\text{MgSO}_4(c)$ table.

$\Delta H_f^\circ = -359.9 \pm 8 \text{ kcal/mol}$
 $\Delta H_f^\circ = -359.15 \pm 8 \text{ kcal/mol}$
 $\Delta H_m^\circ = \text{Unknown}$

$S_{298.15}^\circ = 24.18 \pm 0.2 \text{ gibbs/mol}$
 $T_m = \text{Unknown}$

Heat of Formation.

T. N. Rezhukhina and V. A. Levitskii¹ measured the emf, $E = 0.2433 - 0.0001264T$, for the cell reaction $\text{MgO}(c) + \text{W}(c) + 3\text{FeO}_{0.95}\text{O}(c) \rightarrow \text{MgWO}_4(c) + 2.85 \text{ Fe}(c)$, in the temperature range $1220^\circ - 1370^\circ \text{K}$. Incorporating the results with auxiliary thermal data, the authors obtained $\Delta H_f^\circ = -224,370 + 65.67T$ (cal/mol) for $\text{MgO}(c) + \text{W}(c) + 3/2\text{O}_2(g) \rightarrow \text{MgWO}_4(c)$. Third law analysis of the ΔH_f° equation gives $\Delta H_f^\circ = -218.6 \text{ kcal/mol}$, from which the adopted $\Delta H_f^\circ(298 \text{ K})$, -362.3 kcal/mol , is calculated. The second law analysis gives $\Delta H_f^\circ(298 \text{ K}) = -372.7 \text{ kcal/mol}$. The drift in the third law analysis is 8.0 eu.

T. N. Rezhukhina, Ya. I. Gerasimov and Yu. P. Simanov² determined the Gibbs energy changes $\Delta G_r^\circ = 51,300 - 27.67T$ (cal/mol) for the reaction $\text{MgWO}_4(c) + 3\text{H}_2(g) \rightarrow \text{MgO}(c) + \text{W}(c) + 3\text{H}_2\text{O}(g)$ in the temperature range $1073^\circ \text{K} - 1273^\circ \text{K}$ by a circulation method. This leads to heats of formation of -366.1 kcal/mol by the third law method and -377.2 kcal/mol by the second law method. Both determinations were performed by Rezhukhina and his co-workers, but they considered the data obtained by the emf method to be more reliable than that derived from heterogeneous equilibria.

Heat Capacity and Entropy.

Low temperature heat capacities, $52.92^\circ - 296.09^\circ \text{K}$, were measured calorimetrically by E. G. King and W. W. Weller.³ The heat capacities above 300°K are estimated by comparison with those of $\text{CaWO}_4(c)$,⁴ $\text{CaO}(c)$,⁵ and $\text{MgO}(c)$.⁶ These two sets of data are joined smoothly at 298°K by a graphical method.

The entropy, $S_{298}^\circ = 21.184 \text{ eu}$, is taken from King and Weller,³ based on an extrapolation of $S_{298}^\circ = 1.27 \text{ eu}$. No spin-magnetic entropy is predicted below 51°K based on the diamagnetism observed by Ya. I. Gerasimov.⁷

MAGNESIUM DITITANATE (MgTi₂O₅) (CRYSTAL)

GFW = 200.109

$\Delta H_f^\circ = -596.43 \pm 2.5 \text{ kcal/mol}$

$\Delta H_f^\circ = -599.75 \pm 2.5 \text{ kcal/mol}$

$\Delta H_m^\circ = [35] \text{ kcal/mol}$

$S_{298.15}^\circ = 32.41 \pm 1.5 \text{ gibbs/mol}$

$T_m = 1963 \pm 20^\circ\text{K}$

Heat of Formation

ΔH_f° is calculated from $\Delta H_f^\circ = -4.45 \pm 0.45 \text{ kcal/mol}$ for the reaction $\text{MgO}(c) + 2\text{TiO}_2(\text{rutile}) = \text{MgTi}_2\text{O}_5(c)$ measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. The uncertainty of $\pm 2.5 \text{ kcal/mol}$ assigned to the heat of formation is due primarily to $\text{TiO}_2(\text{rutile})$.

Heat Capacity and Entropy

Low temperature heat capacities are from the data ($52 - 296^\circ\text{K}$) of S. S. Todd, J. Am. Chem. Soc. **74**, 4669 (1952). High temperature enthalpies have been measured ($397 - 1812^\circ\text{K}$) by R. L. Orr and J. P. Coughlin, J. Am. Chem. Soc. **74**, 3186 (1952). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S_{51}^\circ - S_0^\circ = 1.11 \text{ eu}$.

Kelley et al., loc. cit., suggested that there may be a zero-point entropy due to randomness of the cations. The authors estimated S_0° from the following alternative assumptions: (a) all the Mg and Ti ions are randomly distributed among the lattice sites giving 3.79 eu and (b) all the Mg and one-half of the Ti ions are randomly distributed giving 2.75 eu . These assumptions were proposed in order to make MgTi_2O_5 stable relative to MgTiO_3 at high temperatures. Phase data of F. Massazza and E. Sirchia, 16th Int. Congress of Pure and Appl. Chem., Inorg. Sect., Paris (1957), pp. 161-8, Butterworths Scientific Publications, London, 1958, indicate that MgTi_2O_5 melts congruently at $1963\text{-}20^\circ\text{K}$ and that there is a eutectic with MgTiO_3 at $1873\text{-}20^\circ\text{K}$. These data require that $\Delta G^\circ < 0$ for $\text{MgTiO}_3(c) + \text{TiO}_2(\text{rutile}) \rightarrow \text{MgTi}_2\text{O}_5(c)$ in this temperature range. To make $\Delta G^\circ < 0$ would require that $S_{298.15}^\circ$ be $> 32.035 \text{ eu}$. We adopt a compromise zero-point entropy of 2 eu between the upper (3.79 eu) and the lower (0.35 eu) limits.

Melting Data

See liquid table.

Magnesium D titanate (MgTi₂O₅)
(Liquid) GFW = 200.109

MgO₅Ti₂

MAGNESIUM DITITANATE (MgTi₂O₅)

(LIQUID)

GFW = 200.109

$$\Delta H_{298.15}^{\circ} = [-569.385 \pm 2] \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = [35] \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = [47.27] \text{ gibbs/mol}$$

$$T_m = 1963 \pm 20^{\circ} \text{K}$$

Heat of Formation

The heat of formation is obtained from $\Delta H_{298}^{\circ}(\text{c})$ by adding ΔH_m° and the difference between H_m° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. Below 1300°K the heat capacity is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 62/4 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The congruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting at 1925°K. The ΔH_m° is estimated from those of Na₂O·2TiO₂ and Na₂O·TiO₂ observed by Naylor (3) and CaO·TiO₂·SiO₂ observed by King (4).

MAGNESIUM ORTHOSILICATE (Mg_2SiO_4)

(CRYSTAL)

GFW = 140.7076

$\Delta H_f^\circ = -517.12 \pm 1.0$ kcal/mol
 $\Delta H_f^\circ_{298.15} = -520.30 \pm 1.0$ kcal/mol
 $\Delta H_m^\circ = [17 \pm 5]$ kcal/mol

$S^\circ_{298.15} = 22.739 \pm 0.2$ gibbs/mol
 $T_m = 2171 \pm 11$ °K

Heat of Formation

Torgeson et al. (1) have reported a $\Delta H_f^\circ_{298} = -15.1 \pm 0.2$ kcal/mol for reaction (a). They used an HF solution calorimeter and measured the heats of solution of each component. We derive ΔH_f° (Mg_2SiO_4 , c) = -520.30 ± 1.0 kcal/mol using the ΔH_f° of MgO (c) and SiO_2 (c, low quartz) from JANAF tables.

Kapustinikii et al. (2) used the same method but measured only $\Delta H_f^\circ_{298} = 95.00 \pm 0.47$ kcal/mol for reaction (b). We calculate ΔH_f° (Mg_2SiO_4 , c) = -522.27 kcal/mol using the ΔH_f° of H_2SiF_6 (aq) from source 3 and the ΔH_f° of H_2O (l) and H^+ (aq) from source 4.

Reesman et al. (3) calculated a $\Delta G_f^\circ_{298} = 42.45$ kcal/mol for reaction (c) using aqueous solubility data. We use the $\Delta G_f^\circ_{298}$ of H_2O (c) and OH^- (aq) from source 4, $\Delta G_f^\circ_{298}$ of H_4SiO_4 (aq) from source 3 and $\Delta G_f^\circ_{298}$ of Mg^{++} (aq) from source 6 and we obtain a $\Delta G_f^\circ_{298}$ (Mg_2SiO_4 , c) = -498.764 kcal/mol. We derive a $\Delta H_f^\circ_{298}$ (Mg_2SiO_4 , c) = -524.848 kcal/mol using the above $\Delta G_f^\circ_{298}$ of Mg_2SiO_4 (c) and the entropies of Mg (c), Si (c) and O_2 (g) from the JANAF tables.

The adopted value is from the work of Torgeson et al. (1) which is considered to be the most reliable since it relates directly to the oxides. The other reported values are less accurate and involve uncertainties in the auxiliary data used to derive the heat of formation.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53-295°K) of Kelley (7). High temperature enthalpies have been measured (398-1808°K) by Orr (8). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S^\circ_0 = 0.60$ eu.

Melting Data

T_m is obtained from Davis et al. (9). ΔH_m° is estimated from MacGregor's (10) phase diagrams of the Mg_2SiO_4 - TiO_2 system. The phase diagrams were determined at 10 and 20 kbars pressure.

Magnesium Orthosilicate (Mg_2SiO_4)

(Liquid) GFW = 140.7076

GFW = 140.7076

(LIQUID)

MAGNESIUM ORTHOSILICATE (Mg_2SiO_4)

$\Delta H_f^{298.15} = [-505.229 \pm 5] \text{ kcal/mol}$

$\Delta H_m^* = [17 \pm 5] \text{ kcal/mol}$

$S_{298.15}^* = [29.407] \text{ gibbs/mol}$

$T_m = 2171 \pm 11^\circ K$

Heat of Formation

The heat of formation is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^* and the difference between H_m^* and H_{298}^* for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at $1400^\circ K$. Below $1400^\circ K$ the heat capacity is obtained from the heat capacity of the crystal. Above $1400^\circ K$ the heat capacity is assumed constant and estimated as 49 gibbs/mol or 7 gibbs/g-atom . The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See crystal table.

MAGNESIUM ORTHOTITANATE (Mg₂TiO₄) (CRYSTAL)

GFW = 160.5216

ΔH_f⁰ = -514.11 ± 1.5 kcal/mol
 ΔH_f⁰_{298.15} = -517.3 ± 1.5 kcal/mol
 ΔH_m⁰ = [31] kcal/mol

S_{298.15}⁰ = 27.51 ± 1.5 gibbs/mol
 T_m = 2013 ± 20°K

Heat of Formation

The heat of formation is calculated from ΔH_f⁰₂₉₈ = -4.1 ± 0.25 kcal/mol for the reaction 2 MgO(c) + TiO₂(rutile) → Mg₂TiO₄(c) measured by Kelley (1), using a solution calorimetric method. The uncertainty of ± 1.5 kcal/mol assigned to the heat of formation is due primarily to TiO₂(rutile).

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296°K) of Todd (2).

High temperature enthalpies have been measured (182 - 1817°K) by Orr (3). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values.

The entropy is based on S₂₉₈⁰ = 0.66 + 2.75 = 3.41 eu, where the first term is a lattice contribution and the second term is a zero-point entropy of 2Rln2 corresponding to random distribution of Ti and Mg on the octahedral sites of the spinel lattice. The adopted value is S₂₉₈⁰ = 27.51 ± 1.5 eu instead of 24.76 ± 0.15 eu as given by Todd.

Barth (4) showed from intensities of the X-ray diffraction lines that Mg₂TiO₄ is a spinel of the inverse (or variate) class. Thus, half of the Mg ions occupy the tetrahedral interstices in the oxygen lattice, while the remaining Mg ions and the Ti ions are (presumably) randomly located in the octahedral interstices. This conclusion was confirmed by Romeijn (5).

King and Kelley (3) suggested that the degree of structural randomness is not established and that it may vary with the sample of Mg₂TiO₄; thus, they recommended an intermediate value of Rln2 for the zero-point entropy. In a previous review, however, Kelley (1) used the theoretical value of 2Rln2 in order to make Mg₂TiO₄ stable relative to MgTiO₃ at high temperatures. We choose to adopt 2Rln2, although the evidence is not conclusive. Recent studies of solid state reactions by Bartsch and Werner (7) indicate that ΔG⁰ is negative for MgTiO₃(c) + MgO(c) → Mg₂TiO₄(c) at temperatures of 1673°K and above. Both Rln2 and 2Rln2 are consistent with this evidence.

Melting Data

See liquid table.

$$\Delta H_f^\circ = [-489.084 \pm 1.5] \text{ kcal/mol}$$

$$\Delta H_m^\circ = [31] \text{ kcal/mol}$$

$$S_{298.15}^\circ = [41.208] \text{ gibbs/mol}$$

$$T_m = 2013 \pm 20^\circ\text{K}$$

Heat of Formation

ΔH_f° is obtained from $\Delta H_f^\circ(298.15^\circ\text{K})$ by adding ΔH_m° and the difference between $H_m^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400°K . Below 1400°K the heat capacity is obtained from the heat capacity of the crystal. Above 1400°K the heat capacity is assumed constant and estimated as 54.6 gibbs/mol or 7.8 gibbs/g-atom . The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) suggested congruent melting at 2005°K . The ΔH_m° is estimated from those of $\text{Na}_2\text{O} \cdot 2\text{TiO}_2$ and $\text{Na}_2\text{O} \cdot \text{TiO}_2$ observed by Naylor (3) and $\text{CaO} \cdot \text{TiO}_2 \cdot \text{SiO}_2$ observed by King (4).

DIMAGNESIUM SILICIDE (Mg_2Si) (Crystal)

Mol. Wt. = 76.73

$\Delta H_f^* 298.15 = -18.6$ kcal. mole⁻¹

$S_{298.15}^* = [19.5]$ cal. deg.⁻¹ mole⁻¹

$T_m = 1375^\circ K$

$\Delta H_m^* = [15.33]$ kcal. mole⁻¹

Heat of Formation. $\Delta H_f^* 298.15$ was found in the National Bureau of Standards Circular 500 (1952).

Heat Capacity and Entropy. C_p taken from Kubaschewski and Evans, "Metallurgical Thermochemistry," 3rd Edition, Pergamon Press Ltd., New York, (1958). $S_{298.15}$ was estimated.

Melting Data. T_m was taken from NBS Circular 500 (1952). ΔH_m^* was found in Wilson, Beahm, and Cooper, "Determination and Analysis of the Potentials of Thermal Energy Storage Materials," Callery Chemical Co., Callery, Pa., June 30, 1961.

MAGNESIUM ORTHOPHOSPHATE (Mg₃P₂O₈)

(CRYSTAL)

MOL. WT. = 262.91

ΔH_f° = UnknownΔH_f° 298.15 = -895.1 ± 2.5 kcal. mole⁻¹ΔH_m° = [29 ± 10] kcal. mole⁻¹S°_{298.15} = [45] cal. deg.⁻¹ mole⁻¹
T_m = 1621°K.

Heat of Formation.

The selected ΔH_f° 298.15 is a weighted average of a revised calorimetric determination and a third law calculation using equilibrium data.

A calorimetric determination of the heat of formation reported by C. G. Stevens and E. T. Turkdogan, Trans. Faraday Soc. 50, 370 (1954) was revised three ways:

1. The heat of reaction for the reaction 3MgO(c) + P₂O₅(orthorhombic) → Mg₃P₂O₈(c) had been evaluated at 348°K. A small temperature correction to 298.15 was made with thermal data not available to Stevens and Turkdogan (loc. cit.) on MgO (W. F. Glauque, J. Am. Chem. Soc. 71, 3192 (1949)), P₂O₅ (JANAF Table, Dec. 31, 1962) and Mg₃P₂O₈ (this table).

2. A new ΔH_f° 298.15 for P₂O₅(hexagonal) as reported by W. S. Holmen, Trans. Faraday Soc. 58, 1916 (1962) was combined with the heat of reaction, -6.85 ± 1.0 kcal. mole⁻¹, for the reaction: P₂O₅(hexagonal) → P₂O₅(orthorhombic) as reported by W. L. Hill, G. T. Faust, and S. B. Hendricks, J. Am. Chem. Soc. 65, 794 (1943).

3. A correction of +9.35 kcal. mole⁻¹ was made for the change in phosphorus reference state from white (α) → red (V). (The correction is +9.35 kcal./mole of Mg₃P₂O₈ or +4.173 kcal. mole⁻¹ of P.)

This revised ΔH_f° 298.15, -897.60 ± 2.0 kcal. mole⁻¹, would appear to be more reliable than the original value reported by Stevens and Turkdogan (loc. cit.).

For the Reaction

the third law treatment of the equilibrium data of J. B. Boeky, J. Iron Steel Institute (London) 176, 66 (1952) and the JANAF Table free energy functions gave a ΔH_f° 298.15 = -893.11 kcal. mole⁻¹.

The quantity, -895.10 ± 2.50 kcal. mole⁻¹, is taken as the most probable value for the heat of formation of magnesium orthophosphate.

Heat Capacity and Entropy.

The entropy at 298.15 was estimated by considering the additive entropy constants of K. K. Kelley, private communication, June 1960, and E. L. Evans and O. Kubaschewski, "Metallurgical Thermochemistry, 1958. The heat capacity was estimated in a similar manner by considering the heat capacities of the constituent elements and related compounds such as Mg, O₂, MgO, P, P₂O₅, Cr₂P₂O₇, and Ca₃P₂O₈.

Melting Data.

The melting point, 1621°K, as reported by Stevens and Turkdogan (loc. cit.) was selected. There is disagreement on the melting point in the literature. From the work of H. Winter, Dias. Universitäts zu Leipzig 1913, K. K. Kelley, U. S. Bureau of Mines Bulletin 393, (1936) has quoted a melting point of 1457°K and has calculated a "rather uncertain value" of 11,300 kcal./mole for the heat of fusion. J. B. Boeky (loc. cit.) has found a melting point of 1703°K. J. Bereš, Rozniski Chim. 32, 17 (1951) gives 1630°K as the melting point.

S_{298.15}^o = [54.8] cal. deg.⁻¹ mole⁻¹

ΔH_f^o 298.15 = [-877 ± 10] kcal. mole⁻¹

ΔH_m^o = [29 ± 10] kcal. mole⁻¹

ΔH_v^o = Unknown

T_m = 1621°K

T_b = Unknown

Heat of Formation.

The ΔH_f^o 298.15 was calculated from the estimated ΔH_m and the ΔH_f^o 298.15 of the crystal.

Heat Capacity and Entropy.

The heat capacity was estimated as 13/11 of the corresponding heat capacity of Ca₃P₂O₇ as given in K. K.

Kelley, U. S. Bur. Mines Bull. 5841 (1960).

Melting Data.

The heat of melting was estimated by taking 13/11 of the ΔH_m of Ca₃P₂O₇ as given in K. K. Kelley (loc. cit.)

Molybdenum (Mo)
(Reference State)

GF_W = 95.94

$$T_m = 2892 \pm 10^{\circ}\text{K}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Below 20°K several investigators 1,2,3,4,5,6 have determined the heat capacity, and an average of these determinations was used to obtain a Debye theta = 440 and an electronic gamma = 4.7×10^{-4} gibbs/mol-deg. From these the entropy at 20°K was calculated as 0.024 gibbs/mol and the enthalpy as 0.265 cal. Between 20°K and 271°K the data of Clausius and Franzosini⁷ are the adopted heat capacities. The data of Simon and Zeidler⁵ are as much as 2.5% high below 78°K and as much as 1% low above this.

Both the high temperature enthalpies and heat capacity have been measured by several investigators and there is generally good agreement in the 1000-2000°K range. A smooth curve was drawn through the high temperature enthalpy data of several investigators 7,8,9,10,11,12, which was also joined smoothly to the integrated low temperature data of Clausius and Franzosini. The heat capacity was obtained by fitting the smoothed enthalpy data with a polynomial and differentiating. The heat capacity obtained agreed satisfactorily with that reported in several investigations 13,14,15,16,17,18,19.

Sublimation Data.

See Mo(g) for details.

Heat of Formation.

The ΔH_f^{298} was obtained from that of the crystal plus ΔH_m° and the difference between H_{2992}° and H_{2998}° for crystal and liquid.

$$S_{298,15}^\circ = [9.261] \text{ gibbs/mol}$$
$$\Delta H_f^{298,15} = [7.076] \text{ kcal/mol}$$
$$T_m = 2892 \pm 10^\circ \text{K}$$
$$\Delta H_m^\circ = [6652 \pm 600] \text{ kcal/mol}$$
$$T_b = [491.9^\circ \text{K}]$$
$$\Delta H_v^\circ = [140.812] \text{ kcal/mol}$$

The ΔH_{298}° was obtained from that of the crystal plus ΔH_m° and the difference between $H_{2892} - H_{2998}$ for crystal and liquid.

The heat capacity was estimated as 10 gibbs/mol in the real range in order to be comparable with the value in the crystal below the melting point. Below the melting point the heat capacity was assumed constant to a glass transition, assumed to be 2000°K, below which the heat capacity was that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

The heat of melting was obtained from an entropy of melting of 2.3 eu, assumed by comparison with Fe, Cu, Co, Mg and Al. The melting point was reported by E. Rudy and S. Windisch, Aerojet-General Corporation, Report No. AFWT-TN-65-2, Part 1, Vol. III, July 1965. A. O. Worthing, *Phys. Rev.* **25**, 846 (1925), reports a melting point of 2835°K which, corrected to the 1948 International Temperature Scale, is 2882°K.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation

The heat of formation is simply the heat of sublimation at 298°K; this is obtained by second and third law analysis of several vapor pressure sets. A comparison of the results is tabulated below.

Reference Method Points Range °K $\Delta H_{298} \text{ kcal/mol}$

* One point rejected due to failure of statistical test

The data of references 1 and 3 show no drift and thus indicate that the accommodation coefficient is essentially unity. A median value of the 3rd law heat is adopted as $157.3 \pm 0.5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The electronic energy levels are those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467, Washington D. C. (1959). Several individual lines missing from given terms were estimated by analogy with the observed lines in the term. In addition, an estimate of the values of completely missing terms, arising out of low lying multiplets, was made as follows: The $1D$ and $3F$ and $3P$ terms of the $[Kr] 4d^5s^2$ multiplet were estimated at 25000, 30000, 34000 and 36000 cm^{-1} . The triplet P, D, F and G levels and the singlet S, D, F and O levels of the $[Kr] 4d^5$ configuration were estimated at 30000 cm^{-1} and 40000 cm^{-1} respectively.

Higher configurations such as $[Kr] 4d^4s^2$ and $4d^4s^2$ which have many septuplet and quintuplet terms were thought to lie close to the ionization limit. However, upon calculating a table which contains an extra 100 levels at 35000 cm^{-1} and 200 levels each at 40000 and 45000 cm^{-1} , the difference in free energy function at 6000°K is a negligible 0.008 gibbs/mol.

Heat of Formation.

The heat of formation is obtained by adding the heat of ionization to the heat of formation of the gas at 0°K. The heat of ionization, 163.742 kcal/mol (7.10 eV), is obtained from C. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington, D. C. (1958).

Heat Capacity and Entropy.

The electronic energy levels are taken from C. E. Moore, loc. cit. The configuration [Kr] 4d⁵s² is completely missing in Mo⁺, while in the isoelectronic Nb(g) this is a very low lying configuration. However, a comparison of Cr⁺ with Mo⁺ and V(g) with Nb(g) indicates that the similarities are much closer down a given group than across a row to an isoelectronic neighbor. Thus, by analogy with Cr⁺, the missing configuration is expected to lie >50,000 cm⁻¹ and thus be negligible.

The enthalpy at 0°K is calculated to be -1.481 kcal/mol.

Molybdenum Monoxide (MoO)

(IDEAL GAS)

Ground State Configuration [2]

 $S_{298.15}^{\circ} = [56.9 \pm 2] \text{ gibbs/mol}$ $\Delta H_{298.15}^{\circ} = 92.5 \pm 15 \text{ kcal/mol}$ $\Delta H_{298.15}^{\circ} = 92.5 \pm 15 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

E_i, cm^{-1}	g_i
[0]	[3]
[14000]	[1]
[17000]	[2]
[19000]	[6]

 $\omega_e X_e = [3.61] \text{ cm}^{-1}$ $\sigma = 1$ $\omega_e = [955] \text{ cm}^{-1}$ $\tau_e = [1.80] \text{ \AA}$ $B_e = [0.37943] \text{ cm}^{-1}$ $\tau_e = [1.80] \text{ \AA}$

Heat of Formation

The heat of formation, $\Delta H_{298}^{\circ}(\text{MoO}, g) = 92.5 \pm 15 \text{ kcal/mol}$, is derived from the heat of reaction, $\Delta H_{298}^{\circ} = 32.9 \text{ kcal/mol}$ for $\text{Mo}(c) + \text{O}(g) \rightarrow \text{MoO}(g)$ with all JANAF auxiliary data. The value of ΔH_{298}° is calculated by the third law method from the partial pressure data determined mass-spectrometrically in the temperature range from 2262 to 2466°K by G. DeMaria, et al. (1). The drift in the third law analysis is $\pm 11 \text{ eu}$.

Heat Capacity and Entropy

The ground state configuration and the probable electronic levels are assumed to be similar to those for $\text{WO}(g)$ (see JANAF $\text{WO}(g)$ table of Sept. 30, 1966). T. M. Swaminathan and S. G. Krishnamurthy (2) observed ten band systems attributed to molybdenum oxide with lower state values of $\omega_e = 950 \pm 10 \text{ cm}^{-1}$. T. V. Iorns and F. E. Stafford (3) also observed a band with a peak at 969 cm^{-1} in the vapor above $\text{MoO}_3(c)$. It is surprising that the observed vibrational frequency of $\text{MoO}(g)$ is lower than 1055 cm^{-1} observed for $\text{WO}(g)$. The latter comes not only from electronic spectra of the gas but also from infrared observation in matrix isolation; the former comes only from tentative assignments of electronic spectra presumably arising from $\text{MoO}(g)$. It is possible that the observed states could be low lying excited states. We tentatively assume the fundamental vibrational frequency to be 955 cm^{-1} . The bond distance is then calculated by Guggenheimer's relation (4) for multiple bond molecules from the estimated vibrational frequency. The anharmonicity correction x_e is estimated from the relation $x_e^{1/2} = 0.014$ given by R. F. Barrow and A. D. Caunt (5). The constant (0.014) is assumed to be the same as that for $\text{WO}(g)$. The value of τ_e is calculated from the Morse potential function. The rotational constant B_e is calculated from the estimated bond distance.

Heat of Formation

The adopted heat of formation, -140.5 kcal/mol, is a weighted average of values derived from calorimetric determinations, emf measurements and equilibrium studies. The results are given below.

Ignition of the bomb products from the calorimetric studies of Stankiewicz et al. indicated that oxidation was only about 70 per cent complete. The authors also digested the products with NH₄OH to remove the trioxide. The residue was the dioxide, as indicated by both oxidation and reduction. This evidence does not necessarily eliminate the possibility of known intermediate oxides in the combustion products. Mah found 72 - 75 per cent conversion to trioxide by weighing the total combustion products; he performed no additional analysis.

**Auxiliary data for Mo₂O₃(c) are taken from corresponding measurements of the same authors. See JANAF MoO₃(c) table for details.

Reaction: A. MoO₂(c) + 1/2 O₂(g) = MoO₃(c).

B. 2Fe₃O₄(c) + Mo(c) = MoO₂(c) + 2Fe(c).

C. 2NiO(c) + Mo(c) = MoO₂(c) + 2Ni(c).

D. Mo(c) + 2CO₂(g) = MoO₂(c) + 2CO(g).

E. Mo(c) + 2H₂O(g) = MoO₂(c) + 2H₂(g).

F. Mo(c) + O₂(g) = MoO₂(c) derived by the author from the cell reaction 2Fe₃O₄(c) + Mo(c) = MoO₂(c) + 2Fe(c) using ΔG^c data for Fe₃O₄(c).

Heat Capacity and Entropy

E. G. King, J. Am. Chem. Soc. **80**, 1799 (1958), measured the low temperature heat capacities from 53.3° to 296°K. E. G. King, W. W. Weller and A. U. Christensen, U. S. Bur. Mines RI 5684, 1960, measured the high temperature enthalpy changes from 399° to 1801°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -1.3 to +0.7 percent, excluding the point at 1801°K. This point at the highest temperature deviates by +2.3 percent, which suggests that the apparent heat capacity is rising very rapidly. No explanation for this rapid rise is available.

The entropy S°₂₉₈ = 11.054 eu is obtained from the low temperature heat capacity data, based on S°₂₉₈ = 0.31 eu.

B. N. Figgis and J. Lewis, "Progress in Inorg. Chem.", Vol. 5, page 123, Interscience Publishers, New York, 1964, indicated that MoO₂ is probably antiferromagnetic. Its small susceptibility is presumably due to Mo-Mo interactions. It is possible that at temperatures below 50°K entropy due to spin interactions of the d² electrons will appear, contributing up to 2.2 eu. The drifts in the equilibrium data do suggest that additional entropy may be appropriate; however, only the EMF data of Rapp appear to be sufficiently precise to influence the decision. These data suggest addition of 0.8±0.1 eu and 0.9±0.1 eu based on auxiliary data for Wüstite and NiO(c), respectively. We select the entropy of 11.954 eu from equilibrium data for NiO.

Heat of Formation

Burns et al. (1) have investigated mass-spectrometrically the vapor in equilibrium with powdered MoO₂(s) and also reported the partial pressures of MoO₂(g), MoO₃(g), (MoO₂)₂(g), and (MoO₂)₃(g). Second and third analyses of their partial pressure data are given in the table below. The adopted value, $\Delta H_f^\circ(\text{MoO}_2, g) = -3.1 \text{ kcal/mol}$, is calculated from their 3rd law value of $\Delta H_f^\circ = 137.4 \text{ kcal/mol}$ for MoO₂(s) + MoO₂(g), using all JANAF functions.

DeMaria et al. (2) have measured the partial pressures of gaseous oxides MoO, MoO₂, MoO₃ and O(g) in the Mo-Al₂O₃ system by mass spectrometry. Blackburn et al. (3) and Plante (4) have studied the vapor pressures above molybdenum dioxide(c) by the Knudsen effusion method. Second and third law analyses of these three sets of partial pressure data are reported in the following table.

Investigator	Reaction	Temp. °K	No. of Points	ΔH° ₂₉₈ , kcal/mol	ΔHf° ₂₉₈ (MoO ₂ , g)
1. Burns et al.	MoO ₂ (s) + MoO ₂ (g)	1598-1777	11*	137.9±3.1	-3.1
2. DeMaria et al.	Mo(c) + 2O(g) + MoO ₂ (g)	2262-2466	9	-61.8±32.1	-19.9±13.6
3. Blackburn et al.	MoO ₂ (c) + MoO ₂ (g)	1818-2028	7	107.2±6.6	-15.6
4. Plante	MoO ₂ (c) + MoO ₂ (g)	1811-1802	6	149.6±13.0	-0.4

Heat Capacity and Entropy

The MoO₂(g) is assumed to have a C_{2v} symmetry similar to that of TaO₂ reported by Weltner and McLeod (5). The bond angle O-Mo-O is estimated to be 110°. The bond distance Mo-O is estimated to be 1.80 Å, the same as that in MoO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectra of gaseous MoO₂Cl₂ and MoO₂Br₂, reported by Iorns and Stafford (6). The bending vibrational frequency (300 cm⁻¹) is estimated by comparison with other transition metal dioxides. The three principal moments of inertia are: $I_A = 4.2470 \times 10^{-38}$, $I_B = 11.5512 \times 10^{-38}$, and $I_C = 15.7982 \times 10^{-38} \text{ g cm}^2$.

The electronic levels and quantum weights are estimated from the data reported by Weltner and McLeod (2) on MoO₂. The ground state is assumed to be ³A₁ and the first excited level is assumed to lie close to the observed transitions at 7800 Å and 7806 Å in MoO₂. Since both these states are presumed to be triplet, we have assigned a total degeneracy of 6. In addition, we expect from the electronic levels of Mo⁴⁺(g) (g) that other electronic states will also be found and these are arbitrarily estimated in the level at 25000 cm⁻¹.

Heat Capacity and Entropy

Smith et al. (5) measured low temperature heat capacities from 18.3 to 299.8°K. King et al. (8) measured high temperature enthalpy data from 399.3° to 1063.9°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -0.65 percent to +0.17 percent. Seitz et al. (2) have also measured low temperature heat capacities from 70° to 298.7°K which are not in agreement with the values adopted. (The discrepancy has been discussed by Smith.) Cosgrove and Snyder (8) have also measured high temperature enthalpy data from 273° to 1068°K by drop calorimetry. Their smooth values are about 2 percent higher than the values adopted in the tabulation.

The entropy, S₂₉₈^o = 18.585 eu, is obtained from the low temperature heat capacity data of Smith (5), based on S₀^o = 0.197 eu. This starting entropy was obtained by the authors from a τ^2 extrapolation of the data. It is surprising that the entropy of MoO₃(c) is larger than that of WO₃(c) by about 0.4 eu. This may be due to the difference in the crystal structures, MoO₃ being orthorhombic and WO₃ monoclinic, and also to uncertainty in the entropy extrapolation below 80°K for WO₃(c).

Melting Data

The adopted melting point is obtained from King (8), and the heat of melting is calculated from the adopted enthalpies of the crystal and liquid based on the enthalpy data of King. Cosgrove and Snyder (8) found the melting point 1068°K by the cooling curve method, and derived ΔH_m^o = 12.54 kcal/mol from their smooth enthalpy values at the melting point.

MOLYBDENUM TRIOXIDE (MoO₃)
(LIQUID)

S°_{298.15} = 26.971 gibbs/mol
T_m = 1074°

ΔH°_{298.15} = -168.555 ± 0.1 kcal/mol
ΔH_m° = 11.60 kcal/mol

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between H°₁₀₇₄ - H°₂₉₈ for the crystal and liquid.

Heat Capacity and Entropy

The heat capacity between the melting point and 1392.4°K is derived from the enthalpy data measured by E. G. King, W. W. Weller and A. U. Christensen, U. S. Bur. Mines RI 5664 (1960). The heat capacity is assumed constant above and below the measured range. At 700°K, a glass transition is assumed, below which the heat capacity is taken to be the same as that of the crystal. The entropy at 298°K is obtained in a manner analogous to that of the heat of formation. L. A. Cosgrove and P. E. Snyder, J. Am. Chem. Soc. 75, 1227 (1953), also measured the enthalpy changes for MoO₃(l) in the temperature range from 1068° to 1300°K. Their smooth values are ±2.5 percent to ±4.0 percent higher than our tabulated values. They have also found the melting point at 1068°K by the cooling curve method.

Melting Data

See JANAF MoO₃(c) table dated June 30, 1967.

Heat of Formation

Burns et al. (1) have determined the partial pressures of gaseous oxides MoO₂, MoO₃, (MoO₃)₂ and (MoO₃)₃ in equilibrium with powdered MoO₃(c) by mass spectrometry. Plante (2) and Blackburn et al. (3) have also investigated the vapor pressures above molybdenum dioxide (c) by the Knudsen effusion method. They all involve the disproportionation of MoO₂(c) to Mo(c) and MoO₃(g). Delahria et al. (4) have reported the partial pressures of MoO(g), MoO₂(g), MoO₃(g) and O(g) in the Mo-Al₂O₃ system by mass spectrometry. Second and third law analyses of these partial pressure data are listed in the following table, using all JANAF functions.

Investigator	Reaction	Temp., °K	No. of Points	ΔHr°, kcal/mol 2nd Law	3rd Law	ΔHf°(MoO ₃ , g) Kcal/mol*

4. Delahria et al.	Mo(c) + 3 O(g) → MoO ₃ (g)	2281-2416	5	-225.1439.9	-255.1	-76.4

*Based on the third law ΔHr°298 value

The selected heat of formation is -86.2 kcal/mol, based on the third law value of ΔHf°298 of Burns et al. The choice is made because there is serious doubt about the data of Blackburn as discussed by Burns et al. In addition the assumption made by Plante that the only vapor species of any importance is MoO₃ may be erroneous. The mass spectrometric work of Burns et al. is thus preferred.

Heat Capacity and Entropy

The MoO₃(g) is assumed to be a planar D_{3h} molecule with a bond angle O-Mo-O = 120°. The three principal moments of inertia are I_A = I_B = 12.9111 × 10⁻³⁹ and I_C = 25.8222 × 10⁻³⁹ g cm².

Irms and Stafford (5) have observed two vibrational frequencies (969 and 715 cm⁻¹) in the infrared spectra of the vapor above MoO₃(c). They assigned the Mo-O stretching frequency at 969 cm⁻¹ and the trimer ring vibration at 815 cm⁻¹, based on their infrared spectrum observations of gaseous molybdenum oxides and oxyhalides. Barraclough et al. (6) have also concluded that the presence of a metal-oxygen double bond can be correlated with a stretching frequency in the range 900-1100 cm⁻¹. For the MoO₃ molecule, they found the stretching frequency at 985 cm⁻¹ in their spectrometric studies.

SO₄²⁻. Based on the vibrational frequencies of MoO₄²⁻ (aq) reported by Nakamoto (7) and Siebert (8), and those of WO₃, WO₄²⁻, SO₃ and SO₄²⁻, we have estimated 800, 350 and 300 cm⁻¹ for MoO₃(g).

Heat of Formation

The dissociation energy of N_2 has been the subject of considerable controversy and is presented by A. G. Gaydon, "Dissociation Energies", Chapman and Hall, London, 1953. L. Brewer and A. W. Searcy, Ann. Rev. Phys. Chem., 7, 259 (1956), discuss extensive and varied experiments which have now fixed the value of 9.76 e.v. as being highly probable. Additional support for this value is afforded by the recently observed predissociation in the $x^1\Sigma_g$ state by A. Lofthus, Nature 186, 302 (1960).

Heat Capacities and Entropies

The electronic levels noted above are listed by C. E. Moore, Nat. Bur. Standards (U.S.) Circ. 457, Vol. I (1949), Vol. III (1958).

Heat of Formation.

O. Herzberg, Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules, D. van Nostrand Co., Inc., New York, 1950, lists two $D_0(\text{NO})$ values, 5.286 and 6.487 e.v. A. O. Onydon, Dissociation Energies and Spectra of Diatomic Molecules, Chapman and Hall, Ltd., London, 1953, lists $D_0(\text{NO}) = 6.49 \pm 0.05$ e.v. A Birge-Sponer extrapolation of the vibrational levels, up to $v = 19$, of the ground state leads to a D_0 of about 6.5 e.v. Onydon's, loc. cit., analysis on the predissociation of NO also leads to the higher value for $D_0(\text{NO})$.

Y. Tanaka, J. Chem. Phys. 22, 2045 (1954), has observed and analyzed the emission bands of NO in the vacuum ultraviolet region. Tanaka's, loc. cit., observation and interpretation of the abrupt cutoff (predissociation) of certain v' values in the β , δ , and ϵ bands and of the complete non appearance of ϵ and β bands strongly favors a $D_0(\text{NO}) = 6.48$ e.v. $\Delta H_f^{\circ} 298.15(\text{NO})/\text{g}$ was calculated on this basis to be 22.033 ± 1 kcal. mole⁻¹.

More recently M. A. Frisch, Diss. Abstr. 23, 1940 (1961), Thesis, University of Wisconsin, Madison, Wisconsin, 1962, has calorimetrically determined the heat of reaction for

at 298.15°K., from which the author derives a $\Delta H_f^{\circ} 298.15 \text{ NO(g)} = 21.58 \pm 0.04$ kcal. mole⁻¹. The auxiliary values used by Frisch to calculate the heat of formation of nitric oxide were based upon the 1961 atomic weight scale. Recalculating $\Delta H_f^{\circ} 298.15 \text{ NO(g)}$ using auxiliary functions based on the 1956 atomic weight scale had a negligible effect on the final result.

The calorimetrically determined heat of formation for nitric oxide, 21.58 ± 0.04 kcal. mole⁻¹, was selected as the best value.

Heat Capacity and Entropy.

The spectroscopic constants were taken from R. H. Ollivette and E. H. Eyster, Phys. Rev. 56, 1113 (1939), who measured and analyzed the fundamental rotation-vibration band of nitric oxide using a grating spectrometer. The constants used in this calculation were adjusted to correspond to the naturally occurring isotopic mixture.

Heat of Formation

K. Vatanabe, J. Chem. Phys. 22, 1564 (1954), and W. C. Walker and O. L. Weisler, J. Chem. Phys. 23, 1962 (1955), have measured the ionization potential of NO(g) by photoionization, yielding I.P. = 9.25 ± 0.02 and 9.20 ± 0.03 eV, respectively. H. D. Hagstrum, J. Chem. Phys. 23, 1178 (1955), reported I.P. = 9.4 ± 0.2 eV by electron impact. K. P. Huber, Helv. Phys. Acta 34, 929 (1961), determined spectroscopically the ionization potential for NO(g), I.P. = 9.267 ± 0.005 eV (213.72 ± 0.1 kcal/mol). The last value has been selected, and yields the heat of formation of NO⁺(g), ΔHf₀⁰ (NO⁺, g) = 235.18 kcal/mol, using ΔHf₀⁰ (NO, g) = 21.46 ± 0.04 kcal/mol.

Heat Capacity and Entropy

The selected molecular constants were obtained from the ultraviolet spectra by E. Miescher, Can. J. Phys. 33, 355 (1955), Helv. Phys. Acta 29, 135 (1956).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by J. Hilsenrath and Carla G. Messias, NBS Report 8504, July 1, 1964, who have used slightly different molecular constants.

Heat of Formation.

The equilibrium constants for NO(g) + 1/2 O₂ → NO₂(g) of Bodenstein and Lindner, Zeits. fur Physik. Chem. 100, 82 (1922) as given by W. F. Glauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) were subjected to 2nd and 3rd law analysis. Third law analysis gave ΔH₂₉₈ = -13.67 kcal. and 2nd law ΔH₂₉₈ = -13.52 ± 0.01 kcal. The third law value had a very slight trend with temperature which was consistent with an entropy error of 0.25 cal. deg.⁻¹ mole⁻¹, the second law entropy was also consistent with an entropy error of 0.25 cal. deg.⁻¹ mole⁻¹. However the functions for all three gases are well established to about 0.03 cal. deg.⁻¹ mole⁻¹ or better and so this must be interpreted as due to errors in the data. On this basis the 3rd law value of the heat was chosen and combined with JANAF auxiliary data to give ΔH_f 298 = 7.91 ± 0.2 kcal. mole⁻¹, where the uncertainty includes that due to the possible error in the equilibrium constants.

Heat Capacity and Entropy.

O. R. Bird, J. C. Baird, A. W. Jache, J. A. Hodgeson, R. F. Curl Jr., A. C. Kunkle, J. W. Evansford, J. Bastrup-Andersen and J. Rosenthal, J. Chem. Phys. 40, 3378 (1964) have given a complete review of the microwave spectrum of NO₂. They also give a corrected infra-red vibrational assignment, adopted here, which is in excellent agreement with calculations from the microwave data. They report I_A = 0.34981 X 10⁻³⁹ g. cm.² and I_B = 6.45446 X 10⁻³⁹ g. cm.² and I_C = 6.81994 X 10⁻³⁹ g. cm.². The bond length and angle were chosen to give the best fit of the moments of inertia.

Bond Distances: N-O = $[1.23] \text{ \AA}$
 Bond Angle: O-N-O = $[116]^\circ$
 $\sigma = 2$

Product of the Moments of Inertia: $I_A I_B I_C = [25.6905] \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation

The heat of formation of $\text{NO}_2^-(g)$ was calculated from the electron affinity of $\text{NO}_2(g)$ and the JANAF value of ΔH_f^0 for $\text{NO}_2(g)$, $4.0 \pm 0.5 \text{ ev}$ and $8.6 \pm 0.2 \text{ kcal. mole}^{-1}$, respectively. The former was obtained from the National Bureau of Standards Report 8628, "Preliminary Report on the Thermodynamic Properties of Selected Light Element and Some Related Compounds", January 1965.

Heat Capacity and Entropy

The bond distance N-O and the angle O-N-O of $\text{NO}_2^-(g)$ were estimated to be the same as those in $\text{NaNO}_2(c)$ which have been determined by G. B. Carpenter, Acta Cryst. 5, 132(1952). The three individual moments of inertia are $I_A = [0.6872] \times 10^{-39} \text{ g. cm.}^2$, $I_B = [5.7804] \times 10^{-39} \text{ g. cm.}^2$ and $I_C = [6.4676] \times 10^{-39} \text{ g. cm.}^2$.

The vibrational frequencies of $\text{NO}_2^-(g)$ were assumed to be the same as those for nitrite ion in solution which have been measured by D. Williams, J. Am. Chem. Soc. 61, 298(1939). These measured frequencies in nitrite solution are comparable to those in $\text{NO}_2(g)$ (1357.8, 756.8 and 1665.5 cm.^{-1}), reported by G. R. Bird et al., J. Chem. Phys. 40, 3378 (1964).

σ = [6]

Heat of Formation.

The heat of formation is based on equilibrium constants for the reaction N₂O₅(g) → NO₂(g) + NO₃(g) obtained from shock wave studies by Schott and Davidson, J. Am. Chem. Soc. 80, 1941 (1958). These equilibria give a second law value of ΔH_f⁰ 495 = 21.5 ± 1.4 kcal., corresponding to ΔH_f⁰ 298.15 = 22.2 kcal., and a third law value of ΔH_f⁰ 298.15 = 22.2 kcal. The resulting heat of formation is 17.0 kcal. mole⁻¹.

Quillory and Johnston, J. Am. Chem. Soc. 85, 1695 (1963) report an equilibrium constant based on estimated Beer's law constants for NO₃ and attributed to the reaction O₂ + NO → NO₃. This gives a third law heat of formation of 12 ± 2 kcal. mole⁻¹, which was not considered. A tentative value of 23 kcal. mole⁻¹ (or greater) may be derived from the D₀ given by D. A. Ramsay, Proc. 10th Colloq. Spect. Intern. (1962), Univ. Maryland, pp. 583-596, 1963.

Heat Capacity and Entropy.

The structure and frequencies are those estimated by I. C. Haataine, J. Phys. Chem. 65, 2249 (1961). A symmetry of D_{3h} was chosen on the basis of Valah's correlation, J. Chem. Soc. 1953, 2301 (1953) and the bond distance was taken as 2% longer than in the nitrate ion. The planar mode frequencies were calculated from estimated Urey-Bradley force constants, while the out-of-plane wagging frequency (765 cm.⁻¹) was assumed the same as in HNO₃(g).

There are several conflicting bits of information concerning NO₃ radicals. Chantry, Horaeffeld, Horton and Whiffen, Mol. Phys. 5, 589 (1962) studied the electron resonance and optical absorption spectra of what appear to be NO₃ radicals trapped in crystals of urea nitrate. The authors suggest a planar structure without a threefold axis (thus C_{2v} symmetry), at least for the trapped radicals. Quillory and Johnston, loc. cit., report for gaseous NO₃ radicals an infrared frequency at 1840 cm.⁻¹ which they assign as the N-O stretch. The similarity of this frequency to those in N-O and X-N-O molecules led the authors to suggest an OONO structure (thus C_{2v} symmetry) rather than the nitrate structure. The remaining frequencies for such a structure may be crudely estimated by analogy with those measured for (NO₂)₂ by Smith, Keller & Johnston, J. Chem. Phys. 19, 189 (1951). Based on such frequencies and reasonable bond distances, the room temperature entropy for the OONO structure would be 68-72 cal. deg.⁻¹ mole⁻¹. Such an entropy is quite inconsistent with the second law ΔS_f⁰ 495 = 33.2 ± 3 cal. deg.⁻¹ mole⁻¹ for N₂O₅(g) → NO₂(g) + NO₃(g) obtained from the shock wave studies of Schott and Davidson. The Haataine functions based on the nitrate structure were selected because they are consistent with the experimental entropy. The principal moments of inertia for this structure are I_A = 6.427 × 10⁻³⁹, I_B = 6.427 × 10⁻³⁹ and I_C = 12.853 × 10⁻³⁹ g. cm.². A structure of C_{2v} symmetry would result if the nitrate structure were distorted to give one non-equivalent oxygen. Ramsay, loc. cit., suggests that such distortion can only be small, based on the high dispersion optical spectra of the gas phase.

MONOPHOSPHORUS MONONITRIDE (PN) (IDEAL GAS) MOL. WT. = 44.983

ΔH_f^o 0 = 24.9 ± 1.2 kcal. mole⁻¹ ΔH_f^o 298.15 = 25.0 ± 1.2 kcal. mole⁻¹
 Ground State Configuration 1⁺ S_{298.15} = 50.437 cal. deg.⁻¹ mole⁻¹

Electronic Level and Multiplicity

$$\frac{\epsilon, \text{ cm.}^{-1}}{0} \frac{g_i}{1}$$

ω_e = 1337.24 cm.⁻¹ ω_ex_e = 6.983 cm.⁻¹

B_e = 0.7862 cm.⁻¹ α_e = 0.00557 cm.⁻¹

D_e = 1.09 × 10⁻⁶ cm.⁻¹

r_e = 1.4910 Å σ = 1

Heat of Formation.

The selected ΔH_f^o 298.15 was calculated from the D₀^o = 165.8 ± 1.2 kcal. mole⁻¹ reported by R. L. Potter and V. M. Distefano, J. Phys. Chem., **65**, 849 (1961). A D₀^o = 163.7 ± 1.2 kcal. mole⁻¹ was experimentally determined by E. O. Huffman, G. Turbation, K. L. Elmore, W. E. Cate, H. K. Walters, Jr., and G. V. Elmore, J. Am. Chem. Soc., **76**, 6239 (1954). The D₀^o reported by Huffman et. al was derived using a pressure-composition method i.e. measurement of equilibrium vapor pressure at 1173°K for the reaction [PN(g) → P₂(g) + N₂(g)]. Potter and Distefano (loc. cit.) recalculated Huffman's results to obtain their D₀^o value. A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall (1953), lists a D₀^o = 138.4 ± 19 kcal. mole⁻¹. The corresponding heats of formation are:

ΔH_f^o 298.15
 25.0 ± 1.2 kcal. mole⁻¹ Potter and Distefano (loc. cit.)
 27.1 ± 1.2 kcal. mole⁻¹ Huffman et al. (loc. cit.)
 53 ± 19 kcal. mole⁻¹ Gaydon (loc. cit.)

Heat Capacity and Entropy.

The molecular constants are taken from G. Herzburg, "Diatomic Molecules," D. Van Nostrand Co., New York, N. Y., (1960) 2nd Ed.

223	2

(*u*) x_g = 7.75 cm.⁻¹
 α_g = [0.0064] cm.⁻¹
 σ = 1
 r_g = 1.495(7) Å

Heat of Formation

(*u*) = 1220.0 cm.⁻¹
 B₀ = [0.7762] cm.⁻¹
 The dissociation energy is listed by A. O. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London (1965).

Heat Capacity and Entropy

The spectroscopic constants other than B₀ and α_g are from O. Herzberg "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, New York (1950). r_g is from "Tables of Interatomic Distances and Configuration in Molecules and Ions", The Chemical Society, London (1959), and has been used, together with the equation
 α_g = ε ([0.0064] B₀³ - 6B₀²)/ω_e (Herzberg, op. cit., p. 108)
 to calculate B₀ and α_g.

Heat of Formation

A linear Birge-Spencer extrapolation of the ground state gives a dissociation energy of 142.9 kcal. The ground state can correlate with normal atoms Si(³P) + N(²D); in this latter case D₀ would be 88 kcal. The uncertainty in the extrapolation is quite large, ± 30 kcal, since only 6 levels, of the estimated total of 87 levels, are observed.

A dissociation energy can also be calculated from the B²Σ⁺ state by a much shorter extrapolation. This extrapolation is done graphically since some curvature is evident in the first six levels. A value of D₀(B²Σ⁺) = 50.4 kcal is obtained. This corresponds to D₀(X²Σ⁺) = 119.9 kcal for normal products or D₀(X²Σ⁺) = 85 kcal for excited nitrogen as a product. The uncertainty in this extrapolation is less than the ground state and is probably ± 20 kcal.

An estimate of D₀(SiN) may be obtained by equating D₀(SiN)/D₀(SiO) = D₀(CN)/D₀(CO); this yields D₀(SiN) = 135 kcal.

A comparison of the isoelectronic molecules CP, BS and BeCl and the related molecules CN, BO, BeF indicates D₀(SiN) > 115 kcal.

A value of D₀(SiN) = 130 ± 15 kcal/mol is in agreement within the uncertainties of both ground state and B state extrapolations assuming normal atoms as products, and is in agreement with the other estimates. This value is adopted and yields ΔH_f^o(SiN,g) = 89 kcal/mol.

Heat Capacity and Entropy

The B-X transition has been reported by F. A. Jenkins and H. de Laezy, Proc. Roy. Soc. (London) 122, 103 (1929). The rotational and vibrational constants are derived from their work and adjusted to normal isotopic abundance. The A²Π-²Σ⁺ transition has been observed by M. D. Shetlar, Ph.D. Thesis, Univ. of California, Berkeley (1965). The height of the A state is estimated by correlation with CP(g). The level of the B state is taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., 2nd Edition, New York, 1950.

Heat of Formation

K. P. Zmbov and J. L. Margrave, Rice University, private communication, March 1967, have identified Si₂N(g) in a mass spectrometer. They also determined partial pressures of Si₂N(g) in equilibrium with Si(g) and N₂(g). From four of these measurements, in the temperature range 1742° - 1846°K, we obtain a second law ΔH_f°₂₉₈ = 99.6 ± 6 kcal/mol for the reaction Si₂N(g) = 2 Si(g) + 0.5 N₂(g) and a third law ΔH_f°₂₉₈ = 120.2 kcal/mol with a drift of -11.4 ± 3.4 eu. Considering the small temperature range and the uncertainties in the free energy functions, the data appear consistent. We adopt the 3rd law heat of reaction which yields ΔH_f°₂₉₈(Si₂N,g) = 95 kcal/mol.

Heat Capacity and Entropy

Si₂N(g) is considered to be closely related to C₂N(g), and its structure and electronic configuration are adopted by analogy to this species. The bond length was obtained by adding the difference between the bond distances of SiN(g) and CN(g) to the bond length in CN(g). The vibrational frequencies were estimated by comparison with several molecules, CN(g); 1/4 state of C₂(g); NCN(g); and SiC(g). It should be noted that there is a wide variation in observed frequencies for these molecules and ω₁ and ω₃ may be significantly different from the chosen values.

The electronic ground state is considered to be ¹Σ_g⁺ with excited states of ²Δ_g and ²Σ_g⁺ as in the case of CN(g). The levels are obtained from those in CN(g) by use of the shift between C₂(g) and SiC(g).

TITANIUM NITRIDE (TiN)

(CRYSTAL)

GFW = 61.9067

NTi

$\Delta H_f^\circ = -79.8 \pm 1 \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = -80.7 \pm 1 \text{ kcal/mol}$
 $\Delta H_m^\circ = [16] \text{ kcal/mol}$

$S^\circ_{298.15} = 7.23 \pm 0.05 \text{ gibbs/mol}$
 $T_m = 3220 \pm 50^\circ \text{K}$

Heat of Formation

Humphrey (1) and Neumann et al. (2) determined the heat of combustion of titanium nitride by burning the material in an oxygen bomb calorimeter. For reaction (a) Humphrey obtained $\Delta H_{298}^\circ = -145.05 \pm 0.14 \text{ kcal/mol}$ and Neumann et al. $\Delta H_{298}^\circ = -145.0 \text{ kcal/mol}$. From an examination of the combustion products Humphrey reported that the TiO_2 was 95 per cent rutile and <5 per cent anatase, but made no correction for the anatase. The adopted $\Delta H_{298}^\circ = -80.7 \text{ kcal/mol}$ is the average of three values, two from Humphrey (-80.75, -80.61), one as reported and one corrected for anatase, and one from Neumann et al. (-80.8). The uncertainty in the adopted heat is due mainly to the uncertainty in the heat of formation of rutile. Hoch et al. (3) determined the vapor pressure of reaction (b), in the temperature range 1987-2241°K, using a Knudsen effusion method. Third law analysis of the data yields a $\Delta H_{298}^\circ = -79.5 \pm 9 \text{ kcal/mol}$. Linevsky (4) obtained the titanium partial pressures of reaction (c) (2088-2141°K) at fixed nitrogen pressures using atomic absorption spectroscopy. Third law analysis of the data gives a $\Delta H_{298}^\circ = -81 \pm 10 \text{ kcal/mol}$. These equilibrium measurements were not considered in deriving the heat of formation due to their large uncertainties in comparison to the calorimetric data.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52-296°K) of Shomate (5). Naylor (6) measured high temperature heat contents (388-1738°K). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 1738°K the heat capacity is graphically extrapolated. The entropy is based on $S^\circ_{50} - S^\circ_0 = 0.138 \text{ eu}$.

Melting Data

See liquid table.

Reference	Method	Reaction	T°K	$\Delta H_{298}^\circ \text{ kcal/mol}$	Drift eu	$\Delta H_f^\circ \text{ kcal/mol}$

TITANIUM NITRIDE (TiN) (LIQUID)

GFW = 61.9067

 $S_{298.15}^{\circ} = [12.603] \text{ gibbs/mol}$ $\Delta H_{298.15}^{\circ} = [-63.531 \pm 1] \text{ kcal/mol}$ $\Delta H_m^{\circ} = [16] \text{ kcal/mol}$ $T_m = 3220 \pm 50^{\circ}\text{K}$

Heat of Formation

The heat of formation is obtained from $\Delta H_{298}^{\circ}(\text{c})$ by adding ΔH_m° and the difference between ${}^{\circ}T_m$ and ${}^{\circ}T_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200°K . Below 2200°K the heat capacity is obtained from the heat capacity of the crystal. Above 2200°K it is assumed constant and estimated as 15 gibbs/mol or 7.5 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from C. Agte and K. Moers, Z. Anorg. Allgem. Chem. 198, 233-43 (1931). ΔH_m° is derived from an estimated $\Delta S_m = 2.5 \text{ gibbs/g-atom}$ as suggested by O. Kubaschewski, E. L. Evans and C. B. Alcock, "Metallurgical Thermochemistry," Pergamon Press, New York, 1967.

NZr

MONOZIRCONIUM MONONITRIDE (ZrN) (Crystal)

Mol. Wt. = 105.228

$\Delta H_f^\circ = -86.5 \pm 2$ kcal. mole⁻¹

ΔH_f° 298.15 = -87.3 ± 2 kcal. mole⁻¹

$\eta_m = [3225^\circ K]$

$S_{298.15}^\circ = 9.29 \pm 0.05$ cal. deg.⁻¹ mole⁻¹

$\Delta H_m^\circ = [16.1]$ kcal. mole⁻¹

Heat of Formation. The heat of reaction I, -174.25 ± 0.30 kcal. mole⁻¹, was measured by A. D. Mah and N. L. Gelbert. The ΔH_f° 298.15 of ZrN was obtained using -261.5 ± 0.2 kcal. mole⁻¹ for ΔH_f° 298.15 of ZrO₂. For the same reaction B. Neumann, C. Kroger and H. Kunz, Z. anorg. Chem. 218, 379 (1934) obtain -176.0 kcal. mole⁻¹ on a sample of unspecified purity. Vapor pressure measurements of M. Hoch, D. P. Dingley and H. L. Johnston, J. Am. Chem. Soc. 77, 304 (1955) lead to -81 kcal. mole⁻¹ for the ΔH_f° 298.15 of ZrN. However, this value is uncertain by 10% as evidenced by the work on ZrO₂ by W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 26, 1207 (1957).

(I) $ZrN(c) + O_2(g) = ZrO_2(c) + 1/2 N_2(g)$

Heat Capacity and Entropy. Low temperature measurements, 53-297°K, of S. S. Todd, J. Am. Chem. Soc. 72, 2914 (1950), were smoothly joined to those of J. P. Coughlin and E. G. King, J. Am. Chem. Soc. 72, 2262 (1950), 298-1073°K.

Melting. Estimated by C. B. Henderson and R. S. Scheffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

NZr

MOL. WT. = 105.228

(IDEAL GAS)

MONOZIRCONIUM MONONITRIDE (ZrN)

Ground State Configuration [Σ]
 $\Delta H_f^o = [169.4] \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = [55.78] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o \text{ 298.15} = [170.5] \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

$\frac{E_e}{\text{cm.}^{-1}}$	$\frac{g_e}{[2]}$
0	[2]
$\omega_e^x = [5] \text{ cm.}^{-1}$	
$\omega_e = [640] \text{ cm.}^{-1}$	
$\nu_e = [0.4146] \text{ cm.}^{-1}$	
$\sigma_e = [0.0025] \text{ cm.}^{-1}$	
$r_e = [1.83] \text{ \AA}$	

Heat of Formation

ΔH_f^o was estimated as 170.7 kcal. mole⁻¹ by J. S. Gordon, AstroSystems International, Livingston, New Jersey, private communication, January 10, 1963. $\Delta H_f^o \text{ 298.15}$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by J. S. Gordon, loc. cit. r_e was calculated from the relationship $r_e = (16.858778 / \mu^{1/2} B_e)^{1/2} \text{ \AA}$.

 $\sigma^- = 2$
 $r_e = 1.08758 \pm 0.0001 \text{ \AA}$

Heat of Formation.
 The heat of formation (ΔH_f^o) for N_{2(g)} is zero at all temperatures by definition.

Heat Capacity and Entropy.

The functions adopted here are based on the direct summation calculations of L. Glatte, J. Belzer and H. L. Johnston, Ohio State Univ. Res. Found. Proj. 316, Report No. 9, 1953. They calculated the functions for N₂ by a direct summation using spectroscopic data given by O. Herzberg, "Diatomic Molecules", D. Van Nostrand Co., New York, 1950. The entropies were changed by -R ln 9 to remove the effects of nuclear spin included by Glatte, Belzer, and Johnston, and by 0.012 for the difference in spectroscopic constants. J. A. Goff and S. Oretch, Trans. Am. Soc. Mech. Engrs., 72, 741 (1950), calculated a set of functions by a direct summation over the ground state levels only. Agreement with the functions of Glatte, Belzer, and Johnston is within 0.1%.

B. P. Stoicheff, Can. J. Phys. 32, 630 (1954), determined the spectroscopic constants of N₂ by combining his measured rotational spectra with the results of band spectra given in the literature. The constants listed above have been corrected to apply to the naturally occurring isotopic composition listed by D. Strominger, J. M. Hollander and O. T. Seaborg, Rev. Mod. Phys., 30, 565 (1956).

Heat of Formation

An analysis of the heat of reaction data is summarized below. Carlton-Sutton, et al., studied the direct decomposition at pressures of 40 to 50 atmospheres and made P-V-T measurements in order to reduce the data. They obtained a similar but less certain heat of formation by combustion of N₂O in CO. Flame calorimetric measurements of the combustion by Ambler and Griffiths are in good agreement, but the bomb calorimetry of Penning and Cotton gives a heat of formation about 0.2 kcal. larger. The selected heat of formation is a weighted average of these values.

Source	Method	Reaction	ΔH _f ^o (kcal. mole ⁻¹)
1	Bomb Calorimetry	N ₂ O(g) → N ₂ (g) + 0.5 O ₂ (g)	-19.52 ± 0.10
1	Bomb Calorimetry	N ₂ O(g) + CO(g) → CO ₂ (g) + N ₂ (g)	-87.10 ± 0.30
2	Flame Calorimetry	N ₂ O(g) + CO(g) → CO ₂ (g) + N ₂ (g)	-87.09 ± 0.22
3	Bomb Calorimetry	N ₂ O(g) + CO(g) → CO ₂ (g) + N ₂ (g)	-87.37 ± 0.12
3	Bomb Calorimetry	N ₂ O(g) + H ₂ (g) → H ₂ O(l) + N ₂ (g)	-88.03 ± 0.12

*Based on ΔH_f^o 298.15 = -68.32 (H₂O, l), -94.054 (CO₂, g), -26.417 (CO, g)

Heat Capacity and Entropy

The functions are based on the rotational constants of Pilve, J. Mol. Spect. **12**, 360 (1964), and the frequencies determined by Tidwell, Plyler and Benedict, J. Opt. Soc. Am. **50**, 1243 (1960). The bond distances reported by Pilve were obtained from measurements of isotopic shifts in the infrared. They include higher-order corrections for vibration-rotation interaction and are in satisfactory agreement with the infrared and microwave studies of Douglas and Moller, J. Chem. Phys. **22**, 275 (1954) and the electron diffraction data of Schomaker and Spurr, J. Am. Chem. Soc. **61**, 1184 (1942).

Heat of Formation.

Equilibria for the reaction N₂O₃(g) → NO(g) + NO₂(g) have been studied by Beattie and Bell, J. Chem. Soc. 1957, 1681 (1957), Verhoek and Daniels, J. Am. Chem. Soc. 53, 1250 (1931) and Abel and Proiel, Z. Elektrochem. 35, 712 (1939). The results of Beattie and Bell are the most extensive, but they depend on the early analysis of Glaue and Kemp, J. Chem. Phys. 2, 40 (1938), for the simultaneous equilibrium N₂O₄(g) → 2NO₂(g). The JANAF analysis of the tetroxide dissociation has been used to recalculate the data of Beattie and Bell. Non-ideality of N₂O₄ and NO₂ was allowed for by use of the equations of state of Glaue and Kemp, while non-ideality of NO and N₂O₃ was removed by extrapolation of the equilibrium constants to zero pressure in a manner similar to that of Beattie and Bell. The data of Verhoek and Daniels and of Abel and Proiel have not been recalculated. Second and third law analyses of the results are summarized below. The heat of formation was obtained from ΔH°_f 298 = 9.70 kcal. mole⁻¹.

Source	Temp. Range °K	T °K	Third Law ΔS° (cal. deg. ⁻¹ mole ⁻¹)	Second Law ΔH° _f (kcal. mole ⁻¹)	Third Law ΔH° _f 298 (kcal. mole ⁻¹)

Abel - Proiel	281 - 308	294	33.77	—	32.9 ± 0.6

c) From author's K_p values

Heat Capacity and Entropy.

The functions are similar to those calculated by I. C. Hisatsune, J. Phys. Chem. 65, 2249 (1961), based on the analysis of Devlin and Hisatsune, Spectrochim. Acta 17, 218 (1961), of the Raman and infrared spectra in terms of Urey - Bradley force constants. Devlin and Hisatsune used observed isotopic shifts in the spectra along with force constants transferred from nitrogen oxides and oxyhalides in order to select the N-N bond distance and the O-N bond angle.

The unobserved mode was assumed to be free internal rotation around the N-N bond, leading to S°₂₉₈ = 73.91 cal. deg.⁻¹ mole⁻¹ which is in good agreement with 74.13 ± 0.52 cal. deg.⁻¹ mole⁻¹ obtained from the recalculated second law of Beattie and Bell. The principal moments of inertia are I_A = 22.694 X 10⁻³⁹, I_B = 29.577 X 10⁻³⁹, and I_C = 6.883 X 10⁻³⁹ g. cm.², while the reduced moment for internal rotation was calculated as I_r = 0.990 X 10⁻³⁹ g. cm.².

Heat of Formation.

The heat of formation was back calculated from that of the liquid using the measured heat of melting and the enthalpy of the crystal and liquid.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 5, 40 (1939) measured the low temperature heat capacity from 15-295°K. The entropy was obtained by integration of this data using $S_{15}^0 = 0.34$ cal. deg.⁻¹ mole⁻¹.

Melting Data.

The temperature and heat of melting were also measured by Giauque and Kemp, loc. cit.

Heat of Formation.

The heat of formation was back calculated from that of the gas using the calorimetrically measured heat of vaporization to the equilibrium mixture, in conjunction with a dissociation constant $\alpha_c = 0.161$.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 5, 40 (1938) measured the low temperature heat capacity from 15°-295°K., above 295°K. the heat capacity was smoothly extrapolated.

Melting and Vaporization Data.

Giauque and Kemp, loc. cit. measured the temperature and heat of melting and also the boiling point and the calorimetric value of the heat of vaporization to the equilibrium mixture. The heat of vaporization to a hypothetical pure N_2O_4 gas at 294.25°K. was calculated to be 6.91 kcal. mole⁻¹.

Heat of Formation.

W. P. Olsauke and J. D. Kemp, J. Chem. Phys. 5, 40 (1938) calculated idealized equilibrium constants for the reaction N₂O₄(g) = 2NO₂(g) from the work of Bodenstein and Bode (1), Zeits. für physik. Chem. 100, 75 (1922), Verhoek and Daniels (2), J. Am. Chem. Soc. 53, 1250 (1931) and Moutzel (3), Compt. Rend. 169, 1397 (1919). The second and third law analysis of these equilibrium constants has been repeated using more recent functions. The results are shown below.

Ref.	Third Law ΔH° ₂₉₈	Second Law ΔH° ₂₉₈
1.	13.644	13.634 ± 0.015*
2.	13.672	14.429 ± 0.126
3.	13.657	13.599 ± 0.019**

* Ten points rejected because of statistically significant scatter.

** One point rejected.

The second law value of Verhoek and Daniels was not considered significant due to the extremely small temperature range and the use of only three temperatures. The adopted value was 13.65 ± 0.03 kcal. which leads to 2.17 kcal. mole⁻¹ for the heat of formation of N₂O₄(g).

Heat Capacity and Entropy.

The structural parameters were taken from the electron diffraction measurements of D. W. Smith and K. Hedberg, J. Chem. Phys. 25, 1282 (1956). The vibrational frequencies are those chosen by I. C. Hitaatane, J. P. Devlin and Y. Wada, J. Chem. Phys. 33, 714 (1960). The torsional frequency of 50 cm.⁻¹ was estimated in order to bring the entropy of the gas into agreement with that determined by Glaue and Kemp loc. cit. From low temperature heat capacities and heats of fusion and vaporization. The individual moments of inertia were I_A = 12.508 X 10⁻³⁹ g. cm.², I_B = 22.609 X 10⁻³⁹ g. cm.², and I_C = 35.117 X 10⁻³⁹ g. cm.²

Heat of Formation.

The heat of formation was obtained by recalculation of the calorimetric data of Ray and Ogg for the reaction of N₂O₅(g) with NO.The stoichiometry of the reaction products, originally based on the results for N₂O₄ → 2 NO₂ from Oiaque and Kemp, J. Chem. Phys. 5, 40 (1938), was based on the JANAF analysis of this simultaneous equilibrium. A correction of 0.23 kcal. was made in the heat of reaction because of the additional formation of N₂O₃ from NO and NO₂.Confirmation of the heat of formation was obtained by combination of the heats of hydrolysis and sublimation of N₂O₅(c). The results are summarized below. Second law values are given for the heats of sublimation, but third law analyses suggest that the value from Russ and Pokorny is more reliable. Most of the uncertainty in this path, however, arises from the heat of hydrolysis.

Reaction

N₂O₅(g) + NO(g) →N₂O₄(g) + NO₂(g)N₂O₅(c) + H₂O(l) → 2 HNO₃(aq)N₂O₅(c) → N₂O₃(g)

SILICON NITRIDE, ALPHA (α -Si₃N₄)

(CRYSTAL)

GFW = 140.2848

ΔHf° = Unknown

ΔHf°_{298.15} = -176 ± 7 kcal/mol

S°_{298.15} = [27 ± 4] gibbs/mol

T₀ = [2151]°K

Heat of Formation.

The equilibria (A) Si₃N₄(c) = 3 Si(l) + 2 N₂(g) and (B) Si₃N₄(c) = 3 Si(c) + 2 N₂(g) have been investigated by three groups. R. D. Fehlke and J. P. Elliott, Trans. Met. Soc. AIME 215, 781 (1959), made four series of measurements which mainly concerned reaction (A). W. B. Hinke and L. R. Brantley, J. Amer. Chem. Soc. 52, 48 (1930), made a single series of measurements which covered reactions (A) and (B). C. Matignon, Bull. Soc. Chim. France 13, 791 (1913), also gave a single equilibrium point for reaction (C) 3 SiO₂(c) + 6 C + 2 N₂ = Si₃N₄(c) + 6 CO(g). Below are shown 2nd and 3rd law analyses of the data. It should be noted that these analyses are based on the estimated heat capacities above 900°K, and on an estimated entropy. The uncertainty due to these estimates is estimated as ± 7 kcal in ΔHf°₂₉₈.

Reference	Points	Range °K	Reaction	ΔHf° ₂₉₈ kcal/mol	2nd law	3rd law	Drift	*ΔHf° ₂₉₈ kcal/mol

Matignon	1	1700	C			318.9		-175.1

*Calculated from the third law ΔHf°₂₉₈ values.

**Four points rejected due to failure of a statistical test; this set is a combination of the first four sets.

The adopted ΔHf°₂₉₈(α -Si₃N₄) = -178±7 kcal/mol.

L. A. McClaine and C. F. Coppel, A. D. Little, Inc., "Equilibrium Studies of Refractory Nitrides," Tech. Rept. AFML-TR-65-99, Part 11, Dec. 1966, have investigated the decomposition reaction (B). They conclude that at 1618°K the equilibrium pressure is roughly 0.15 mm. This corresponds to ΔHf°₂₉₈ = -182.3 kcal, and was not given any weight in the adopted value.

Heat Capacity and Entropy.

The enthalpy of α -Si₃N₄ has been measured at three temperatures, in the range 373° - 858°K, by S. Sato, Bull. Chem. Soc. Japan 13, 41 (1938). The heat capacity is calculated from the data assuming that a limit of 45 gibbs/mol is attained by 3000°K. The entropy is obtained from the equilibrium data of Fehlke and Elliott, loc. cit.

Decomposition Data.

The temperature of decomposition is calculated as the point at which the decomposition pressure of nitrogen reaches 1 atm.

TRIPHOSPHORUS PENTANITRIDE (P_3N_5)

(CRYSTAL)

GFW = 162.9549

$S_{298.15}^0 = [44 \pm 6] \text{ gibbs/mol}$
 $T_d = [730]^\circ K$
 $\Delta H_f^0 = \text{Unknown}$
 $\Delta H_f^0_{298.15} = -64 \pm 5 \text{ kcal/mol}$

Heat of Formation.

The heat of formation is based on the work of A. Stock and F. Wrede, Chem. Ber. 40, 2923 (1907), who burned P_3N_5 in oxygen. They report a $\Delta H_f^0_{298} = -949.4 \text{ kcal}$ for the reaction $2 P_3N_5(c) + 7.5 O_2(g) = 1.5 P_4O_{10}(\text{amorph}) + 5 N_2(g)$. In NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Washington, D.C. (1965), a value of -947.7 kcal is used for the above reaction and we adopt this value. Using the JANAP value for $P_4O_{10}(c)$ and correcting this to $P_4O_{10}(\text{amorph})$ by adding -13.8 kcal/mol , from Technical Note 270-1, we obtain $\Delta H_f^0_{298} P_4O_{10}(\text{amorph}) = -716.5 \text{ kcal/mol}$. Thus, we derive $\Delta H_f^0_{298} P_3N_5(c) = -63.525 \text{ kcal/mol}$; however, because of the uncertainties in the heat of reaction and correction for amorphous P_4O_{10} we round the value to $-64 \pm 5 \text{ kcal/mol}$.

Heat Capacity and Entropy.

S. Sato, Sci. Papers Inst. Phys. Chem. Res. (Tokyo) 34, 594 (1958), gave an equation for the heat capacity in the range $273^\circ - 578^\circ K$. Judging from his results for $Be_3N_2(c)$ in the same paper, we believe his values will be slightly high at the upper end of the range. Thus, taking 6.2 gibbs/g-atom as the limiting value, a curve was drawn through Sato's values at the low end and approaching the limit asymptotically. The entropy was estimated from that of $Si_3N_4(c)$ by assuming that the ratio Op_{298}/S_{298} on a gram atom basis would be the same for $P_3N_5(c)$.

Temperature of Decomposition.

T_d is calculated as the point at which the total pressure reaches 1 atm. This corresponds to $\log K_p = -0.76$ for the reaction $P_3N_5(c) = 0.75 P_4(g) + 2.5 N_2(g)$. The temperature of decomposition has been reported by V. P. Postnikov and L. L. Kuzmin, J. Appl. Chem. (USSR) 2, 429 (1935) as $1075^\circ K$. This has been confirmed by H. Moreau and P. Rocquet, Compt. Rend. 199, 1691 (1934) and Bull. Chim. France, 3, 1801 (1936); and E. O. Huffman, G. Tarbuton, G. V. Elmore, A. J. Smith and M. G. Rountree, J. Am. Chem. Soc. 79, 1765 (1957). However, it was also noted that $P_3N_5(c)$ is not reformed on cooling the decomposition products; thus the decomposition is non-equilibrium. It is known that the decomposition of AlN , BN and Be_3N_2 is kinetically limited and the equilibrium pressure is not attained until the average energy is greater than the activation energy. It appears that this is also the case for P_3N_5 and a high activation energy is expected.

SODIUM (Na)

(CRYSTAL)

AT. WT. = 22.991

$$\Delta H^\circ_f 298.15 = 0$$

$$\Delta H^\circ_g 298.15 = 25.755 \text{ kcal. mole}^{-1} \text{ (Monatomic gas)}$$

$$\Delta H^\circ_g 298.15 = 32.87 \text{ kcal. mole}^{-1} \text{ (Diatomic gas)}$$

$$S^\circ_{298.15} = 12.296 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H^\circ_m = 0.622 \text{ kcal. mole}^{-1}$$

$$T_m = 370.98 \pm 0.02^\circ\text{K.}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

D. L. Martin, Proc. Roy. Soc. A254, 433 (1960) reports that the low temperature heat capacity of sodium depends on the thermal history of the sample and ascribes this to a martensitic transformation. The effect is most pronounced in the range 40-80°K., where the graph of C_p against T increases continually for some samples and rises to a peak at 55°K. for others. Martin lists heat capacities obtained in several runs on "high purity" sodium at 21° to 300°K. and the higher values, those defining the peak at 55°K., have been selected here. The heat capacities reported by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas, Proc. Roy. Soc. A233, 214 (1955), have not been used, since one of the authors in a later publication (Martin, loc. cit.) questions the accuracy of the measurements above 100°K. and at lower temperatures there is no rise to a peak at 55°K. In the range 1.5° to 20°K., L. M. Roberts, Proc. Phys. Soc. B70, 744 (1957) and D. H. Parkinson and J. E. Quarrington Proc. Phys. Soc. A62, 782 (1955) have measured the heat capacity of very high purity sodium. The values of Parkinson and Quarrington are somewhat higher than those of Roberts and have been given greater weight, since they show better continuity with Martin's results. The results of O. L. Picard and F. E. Simon, Proc. Phys. Soc. 61, 1 (1948) have been rejected below 10°K., since they show a peak between 5° and 8°, a feature not verified by other workers; between 10° and 25°K they agree exactly with the results of Parkinson and Quarrington. J. Rayne, Phys. Rev. 95, 1428 (1954) states that the graph of C_p against T has a small peak at about 0.9°K. This peak has not been observed in the work of W. H. Liden and N. E. Phillips, Phys. Rev. 119, 959 (1960) from 0.15° to 1°K. R. E. Osamer and C. V. Heer, Phys. Rev. 119, 955 (1960) from 0.4° to 2°K and D. L. Martin, Phys. Rev. 124, 438 (1961) from 0.4 to 1.5°K.

T. B. Douglas, A. P. Ball, D. C. Olinings, and W. D. Davis, J. Am. Chem. Soc. 74, 2472 (1952) report heat capacities in the range 273° to 1173°K on a sample of not less than 99.9% purity. These values agree to within 1% with those of Martin in the range 273° to 300°K, and the two sets of data have been smoothly joined.

Melting.

Douglas et al. (loc. cit.) have determined the triple point to be $97.82 \pm 0.02^\circ\text{C.}$, from which the melting point is calculated to be $97.83 \pm 0.02^\circ\text{C.}$, and have measured the heat of fusion.

Heat of Sublimation.

At the boiling point and higher temperatures sodium vapor contains an appreciable proportion of diatomic molecules. O. W. Thompson and E. Oerelia "Sodium - its Manufacture, Properties and Uses," Ed. M. Sittig, Chapter 3, Reinhold Publishing Corporation, Inc., New York (1956), have made a careful analysis of the available vapor pressure data. Their results are consistent with the free energy functions calculated in the present work and have been adopted.

SODIUM (Na)

(LIQUID)

AT. WT. = 22.991

$\Delta H_f^o 298.15 = 0.575 \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = 13.827 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_m^o = 0.622 \text{ kcal. mole}^{-1}$
 $T_m = 370.99 \pm 0.02^\circ \text{K}$
 $T_b = 1156^\circ \text{K (Equilibrium mixture)}$
 $\Delta H_v 1176.9 = 23.285 \text{ kcal. mole}^{-1}$
 $T_b \text{ (Monatomic Gas)} = 1176.9^\circ \text{K}$

Heat of Formation.

Obtained from the heat of fusion by adding $H_{370.99}^o - H_{298.15}^o$ for the solid and subtracting $H_{370.99}^o - H_{298.15}^o$ for the liquid.

Heat Capacity.

The heat capacity data of T. B. Douglas, A. F. Ball, D. C. Ginnings and W. D. Davis, J. Am. Chem. Soc. **74**, 2472 (1952) were used and were extrapolated below T_m and above 1173°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K .

Vaporization.

Sodium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1156°K . The vapor pressure of the monatomic gas reaches 1 atm. at 1176.9°K and the heat of vaporization to monatomic gas is $23.285 \text{ kcal. mole}^{-1}$ [See Na(cryatal)].

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic sodium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation Na(ref. state) - e⁻(ref. state) = Na⁺(monatomic gas), thus Na⁺ involves the difference in enthalpies of the two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Na⁺

Mar. 31, 1965

Sodium Monoxide (NaO)
(Ideal Gas)

GFW = 38.9892

SODIUM MONOXIDE (NaO)

(IDEAL GAS)

NaO

GFN = 38.9892

Ground State Configuration [2P]
 $S_{298.15}^\circ = [54.7 \pm 0.5] \text{ gibbs/mol}$
 $\Delta H_f^\circ = [20.3 \pm 10] \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = [20.0 \pm 10] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$\frac{E_i, \text{ cm}^{-1}}{0}$ $\frac{g_i}{[4]}$

$\omega_e = [440] \text{ cm}^{-1}$
 $\omega_e x_e = [3.0] \text{ cm}^{-1}$
 $\sigma = 1$
 $\alpha_e = [0.4467] \text{ cm}^{-1}$
 $r_e = [2.0] \text{ \AA}$

Heat of Formation

Bawn and Evans (2) have studied the reaction rate of sodium vapor with nitrous oxide, nitrogen peroxide, nitromethane, ethyl nitrate and amyl nitrite, using the diffusion flame method. On the avoidance of reaction rate measurements they estimated the value, $\Delta H_{298}^\circ < 0$, for the reaction $\text{Na(g)} + \text{NO}_2(\text{g}) = \text{NaO(g)} + \text{NO(g)}$. Based on this result, we calculate $\Delta H_{298}^\circ(\text{NaO, g}) > 12 \text{ kcal/mol}$, using $\Delta H_{298}^\circ = 25.8, 7.9$ and 21.6 kcal/mol for $\text{Na(g)}, \text{NO}_2(\text{g})$ and NO(g) , respectively.

Assuming that $D_0(\text{NaO}) = 1/2 D_0(\text{Na}_2) + D_0(\text{O}_2)$, or $\Delta H_0^\circ = 68.1 \text{ kcal/mol}$ for the reaction $\text{NaO(g)} = \text{Na(g)} + \text{O(g)}$, we derive $\Delta H_0^\circ = 16.7$ and $\Delta H_{298}^\circ = 16.4 \text{ kcal/mol}$, using $\Delta H_0^\circ = 25.8$ and 59.0 kcal/mol for Na(g) and O(g) , respectively.
Somayajulu (2) found that in a sequence of similar diatomic molecules the force constant (k_e), dissociation energy (D_0) and equilibrium bond distance (r_e) are related by the expression $k_e r_e^2/D_0 = \text{constant}$. Using $r_e = 1.62 \text{ \AA}$, $D_0 = 77.9 \text{ kcal/mol}$ for LiO(g) , $r_e = 2.0 \text{ \AA}$ for NaO(g) and $k_e(\text{NaO})/k_e(\text{LiO}) = 0.4827$, we evaluate $D_0 = 65.4 \text{ kcal/mol}$ for NaO(g) , yielding $\Delta H_{298}^\circ(\text{NaO, g}) = 19.4 \text{ kcal/mol}$. The value k_e is calculated from the relation $k_e = 4\pi^2 \nu^2 \mu$ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass.

The value of $\Delta H_{298}^\circ(\text{NaO, g})$ is tentatively adopted as $20 \pm 10 \text{ kcal/mol}$. The corresponding $D_0^\circ(\text{NaO})$ is $65 \pm 10 \text{ kcal/mol}$.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for OH(g) which has the same number of valence electrons as NaO(g) . The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for LiO(g) , LiF(g) and NaF(g) . The value of r_e is estimated from those for OH(g) , HF(g) and NaF(g) . B_e and α_e are derived from r_e , ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

NaO⁻SODIUM MONOXIDE UNINEGATIVE ION (NaO⁻)

(IDEAL GAS)

GFW = 38.98975

Ground State Configuration {²S}ΔH_f^o = [-29 ± 20] kcal/molS_{298.15}^o = [52.0 ± 0.5] gibbys/molΔH_f^o_{298.15} = [-29 ± 20] kcal/mol

Electronic Levels and Quantum Weights

 $\frac{g_i}{0}$
 $\frac{g_i}{(1)}$ $\omega_{e'X} = [3.2] \text{ cm}^{-1}$
 $\omega_{e'e} = [0.00493] \text{ cm}^{-1}$
 $\sigma = 1$
 $r_e = [2.0] \text{ \AA}$

Heat of Formation

The electron affinity (E. A.) of NaO⁻(g) is unavailable, therefore the value of ΔH_f^o(NaO⁻, g) is estimated. We first assume that the enthalpy change (ΔH_f^o) of the reaction (1) NaO⁻(g) = Na(g) + O⁻(g) is close to the average of the ΔH_f^o values for the reactions (2) NaO(g) = Na(g) + O(g) and (3) NaF(g) = Na(g) + F(g). The atom F(g) is isoelectronic with O⁻(g). In other words, the ΔH_f^o for reaction (1) is approximately 1/2(64.8 + 113.4) = 89.3 kcal/mol. Then we compare the ΔH_f^o values for the reactions (4) HO(g) = H(g) + O(g), (5) HO⁻(g) = H(g) + O⁻(g), and (6) HF(g) = H(g) + F(g), and find that ΔH_f^o for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔH_f^o values for reactions (4) and (6). Based on this fact we estimate ΔH_f^o = 80 kcal/mol for reaction (1), yielding ΔH_f^o₂₉₈(NaO⁻, g) = -29 kcal/mol which is tentatively adopted. The uncertainty of this value may be ±20 kcal/mol. Based on this ΔH_f^o₂₉₈ value we calculate E. A. = 2.1 ± 0.9 eV for NaO(g). The corresponding value for HO(g) is 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of NaF(g) which is isoelectronic with NaO⁻(g). The values of ω_e, ω_{e'X} and r_e are estimated by comparison with the observed data for NaF(g). The values of B_e and g_e are calculated from r_e, ω_e and ω_{e'X} using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules." D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.248 kcal/mol.

$S_{298.15}^0 = 27.7 \pm 0.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_{t_1} = 196.5^\circ \text{K.}$
 $T_{t_2} = 223.5^\circ \text{K.}$
 $T_m = 825^\circ \pm 10^\circ \text{K.}$

Heat of Formation.

ΔH_f^0 298.15 was obtained from National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1962. P. W. Olliea and J. L. Margrave, J. Phys. Chem. 60, 1333 (1956) measured the heat of decomposition of NaO₂(c) in H₂O, yielding ΔH_f^0 298.15 = -62.1 + 0.7 kcal. mole⁻¹. From the original experimental data by R. de Forcrand, Compt. rend., 127, 514 (1898); 158, 843, 931 (1914), the value of ΔH_f^0 298.15 was recalculated to be -65.0 kcal. mole⁻¹ by P. W. Olliea and J. L. Margrave, loc. cit.

Heat Capacity and Entropy.

The low temperature heat capacities, $52.13^\circ \sim 296.46^\circ \text{K.}$, were measured by S. S. Todd, J. Am. Chem. Soc., 75, 1229 (1953). The heat capacities above 298.15°K. were estimated by comparison with those for Na₂O(c). $S_{298.15}^0$ was given by S. S. Todd, loc. cit., using S_{51}^0 (extrap.) = 2.23 cal. deg.⁻¹ mole⁻¹.

Transition Data.

T_{t_1} , T_{t_2} , $\Delta H_{t_1}^0$, and $\Delta H_{t_2}^0$ were calculated from the data reported by S. S. Todd, loc. cit.

Temperature of Melting.

The melting temperature was obtained from J. L. Margrave, private communication, May 21, 1963.

Heat of Formation

The enthalpy change of the reaction $\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(aq)$ has been determined by Matsui (1, 2), Roth (3, 4) and Rengade (5). Based on their reported ΔH_f° values, the corresponding ΔH_f° for $\text{Na}_2\text{O}(c)$ are calculated, using $\Delta H_f^{\circ}(\text{H}_2\text{O}, l) = -68.315 \text{ kcal/mol}$ obtained from U. S. Natl. Bur. Std. Tech. Note 270-1, 1955, and $\Delta H_f^{\circ}(\text{NaOH}, \text{aq})$ derived from JANAF $\Delta H_f^{\circ}(\text{NaOH}, c)$ and ΔH_{soln} and ΔH_{dil} reported by V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965. The sample employed by Matsui was prepared by the method of Rengade (2) and contains $\text{Na}_2\text{O}_2(c)$ and $\text{Na}(c)$ as impurities. The sample used by Roth also contains 3.96 per cent (by weight) $\text{Na}_2\text{O}_2(c)$. Corrections in the reported results for such impurities have been made by the authors. However, in order to obtain better results, more measurements using purer samples are necessary. The enthalpy change of the reaction $2\text{Na}(c) + \text{H}_2\text{O}(l) = \text{Na}_2\text{O}(c) + \text{H}_2(g)$ was calculated by Rengade (5) from his measurements (5) incorporating with $\Delta H_f^{\circ} = -85.2 \text{ kcal/mol}$ for the reaction $2\text{Na}(c) + 2\text{H}_2\text{O}(l) = 2\text{NaOH}(aq) + \text{H}_2(g)$ determined by Joannis (6). The value $\Delta H_f^{\circ} = -94.9 \text{ kcal/mol}$ is derived from the data of Forcand (6) using $\Delta H_f^{\circ}(\text{Na}_2\text{O}_2, c) = -122.6 \text{ kcal/mol}$. The results are presented in the table below.

Brewer (11) determined the equilibrium constants, 918-1467°K, for the vaporization of $\text{Na}_2\text{O}(c)$, using an effusion method. The Na_2O vapor consists predominantly of $\text{Na}(g)$ and $\text{O}_2(g)$ molecules with any oxide molecules being not important. The Na/O ratio was not measured and assumed to be 2/1 in all calculations on Na_2O . Based on the reported data, we derive the equilibrium constants for the reaction $\text{Na}_2\text{O}(c) = 2\text{Na}(g) + 1/2\text{O}_2(g)$ and evaluate the third law ΔH_f° as $117.1 \pm 10 \text{ kcal/mol}$. From this ΔH_f° value, we obtain $\Delta H_f^{\circ}(\text{Na}_2\text{O}, c) = -65.6 \pm 10 \text{ kcal/mol}$, employing $\Delta H_f^{\circ}(\text{Na}, g) = 25.76 \text{ kcal/mol}$ for $\text{Na}(g)$. The value -65.6 kcal/mol is not consistent with the other values described above. This may be caused by an invalid assumption used in the calculation.

The heat of formation at 298°K for $\text{Na}_2\text{O}(c)$ is tentatively selected as $-99.90 \pm 1.0 \text{ kcal/mol}$.

Investigator	Reaction	ΔH_f° , kcal/mol	ΔH_f° , kcal/mol
1. Matsui (1929)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(7890 \text{ H}_2\text{O})$	-56.61 ± 0.16	-100.08
2. Matsui (1929)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(4500 \text{ H}_2\text{O})$	-56.70 ± 0.07	-99.89
3. Roth (1947)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(825 \text{ H}_2\text{O})$	-56.03 ± 0.13	-100.55
4. Roth (1948)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(825 \text{ H}_2\text{O})$	-55.98 ± 0.13	-100.60
5. Rengade (1907)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(aq)$	-56.50	-100.09
6. Forcand (1900)	$2\text{Na}(c) + \text{H}_2\text{O}(l) = \text{Na}_2\text{O}(c) + \text{H}_2(g)$	-28.70	-97.02
	$\text{Na}_2\text{O}(c) + 1/2\text{O}_2(g) = \text{Na}_2\text{O}_2(c)$	-27.76	-94.90

Heat Capacity and Entropy

The low temperature heat capacities, 15-380°K, were obtained from Furukawa (9). We make the corrections in the reported Cp values for impurity $\text{Na}_2\text{CO}_3(c)$ 2.33 per cent (by weight), analyzed by Grimley (10). The effect on heat capacity due to the presence of $\text{Na}_2\text{O}_2(0.91 \text{ per cent})$ impurity is insignificant. Using the smoothed low temperature Cp data the $S_{298.15}^{\circ}$ is calculated, based on $S_{15}^{\circ} = 0.0122 \text{ eu}$.

Grimley (10) measured the high temperature enthalpies, 380.1-1174.6°K, with a copper block drop-type calorimeter. The enthalpies for the γ phase, 380.1-980.4°K, are joined smoothly with the low temperature data and extrapolated to 1023.2°K (the $\gamma + \beta$ transition temperature). The enthalpies above 1023.2°K are obtained by extrapolation. The enthalpies measured at 1078.3 and 1174.6°K by Grimley are unreasonably large, and are not adopted.

Transition Data

The transition temperature and heats of transition were determined calorimetrically by Bouaziz (12) who used a very pure sample. The adopted $\Delta H^{\circ} = 0.42$ and 2.85 kcal/mol , are averages of the derived values, $0.36 - 0.48$ and $2.7 - 3.0 \text{ kcal/mol}$, respectively.

Melting Data

Tm and ΔH_m° were obtained from Bouaziz (12). The adopted ΔH_m° is an average of the reported 10.8-12.0 kcal/mol. Tm has been reported as 1193 and 1190 ± 10°K by Bunzel (13) and Brewer (11), respectively, which are not adopted.

DISODIUM MONOXIDE (Na₂O)

(LIQUID)

GFw = 61.979

S_{298.15} = [21.895] gibbs/molΔH_{298.15} = [-89.112] kcal/mol

Tm = 1405.2°K

ΔHm° = 11.4 kcal/mol

Td = 2223°K

Heat of Formation

The heat of formation is obtained from ΔH_{298.15}(c) by adding ΔHm° and the difference between H_{1405.2} - H₂₉₈ for Na₂O(c) and Na₂O(l).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for Na₂SiO₃(l) and SiO₂(l). The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the Na₂O(c) table.

Decomposition Temperature

Td is the temperature at which the Gibbs energy change of the decomposition reaction Na₂O(l) = 2Na(g) + 1/2O₂(g) approaches zero.

Heat of Formation

The enthalpy change of the reaction Na₂O₂(c) + H₂O(l) = 2NaOH(1200 H₂O) + 1/2O₂(g) was measured at 10.5°C by Roth (1). He employed a sample with composition 96.81 per cent Na₂O₂ and 3.43 per cent Na₂O by weight. Using ΔH_f⁰soln(Na₂O₂, c) = -56.02 kcal/mol, Roth derived the value ΔH_f⁰soln(Na₂O₂, c) = -34.55 kcal/mol. This value was later corrected to be -35.75 kcal/mol (2).

From this data we calculate the heat of formation (298°K) of Na₂O₂(c) as -121.0 kcal/mol. Forcand obtained ΔH_{soln} = -36.55 kcal/mol for the same reaction, quoted by Roth (1), yielding ΔH_f²⁹⁸(Na₂O₂, c) = -120.0 kcal/mol. The auxiliary data ΔH_f²⁹⁸(H₂O, l) = -68.315 kcal/mol is taken from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965; and ΔH_f²⁹⁸(NaOH·1200 H₂O) = -112.488 kcal/mol is derived based on ΔH_f²⁹⁸(NaOH, c) = -101.90 kcal/mol from JANAF Table and ΔH_f⁰ = -10.637 kcal/mol and ΔH_{soln}(1200 H₂O + aq.O) = -0.079 kcal/mol from V. B. Parker, U. S. Natl. Bur. Std. NBS-2, 1965.

Gilles (3) determined the enthalpy change of the reaction Na₂O₂(c) + H₂O(l) = 2NaOH(3800 H₂O) + 1/2O₂(g), using a purer sample (Na₂O₂ 99.2 per cent, Na₂O 0.8 per cent). Based on the reported value ΔH_f²⁹⁸ = -34.0 ± 0.3 kcal/mol and derived ΔH_f²⁹⁸(NaOH·3800 H₂O) = -112.487 kcal/mol, we calculate ΔH_f²⁹⁸ = -122.66 ± 1.2 kcal/mol for Na₂O₂(c).

Leffler (4) studied the oxygen pressure-melt composition for the liquid sodium-oxygen system between 760 and 960°C. These results, together with the thermodynamic data for Na₂O₂, were used to calculate the heats and free energies of formation of melt compositions between Na₂O and Na₂O₂. However, there are no numerical results reported. Therefore this data is not used for evaluation.

The heat of formation at 298°K is adopted as -122.66 ± 1.2 kcal/mol.

Heat Capacity and Entropy

The low temperature heat capacities, 52.31-256.22°K, were measured by Todd (5). His sample contains (per cent) 94 Na₂O₂(c), 3.6 Na₂O(c) and 2.4 Na₂CO₃. Corrections in the reported results have been made for Na₂CO₃ content, but not for Na₂O content which was estimated to be small. The Cp values below 52.31°K are calculated using the equation Cp = D(ΔH_f²⁹⁸) + 3E(ΔH_f²⁹⁸), reported by Todd. S₂₉₈⁰ is derived from the adopted Cp, based on S₂₉₈⁰ = 1.012 eu.

The high temperature enthalpies, 375.4-869.2°K, were determined by Chandrasekhariah (6), using drop calorimetry. Corrections were made for the contributions from impurities (Na₂O 1.5 and Na₂O 0.2 per cent). A discontinuity was observed in the enthalpies between 773 and 793°K, indicating some kind of transition (see Transition Data). The Cp for Na₂O₂(c) at temperatures 298-769.5°K are derived from the enthalpy measurements, 375.4-769.5°K, and joined smoothly with the low temperature data at 298°K, and extrapolated to 765°K(Tt). The Cp for Na₂O₂(p) is derived from the enthalpy data, 794-869.2°K, as constant, 27.15 gibbs/mol, and extrapolated to 2500°K.

Vedenev (7) measured the high temperature specific heat of Na₂O₂(c) in the temperature interval 292-373°K using adiabatic calorimetry. The reported average value, 21.46 gibbs/mol, is in fair agreement with the adopted ones.

Transition Data

It was reported by Tallman (8), who measured the X-ray powder diffraction pattern by a Geiger-counter diffractometer and found that at about 510°C the pattern changes entirely and a new set of peaks indicates a new phase. Separate thermal analysis measurements (9) confirm the transition temperature (α → β) is 512 ± 1°C or 785 ± 1°K, which is adopted here. Poppl (9) found a thermal anomaly at 485°C in both heating and cooling curves. ΔH⁰ is derived from the adopted enthalpy and Cp data on Na₂O₂(c) and Na₂O₂(p).

Melting Data

T_m is obtained from Benzel (10). T_m = 733 and 783°K were reported by Blumenthal (11) and Rode (12), respectively, which are not adopted.

S_{298.15} = 27.21 ± 0.3 gibbs/mol

T_m = 1362 ± 0.5°K

Heat of Formation

The heats of solution of NaCl(c), Na₂SO₄(c), SiO₂(quartz), Na₂SiO₃(c), HCl(aq) and H₂SO₄(aq) in 20 percent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1933). The author derived two values of ΔH_{soln} of Na₂O(c) from those of NaCl(c), Na₂SO₄(c), HCl(aq) and H₂SO₄(aq) presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate ΔH_{soln} of Na₂O(c) in the calorimetric solution as -87.50 (chloride scheme, originally -87.66) and -86.74 kcal/mol (sulfate scheme, originally -89.19), using recent ΔH^f₂₉₈ values for NaCl(c), Na₂SO₄(c), HCl(aq), H₂SO₄(aq), and Na₂O(c). The corresponding enthalpy changes, ΔH^f₂₉₈, for the reaction Na₂O(c) + SiO₂(quartz) = Na₂SiO₃(c) are derived as -55.20 and -56.38 kcal/mol. Adopting the weighted average ΔH^f₂₉₈ = -55.59 kcal/mol with ΔH^f₂₉₈(Na₂O, c) = -99.9 kcal/mol and ΔH^f₂₉₈(SiO₂, quartz) = -217.7 kcal/mol, we obtain ΔH^f₂₉₈ = -373.19 kcal/mol for Na₂SiO₃(c). This ΔH^f₂₉₈(Na₂O, c) value is independent of future change in ΔH^f₂₉₈ of Na₂O(c) but the value of ΔH_{soln} and ΔH^f are not independent. The adopted value of ΔH^f₂₉₈(Na₂O, c) is the average of -100.1 and -99.7 kcal/mol reported by W. A. Roth and H. L. Kaule, Z. Anorg. Chem. 253, 352 (1947); ibid. 255, 324 (1948), and M. Matsui and S. Oka, J. Soc. Chem. Ind. (Japan) 32, 79 (1929), respectively.

W. A. Roth and H. Troitzsch, Z. Anorg. Chem. 260, 337 (1949), have measured the heats of solution of SiO₂(quartz), Na₂SiO₃(c) and Na₂O(c) in 10.3 percent HF at 22°C to be -32.85, -67.96 and -86.9 kcal/mol, respectively. Using these results, we calculate the enthalpy change of the reaction Na₂O(c) + SiO₂(quartz) = Na₂SiO₃(c) as -53.79 kcal/mol and ΔH^f₂₉₈(Na₂SiO₃, c) = -371.39 kcal/mol.

By use of high temperature reaction calorimetry D. C. Kroger and W. Janetzko, Z. Anorg. Allgem. Chem. 284, 83 (1956), have determined the enthalpy change of the reaction Na₂CO₃(c) + Na₂SiO₃(gl) = 2Na₂SiO₃(c) + CO₂(g) as 17.99 kcal/mol. Based on ΔH^f₂₉₈ = -270.26, -582.92 and -94.05 kcal/mol for Na₂CO₃(c), Na₂SiO₃(gl) and CO₂(g), respectively, we evaluate ΔH^f₂₉₈ = -370.57 kcal/mol for Na₂SiO₃(c).

The heats of solution of Na₂CO₃(c), SiO₂(quartz) and Na₂SiO₃(c) in 39 percent HF at 26.5°C were measured to be -244.1, -564.5 and -673.6 cal/g, by C. Hummel and H. E. Schwiete, Glasstech. Ber. 32, 327 (1959). From these results we calculate the enthalpy change to be 22.43 kcal/mol for the reaction Na₂CO₃(c) + SiO₂(quartz) = Na₂SiO₃(c) + CO₂(g), yielding ΔH^f₂₉₈(Na₂SiO₃, c) = -371.48 kcal/mol.

Many other older calorimetric measurements have been made in order to derive the heat of formation for Na₂SiO₃(c), but most of these are of questionable accuracy and in some cases the products of the reaction are uncertain. For further details the review by N. W. McCready, J. Phys. Colloid. Chem. 52, 1277 (1948).

Heat Capacity and Entropy

The low temperature heat capacities, 53.6 - 294.5°K, were measured by K. K. Kelley, J. Am. Chem. Soc. 61, 471 (1939), and high temperature enthalpies, 360.5 - 1747°K, were determined by B. F. Maylor, J. Am. Chem. Soc. 67, 466 (1945). The high temperature heat capacities are derived from the measured enthalpy data and joined smoothly with the low temperature Cp values. The entropy at 298°K is calculated using the adopted low temperature heat capacities, based on S₂₉₈ = 1.195 eu.

Melting Data

See Na₂SiO₃(l) table for details.

Dec. 31, 1960; June 30, 1965; Sept. 30, 1967

Heat of Formation

 $\Delta H_f^{298}(t)$ is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^* and the difference between H_{1362}^* and H_{298}^* for crystal and liquid.

Heat Capacity and Entropy

The heat capacity above 900°K is derived as constant from the high temperature enthalpy data, 1414 - 1747°K, measured by B. F. Naylor, J. Am. Chem. Soc. **57**, 466 (1945). A glass transition temperature is assumed at 900°K; i.e. the heat capacities below 900°K are taken to be the same as those for Na₂SiO₃(c).

The entropy is obtained in a manner analogous to that of the heat of formation. The low temperature heat capacities, 63.74 - 162.48°K, have been measured by V. V. Tarasov and Y. S. Savitskaya, Dokl. Akad. Nauk SSSR, **88**, 1019 (1953); however, these are not adequate to be used to evaluate S_{298}^* .

Melting Data

The adopted $T_m = 1362^\circ\text{K}$, determined by F. C. Kracek, J. Phys. Chem. **24**, 1583 (1930), is in good agreement with the value 1261°K reported by F. M. Jaeger, J. Wash. Acad. Sci., **1**, 49 (1911), and later confirmed by G. W. Morey and N. L. Bowen, J. Phys. Chem. **28**, 1167 (1924).

Other reported T_m values are 1280, 1291 and 1329°K by N. V. Kultascheff, Z. Anorg. Chem. **35**, 186 (1903); R. C. Wallace, *ibid.*, **53**, 1 (1909); and H. S. van Klooster, *ibid.*, **53**, 135 (1910), respectively. These values are all lower than the adopted T_m value, probably because the sample compositions were not the exact composition of metasilicate.

The value of ΔH_m^* is evaluated from the adopted heat capacities for Na₂SiO₃(c) and Na₂SiO₃(l), and the enthalpy data reported by B. F. Naylor, *loc. cit.*, assuming the final state of the calorimetric sample to be Na₂SiO₃(c). From the phase diagrams of Na₂SiO₃ with other compounds, K. K. Kelley, U. S. Bur. Mines Bull. **393**, 1936, derived the values of ΔH_m of 9.8 - 10.5 kcal/mol.

SODIUM SULFATE, V (Na_2SO_4)

(CRYSTAL)

GFW = 142.0412

$\Delta H_f^\circ = -328.82 \pm 0.2$ kcal/mol
 $\Delta H_f^\circ(298.15) = -331.55 \pm 0.2$ kcal/mol
 $\Delta H_f^\circ(V-T) = 2.584$ kcal/mol

$S^\circ_{298.15} = 35.76 \pm 0.1$ gibbs/mol
 $\pi(V-T) = 521.7^\circ K$

Heat of Formation.

P. L. E. Shibata, S. Oda and S. Furukawa, J. Sci. Hiroshima Univ. (Japan) Ser. A, 3, 227 (1933), measured the ent of the cell: Na-amalg. (0.207%) $|Na_2SO_4$ (sat. soln.) $|Hg_2SO_4|Hg$ at 33-37°C. Extrapolating their results to 25°C, we obtain the $\Delta H_f^\circ(298.15) = -153.77$ kcal/mol for the reaction $2Na(c) + Hg_2SO_4(c) = 2Hg(l) + Na_2SO_4(c)$, which yields $\Delta H_f^\circ(298.15) = -303.36$ and $\Delta H_f^\circ(298.15) = -331.53$ kcal/mol for $Na_2SO_4(c)$. The auxiliary value, $\Delta H_f^\circ(298.15) = -149.59$ kcal/mol, for $Hg_2SO_4(c)$ is obtained from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Tech. Note 270-1, Natl. Bur. Std., Washington, D.C., 1965.

The heat of formation for $Na_2SO_4(\infty H_2O)$ is evaluated as -332.10 kcal/mol, using $\Delta H_f^\circ(298.15) = -57.39$ and -217.32 kcal/mol for $Na^+(\infty H_2O)$ and $SO_4^{2-}(\infty H_2O)$, respectively, from Tech. Note 270-1, loc. cit. J. F. Coughlin, J. Am. Chem. Soc. 77, 868 (1955), determined the enthalpy change, $\Delta H_f^\circ(298.15) = -0.301 \pm 0.035$ kcal/mol for the reaction $Na_2SO_4(c, V) = Na_2SO_4(1050 H_2O)$. Adopting $\Delta H_f^\circ(298.15) = 0.244$ kcal/mol for the reaction $Na_2SO_4(\infty H_2O) = Na_2SO_4(1050 H_2O)$ from Natl. Bur. Std. Circ. 500, Washington, D.C., 1952, we derive the value, $\Delta H_f^\circ(298.15) = 0.545$ kcal/mol for the reaction $Na_2SO_4(\infty H_2O) = Na_2SO_4(c, V)$, yielding $\Delta H_f^\circ(298.15) = -331.56$ kcal/mol for $Na_2SO_4(c, V)$.

The heat of formation for $Na_2SO_4(c, V)$ is adopted as -331.55 ± 0.2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 13.74 - 313.44°K, have been measured by K. S. Pitzer and L. V. Coulter, J. Am. Chem. Soc. 60, 1310 (1938). The heat capacities in the temperature range 324.61 - 503.05°K were determined by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 5, 1321 (1961), using an adiabatic calorimeter. These two sets of data are joined smoothly and extrapolated graphically to 1500°K. The enthalpy values derived from the adopted Cp data are in fair agreement with those determined by J. P. Coughlin, J. Am. Chem. Soc. 77, 868 (1955). The corresponding Cp values, reported by M. M. Popov and O. L. Galchenko, J. Gen. Chem. USSR, 21, 2489 (1951), seem too high at the high temperature end. $S^\circ_{298.15}$ is derived using the low temperature Cp data reported by K. S. Pitzer and L. V. Coulter, loc. cit., based on $S^\circ_{14} = 0.057$ eu.

Transition Data.

Polymorphism studies by P. C. Kracek, J. Phys. Chem. 33, 1281 (1929), and P. C. Kracek and R. E. Gibson, J. Phys. Chem. 33, 1304 (1929); ibid., 34, 188 (1930), indicate five distinct modifications, 1.e. V, IV, III, II, I, of which only V and I are stable forms. Calorimetric studies of Shmidt and Sokolov, loc. cit., suggest another form, stable at high temperatures, which is labeled as δ .

The transition temperature and heat of transition are from the calorimetric data for thenardite reported by Shmidt and Sokolov, loc. cit.

SODIUM SULFATE, I (Na₂SO₄)

GFW = 142.0412

$$\Delta H_f^{298.15} = -330.096 \text{ kcal/mol}$$

$$\Delta H_t^{\circ}(V \rightarrow I) = 2.584 \text{ kcal/mol}$$

$$\Delta H_t^{\circ}(I \rightarrow \delta) = 0.06 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 5.67 \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = 37.733 \text{ gibbs/mol}$$

$$T_t(V \rightarrow I) = 521.7^{\circ}\text{K}$$

$$T_t(I \rightarrow \delta) = 980^{\circ}\text{K}$$

$$T_m = 1157^{\circ}\text{K}$$

Heat of Formation.

The ΔH_f° $\text{Na}_2\text{SO}_4(I)$ is obtained from $\Delta H_f^{298.15}(\text{Na}_2\text{SO}_4, V)$ by adding $\Delta H_t^{\circ}(V \rightarrow I)$ and the difference between $H_{521.7}^{\circ} - H_{298.15}^{\circ}$ for $\text{Na}_2\text{SO}_4(V)$ and $\text{Na}_2\text{SO}_4(I)$.

Heat Capacity and Entropy.

The heat capacities in the temperature range 538.65 - 917.65°K were measured with an adiabatic calorimeter by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. **6**, 1321 (1961). The Cp values below 538.65°K and above 917.65°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data.

The value $\Delta H_t^{\circ}(V \rightarrow I) = 2.584 \pm 0.015 \text{ kcal/mol}$ is the average of two determinations from the calorimetric studies of Shmidt and Sokolov, loc. cit. The transition temperature was derived from the heating curve obtained in measuring the heat of transition. It was taken to be the temperature at which the specimen began to show its lowest heating rate. The heat of transition was the difference between the quantity of heat actually dissipated and the sum of the heats calculated from the heat capacity curve of the apparatus and from the specific heat curves of (V) and (I) linearly extrapolated to the transition temperature.

The values of T_t and ΔH_t° for $\text{Na}_2\text{SO}_4(I) \rightarrow \text{Na}_2\text{SO}_4(\delta)$ transition were reported by Shmidt and Sokolov, loc. cit. See $\text{Na}_2\text{SO}_4(\delta)$ table for details.

Melting Data.

See $\text{Na}_2\text{SO}_4(I)$ table for details.

Dec. 31, 1966

(CRYSTAL)

SODIUM SULFATE, δ (Na₂SO₄)

OPW = 142.0412

 $\Delta H^{\circ}_{298.15} = -330.089$ kcal/mol $\Delta H^{\circ} (I \rightarrow \delta) = 0.08$ kcal/mol $\Delta H^{\circ} = 5.50$ kcal/mol $S^{\circ}_{298.15} = 37.741$ gibbs/mol $T_f (I \rightarrow \delta) = 980^{\circ}\text{K}$ $T_m = 1157^{\circ}\text{K}$

Heat of Formation

The heat of formation ($\Delta H^{\circ}_{298.15}$) is obtained from $\Delta H^{\circ}_{298.15}$ for Na₂SO₄ (I) by adding $\Delta H^{\circ} (I \rightarrow \delta)$ and the difference between $H_{980} - H^{\circ}_{298.15}$ for Na₂SO₄ (I) and Na₂SO₄ (δ).

Heat Capacity and Entropy

The heat capacities in the temperature range 930 - 1010°K were measured by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. **5**, 1321 (1961). The Cp values below 900°K are assumed to be the same as those for Na₂SO₄ (I). The heat capacities above 1010°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

A small anomalous region between 690 - 720°C (963.15 - 993.15°K) on the Cp curve for Na₂SO₄ (c) was reported by N. E. Shmidt and V. A. Sokolov, loc. cit. By use of graphical integration of the area between the measured Cp curve and an arbitrary base line over the region 900 - 1100°K, a value of $\Delta H^{\circ} (I \rightarrow \delta) = 0.08$ kcal/mol was obtained. It is assumed to be 980°K. This anomalous region was first observed by G. W. Wyrouboff, Z. Krist. **21**, 284 (1933), and later confirmed by Y. P. Simanov and D. P. Kirikina, Zh. Neorg. Khim. **2**, 699 (1957), as a transition from a hexagonal to an orthorhombic structure. This transition was not observed by the earlier investigators because their measurements did not extend to that temperature range.

Melting Data

The temperature and heat of melting of Na₂SO₄ (I) $\rightarrow$ Na₂SO₄ (I) were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ and liquid Na₂SO₄, we derive $H_m^{\circ}(\delta \rightarrow I) = 5.50$ kcal/mol, using Coughlin's enthalpy data on Na₂SO₄ (I). The melting temperature is assumed to be the same as that reported by Coughlin.

T_m was reported to be 880°C (1153°K), 897°C (1170°K) and 888°C (1161°K) by Ruff and Plato, Ber. Deutsch. Chem. Ges. **35**, 2357 (1903); K. Hiltner and O. Temmeln, Z. Anorg. Chem. **43**, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. **50**, 355 (1906), respectively.

3000	47.180	145.675	104.131	124.634	- 352.363	19.493	1.420

S_{298.15} = 42.777 gibbs/mol

Tm(δ = 1) = 1157°K

ΔH°_{298.15} = -324.241 kcal/mol

ΔHm°(δ = 1) = 5.50 kcal/mol

Heat of Formation.

The value of ΔH°_{298.15}(1) is obtained from ΔH°_{298.15}(I) by adding ΔHm° and the difference between H°₁₁₅₇ - H°_{298.15} for Na₂SO₄(δ) and Na₂SO₄(I).

Heat Capacity and Entropy.

The enthalpies for Na₂SO₄(l) were measured by drop calorimetry in the temperature range 1157 - 1828°K by J. P. Coughlin, J. Am. Chem. Soc. **77**, 868 (1955); and in the temperature range 1173 - 1250°K by M. M. Popov and D. M. Ginzburg, J. Gen. Chem. USSR **25**, 1107 (1956). The constant heat capacity adopted here is derived from the enthalpy measurements reported by J. P. Coughlin, loc. cit. Below 800°K, the heat capacities are assumed to be the same as those of the δ phase. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data.

The temperature and heat of melting of Na₂SO₄(I) → Na₂SO₄(l) were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase, and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ liquid Na₂SO₄, we derive ΔHm°(δ = 1) = 5.50 kcal/mol, using Coughlin's enthalpy data on Na₂SO₄(l). The melting temperature is assumed to be the same as that reported by Coughlin.

Tm was reported to be 880°K(1153°K), 897°K(1170°K) and 889°K(1161°K) by Ruff and Plato, Ber. Deutsch. Chem. Ges. **36**, 2357 (1903); K. Hüttner and G. Tammann, Z. Anorg. Chem. **43**, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. **50**, 355 (1906), respectively.

$\Delta H_f^\circ = -366.8 \pm 2 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = -369.2 \pm 2 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = 0.983 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = 7.373 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = 5.688 \text{ kcal/mol}$

$S_{298.15}^\circ = 38.32 \pm 0.5 \text{ gibbs/mol}$

$T_1 = 862.0^\circ\text{K}$

$T_2 = 860.8^\circ\text{K}$

$T_m = 968.7^\circ\text{K}$

Heat of Formation

The adopted heat of formation, $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c}) = -369.2 \text{ kcal/mol}$, is calculated from $\Delta H_{298}^\circ(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \text{ kcal/mol}$ for the reaction $\text{H}_2\text{WO}_4(\text{c}) + 2\text{HCl}(\text{l}) = \text{Na}_2\text{WO}_4(\text{c}) + 2\text{HCl}(\text{l})$ (12.731 H_2O), using the JANAF value of $\Delta H_{298}^\circ(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \text{ kcal/mol}$ and $\Delta H_{298}^\circ(\text{NaCl}, \text{c}) = -98.26 \text{ kcal/mol}$, and auxiliary data for $\text{HCl}(\text{aq})$ (11). The value of $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c})$ was determined by solution calorimetry by M. F. Koehler, L. B. Pankratz and R. Barany (1).

J. M. Sherfey and A. Brenner (2) measured by electrochemical calorimetry the heat of reaction $\Delta H_{298}^\circ = -7 \pm 1.5 \text{ kcal/mol}$ for $\text{W}(\text{c}) + \text{NaOH}(\text{ss}, 55\text{H}_2\text{O}) + 2\text{H}_2\text{O}(\text{l}) = \text{Na}_2\text{WO}_4(\text{c}) + \text{H}_2(\text{g})$. This value, combined with the heat of solution (3.33), $\Delta H_{\text{sol}}^\circ = -1.7 \pm 0.1 \text{ kcal/mol}$ for $\text{Na}_2\text{WO}_4(\text{c}) = \text{Na}_2\text{WO}_4(\text{aq})$, gives $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c}) = -369.4 \text{ kcal/mol}$, which is in good agreement with the value adopted.

The previously accepted value (1,3), $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c}) = -379 \pm 0.5 \text{ kcal/mol}$, was based on the unreliable $\Delta H_{298}^\circ(\text{H}_2\text{WO}_4, \text{c}) = -280.2 \pm 0.4 \text{ kcal/mol}$. (See JANAF $\text{H}_2\text{WO}_4(\text{c})$ table of March 31, 1967.) The other quoted value (4), $\Delta H_{298}^\circ(\text{Na}_2\text{WO}_4, \text{c}) = -395 \text{ kcal/mol}$, was obtained from W. G. Mixer's (5) measurement of the heat of reaction of tungsten powder with excess Na_2O_2 . This value was probably in error because the complex tungstate and peroxytungstates were formed in the reaction.

Heat Capacity and Entropy

Low temperature heat capacities (52-299.87°K) were measured calorimetrically by E. G. King and W. W. Weller (6). The heat capacities above 300°K are estimated by extrapolation of the low temperature heat capacity curve to $\text{Cp}_{860} = 49.0 \text{ gibbs/mol}$. The latter is obtained from an estimate of Cp equal to 7 gibbs/g-atom at the first transition temperature.

The entropy, $S_{298}^\circ = 38.32 \pm 0.5 \text{ eu}$, is calculated from low temperature heat capacity data of King and Weller (6), based on an extrapolation of $S_{298}^\circ = 2.77 \pm 0.5 \text{ eu}$.

Transition Data

Transition temperatures and heats were obtained from differential heating and cooling curves both at atmospheric and higher pressures by R. W. Goranson and F. C. Kracek (7). Existence of three phases is confirmed by the earlier birefringence studies of H. E. Boeke (8).

R. Riccardi and C. Sinistri (10) found only one transition at 864°K with $\Delta H^\circ = 8.23 \text{ kcal/mol}$ by differential thermal analysis. This heat is apparently the sum of the two adopted heats of transition.

Melting Data

The adopted melting data were measured by the differential heating and cooling curve method by Goranson and Kracek (7). R. Riccardi and C. Sinistri (10) found the melting point at 871°K with $\Delta H^\circ = 7.52 \text{ kcal/mol}$ by differential thermal analysis.

Heat of Formation

The heats of solution of NaCl(c), Na₂SO₄(c), SiO₂(quartz), Na₂Si₂O₅(c), HCl(aq) and H₂SO₄(aq), in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (3). The author derived two values of ΔH_{soln} of Na₂O(c) from those of NaCl(c), Na₂SO₄(c), HCl(aq) and H₂SO₄(aq), presumably employing auxiliary data from (2). We recalculate ΔH_{soln} of Na₂O(c) in the calorimetric solution as -87.50 (chlorine scheme, originally -87.66) and -88.74 kcal/mol (sulfate scheme, originally -89.19), using recent ΔH_f° values (16, 17, 18) for NaCl(c), HCl(aq), H₂SO₄(aq), Na₂SO₄(c), and Na₂O(c). The corresponding enthalpy changes, $\Delta H_f^\circ(298)$ for the reaction Na₂O(c) + 2SiO₂(quartz) = Na₂Si₂O₅(c) are derived as -94.65 and -95.89 kcal/mol. Adopting the weighted average $\Delta H_f^\circ(298) = -95.06$ kcal/mol with $\Delta H_f^\circ(298)$ (Na₂O, c) = -99.9 kcal/mol and $\Delta H_f^\circ(298)$ (SiO₂, quartz) = -217.7 kcal/mol, we obtain $\Delta H_f^\circ(298) = -590.36$ kcal/mol for Na₂Si₂O₅(c). This $\Delta H_f^\circ(298)$ (Na₂Si₂O₅, c) value is independent of future changes in $\Delta H_f^\circ(298)$ of Na₂O(c), but the values of ΔH_{soln} and ΔH_m° are not independent.

Stevens et al. (3) measured the heats of solution of Na₂Si₂O₅(c), Na₂O(c) and SiO₂(quartz) in HF(aq) at 25°C. Based on the reported results, the enthalpy change for the reaction Na₂O(c) + 2SiO₂(quartz) = Na₂Si₂O₅(c) is calculated as -93.25 $\pm$ 0.32 kcal/mol, yielding $\Delta H_f^\circ(298)$ (Na₂Si₂O₅, c) = -588.55 kcal/mol.

Hummel (4) determined the heats of solution of Na₂Si₂O₅(c), SiO₂(quartz) and Na₂CO₃(c) in 39 percent HF at 26.5°C. From the data reported we derive the enthalpy change to be 70.68 kcal/mol for the reaction Na₂CO₃(c) + 2SiO₂(quartz) = Na₂Si₂O₅(c) + CO₂(g). Employing $\Delta H_f^\circ(298) = -270.26$, -217.7 and -94.05 kcal/mol for Na₂CO₃(c), SiO₂(quartz) and CO₂(g), respectively, we obtain $\Delta H_f^\circ(298) = -590.73$ kcal/mol for Na₂Si₂O₅(c) which is in good agreement with the adopted one.

Heat Capacity and Entropy

The low temperature heat capacities, 54.3 - 294.7 J K⁻¹ mol⁻¹, have been measured by Kelley (5) and the high temperature enthalpies, 376.8 - 1100.2 J K⁻¹ mol⁻¹, by Naylor (6). The derived high temperature heat capacities are joined smoothly with the low temperature ones at 298 K. An approximate Cp of 70 gibbs/mol is derived from the enthalpies above 980 K; this value is extrapolated to 2000 K. The value of S_{298}° is calculated from the adopted low temperature heat capacities based on $S_{298}^\circ = 2.945$ eu. The entropy extrapolation derives from the Debye-Einstein extrapolation of Kelley (5) which yields a Cp curve with an extra inflection in the region from 15 to 50 K. A more normal extrapolation would lead to a value of S_{298}° which is lower by 0.5 eu.

Transition Data

There are six slowly inverting polymorphous phases (1, 2-9), namely A, B, C, D, E and F, of which only the first two phases are stable. Two rapid transitions have been reported at 951 and 980 K (1, 10). Phase A, which has two subphases, A α and A β , is stable above 951 K. The stable phase below 951 K is known as phase B, previously called β -Na₂Si₂O₅. The two values of ΔH° are derived from the enthalpy data of Naylor (6) using the adopted Cp values. Three more rapid transitions have been reported at 822, 846 and 866 K (1, 10) in E, previously called γ -Na₂Si₂O₅. A recent examination of these transitions was reported by Willgallis and Range (10).

Melting Data

T_m is obtained from Morey (11). The selected value of ΔH_m° is based on the following ΔH_m° values derived from four different kinds of measurements.

Investigator	ΔH_m° , kcal/mol*		Method**	Reference
	at 298 K	at 1147 K		
Kelley (1936)	(7.51)	8.46	I	12
Kracek (1953)	5.25	(6.20)	II	1
Kröger-Janetzko (1956)	8.81	(9.76)	III	13
Kröger-Kreitlow (1956)	8.83	(9.78)	II	14
Schwiete-Ziegler (1958)	(7.50)	8.45	IV	15
Hummel-Schwiete (1959)	8.09	(9.04)	II	4

*The numbers in parentheses are derived from the measured ones at the other listed temperatures.
**I = phase diagram; II = solution calorimetry; III = high temperature reaction calorimetry; and
IV = dynamic-differential calorimetric method.

S[°]_{298.15} = 45.101 gibbs/mol

T_m = 1147°K

ΔH_f° _{298.15} = -582.811 kcal/mol

ΔH_m° = 8.5 kcal/mol

GFw = 182.1586

Heat of Formation

The ΔH_f° ₂₉₈(*l*) is obtained from ΔH_f° ₂₉₈(*c*) by adding ΔH_m° and the difference between $H^\circ_{1147} - H^\circ_{298}$ for crystal and liquid. The heats of solution of NaCl(*c*), Na₂SO₄(*c*), HCl(aq), H₂SO₄(aq), SiO₂(quartz) and Na₂Si₂O₅(gl) in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). Following the same procedure as described in the Na₂Si₂O₅(*c*) table, we derive the enthalpy changes, ΔH_f° ₂₉₈, for the reaction Na₂O(*c*) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) as -49.40 and -50.64 kcal/mol using the heats of solution of Na₂O(*c*) as -87.50 (chloride scheme) and -88.74 kcal/mol (sulfate scheme), respectively. Adopting the weighted average ΔH_f° ₂₉₈ = -49.81 kcal/mol with ΔH_f° ₂₉₈(Na₂O, *c*) = -99.9 kcal/mol and ΔH_f° ₂₉₈(SiO₂, quartz) = -217.7 kcal/mol, we obtain ΔH_f° ₂₉₈ = -585.113 kcal/mol for Na₂Si₂O₅(gl).

Using high temperature reaction calorimetry, Krögar (2) determined the enthalpy changes as 25.28 ± 0.22 and -18.58 ± 0.36 kcal/mol for the reactions Na₂CO₃(*c*) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + CO₂(g) and 2NaOH(*c*) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + H₂O(*l*), respectively. From the given results, we calculate the corresponding values of ΔH_f° ₂₉₈(Na₂Si₂O₅, gl) to be -586.32 and -589.46 kcal/mol, using ΔH_f° ₂₉₈ = -270.26, -217.70, -94.05, -101.90 and -68.32 kcal/mol for Na₂CO₃(*c*), SiO₂(quartz), CO₂(g), NaOH(*c*) and H₂O(*l*), respectively. These two ΔH_f° ₂₉₈(Na₂Si₂O₅, (*l*)) values, as well as the value -585.113 kcal/mol based on Kracek's data, are not adopted, because incorporating these ΔH_f° ₂₉₈(gl) values with the value of ΔH_f° ₂₉₈(*c*), gives values of the heat of melting at 298°K which are too low in comparison with the other values (see the Na₂Si₂O₅(*c*) table).

Hummel (3) measured the heats of solution of Na₂CO₃(*c*), SiO₂(quartz) and Na₂Si₂O₅(gl) in 39 percent hydrofluoric acid at 26.5°C, as -244.1, -584.5 and -673.7 cal/g, respectively. Based on these results, we derive the enthalpy change for the reaction Na₂CO₃(*c*) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + CO₂(g) to be 79.01 kcal/mol, yielding ΔH_f° ₂₉₈(Na₂Si₂O₅, gl) = -582.6 kcal/mol which is in good agreement with the adopted value.

Heat Capacity and Entropy

Using drop calorimetry, Naylor (4) has measured the enthalpies of Na₂Si₂O₅(gl), 445.5 - 1120.7°K, and Na₂Si₂O₅(*l*), 1173.2 - 1744°K. Based on the liquid enthalpy data, we evaluate the heat capacity of Na₂Si₂O₅(*l*) to be 62.43 gibbs/mol. The Cp values below 1147°K are derived from the enthalpies measured at 445.5 - 1120.7°K by Naylor (4). Below 600°K, Cp is identical with that of the crystal. The adopted curve rises rapidly to a maximum in the glass transition region, 650-950°K, then smoothly approaches the value of the real liquid near T_m. The heat capacity of Na₂Si₂O₅(*l*) is assumed to be constant in the temperature range 1147 to 2500°K.

S[°]₂₉₈ is obtained in a manner analogous to that of the heat of formation.

Melting Data

See Na₂Si₂O₅(*c*) table for details.

Heat of Formation

P. Brin and G. Herzberg, Can. J. Phys. 32, 110 (1954), observed 21 bands in the transition $X^3\Sigma^- \rightarrow B^3\Sigma^-$. The Birge-Sponer extrapolation to the dissociation products $^3P_2 + ^1D_2$ was corrected to the zero levels, $^3P_2 + ^3P_2$, to give the dissociation energy 41260 ± 15 cm.⁻¹. This is in agreement with the extrapolation of the band heads 3P_2 of the $X^3\Sigma^- \rightarrow A^3\Sigma^+$ transition which goes to the normal products. The extrapolation of the B level is very small, the lowest ΔG_{1/2} is 34 cm.⁻¹

Heat Capacity and Entropy

The electronic levels from C. E. Moore, Nat. Bur. Standards, Circ. 467, (1949), were averaged above 80,000 cm.⁻¹

OXYGEN UNINEGATIVE ION (O⁻)

(IDEAL GAS)

MOL. WT. = 15.99995

Ground State Configuration $2p_{3/2}^2$

$\Delta F_f^0 = 25.2 \pm .5$ kcal/mole

$\Delta F_f^0 = 298.15 = 24.3 \pm .5$ kcal/mole

Electronic Levels and Quantum Weight

$\mathcal{E}_l$, cm. ⁻¹	$\frac{g_l}{4}$
0.0	2
[150.0]	2

Heat of Formation.

The heat of formation was calculated from the equation: $O(g) + e^- \rightarrow O^-(g)$ with the JANAF auxiliary value for $O(g)$; using the measured electron affinity = 1.465 e.v. (33.783 kcal/mole) obtained from L. M. Branscomb, D. S. Burch, S. J. Smith and S. Oulman, Phys. Rev. **111**, 504 (1958). Other calculated values for the electron affinity are: 1.22 e.v. E. Clementi and A. D. McLean, Phys. Rev. **133**, 4419 (1964); 1.16 e.v. E. Clementi, A. D. McLean, D. L. Rainondi, and M. Yoshimine, Phys. Rev. **133**, A1274 (1964); and 1.47 e.v. B. Edlén, J. Chem. Phys. **33**, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were estimated by assuming that the extra electron would produce an electronic structure similar to the next higher atomic numbered element, in this case F(I). An analogy was then made between O^- and F(I) with $O(I)$ and F(II), and $O(II)$ and F(III) in order to estimate the height of the first level above the ground state. The data for F(I), O(I), F(II), O(II) and F(III) were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949. It is possible that the entropy below 3000°K. could be in error by 0.5 e.v. due to the estimation of the low lying electronic level. The electronic levels above 1×10^5 cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The $H^\circ - H^\circ_{298}$ value at 0°K. is -1.567 kcal/mole.

Phosphorus Monoxide (P₀)

March 31, 1952

Lead Monoxide, Red (PbO) (Crystal)

Mol. Wt. = 223.21
 $\Delta H_f^o 298.15 = -52.41 \pm 0.16 \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = 15.6 \pm 0.2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o 298.15 = 63.88 \pm 0.22 \text{ kcal. mole}^{-1}$
 $T_f = 762^\circ \text{K}$
 $\Delta H_f^o = 0.18 \pm 0.23 \text{ kcal. mole}^{-1}$

Heat of Formation. Calculated from the cell reaction

reported by D. P. Smith and H. K. Woods, J. Am. Chem. Soc., 45, 2632 (1923), using $\Delta H_f^o 298.15$ for $\text{H}_2\text{O}(\text{l})$, $-68.317 \text{ kcal. mole}^{-1}$, given by Natl. Bur. Standards Circular 500 (1952). ΔH_f^o values reported by other investigators were discussed by R. W. Miller, J. Am. Chem. Soc., 51, 207 (1929).

Heat Capacity and Entropy. Heat capacity values (51° to 230.15°K) were obtained from E. O. King, J. Am. Chem. Soc., 80, 2400 (1958). For the higher temperature range, heat capacity given by K. K. Kelley, U. S. Bur. Mines Bull. 504 (1960) was used and joined smoothly to data of King at 230.15°K by graphical extrapolation. King obtained entropies below 51°K by empirical extrapolation of the heat capacity curve which fits the measured heat capacities within 1.3%.

Transition Data. Heat of transition recalculated from the data given by E. O. King, loc. cit.

Heat of Sublimation. Calculated from free-energy functions and vapor pressure reported by A. N. Neumayr, L. P. Pirova and E. P. Lukova, Zhur. Fiz. Khim. 33, 1699 (1960) and R. H6rbe and O. Knecko, Z. Erzhbergbau u. Metallurgie, 12, 321 (1959).

Lead Monoxide, Yellow (PbO)
(Crystal) Mol. Wt. = 223.21

Lead Monoxide, Yellow (PbO) (Crystal)

Mol. Wt. = 223.21
 $\Delta H_f^{298.15} = -52.07 \pm 0.28$ kcal. mole⁻¹
 $S_{298.15}^{298.15} = 16.1 \pm 0.2$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_s^{298.15} = 63.54 \pm 0.32$ kcal. mole⁻¹
 $T_m = 1170 \pm 4^\circ K.$
 $\Delta H_m^{298.15} = 6.1 \pm 0.1$ kcal. mole⁻¹

Heat of Formation. Calculated from $\Delta H_f^{298.15}$ for PbO (c, red) and $\Delta H_c^{298.15}$ between PbO (c, red) and PbO (c, yellow).

Heat Capacity, Entropy, and Melting Data. C_p values (51° to 298.15°K.) obtained from E. G. King, J. Am. Chem. Soc., 80, 2400 (1958). For the higher temperature range, the heat capacity reported by E. N. Rodigina, K. Z. Gornel'skii and V. P. Luginina, Zhur. Fiz. Khim., 35, 1799 (1961) was used and joined smoothly to data of King at 298.15°K. by graphical extrapolation. T_m and $\Delta H_m^{298.15}$ given by E. N. Rodigina, K. Z. Gornel'skii and V. P. Luginina, loc. cit.

Heat of Sublimation. Calculated from $\Delta H_c^{298.15}$ and $\Delta H_s^{298.15}$ for PbO (c, red).

Lead Monoxide (PbO) (Liquid)

Mol. Wt. = 223.21

 ΔH_f^0 298.15 = [-46.712] kcal. mole⁻¹ $S_{298.15}^0$ = [20.546] cal. deg.⁻¹ mole⁻¹ T_m = 1170 ± 4°K. ΔH_m^0 = 6.1 ± 0.1 kcal. mole⁻¹ T_b = 1769°K. ΔH_v^0 = 49.53 ± 0.22 kcal. mole⁻¹

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p , T_m , and ΔH_m^0 are obtained from E. N. Rodigina, K. Z. Gmel'skii and V. P. Lugina, Zhur. Fiz. Khim., **35**, 1799 (1961). The reported heat capacity is extrapolated to an assumed glass transition temperature of 780°K., below which the heat capacity is taken to be equal to that of the crystal, PbO (c, red).

Vaporization Phenomena. T_b and ΔH_v^0 calculated from ΔH_f^0 298.15 for PbO (c, red) and functions for condensed and gaseous states.

SULFUR MONOXIDE (SO)

(IDEAL GAS)

MOL. WT. = 48.0634

Ground State Configuration $3 \sum^-$
 $S_{298.15} = 53.0 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H_f^\circ = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ S_{298.15} = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{E_i, \text{cm.}^{-1}}{0} \frac{g_i}{3}$$

$$\sigma = 1$$

$$r_e = 1.481 \text{ \AA}$$

$$\omega_e = 1148.19 \text{ cm.}^{-1}$$

$$\alpha_e = 0.00562 \text{ cm.}^{-1}$$

$$B_e = 0.7207 \text{ cm.}^{-1}$$

Heat of Formation

The dissociation energy of sulfur monoxide has been reported by following investigators:

D ₀ (SO) e.v.	(kcal. mole ⁻¹)	(116.5)	(119.5)	(92.3)	(123.5)	(127.1)

O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. 2nd Ed., 1950.						
R. G. W. Norrish and G. A. Oldershaw, Proc. Roy. Soc. A249 , 498 (1959).						
J. J. McDermott, W. D. McOrath, Proc. Roy. Soc. A278 , 490 (1964).						

E. V. Martin, loc. cit., has measured the spectrum of SO(g) in the region 2400-4000 Å, and both Herzberg's and Gaydon's data were based on Martin's spectroscopic measurement. Because of the ambiguity of defining the state of excitation of the atomic products resulting from predissociation, the dissociation energy of SO was in question. Herzberg favored D_0 (SO) = 92.3 kcal. mole⁻¹ but Gaydon D_0 (SO) = 119.5 kcal. mole⁻¹.

Norrish and Oldershaw, loc. cit., redetermined the absorption spectrum of SO by flash photolysis, and also corrected Martin's original vibrational numbering, and then obtained the dissociation energy, D_0 (SO) = 123.5 kcal. mole⁻¹, based on the assumption of predissociation into S(¹D) and O(³P). This value, D_0 = 123.5 kcal. mole⁻¹, has been selected as the dissociation energy for SO(g) and combination with JANAF values of ΔH_f° (S; g) and ΔH_f° (O; g) gives the heat of formation of sulfur monoxide, $\Delta H_f^\circ S_{298} = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$, which is adopted in this tabulation.

R. Colin, P. Goldfinger and M. Jeunehomme, Trans. Faraday Soc. **60**, 306 (1964), have confirmed the selected D_0 (SO) = 123.5 kcal. mole⁻¹ in their mass spectrometric studies on the vaporization of CuS, SiS and BaS. J. J. McDermott and W. D. McOrath, loc. cit., reported the dissociation energy to be 127.1 kcal. mole⁻¹ based on their ultraviolet spectroscopic studies. This value appears to be the D_e from the minimum of the potential curve which corresponds to D_0 (SO) = 125 ± 1.5 kcal. mole⁻¹.

Besides the spectroscopic information, G. St. Pierre and J. Chipman, J. Am. Chem. Soc. **76**, 4787 (1954), have reported $\Delta H_f^\circ S_{298} = -19 \text{ kcal. mole}^{-1}$ for the reaction $0.5 \text{ S}_2(\text{g}) + 0.5 \text{ O}_2(\text{g}) \rightarrow \text{SO}(\text{g})$ in the equilibrium study of lime-iron oxide slags with SO₂ or SO₂-CO mixtures. Using $\Delta H_f^\circ S_{298}(\text{S}_2; \text{g}) = 30.8 \text{ kcal. mole}^{-1}$, the derived heat of formation, $\Delta H_f^\circ S_{298}(\text{SO}; \text{g}) = -3.6 \text{ kcal. mole}^{-1}$ was obtained. However, this value is doubtful because the reported $\Delta H_f^\circ S_{298} = -19 \text{ kcal. mole}^{-1}$ was dependent upon many assumptions and subsidiary data. E. W. Dewing and P. D. Richardson, Trans. Faraday Soc. **54**, 675 (1958) have measured the equilibrium constants for the reaction $\text{S}_2(\text{g}) + 2\text{SO}(\text{g}) \rightarrow 4\text{SO}(\text{g})$ at 1250°C. and $\text{SO}_2(\text{g}) \rightarrow \text{SO}(\text{g}) + 1/2 \text{ O}_2(\text{g})$ at 1500°C. Using the JANAF auxiliary data, the former yields $\Delta H_f^\circ S_{298}(\text{SO}; \text{g}) = +0.13 \text{ kcal. mole}^{-1}$ and the latter -0.17 kcal. mole⁻¹, respectively. The average of these two values is $\Delta H_f^\circ S_{298} = 0 \text{ kcal. mole}^{-1}$. Although D. Meschi and R. Myers, J. Mol. Spectry. **3**, 405 (1959) and U. Blukis and R. Myers, J. Phys. Chem. **69**, 1154 (1965), have certainly concluded in their microwave spectroscopic studies that the S₂O species was one of the important products in the Sulfur - SO₂ equilibrium which was considered as unimportant by Dewing and Richardson, the value, $\Delta H_f^\circ S_{298}(\text{SO}; \text{g}) = 0 \text{ kcal. mole}^{-1}$, derived from Dewing and Richardson is still very close to the selected value, $\Delta H_f^\circ S_{298}(\text{SO}; \text{g}) = 1.64 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy

The molecular constants ω_e , $\omega_e x_e$ and α_e were obtained from R. Norrish and G. Oldershaw, loc. cit., and the values of r_e and B_e were recently measured in the microwave spectrum by F. X. Powell and D. R. Lide, Jr., J. Chem. Phys. **41**, 1413 (1964).

Heat of Formation.

There is no direct measurement of the standard enthalpy of formation for S₂O(g). U. Blukis and R. Myers, J. Phys. Chem., 69, 1154 (1965), have discussed the discrepancy of the values of ΔH_f° O which vary from -1 to -35 kcal. mole⁻¹. R. Hagemann, Compt. Rend., 225, 1102 (1962), reported ΔH_f° O = -17 kcal. mole⁻¹ from his ionization and appearance potential measurements by mass spectrometry. R. Steudel and P. W. Schenk, Z. Physik Chem., 43, 33 (1964), estimated the enthalpy of formation as -22.7 kcal. mole⁻¹. If the bond dissociation energies D(S-O) = 123.5 kcal. mole⁻¹ and D(S-S) = 103 kcal. mole⁻¹ were used to estimate the dissociation energy of S₂O (i.e. D(S₂O) = 224.5 kcal. mole⁻¹), one will obtain ΔH_f° O = -35.3 kcal. mole⁻¹. A. V. Jones, J. Chem. Phys., 18, 1263 (1950), reported the predissociation energy, 91 kcal. mole⁻¹, for sulfur monoxide from the infrared and ultraviolet spectra. [D. Meschi and R. Myers, J. Mol. Spectro., 3, 405 (1959), have concluded from their experiment that the so called sulfur monoxide is S₂O.] Therefore, if 30(g) + S(g), were the dissociation products, the ΔH_f° O would be -25.4 kcal. mole⁻¹; and if S₂(g) + O(g) were the products, the ΔH_f° O would be -1.2 kcal. mole⁻¹. (All JANAP auxiliary data used in calculation.)

E. Dewing and P. Richardson, Trans. Faraday Soc., 54, 679 (1958), have investigated the gas phase equilibria in the sulfur-oxygen vapor at 1250° and 1500°C respectively. U. Blukis and R. Myers (loc. cit.) recalculated their data based on the assumption that the S₂O (instead of SO) was the major product in the equilibrium, and obtained ΔH_f° O = -13 kcal. mole⁻¹ for S₂O(g) which is adopted in this table.

Heat Capacity and Entropy.

The bond distance, angle, and vibrational frequencies were obtained from the microwave and infrared spectra measurements by D. Meschi and R. Myers, loc. cit., and U. Blukis and R. Myers, loc. cit. The three principal moments of inertia are $I_A = 2.0219 \times 10^{-39}$, $I_B = 16.6342 \times 10^{-39}$, and $I_C = 18.6560 \times 10^{-39}$ g. cm.²

Heat of Formation

The adopted value is based on equilibrium data summarized below. The more reliable results from three different reactions lie in the range from about -23 to -26 kcal/mol. Extreme values, including -20 and -32 kcal/mol, can be discounted on experimental grounds. Margrave (1) recently reported $\Delta H_f^{\circ} = 82.8 \pm 1.5$ kcal/mol for $0.5SiO_2(g) + 0.5Si(s) = SiO(g)$, but details are not yet available. Assuming that this corresponds to reaction A below, we calculate $\Delta H_f^{\circ} = -25.4$ kcal/mol. Reaction A involves the nominal composition $SiO(s)$ which is treated as an intimate mixture of $0.5Si(c) + 0.5SiO_2$ (high cristobalite). X-ray studies (13, 14) suggest that the condensed " SiO " used in (1, 2) is probably a mixture of Si and amorphous or vitreous SiO_2 . The adopted ΔH_f° corresponds to $D_0^{\circ} = 190 \pm 3$ kcal/mol. This may be compared with $D_0^{\circ} = 179$ kcal/mol obtained by linear Birge-Sponer extrapolation of the ground state vibrational constants and with $D_0^{\circ} = 185 \pm 7$ kcal/mol obtained by Barrow (15) from $D_0^{\circ}(LiX) = 77.5$ kcal/mol for the excited state at 5280 cm⁻¹. Barrow assumed $D_0^{\circ}(LiX) = 0.456$ based on related molecules.

Heat Capacity and Entropy

All constants for the ground state and the $A^1\Pi$ state at 42600 cm⁻¹ are taken from the analysis of the A-X system reported by Lagarkov (16). An intercombination transition has been observed and assigned as $1s^2 3^1\Pi$ by Verma (17). The value of the a-X excitation energy is unknown but is estimated here as 30000 ± 5000 cm⁻¹ by comparison with the A and A states of CO and ACl. Several additional excited states are known (15, 16) to lie near or above the A state, but they are omitted because their contribution to the thermal functions is negligible.

Dec. 31, 1960; Mar. 31, 1967

$S_{298.15}^{\circ} = [12.2] \text{ gbbu/mol}$
 $T^{\circ} = 1264^{\circ}\text{K}$
 $\Delta H_f^{\circ} = -123.48 \pm 1 \text{ kcal/mol}$
 $\Delta H_f^{\circ}{}_{298.15} = -124.19 \pm 1 \text{ kcal/mol}$
 $\Delta H^{\circ} = 0.83 \text{ kcal/mol}$
 $\Delta H_{298.15}^{\circ} = 128 \pm 10 \text{ kcal/mol}$

Heat of Formation.
O. L. Humphrey, *J. Am. Chem. Soc.* **73**, 1587 (1951), determined the heat of combustion $\Delta H_{298}^{\circ} = -101.61 \pm 0.12$ kcal/mol for the reaction $\text{TiO}(\alpha) + 1/2\text{O}_2(\text{g}) = \text{TiO}_2(\text{rutile})$. Based on this result and on $\Delta H_{298}^{\circ}(\text{rutile}) = -225.8 \pm 1$ kcal/mol, the adopted ΔH_f° for $\text{TiO}(\alpha)$ is calculated to be -124.19 ± 1 kcal/mol. A value of -125.4 ± 0.4 kcal/mol was reported by S. M. Ariya, M. P. Morozova and E. Vol'f, *Russ. J. Inorg. Chem. (English Transl.)* **2**, 16 (1957), who measured the heats of combustion of various compositions in the Ti-O system. Ariya et al. used an estimated correction for the formation of $\text{TiO}_2 \cdot x$ while Humphrey obtained values of $0.2 - 0.4$ kcal/mol by grinding the product and returning it with white oil. Most of the assigned uncertainty arises from this problem of non-stoichiometry [see $\text{TiO}_2(\text{rutile})$ for further details].

Heat Capacity and Entropy.
The low temperature heat capacities, $52.6 - 296.3^{\circ}\text{K}$, were measured by C. H. Shomate, *J. Am. Chem. Soc.* **68**, 310 (1946). The high temperature enthalpies, $357.0 - 1771^{\circ}\text{K}$, were determined by B. F. Naylor, *J. Am. Chem. Soc.* **69**, 1077 (1946), by use of drop calorimetry. The high temperature Cp's, $357 - 1200.5^{\circ}\text{K}$, derived from the enthalpy data, are joined smoothly with the low temperature heat capacities at 298°K . The Cp values above 1200°K are obtained by extrapolation. The entropy is obtained from Cp° using $S_0^{\circ} = 4.13$ eu; this extrapolation includes 0.23 , 1.7 and 2.2 eu for contributions of the lattice, of vacancies and of spin magnetic effects, respectively.

P. W. Ollies, *J. Chem. Phys.* (in press), discussed the inconsistencies in the thermodynamic properties of TiO as derived from widely different measurements. These inconsistencies include (1) a difference of 10 kcal/mol in H_0° values for $\text{TiO}(\text{g})$ obtained from vaporization of TiO and Ti_2O_3 , (2) a difference of about 10 kcal/mol between the calorimetric data for $\text{TiO}(\beta)$ and a recent re-assessment of the partial free energy of dissociation for the TiO system, and (3) emf. data which suggest that the entropy of $\text{TiO}(\beta)$ should be increased relative to those of Ti and Ti_2O_3 . In order to minimize these discrepancies, we tentatively increase the experimental value of S_{298}° by addition of estimated contributions due to vacancies in the crystal lattice and to spin-magnetic effects of Ti^{3+} ion.

P. Enrich, *Z. Elektrochem.* **45**, 362 (1959) and Z. Anorg. Chem. **247**, 53 (1941), concluded from the difference in pycnometric and x-ray densities of $\text{TiO}(\beta)$ that about 25 percent of the Ti and O lattice sites are vacant. This was confirmed later by S. Anderson, B. Collen, U. Kuylenstierna and A. Magnelli, *Acta. Chem. Scand.* **11**, 1641 (1957), A. D. Pearson, *J. Phys. Chem. Solids* **5**, 316 (1958), and M. E. Strueman and H. W. Li, *Z. Anorg. Allgem. Chem.* **305**, 143 (1960). Anderson et al. noted that there may be a "close structural kinship" between the α and β forms, based on the similarity of their densities and the pronounced relationship between their powder diffraction patterns. The authors suggested that the (presumably) random vacancies in $\text{TiO}(\beta)$ may occur in an ordered way in $\text{TiO}(\alpha)$. Recent electron diffraction studies by J. M. Cowley, *Acta Cryst.* (to be published), may provide an answer to this problem. Assuming the vacancies to be randomly arranged, we estimate the residual entropy of $\text{TiO}(\alpha)$ due to vacancies as $-2R(0.85 \ln 0.85 + 0.15 \ln 0.15) = 1.7$ eu, based on the method proposed by M. Hoch, A. S. Iyer and J. Neiken, *J. Phys. Chem. Solids* **23**, 1463 (1962). An alternative possibility for increasing the entropy of $\text{TiO}(\beta)$ is discussed in the Transition Data section of the table for $\text{TiO}(\beta)$.

Metallic-type conductivity of $\text{TiO}(\alpha)$ at temperatures $80 - 1000^{\circ}\text{K}$ was reported by A. D. Pearson, loc. cit., and P. J. Morin, *Phys. Rev. Letters* **3**, 34 (1959). This led J. B. Goodenough, *Phys. Rev.* **117**, 1442 (1960), to suggest the existence of strong cation-cation interactions and the possibility of a low temperature transformation of the martensitic or antiferromagnetic type. Goodenough noted that the isolectric compound VN becomes superconducting below 8.2°K . We approximate the entropy contribution of these various possibilities at 50°K by a spin-magnetic term of $R \ln 3 = 2.2$ eu.

Transition Data.
See $\text{TiO}(\beta)$ table.

Heat of Sublimation.
The difference between ΔH_{298}° for $\text{TiO}(\text{g})$ and $\text{TiO}(\alpha)$ is ΔH_{298}° .

Mar. 31, 1967

TITANIUM MONOXIDE, BETA (β -TiO) (CRYSTAL) OFW = 63.8994

$S_{298}^{\circ} = 12.372$ e.u./mol
 $T_f = 1264^{\circ}\text{K}$
 $T_m = 2023^{\circ}\text{K}$

$\Delta H_f^{\circ} = -123.872$ kcal/mol
 $\Delta H^{\circ} = 0.83$ kcal/mol
 $\Delta G_m^{\circ} = [13]$ kcal/mol

Heat of Formation.
 The $\Delta H_f^{\circ} 298(\beta)$ is obtained from $\Delta H_f^{\circ} 298(\alpha)$ by adding ΔH_t° and the difference between $H_{1264}^{\circ} - H_{298}^{\circ}$ for TiO(α) and TiO(β).

Heat Capacity and Entropy.

High temperature enthalpies, 1273 - 1771°K, have been measured with a drop calorimeter by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946). The adopted heat capacities are derived from these data, assuming the final state to be TiO(α). This problem is discussed in the Transition Data section. Cp values below 900°K are assumed to be the same as those for TiO(α). The heat capacities at temperatures 900 - 1273°K and above 1771°K are obtained by extrapolation. The S_{298}° is derived in a manner analogous to that of the heat of formation.

Transition Data.

Tt and ΔH_t° are derived from the enthalpy data of Naylor, loc. cit., assuming that TiO(α) is the final state of the drop experiment. The X-ray studies of C. C. Wang and N. J. Grant, J. Metals 5, 184 (1956), and A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), appear to contradict this assumption. These authors found that the α form of stoichiometric TiO was obtained at room temperature only by annealing the β phase for long periods below 1223°K. Samples quenched from temperatures of 1223°K or higher retained the NaCl structure of the β form. Since the drop calorimetric experiment is similar to quenching, it is possible that the final state was mostly the β form. If this is the case, then the derived values of ΔH_t° and ΔS_t° are probably much too small. This would be an alternative means for increasing the entropy of TiO(β). It is possible, however, that differences in particle size allowed Naylor's sample to drop to the α form, or that the β form was stabilized by impurities in the X-ray studies. Further experiments are desirable in order to resolve this question. Also related to the question is the fact that the structure of TiO(α) has not been reported, probably because the X-ray diffraction pattern is quite complex.

P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), reviewed the phase data and presented the most current phase diagram for the Ti-O system. This diagram suggests that stoichiometric TiO(α) starts to transform near 1210°K with formation of the two phases TiO_{1+x}(β) and Ti₂O. Transformation to stoichiometric TiO(β) is complete near 1270°K, which is essentially the Tt chosen by Naylor. This behavior is consistent with Naylor's observation of "pre-transition effects" in the enthalpy between 1224 and 1264°K.

Melting Data.

See TiO(1) table for details.

TITANIUM MONOXIDE (TiO)

(LIQUID)

GFW = 63.8994

$$\Delta H_f^{298,15} = [-112.801] \text{ kcal/mol}$$

$$\Delta H_m^\circ = [13] \text{ kcal/mol}$$

$$\Delta H_v^\circ = [91.6] \text{ kcal/mol}$$

$$S_{298,15}^\circ = [14.235] \text{ gibbs/mol}$$

$$T_m = 2023^\circ \text{K}$$

$$T_b = [3934]^\circ \text{K}$$

Heat of Formation.

The value of ΔH_f^{298} for TiO(l) is obtained from that of TiO(s) by adding ΔH_m° and the difference between $H_{2023}^\circ - H_{298}^\circ$ for TiO(s) and TiO(l).

Heat Capacity and Entropy.

The heat capacity for TiO(l) is estimated on the basis of 8 cal/g-atom. S_{298}° is obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m is taken from W. Dawid and K. Schröter, Z. Anorg. Allg. Chem. 233, 178 (1937). The heat of melting is estimated by comparison with that of VO(c) reported by C. E. Wicks and P. E. Block, U. S. Bur. Mines Bull. 605, 1963.

T_m has also been reported as 2023 and 2103°K by H. Nishimura and H. Kimura, J. Japan Inst. Metals (Sendai) 20, 589 (1956), and R. DeVries, R. Roy, and E. Osborn, Trans. Brit. Ceram. Soc. 53, 525 (1954), respectively. According to the Ti-O phase diagram reported by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), TiO melts incongruently.

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energy change of the reaction TiO(l) = TiO(g) approaches zero. The difference between ΔH_f° for TiO(g) and TiO(l) at T_b is ΔH_v° .

TUNGSTEN MONOXIDE (W0)

(IDEAL GAS)

GFW = 199.8494

Ground State Configuration [$5s^2$] gibbs/mol
 $S_{298.15}^o = [58.7]$ gibbs/mol
 $\Delta H_{298.15}^o = 101.6 \pm 10$ kcal/mol
 $\Delta H_{298.15}^o = 101.6 \pm 10$ kcal/mol

Electronic Levels and Quantum Weights

ϵ_1 , cm ⁻¹	g_1
[0]	[3]
[14160]	[1]
[17211]	[2]
[19189]	[6]

$w_e = 1055$ cm⁻¹
 $B_e = [0.3498]$ cm⁻¹
 $w_e x_e = [3.85]$ cm⁻¹
 $a_e = [0.0016]$ cm⁻¹
 $r_e = [1.81]$ Å

Heat of Formation

The heat of formation, $\Delta H_{298}^o(WO, g) = 101.6$ kcal/mol, was derived from the heat of reaction, $\Delta H_{298}^o = -42.0$ kcal/mol for $WO(g) \rightarrow W(c) + O(g)$ with all JANAF auxiliary data. The value of ΔH_{298}^o was calculated by the third law method from the partial pressure data, which were determined mass-spectrometrically in the temperature range 2188° to 2475°K, by G. DeMaris, R. P. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. **32**, 1373 (1960). The drift in the third law analysis was $\pm 20 \pm 7$ eu.

Heat Capacity and Entropy

The fundamental vibrational frequency, the ground state configuration, and the probable electronic levels for tungsten monoxide (g) were obtained from the infrared and ultraviolet spectroscopic investigations by matrix isolation by W. Weitzer, Jr., and D. McLeod, J. Mol. Spectry. **17**, 276 (1965). The rotational constant B_e was calculated from an estimated bond distance, $r_e = 1.81$ Å. The value of x_e was calculated from the relation $x_e u^2/2 = 0.014$ which was given by R. F. Barrow and A. D. Caunt, Proc. Roy. Soc. (London) **219A**, 120 (1953). The constant, 0.014, was estimated, based on those for $ZrO(g)$ and $VO(g)$. The value of a_e was calculated from the Morse potential function.

ZIRCONIUM MONOXIDE (ZrO)

(IDEAL GAS)

MOL. WT. = 107.2194

Ground State Configuration $1\Sigma^+$ $\Delta H_f^0 = 14.26 \pm 12 \text{ kcal. mole}^{-1}$ $S_{298.15}^0 = 54.33 \pm 2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^0 = 14.0 \pm 12 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

E_i , cm. ⁻¹	g_i	E_i , cm. ⁻¹	g_i
0	1	(18000)	2
(4000)	6	(22000)	6
(6000)	2	(25500)	2
15500	2	27500	1
(15700)	6	(28500)	6
(17500)	6		

 $\omega_e x_e = 4 \text{ cm.}^{-1}$ $r_e = 1.711 \text{ \AA}$ $\omega_e = 978 \text{ cm.}^{-1}$ $\sigma = 1$ $\omega_e x_e = 0.0023 \text{ cm.}^{-1}$ $B_e = 0.4142 \text{ cm.}^{-1}$

Heat of Formation.

The ΔH_f^0 298.15 = 14.0 ± 12 kcal. mole⁻¹ was calculated from the ΔH_f^0 298.15 = 290.342 ± 12.8 kcal. mole⁻¹ for the reaction $\text{Zr(c)} + \text{ZrO}_2(\text{c}) = \text{ZrO(g)}$. The value of ΔH_f^0 298.15 was obtained by the third law analysis from the mass spectrometric studies of M. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 28, 1207 (1957). They observed the variation of the ZrO⁺ ion intensity over the system Zr + ZrO₂ and reported equilibrium constants for the reaction $\text{Zr} + \text{ZrO}_2 \rightarrow \text{ZrO} + \text{ZrO}_2$ in the range 2124-2322°K. The third law drift is $-58 \pm 28 \text{ a.u.}$

Heat Capacity and Entropy.

The ground state of ZrO(g) was assumed to be $1\Sigma^+$ as determined from the matrix isolation spectra of W. Weltner, Jr., and D. McLeod, Jr., J. Phys. Chem. 69, 3488 (1965). Previously this had been described as the lower state in the A band system reported by V. Uhler and L. Akerlind, Arkiv Fysik 10, 431 (1955).

All molecular constants were obtained from Uhler and Akerlind, loc. cit., except $\omega_e = 978 \text{ cm.}^{-1}$ and $\omega_e x_e = 4 \text{ cm.}^{-1}$ which were calculated from ω and $\omega_e = 0.0023 \text{ cm.}^{-1}$ using the equations

$$\omega_e x_e = \frac{6 \sqrt{\omega_e x_e} \cdot B_e^3}{\omega_e} - \frac{6 B_e^2}{\omega_e} \quad \text{and} \quad \omega_e = \omega_e - 2 \omega_e x_e = 969.76 \text{ cm.}^{-1}$$

The higher electronic levels were obtained or estimated from the correlation diagram given by Weltner and McLeod, loc. cit.

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1965

OXYGEN, DIATOMIC (O_2)

MOL. WT. = 31.9988

Ground State Configuration $3 \Sigma_g^-$ $\Delta H_f^\circ O = 0$

$S_{298.15}^\circ = 49.00 \pm 0.01$ cal. deg.⁻¹ mole⁻¹ $\Delta H_f^\circ 298.15 = 0$

$\omega_e x_e = 12.071$ cm.⁻¹ $\sigma^- = 2$

$B_e = 1.445$ cm.⁻¹ $r_e = 1.2074$ Å

Heat of Formation.

The heat of formation (ΔH_f°) for $O_2(g)$ is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here are based on those of H. W. Woolley, J. Research, Nat. Bur. Standards 40, 163 (1948), who used a direct summation to 5000°K. The spectroscopic constants used were the same as those listed by O. Herzberg, Spectra of Diatomic Molecules, D. Van Nostrand Co., 1950. Raman measurements of rotation-vibration levels by A. Haber and E. A. McGinnis, J. Molec. Spect., 4, 195 (1960), support the constants selected by Herzberg which were changed on this table to apply to the naturally occurring isotopic composition given by D. Strominger, J. M. Hollander, and T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The entropies listed by Woolley were reduced by 0.0065 cal. deg.⁻¹ mole⁻¹ which was added by Woolley to account for the contribution due to the presence of both odd and even rotational levels in O_2^{16} and O_2^{18} molecules. This correction is not necessary when isotope mixing entropy is neglected, cf. W. F. Giauque and R. Overstreet, J. Am. Chem. Soc. 55, 1731 (1933).

Heat of Formation

The electron affinity of $O_2(g)$ has been measured in the electron detachment experiments of J. L. Pack and A. V. Phelps, J. Chem. Phys. 44, 1870 (1966). The value reported is $0.43 \pm 0.02 \text{ eV}$ ($9.92 \pm 0.48 \text{ kcal/mol}$) which is in good agreement with the value $0.46 \pm 0.10 \text{ eV}$ selected by C. W. Beckett and E. C. Casady, Natl. Bur. Std. Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy

J. Rolfe, J. Chem. Phys. 40, 1664 (1964), has deduced from fluorescence emission spectra of O_2^- in alkali halides, the vibrational constants and an excited electronic level. The $^2\Pi$ ground state is that predicted by molecular orbital theory and the first excited state should also be $^2\Pi$. By analogy with Cl_2^+ , which is isoelectronic, the first excited level is estimated to lie in the 20000 - 30000 cm^{-1} region. Thus, the level observed by Rolfe is assumed to be the first excited $^2\Pi_u$ state. The bond length is taken from F. R. Olmstead, The Rand Corporation, Memo- randum RM-4034-1-PR, AD 630997. B_e was calculated from the bond length, and a_e was estimated from the above quantities using the Morse potential function relation.

The enthalpy at 0°K is -2.086 kcal/mol .

Phosphorus Dioxide (PO₂)

(Ideal Gas) Mol. Wt. = 62.975

 [960] (1)
 [515] (1)
 [1044] (1)

Angle O-P-O = 134° 4'

P-O distance = 1.485 Å

I_A = [10.81 X 10⁻³⁹] g. cm.²I_B = [9.933 X 10⁻³⁹] g. cm.²I_C = [0.977 X 10⁻³⁹] g. cm.²Heat of Formation. ΔH_f^o 298.15 was calculated from an estimated heat of dissociation (270 ± 25 kcal. mole⁻¹) reported by L. Brewer and O. M. Rosenblatt, Chem. Reviews, **61**, 257 (1961).

Heat Capacity and Entropy. The molecular constants selected for this table were estimated by J. S. Gordon. The molecular constants for PO₂(g) have been estimated by (1) J. S. Gordon, "Thermodynamic Data for Combustion Products," January 1960, Thiokol Chemical Corp., Reaction Motor Division, Denville, N. J. (2) R. L. Potter, V. N. DiStefano and S. N. Fox, "The Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I," American Cyanamid Company and (3) C. B. Henderson and R. S. Scheffer, "Survey of Thermochemical Data," January 1960, Atlantic Research Corp., Alexandria, Virginia. The entropies at 3000° calculated from these three estimates differ by less than 0.8 cal. deg.⁻¹ mole⁻¹.

Lead Dioxide (PbO₂) (crystal)

Mol. Wt. = 239.21

ΔH°_f 298.15 = -64.55 ± 0.16 kcal. mole⁻¹S°_{298.15} = 18.3 ± 0.5 cal. deg.⁻¹ mole⁻¹

Heat of Formation. Recalculated from ΔH°_{298.15} = 12.14 kcal. mole⁻¹ for the reaction: PbO(c) + 1/2O₂(g) = PbO₂(c) reported by M. Tschelizow, Compt. rend., 100, 1458 (1885).

Heat Capacity and Entropy. C_p (69.9° to 297.2°K.) reported by R. W. Miller, J. Am. Chem. Soc. 51, 207 (1929). Above 298.15°K., the heat capacity value estimated by K. K. Kelley, U. S. Bur. Mines Bull. 594 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation.

Heat of Formation

J. R. Eickman and P. D. Rossini, J. Research Nat. Bur. Standards **53**, 597 (1929), measured the heat of combustion of rhombic sulfur to SO₂. Changes due to different atomic weights and electrical constants though negligible have been made.

Heat Capacities and Entropies

The functions were calculated by J. Gordon, private communication, Feb. 2, 1961, using the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. **22**, 1442 (1954). Structural parameters are given by M. H. Sirlatz, J. Chem. Phys. **19**, 938 (1951), obtained from microwave measurements. Frequencies were measured by R. D. Shelton, A. H. Nielsen, W. H. Fletcher, J. Chem. Phys. **21**, 2178 (1953) and **22**, 1791 (1954). A third law value of S_{298.15} = 59.24 cal. deg.⁻¹ mole⁻¹ was obtained by W. F. Clauqua and C. C. Stevenson, J. Am. Chem. Soc. **80**, 1389 (1958).

$$\begin{aligned}\Delta H_f^\circ &= -216.5 \pm 0.4 \text{ kcal/mol} \\ \Delta H_{298.15}^\circ &= -217.7 \pm 0.4 \text{ kcal/mol} \\ \Delta H_1^\circ &= 0.174 \pm 0.04 \text{ kcal/mol} \\ \Delta H_2^\circ &= 0.48 \pm 0.15 \text{ kcal/mol} \\ \Delta H_m^\circ &= 1.84 \pm 0.2 \text{ kcal/mol}\end{aligned}$$

$$\Delta H_{298.15}^\circ = 9.91 \pm 0.03 \text{ gibbs/mol}$$

$$T_1 = 847 \pm 1.5^\circ \text{K (low quartz} \rightarrow \text{high quartz)}$$

$$T_2 = 1079 \pm 250^\circ \text{K (high quartz} \rightarrow \text{high cristobalite)}$$

$$T_m = 1696 \pm 50^\circ \text{K (high quartz} \rightarrow \text{liquid)}$$

Heat of Formation

The heat of formation is based on data of Wise (1) for combustion of SiO₂ (low quartz) and Si(c) in F₂ to form SiF₄(g). Good (2) burned a mixture of Si(c) and vinylidene fluoride polymer in oxygen in the presence of HF(aq) to form H₂SiF₆(aq HF). Combining this result with a previous heat of solution of quartz (3), the authors derived $\Delta H_{298}^\circ = -217.5 \pm 0.5 \text{ kcal/mol}$. Agreement with the adopted value is excellent, considering the complexity of the latter scheme. Both schemes are independent of ΔH_f° (HF), although the polymer-Si scheme depends on the heat of dilution of HF(aq). Wise (1) has reviewed other data which confirm the adopted value rather than the oxygen combustion value (4) of -209.9 kcal/mol . Pertinent equilibrium data are analyzed on the table for SiO₂ (low cristobalite), while the calorimetric results are summarized below.

Reaction
 $\text{SiO}_2(\text{low quartz}) + 2\text{F}_2(\text{g}) \rightarrow \text{SiF}_4(\text{g}) + \text{O}_2(\text{g})$
 See text.
 $\text{Si(c)} + 2\text{O}_2(\text{g}) \rightarrow \text{SiO}_2(\text{low quartz})$

$$\begin{aligned}\Delta H_{298}^\circ, \text{ kcal/mol} & -188.26 \pm 0.28 \\ \Delta H_{298}^\circ, \text{ kcal/mol} & -217.72 \pm 0.34 \\ \Delta H_{298}^\circ, \text{ kcal/mol} & -217.5 \\ \Delta H_{298}^\circ, \text{ kcal/mol} & -209.9\end{aligned}$$

$$\text{SiO}_2(\text{low quartz}) + 2\text{F}_2(\text{g}) \rightarrow \text{SiF}_4(\text{g}) + \text{O}_2(\text{g})$$

See text.

$$\text{Si(c)} + 2\text{O}_2(\text{g}) \rightarrow \text{SiO}_2(\text{low quartz})$$

Heat Capacity and Entropy

Heat capacities below 300°K are based on data of Jones (5) and Westrum (6). Earlier data of Anderson (7) are in good agreement. The entropy is obtained from Cp using $S_2^\circ = 0.00001 \text{ eu}$. Cp° from 300° to 847°K is derived from adiabatic calorimetric data of Moser (8) and Sineil'nikov (9). The adopted Cp° is discontinuous at 847°K and $\Delta C_p^\circ = -2.17 \text{ gibbs/mol}$. Values above the transition temperature are based on data of Moser and on data up to 1473°K obtained with a thermal analysis method by Leonidov (10). Cp° is extrapolated linearly to higher temperatures.

From a review of data available before 1953, Kelley (11) selected almost identical enthalpies below 847°K but a value higher by 96 cal/mol at 900°K. The higher value, due to use of a larger ΔH_{298}° , was presumably based on Roth (12), Wietzel (13) and White (14) whose enthalpy data were given the most weight by Kelley. Near 900°K these three sets of data deviate from the adopted function by -150 ± 30 , $+130 \pm 40$ and $+1535 \text{ cal/mol}$, respectively; however, a recent enthalpy datum (15) obtained by transposed temperature drop calorimetry deviates by $+75 \text{ cal/mol}$ at 968°K.

Transition Data

T₁ is taken as $847 \pm 1.5^\circ \text{K}$ based on thermal analysis of many specimens by Kieth and Tuttle (16). Wide variations in T₁ for some specimens were attributed by the authors to small amounts of impurities. The discontinuity in the volume curve (17) during inversion from trigonal low quartz to hexagonal high quartz suggests that the transition should be treated as first order. Thus, the heat of transition is derived as $(1011-854)/17 = 174 \text{ cal/mol}$, where 1011 ± 6 is $(H_{298.15}^\circ - H_{823.15}^\circ)$ measured by Moser (8), 854 is the corresponding increment calculated from the JANAF Cp°, and 17 is an endpoint correction for the difference between the observed and adopted curves below 823.15°K. Some of the more recent data which confirm the adopted ΔH_1° are summarized below.

Source	Method	ΔH_1° , kcal/mol
8. Moser (1936)	H and Cp from adiabatic calorimetry	0.174
9. Sineil'nikov (1953)	Integration of Cp from adiabatic calorimetry	0.143
10. Leonidov (1964)	Thermal analysis	0.198
17. Berger (1964)	ΔV with $dT/dP = 0.026^\circ \text{K/atm}$	0.12
18. Berger (1965)	Microcalorimetric thermal analysis	0.156, 0.165, 0.178 ± 0.010
	Single crystal	0.124 to 0.193
	Various crushed samples	

Additional polymorphism of SiO₂ is discussed on the table for high cristobalite. Quartz has been superheated through the cristobalite region to some 300° above its metastable melting point. This melting point is calculated from the adopted tables as $1895 \pm 50^\circ \text{K}$, which agrees well with the range $1673 - 1723^\circ \text{K}$ indicated by the data of Mackenzie (18). The adopted tables predict the inversion of high quartz to high cristobalite at $1079 \pm 250^\circ \text{K}$. Holmquist (20) tentatively placed this inversion at $1298 \pm 25^\circ \text{K}$. ΔH_2° and ΔH_m° are calculated from the differences in heats of formation of the appropriate phases at T₂ and T_m.

CRISTOBALITE, LOW (SiO₂)

(CRYSTAL)

GFW = 60.0848

O₂Si

$$\Delta H_f^\circ = -215.9 \pm 0.5 \text{ kcal/mol}$$

$$\Delta H_f^\circ = -217.1 \pm 0.5 \text{ kcal/mol}$$

$$\Delta H_f^\circ = 0.321 \pm 0.06 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 10.372 \pm 0.03 \text{ gibbs/mol}$$

$$T_t = 543 \pm 3^\circ \text{K (Low cristobalite + high cristobalite)}$$

Heat of Formation

The heat of formation is calculated from that of quartz using $\Delta H_f^\circ = 0.45 \pm 0.15 \text{ kcal/mol}$ for high quartz + high cristobalite, as determined by Holm(1) from ΔH_{soln} in an oxide melt. This value reduces to $\Delta H_f^\circ = 0.60 \text{ kcal/mol}$ for low quartz + low cristobalite. Kracek(2) obtained essentially the same value, $\Delta H_f^\circ = 0.63 \text{ kcal/mol}$, from ΔH_{soln} in HF(aq, 74.7°C), while Hummel(3) found $\Delta H_f^\circ = 1.80 \text{ kcal/mol}$ from ΔH_{soln} in HF(aq, 26.5°C). The larger ΔH_f° corresponds to a less negative ΔH_f° (i.e., less stable) and suggests that the sample of Hummel has disorder approaching that of vitreous silica. Presumably, this disagreement arises from different methods of preparation of cristobalite from quartz. Holm heated for 24 hours at 1743°K, while Hummel heated for 4 hours at 1793°K. Hummel's sample was then ground and treated with dilute HF to remove amorphous surface layers created by grinding; particles smaller than 2.5 microns were used in order to obtain adequate rates of dissolution. Neither author gave X-ray or DTA evidence to confirm that the samples were the more stable, ordered form of cristobalite(13).

The calorimetric data are summarized below along with equilibrium data which confirm the adopted values of ΔH_f° for cristobalite and quartz. Data from Matoba(5) and Rein(6) were reduced to the standard state of Si(l) using activity coefficients from the curves of (10).

Source	Method	Reaction	Range, °K	No. of Points	ΔH_f° , kcal/mol	ΔH_f° , kcal/mol	Drift, eu	ΔH_f° , kcal/mol

 C. SiO_2 (high cristobalite) + $2\text{C}(\text{graph}) = \text{Si}(\text{l}) + 2\text{CO}(\text{g})$
 D. SiO_2 (high cristobalite) + $2\text{SiC}(\text{g}) = 3\text{Si}(\text{l}) + 2\text{CO}(\text{g})$
 E. SiO_2 (high cristobalite) + $3\text{C}(\text{graph}) = 3\text{SiC}(\text{g}) + 2\text{CO}(\text{g})$

Heat Capacity and Entropy

Cp° below 300°K is based on data of Westrum(11). Earlier data of Anderson(12) are in satisfactory agreement. The entropy is obtained from Cp° using $S_0^\circ = 0.0007 \text{ eu}$. Cp° above 300°K is derived from enthalpy data of Moesman(13) and White(14). The former deviate from the adopted functions by -0.7 to 0.5 and the latter by +0.44. Although the functions above 300°K appear to be reliable, it would be desirable to have new data for a well-characterized sample (see Transition Data).

Transition Data

Low cristobalite is metastable with respect to quartz but persists up to Tt. Tt is taken as the temperature at the peak in the heating curve for well-ordered cristobalite; however, see (15, 16) for detailed discussions of temperatures about 25° lower which were found from cooling curves. ΔH_t° is derived from enthalpy data(13, 14) for high cristobalite using the adopted enthalpy for the low form. The enthalpy data of Moesman(13) gave a lower Tt which suggests that the sample was less well-ordered than desirable. ΔH_t° is confirmed, however, by other data which are summarized below. Additional polymorphism is discussed on the table for high cristobalite.

CRISTOBALITE, HIGH (SiO₂)

(CRYSTAL)

GFW = 60.0848

$S_{298.15}^{\circ} = 11.963$ gibbs/mol
 $\Delta H_{298.15}^{\circ} = -216.417$ kcal/mol
 $\Delta H^{\circ} = 0.321 \pm 0.06$ kcal/mol
 $\Delta H^{\circ} = 0.48 \pm 0.15$ kcal/mol
 $\Delta H^{\circ} = 2.29 \pm 0.5$ kcal/mol

Heat of Formation

The heat of formation is calculated from that of low cristobalite by addition of $\Delta H^{\circ} = 0.321$ kcal/mol and the difference between $H_{543}^{\circ} - H_{298}^{\circ}$ for low and high forms.

Heat Capacity and Entropy

C_p° is derived from enthalpies of Nossaman (1) and White (2), whose data deviate from the adopted functions by -0.6 to $+0.5\%$ and $+0.9$ to 0.0% , respectively. White's deviations for cristobalite have a magnitude and trend similar to his deviations for quartz and vitreous silica. Data of Wietzel (3) for his sample prepared at 1600°C deviate by $+3\%$ at 673°K and $+1.6\%$ at 1773°K . C_p° below 543°K is smoothly extrapolated to give the proper trend in the Gibbs energy, but the heat capacity at 298°K is not realistic. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

Literature on the polymorphism of SiO₂ is voluminous but is summarized in detail in recent books by Sosman (4) and Eitel (5). The known phases of SiO₂ include quartz, tridymite(?), cristobalite, vitreous silica and the more recently discovered high pressure phases. Muan (6) concisely reviewed the still controversial question of whether tridymite is stabilized only by the presence of foreign ions or whether it is a stable phase of SiO₂ intermediate between quartz and cristobalite. Transitions among the different phases are generally sluggish because of large energy barriers to the structural change and small differences in Gibbs free energies. As a result, the phases often persist far into metastable regions. In contrast, transitions within a particular phase are rapid and reversible (i.e., the low + high inversions of quartz or cristobalite).

High cristobalite is the stable phase near T_m . It becomes metastable with respect to quartz at lower temperatures but persists down to the high + low inversion at 543°K (see table for low cristobalite). The high form is cubic and the low form tetragonal (12, 13).

The adopted tables give 1079.250°K as the temperature at which $\Delta G^{\circ} = 0$ for high quartz + high cristobalite; $\Delta H^{\circ} = 0.48 \pm 0.15$ kcal/mol is the corresponding enthalpy difference. The uncertainty in T_t is derived from that in ΔH° which, in turn, is taken from $\Delta H_{970}^{\circ} = 0.45 \pm 0.15$ kcal/mol obtained by Holm (7) from ΔH_{soln} measurements in an oxide melt. It is apparent that T_t is extremely sensitive to small changes in G or H . Holmquist (8) tentatively placed this inversion at 1298.25°K but did observe cristobalite formation at temperatures as low as 1171°K .

Melting Data

Melting point data were reviewed by Schneider (9) and adjusted to the 1948 International Temperature Scale. The adopted melting point for cristobalite is based on Greig (10). ΔH_m° is calculated as the difference in ΔH_f° for liquid and crystal at T_m . Mackenzie et al. (11) showed that cristobalite may be superheated by as much as 40° above T_m due to its slow rate of fusion.

Silicon Dioxide (SiO₂)

(Liquid) GFW = 60.0848

SILICON DIOXIDE (SiO₂)

(LIQUID)

GFW = 60.0848

$$\Delta H_{298.15}^\circ = 11.465 \pm 0.3 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^\circ = -215.74 \text{ kcal/mol}$$

$$\Delta H_m^\circ = 1996 \pm 5^\circ \text{K (high cristobalite} \rightarrow \text{liquid)}$$

$$\Delta H_m^\circ = 2.29 \pm 0.5 \text{ kcal/mol}$$

Heat of Formation

The heat of formation is calculated from that of quartz using $\Delta H_{970}^\circ = 1.45 \pm 0.15 \text{ kcal/mol}$ for high quartz + SiO₂(l), as determined by Holm (1) from ΔH_{soln} in an oxide melt. This value reduces to $\Delta H_{298}^\circ = 1.96 \text{ kcal/mol}$ for low quartz + SiO₂(l) and is consistent within $\pm 0.3 \text{ kcal/mol}$ with other calorimetric data summarized below. Earlier results were reviewed by Hummel (4).

Source	Method	Reaction	T, °K	ΔH_{298}° kcal/mol	ΔH_{298}° kcal/mol	ΔH_{298}° kcal/mol
1. Holm (1967)	ΔH_{soln} in oxide melt	A	970	1.45 $\pm$ 0.15	1.96	-215.74

4. Hummel (1959)	ΔH_{soln} in HF(aq, 26.5°C)	A	300	2.27 $\pm$ 0.2	2.27	-215.43
A. SiO ₂ (quartz, low or high) + SiO ₂ (l)						
B. SiO ₂ (l) + 2F ₂ (g) + SiF ₄ (g) + O ₂ (g)						

Heat Capacity and Entropy

C_p below 300°K is based on data of Flubacher (5) and Westrum (6) for samples annealed at 1100 and 1070°C, respectively. Data of Turdakin (7) are higher by about 1 percent in the range 60-160°K and at 300°K but are in agreement elsewhere. The entropy is calculated from C_p using $S_{2.34}^\circ - S_0^\circ = 0.0001 \text{ eu}$ and $S_0^\circ = 1.098 \text{ eu}$. C_p data (8) for a different sample annealed at 1300°C yield an entropy larger by $<0.04 \text{ eu}$. Earlier data were reviewed by Kelley (9). The residual entropy is calculated from $S_0^\circ = S_{298}^\circ - (S_{298}^\circ - S_0^\circ) = 41.258 - 40.160 = 1.098 \text{ eu}$, where 40.160 is obtained from the adopted functions, while 41.258 is the sum of $\Delta S_m^\circ = 1.147 \text{ eu}$ and $S_0^\circ = 40.111 \text{ eu}$ for high cristobalite. We estimate the uncertainty as $\pm 0.3 \text{ eu}$, primarily from the uncertainty in ΔH_m° .

C_p above 300°K is based on adiabatic calorimetric data of Moser (5) up to 900°K. Enthalpy data of White (10) and Fischer (11) are in excellent agreement. C_p from 900 to 1500°K is derived from enthalpy data of Southard (12) and White (10). Maximum deviation of the data from the adopted values in this range is 0.5 percent. Enthalpy data of Egan (13) and Kelley (14) deviate from the adopted values by less than 1 percent in the range 1000-1500°K, although large positive deviations appear at lower temperatures.

In the region 1500-1700°K, the adopted C_p shows a rapid, sigmoidal rise which is suggested by the enthalpy data of Wiestel (15). This is presumed to be the glass transition region in which C_p rises to that of the stable liquid. C_p above 1700°K is estimated as 20.5 gibbs/mol or 6.83 gibbs/g-atom. This value is consistent with the enthalpy data (15) and with liquid heat capacities of Al₂O₃, Na₂SiO₃ and Na₂SiO₃.

Melting Data

The melting point of high cristobalite is $1996 \pm 5^\circ \text{K}$, while the metastable melting point of high quartz is $1696 \pm 50^\circ \text{K}$. ΔH_m° is the difference between ΔH_f° for liquid and high cristobalite at T_m . Values ranging from 1.6 to 3.6 kcal/mol have been derived from various interpretations of phase diagrams (1).

Bond Angle: O-Si-O = [180°]

Rotational Constant: B₀ = [0.2193] cm⁻¹

Heat of Formation

The adopted value is based on the data summarized below. Margrave (1) has reported a value of ΔH°₂₉₈ = 140.9 ± 1 kcal/mol but details are not yet available. Assuming that this corresponds to reaction A below, we calculate ΔH°₂₉₈ = -75.5 kcal/mol. Firssova (2) reported two values of the sublimation pressure which were derived from Knudsen effusion data using auxiliary data for SiO(g). Porter (4) derived two pressures from a mass spectrometric study and also obtained a 2nd Law value for ΔH°₂₉₈ from ion intensities. The resulting range for ΔH°₂₉₈, 136 to 141 kcal/mol, is consistent with the lower limit of 130 kcal/mol obtained by Bergman (3) from a method involving explosion in a spherical bomb. An alternative analysis of the mass spectrometric data (4) using the gas phase reaction B suggests an even higher ΔH°₂₉₈ of 148 kcal/mol. The adopted ΔH°₂₉₈ corresponds to ΔH°₂₉₈ = 143.4 ± 4 kcal/mol and to ΔH°_{atom} = 297.3 ± 8 kcal/mol.

Source	Reaction	Method	Range, °K	ΔH° ₂₉₈ , kcal/mol	Drift
Margrave (1967)	A	-	-	- 140.9 ± 1	-
Firssova (1960)	A	Knudsen, calculation	1600-1800	-	- 75.5
Bergman (1959)	A	Explosion	-	- 137.0 ± 2	-
Porter (1955)	A	Knudsen mass spec.	1800-1900	128	- 86
	A	Ion intensities	1750-1980	136 ± 8	- 76.8
	B	Knudsen mass spec.	1800-1900	- 2	- 80
	A. SiO ₂ (high cristobalite) = SiO ₂ (g)			- 44.8 ± 1.2	- 23
	B. SiO(g) + 1/2 O ₂ (g) = SiO ₂ (g)			- 68.8	-

Heat Capacity and Entropy

Point group, ground state quantum weight and the linear symmetrical configuration are estimated by analogy with the properties of CO₂. From the bond lengths in SiO, CO₂ and CO, the length in SiO₂ is estimated as 1.509 × 1.180/1.128. Bond lengths and atomization energies for these molecules are reasonably consistent with the existence of six-electron bonds in the monoxides and four-electron bonds in the dioxides (5). Vibrational frequencies are estimated from a valence bond calculation using force constants, k = 9 × 10⁵ and k₆/k₂ = 0.3 × 10⁵ dyne/cm, which are obtained from those of SiO, CO₂ and CO. The moment of inertia is 12.76 × 10⁻³⁹ g cm².

TITANIUM DIOXIDE, ANATASE (TiO₂)

(CRYSTAL)

OPW = 79.8988

$$\Delta H_f^\circ = -221.8 \pm 1 \text{ kcal/mol}$$

$$\Delta H_{298}^\circ = -223.0 \pm 1 \text{ kcal/mol}$$

$$\Delta H^\circ = [0.0] \text{ kcal/mol}$$

$$\Delta H_m^\circ = \text{Unknown}$$

$$\Delta H_{298}^\circ = 161 \text{ kcal/mol}$$

$$S_{298}^\circ = 11.93 \text{ gibbs/mol}$$

$$T_f = 918^\circ \text{K}$$

$$T_m = \text{Unknown}$$

Heat of Formation.

The value of ΔH_f° (anatase) is obtained from J. L. Margrave and B. D. Kybett, "Thermodynamic and Kinetic Studies of Borides and Other Refractory Materials at High Temperatures," Tech. Rept. AFML-TR-65-123, August 1965, Rice University, Houston, Texas. The authors measured the heat of fluorination of anatase, according to the reaction $\text{TiO}_2 (\text{anatase}) + 2\text{P}_2(\text{g}) = \text{TiP}_4(\text{c}) + \text{O}_2(\text{g})$, but no experimental data were given.

P. W. Vahldek, J. Less-Common Metals 11, 99 (1966), studied the irreversible anatase-rutile phase transition at pressures of 3.8 to 24 kbars and temperatures 20 to 1000°C. Isothermal phase-transition studies were also carried out at 1 bar pressure and 880-950°C. From the slope, dT/dP , the enthalpy differences between rutile and anatase were calculated to be -2.79 and -2.89 kcal/mol at 1183 and 1223°K, respectively. Using these data and $\Delta H_f^\circ(\text{rutile}) = -225.8$ kcal/mol, the value of $\Delta H_f^\circ(\text{anatase})$ is derived as -223.23 kcal/mol, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy.

Low temperature heat capacities, 52-296°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 59, 218 (1947). Enthalpy data were determined in the range 416-1305°K by B. P. Naylor, J. Am. Chem. Soc. 58, 1077 (1946), and in the range 580 - 1000°K by J. Lietz, Hamburger Beitr. Angew. Mineral. Kristallphysik 1, 229 (1956). High temperature heat capacities are derived from the enthalpy data, subject to the constraint that there be a smooth joint at 298°K. The resulting enthalpies are higher by 1 to 3% than those measured by Lietz and lower by 1 to 4% than those measured by Naylor. Values above 1300°K are smoothly extrapolated. S_{298}° is calculated from the low temperature C_p° using $S_{50}^\circ = 0.45 \text{ eu}$.

In view of the discrepancies in the enthalpy data, a review of the anatase samples is pertinent. Those of Shomate and Lietz were prepared by precipitation of the hydrated oxide and conversion to the oxide at 550 - 565°C. Shomate's starting material was high purity Ti and the product analyzed as 99.3% TiO₂. Lietz' starting material was high purity TiCl₄. Naylor's sample, obtained from J. T. Baker Co., was dried at 1050°C; spectrographic analysis indicated 0.3% SiO₂ and 0.15% CaO. All three samples gave only the X-ray lines of anatase.

Transition Data.

$T_m = 918^\circ \text{K}$ and $\Delta H^\circ = 0.040 \text{ kcal/mol}$ have been reported by J. Lietz, loc. cit. A. Schröder, Z. Krist. 55, 493 (1928), suggested a transition temperature at 915°K on the basis of a peak in the thermal expansion curve. Lietz reported $\Delta H^\circ = 0.04 \text{ kcal/mol}$, but this value is not adopted since its magnitude is much less than the uncertainty in the selected enthalpies. Further study is desirable to confirm this transition.

Heat of Sublimation.

ΔH_{298}° is calculated as the difference between ΔH_f° for TiO₂(g) and TiO₂(anatase).

Dec. 31, 1960; Mar. 31, 1967

$$\Delta H_{\text{f}}^{\circ} = -224.6 \pm 1 \text{ kcal/mol}$$
$$\Delta H_{\text{f}}^{\circ}{}_{298.15} = -225.8 \pm 1 \text{ kcal/mol}$$
$$\Delta H^{\circ} = [16] \text{ kcal/mol}$$
$$\Delta H_{\text{f}}^{\circ}{}_{298.15} = 163.8 \text{ kcal/mol}$$

Heat of Formation.

The heat of formation for rutile has been determined from combustion calorimetry by many investigators. Several of the more consistent $\Delta H_{\text{f}}^{\circ}{}_{298}$ values are listed in the table below. Ariys et al.³ reported that the composition of the rutile obtained from combustion of Ti(c) was between TiO_{1.94} and TiO_{1.95}. Emf studies by R. N. Blumenthal and D. H. Whitmore, *J. Electrochem. Soc.* **110**, 92 (1963), indicate that at 1200°K there is a two-phase region beginning at about TiO_{1.99}. If this region extends to 298°K, then the non-atmospheric combustion products probably involve a mixture of two phases. Meh et al.⁴ applied an approximate energy correction for incomplete combustion which corresponds to 0.7 - 1.5 kcal/mol. In $\Delta H_{\text{f}}^{\circ}{}_{298}$. Analogous corrections were applied by Ariys et al.³ but were not mentioned by Neumann et al.¹ and Humphrey.⁵

The $\Delta H_{\text{f}}^{\circ}{}_{298}$ value reported by Margrave and Kybett⁵ was obtained by fluorine bomb calorimetry, according to the reaction $\text{TiO}_2(\text{rutile}) + 2\text{F}_2(\text{g}) = \text{TiF}_4(\text{c}) + \text{O}_2(\text{g})$. No experimental data were given.

Comparison of the fluorine result with the oxygen results indicates that the magnitude of the corrections for the oxygen data is reasonable, probably within ± 1 kcal/mol, provided that the fluorine data refer to stoichiometric TiO₂. Corresponding $\Delta H_{\text{f}}^{\circ}$ corrections for TiO_{2-x} are of the same order of magnitude when estimated from the partial molar free energy values given by P. Kofstad, *J. Phys. Chem. Solids* **23**, 1579 (1962), and J. B. Meier, R. N. Blumenthal and D. H. Whitmore, *J. Am. Ceram. Soc.* **49**, 384 (1965).

The $\Delta H_{\text{f}}^{\circ}{}_{298}$ value determined by Meh et al.⁴ is adopted.

Heat Capacity and Entropy.

The low temperature heat capacities, 10 - 297.7°K, have been measured by the following investigators: P. H. Keenan and N. Pearlman, *Phys. Rev.* **112**, 800 (1958), 10 - 20°K; J. S. Dugdale, J. A. Morrison and D. Patterson, *Proc. Roy. Soc. (London)* **A224**, 228 (1954), 20 - 50°K; H. Shomate, *J. Am. Chem. Soc.* **69**, 218 (1947), 52.5 - 297.7°K; and H. J. McDonald and H. Seltz, *J. Am. Chem. Soc.* **61**, 2405 (1939), 68.78 - 295.0°K. The first three sets of Cp data are joined smoothly and extrapolated to 298°K, yielding $S^{\circ}_{298} = 12.03$ eu, based on $S^{\circ}_0 = 0.0014$ eu. The Cp values reported by McDonald and Seltz seem too high and are not used.

The high temperature enthalpies have been determined by B. P. Naylor, *J. Am. Chem. Soc.* **68**, 1077 (1946), 393.5 - 1746°K; J. S. Arthur, *J. Appl. Phys.* **21**, 732 (1950), 293.2 - 1073.2°K; and J. Lietz, *Hamburger Beiträge Angew. Mineral u. Kristall Phys.* **1**, 229 (1956), 577.7 - 1283.0°K. The Cp values are derived from the data of Lietz and join smoothly at 298°K with the low temperature data. Deviations from the selected values are -1.6 to +1.0% for Lietz, -5.1 to +4.0% for Arthur, and +8.6 to +0.8% for Naylor. The data point of Lietz at 947.95°K is omitted as a probable typographical error. The largest deviations in the case of Naylor and Arthur are near 400 and 500°K, respectively.

The mean specific enthalpies have also been measured by L. P. Nilson and O. Patterson, *Z. Physik, Chem.* **1**, 27 (1987), 373.2 - 717.2°K.

The samples used by Keenan and Pearlman, Dugdale et al., Shomate, Arthur and Lietz were of high purity, according to chemical and spectroscopic analysis. However, the sample employed by Naylor was black-colored and chemical analysis gave 97.9% TiO₂. The main impurities were: 0.55% ZrO₂, 0.50% SiO₂, 0.27% V₂O₅, 0.15% CaO, 0.15% Fe₂O₃ and 0.12% Al₂O₃. The sample of McDonald and Seltz was obtained commercially. Therefore the results reported by Naylor and McDonald et al. are given the least weight.

Melting Data.

See TiO₂(1) table for details.

Heat of Sublimation.

The difference between $\Delta H_{\text{f}}^{\circ}{}_{298}$ for TiO₂(g) and TiO₂(rutile) is $\Delta H_{\text{f}}^{\circ}{}_{298}$.

Titanium Dioxide (TiO₂)
(Liquid) GFW = 79.8988

O₂Ti

TITANIUM DIOXIDE (TiO₂) (LIQUID) OFW = 79.8988

$S_{298.15}^{\circ} = [18.934] \text{ gibbs/mol}$
 $\Delta H_m^{\circ} = [16] \text{ kcal/mol}$
 $T_m = 2143^{\circ} \text{K}$

$\Delta H_f^{\circ} 298.15 = [-210.726] \text{ kcal/mol}$

Heat of Formation.

The $\Delta H_f^{\circ} 298(1)$ is calculated from $\Delta H_f^{\circ} 298(\text{rutile})$, c) by adding ΔH_m° and the difference between $H_{2143}^{\circ} - H_{298.15}^{\circ}$ for TiO₂(rutile, c) and TiO₂(l).

Heat Capacity and Entropy.

The heat capacity of TiO₂(l) is estimated on the basis of 7.0 gibbs/g-atom. The value of S_{298}° is obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting point of TiO₂(rutile) has been measured by many investigators. Eleven pertinent T_m values were reviewed and corrected, according to the International Temperature Scale of 1948, by S. J. Schneider, Natl. Bur. Std. Monograph 68, October 10, 1963. The adopted melting point is obtained from G. Brauer and W. Litke, J. Inorg. Nucl. Chem. 16, 67 (1960). These authors found that TiO₂ loses oxygen on heating and the solid residue consists of a non-stoichiometric compound of the composition TiO_{2-x}. The value of the coefficient x depends on the temperature and on the oxygen pressure of the gaseous phase. Under oxygen pressures greater than or equal to 300 torr, the solid residue was TiO_{2.000} within the sensitivity of chemical analysis; however, color of the residue was a more sensitive indicator of composition. At pressures of 600 torr or greater, the residue was bright yellow rather than blue-gray and the melting point was constant at the maximum value of 2143 ± 15°K. This value is adopted.

The heat of melting is calculated using an estimated entropy of melting, $\Delta S_m^{\circ} = 2.5 \text{ eu/g-atom}$.

Rotational Constant: B₀ = [0.2007] cm⁻¹

o = 2

Heat of Formation.

P. W. Gilles, K. D. Carlson, H. F. Frenzen, and P. O. Wahlbeck, *J. Chem. Phys.* **45**, 2461 (1967), studied the vaporization behavior of the titanium-oxygen system and found that Ti₃O₅ is the final residue of both higher and lower titanium oxides; hence Ti₃O₅ is the congruently vaporizing phase. This conclusion was obtained by measurement of the change in composition of the solid residue accompanying vaporization as determined by x-ray diffraction, chemical analysis, and color of sample.

From mass spectrometric studies over Ti₃O₅(s) near 2000°K, P. O. Wahlbeck and P. W. Gilles, *J. Chem. Phys.* **45**, 2465 (1967), concluded that the partial pressure of TiO₂ is probably less than 1% of the pressure of TiO produced by the main vaporization: Ti₃O₅(s) = 3 TiO(g) + 2 O(g). This yields ΔH_f⁰2000 ≥ 228 kcal for the reaction Ti₃O₅(s) = 2 TiO₂(g) + TiO(g) and ΔH_f⁰298(TiO₂, g) ≥ -62 kcal/mol, which is the value adopted. The corresponding atomization energy is D₀ ≤ 292 kcal/mol.

Earlier vaporization studies over TiO₂-x gave apparent heats of formation which are more negative by 20-35 kcal; however, the results appear to be uncertain due to lack of sufficient auxiliary data for the oxygen-deficient condensed phase. Knudsen effusion-mass spectrometric studies of J. Berkowitz, W. A. Chupka and M. O. Inghram, *J. Phys. Chem.* **61**, 1569 (1957), revealed the initial evolution of large amounts of MoO₃(g), suggesting that the reduction of TiO₂ is enhanced by the Mo cell. In order to reduce the effect of the initial high rate of evaporation, W. O. Groves, M. Hoch and H. L. Johnston, *J. Phys. Chem.* **59**, 127 (1955), conducted their Knudsen effusion-weight loss studies on TiO₂. Preferential loss of oxygen during the experiment, as indicated by a residue of TiO_{1.85}, was apparently ignored. Groves et al. estimated the activity of TiO₂(rutile) as 0.53; Berkowitz et al. assumed unit activity but did not indicate the composition of their condensed phase. These activities may be in serious error due to the presence of a series of distinct phases between TiO_{1.8} and TiO₂ [cf. S. Anderson, *Acta Chem. Scand.* **14**, 1161 (1960)] and to the possible existence of a two phase region near TiO_{1.99} [cf. R. N. Blumenthal and D. H. Whitmore, *J. Electrochem. Soc.* **110**, 82 (1963)]. Second and third law analyses of the data, using the authors' original assumptions, are summarized below. No weight is given to these results.

Investigator	Temperature, °K	No. of Points	ΔH _f ⁰ 298 kcal/mol	Drift eu
Oroven et al.	1849 - 2010	14	128.7 ± 7.5	1.1 ± 4.0
Berkowitz et al.	1891	3	142.7 ± 5**	142.8
				-85.7
				-83.0

*Calculation based on the third law ΔH_f⁰298.

**Obtained from the temperature variation experiments, reported in the original paper.

Heat Capacity and Entropy.

The molecular structure is assumed to be linear. The Ti-O bond distance is estimated as the same as that in TiO(g). The vibrational frequency 940 cm⁻¹ was observed in matrix isolation by W. Weltner, Jr., and D. McLeod, Jr., *J. Phys. Chem.* **69**, 3488 (1965). The other two frequencies are calculated, based on the valence bond method as suggested by Berkowitz, Chupka and Inghram, loc. cit. The moment of inertia is 1.3944 x 10⁻³⁸ g cm².

TUNGSTEN DIOXIDE (WO₂)

(CRYSTAL)

OPW = 215.8488

$\Delta H_f^\circ = -139.76 \pm 0.21$ kcal/mol
 $\Delta H_f^{298.15} = -140.94 \pm 0.21$ kcal/mol
 $\Delta H_f^{298.15} = -140.94 \pm 0.21$ kcal/mol
 $\Delta H_f^{298.15} = 159.24$ kcal/mol
 $T_d = 1997^\circ K$
 $S_{298.15}^\circ = 12.08 \pm 0.07$ gibbs/mol
 $T_d = 1997^\circ K$

Heat of Formation.

The adopted heat of formation, -140.94 ± 0.21 kcal/mol, was determined by combustion calorimetry by A. D. Mah, J. Am. Chem. Soc. **81**, 1582 (1959). R. C. Griffiths, J. Electrochem. Soc. **105**, 398 (1958), has measured the heat of combustion to WO₃(c) which yields $\Delta H_f^{298}(\text{WO}_3, c) = -139.8 \pm 1.5$ kcal/mol when recalculated with $\Delta H_f^{298}(\text{WO}_3, c) = -201.46$ kcal/mol. This result is less certain because of the incomplete characterization of the final products.

Recent equilibrium data yield essentially the same average of the heat of formation by the third law method. The results are presented as follows.

Author	Reaction*	Temp. (°K)	No. of Points	ΔH ²⁹⁸ (kcal/mol)	Drift (eu)	ΔH ²⁹⁸ (kcal/mol)
1. St. Pierre (1962) et al.	A	1275 - 1497	10	2.672	0.036	-140.62
	B	973 - 1467	6	11.994	12.076	-139.58

Heat Capacity and Entropy.

E. G. King, W. W. Weller, and A. U. Christensen, U. S. Bur. Mines RI 5664, (1960), have measured the low temperature heat capacities from 53° to 297°K and high temperature enthalpy changes from 398° to 1800°K by drop calorimetry. The low temperature and high temperature heat capacities were joined smoothly at 298.15°K. The entropy was obtained from the heat capacities based on $S_{298.15}^\circ = 0.52$ eu. It is possible that at temperatures below 50°K the entropy due to the uncoupling of the d² electrons will appear, contributing an additional 2.2 eu.

Temperature of Decomposition.

Tungsten dioxide (c) has no melting point, since disproportionation occurs to yield W(c) and WO₃(l) before melting starts. The Td is calculated as the temperature at which ΔG equals zero for $3 \text{ WO}_2(c) = 2 \text{ WO}_3(l) + \text{W}(c)$.

Heat of Sublimation.

The heat of sublimation was calculated from the difference between the heats of formation of WO₂(g) and WO₃(c).

Tungsten Dioxide (WO₂)

Product of the Moments of Inertia: I_AI_BI_C = [9.433 x 10⁻¹¹⁵] g³cm⁶

σ = [2]

Heat of Formation

G. DeMaris, R. F. Burns, J. Dromart and M. O. Inghram, J. Chem. Phys. **32**, 1373 (1960), have reported the partial pressures of WO₂(g), WO₃(g) and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2188° to 2475°K. The adopted value, ΔH_f^o₂₉₈ (WO₂g) = 18.3 ± 7 kcal/mol, was calculated from ΔH_f^o₂₉₈ = -100.9 kcal/mol for W(c) + 2 O(g) → WO₂(g), which was obtained from third law treatment of their partial pressure data, using all JANAF functions. The third law drift is 15.0 ± 5.2 eu. Partial pressures of WO₂(g), WO₃(g) and O(g) at 2242°K have also been reported by W. A. Chupka, J. Berkowitz and C. F. Olene, J. Chem. Phys. **30**, 827 (1959), in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives ΔH_f^o₂₉₈ = -105.9 kcal/mol, which yields ΔH_f^o₂₉₈ (WO₂g) = 13.2 kcal/mol.

Heat Capacity and Entropy

The WO₂(g) was assumed to have a C_{2v} symmetry with a bond angle O-W-O = 110°. The bond distance W-O was estimated to be the same as that in WO(g). The asymmetric and asymmetric stretching frequencies were obtained from the infrared spectrum of WO₂ in an inert matrix by W. Weltner, Jr., and D. McLeod, Jr., J. Mol. Spectry. **11**, 276 (1965). The bending vibrational frequency (300 cm⁻¹) was estimated by comparison with other dioxides. The electronic levels and quantum weights were estimated from W⁴⁺ ion by analogy with Mo⁴⁺ ion. The three principal moments of inertia are: I_A = 4.8776 x 10⁻³⁹, I_B = 1.1680 x 10⁻³⁸ and I_C = 1.6559 x 10⁻³⁸ g cm².

$$\Delta H_f^0 = -261.0 \pm 0.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -262.3 \pm 0.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = 1.42 \pm 0.1 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = [20.8] \text{ kcal. mole}^{-1}$$

Heat of Formation.

The ΔH_f^0 298.15 = -263.1 ± 0.5 kcal. mole⁻¹ is the average value of the ΔH_f^0 298.15 = -261.5 ± 0.2 kcal. mole⁻¹ and ΔH_f^0 298.15 = -263.1 ± 0.5 kcal. mole⁻¹ measured (by combustion calorimetry) by O. L. Humphrey, J. Am. Chem. Soc. 76, 978 (1954) and E. J. Huber, Jr., E. L. Head and C. E. Holley, Jr., J. Phys. Chem. 68, 3040 (1964) respectively. Also the heat of formation was measured calorimetrically by B. Neumann, C. Kröger and H. Kunz, Z. anorg. Chem. 218, 379 (1934), by W. A. Roth, E. Bödger, and H. Siemensen, ibid., 239, 321 (1938) and by A. Sievert, A. Gotta and S. Halberstadt, ibid., 187, 155 (1930) and was found -259.2, -259.8 and -256.1 kcal. mole⁻¹ respectively. However more weight was given to the Humphrey and Huber values.

Heat Capacity and Entropy.

The low temperature heat capacities, 54.3-295°K., were measured by K. K. Kelley, Ind. Eng. Chem. 36, 377 (1944). The heat capacities in the temperature range 298-1478°K. were calculated by using the J. P. Coughlin and E. O. King equation $C_p = 16.64 + 1.80 \times 10^{-3}T + 3.36 \times 10^{-5}T^2$ obtained from their measured enthalpy data in the range 396.8 - 1841°K., J. Am. Chem. Soc. 72, 2252 (1950). The values from the two sources join smoothly at 298°K. Above the transition 1478°K. the heat capacity was taken as constant at 17.80 cal. mole⁻¹ deg⁻¹, Coughlin and King, loc. cit. The entropy was calculated at 54.30 using the Debye and Einstein Function $D(\frac{345}{T}) + E(\frac{513}{T})$ given by Kelley, loc. cit. The value of $S_{54.3}^0 = 0.5507$ cal. deg⁻¹ mole⁻¹.

Transition Data.

T_t and ΔH_t^0 were taken from Coughlin and King loc. cit.

Melting Data.

The T_m and ΔH_m^0 were taken from Natl. Bur. Standards Circ. 500 Washington (1952).

O₂Zr

Zirconium Dioxide (ZrO₂)

(Liquid) Mol. Wt. = 123.2188

O₂Zr

MOL. WT. = 123.2188

ZIRCONIUM DIOXIDE (ZrO₂) (LIQUID)

$$\Delta H_f^{298.15} = -17.641 \text{ kcal. deg.}^{-1}$$

$$\Delta H_m^{298.15} = -244.55 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = [20.8] \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{298.15} = [149.2] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = -17.641 \text{ cal. deg.}^{-1}$$

$$T_m = 2950^\circ \text{K.}$$

$$T_b = 4548^\circ \text{K.}$$

Heat of Formation

The $\Delta H_f^{298.15}$ (1) was obtained from $\Delta H_f^{298.15}$ (c) by adding $\Delta H_m^{298.15}$ and the difference between $H_m^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition was assumed at 2000°K. The heat capacity below 2000°K. was obtained from the heat capacity of the crystal. Above 2000°K. the heat capacity was assumed constant and estimated to be 21.0 cal. deg.⁻¹ mole⁻¹ or 7 cal. deg.⁻¹ per g-atom as suggested by O. Kubachewski and E. L. Evans, "Metallurgical Thermochemistry" Pergamon Press, New York (1958). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data

See ZrO₂(c) table.

Vaporization Data

T_b was calculated as the temperature at which the free energy change of the reaction $\text{ZrO}_2(l) \rightarrow \text{ZrO}_2(g)$ approaches zero. The difference between $\Delta H_f^{298.15}$ for $\text{ZrO}_2(g)$ and $\text{ZrO}_2(l)$ is $\Delta H_v^{298.15}$.

 1377 (1)
 818 (1)

Bond Distance: $O-Zr = 1.711$ Å
 Bond Angle: $O-Zr-O = 109^\circ$
 Product of the Moments of Inertia: $I_A I_B I_C = 5.679836 \times 10^{-115}$ g.³ cm.⁶
 $\sigma^- = 2$

Heat of Formation.

The $\Delta H_f^\circ 298.15 = -68.4 \pm 11$ kcal. mole⁻¹ was calculated from the $\Delta H_f^\circ 298.15 = 133.867 \pm 11.25$ kcal. mole⁻¹ for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$. The value of $\Delta H_f^\circ 298.15$ was obtained by the third law method using the determined vapor pressures (at the range 2331-2480°K) by W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 25, 1207 (1957). They observed the variation of the ZrO_2^+ ion intensity over ZrO_2 and reported equilibrium constants for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$ in the range 2331-2480°K. The third law drift is 80 ± 23 e.u.

Heat Capacity and Entropy.

The vibrational frequencies $\nu_1 = 884$, $\nu_2 = 1377$, $\nu_3 = 818$ and angle $O-Zr-O = 109^\circ$ were obtained from M. J. Linevsky, Spectroscopic Studies of the Vaporization of Refractory Materials, Technical Report Nr. AFML TR-64-420 Air Force Materials Lab. Research and Technology Division, Wright Patterson Air Force Base, Ohio (1965). The bond distances (r_e) $O-Zr = 1.711$ Å was obtained from U. Uhler and L. Akerlind, Arkiv Fysik 10, 431 (1955). The three principal moments of inertia are: $I_A = 1.03083 \times 10^{-38}$, $I_B = 3.8828 \times 10^{-38}$, $I_C = 1.41903 \times 10^{-38}$ g. cm.²

TUNGSTEN OXIDE (WO_{2.72}) (CRYSTAL) OPW = 227.3684

ΔH°_{298.15} = [16.35] gibbs/mol
ΔH°_{298.15} = -186.70 ± 0.5 kcal/mol
ΔH°₂₉₈ = Unknown

Heat of Formation.

The adopted heat of formation, -186.7 ± 0.5 kcal/mol, is derived from recent equilibrium data which are in excellent agreement; the results are summarized below. In addition R. C. Oriffis, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to WO₃(c) which yields ΔH°₂₉₈(WO_{2.72}, c) = -185.4 ± 1 kcal/mol when recalculated with ΔH°₂₉₈(WO₃, c) = -201.48 kcal/mol. This result is less certain because of the incomplete characterization of the final products. The EMF data reported by Ya. I. Gerasimov, I. A. Vasil'eva, T. P. Chusova, V. A. Gelderikh, and M. A. Timofeeva, Zh. Fiz. Khim. 36, 358 (1962), give the value of -186.89 kcal/mol for the heat of formation at 298° K. R. J. Ackermann and E. O. Rauh, J. Phys. Chem. 67, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600° K, they have derived indirectly from their measurements the heat of formation, -182.2 kcal/mol (corresponding to -187.2 kcal/mol at 298° K, using the JANAF functions).

Heat Capacity and Entropy.

The monoclinic unit cell of WO_{2.72} corresponds to W₁₀O₂₇, as shown by the x-ray diffraction studies of A. Magneli, O. Andarson, B. Blomberg and L. Kihlberg, Anal. Chem. 24, 1998 (1952). The tabulated heat capacities of WO_{2.72}(c) were estimated from those of WO₂(c) and WO₃(c), because all three have similar monoclinic structures as identified by Magneli et al.

The entropy (S°₂₉₈ = 18.35 eu) was calculated from ΔS°₂₉₈ = 7.96 ± 0.09 eu for reaction A, using all JANAF values. The value of ΔS°₂₉₈ was derived from the second law analysis of Oriffis' data, loc. cit.

Heat of Formation.
The adopted heat of formation, -196.0 ± 3 kcal/mol, is a weighted average of those derived from equilibrium data; in addition the following results have been reported.

R. C. Oriffia, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to WO₃(c), which yields -195.6 kcal/mol when recalculated with ΔH°₂₉₈(WO₃, c) = -201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products. R. J. Ackermann and E. O. Raub, J. Phys. Chem. 67, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600°K, they have derived indirectly two values of ΔH°(WO_{2.90}, c) -190.9 and -188.0 kcal/mol (corresponding to -196.1 and -193.3 kcal/mol, respectively, at 298.15°K, using all JANAF functions).

Heat Capacity and Entropy.

The monoclinic unit cell of WO_{2.90} corresponds to WO₃0.9 as shown by the X-ray diffraction studies of A. Magnell, O. Anderson, B. Blomberg and L. Kihlberg, Anal. Chem. 24, 1998 (1952). The tabulated heat capacities and the entropy (S°₂₉₈ = 17.536 eu) were estimated from those of WO₂(c) and WO₃(c), because all three have the similar monoclinic structure as identified by Magnell et al.

ΔH_f^o = Unknown

ΔH_f^o_{298.15} = -199.56 ± 3 kcal/mol

S_{298.15} = [17.90] gibbs/mol

Heat of Formation.

The adopted value, ΔH_f^o₂₉₈ (WO_{2.96}, c) = -199.56 kcal/mol, was obtained by third law treatment of ΔH_f^o = 191,600 ± 54.0 T (cal/mol) in the temperature range from 1300 - 1550°K, using all JANAF functions. The equation for ΔH_f^o was reported by R. J. Ackermann and E. G. Rauh, J. Phys. Chem. **67**, 2536 (1963), based on studies by mass spectroscopy and x-ray diffraction. In this study ΔH_f^o was obtained by comparison of the Gibbs energies of sublimation (to gaseous WO₃, W₂O₆, W₂O₉, and W₄O₁₂) over the two systems W-WO₂(c) and WO_{2.96}(c); thus WO_{2.96}(c) was related to WO₂(c) through the gaseous species.

J. E. Battles, Ph. D. Thesis, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, (1964), has reported partial pressures of W₂O₉(g) and W₄O₁₂(g) in equilibrium with WO₃ - WO_{2.96}(c). In light of Ackermann and Rauh's observation, the condensed phase was presumed to have the composition of WO_{2.96}(c). The pressure data are in reasonable agreement with the studies of Ackermann and Rauh as summarized below. Values of ΔH_f^o₂₉₈ for WO_{2.96}(c) derived from the data of Battles are based on the same author's data for W₂O₉(g), and W₄O₁₂(g) in order to relate WO_{2.96} to WO₂ directly.

Investigator	Reaction	Temperature (°K)		ΔH _f ^o ₂₉₈ (kcal/mol)	Drift (cal)	ΔH _f ^o ₂₉₈ (WO _{2.96} , c) ^a (kcal/mol)
		1st law	2nd law			
1. Ackermann & Rauh	A	1300-1550	60.82	56.32	3.2 ± 0.6	-199.57
2. Ackermann & Rauh	B	1300-1550	41.37	38.35	2.094 ± 0.09	-199.58
3. Battles	B	1274-1418	40.82	43.28	-1.854 ± 0.05	-199.72
4. Ackermann & Rauh	C	1300-1550	35.81	33.58	1.551 ± 0.09	-199.60
5. Battles	C	1333-1418	35.37	38.74	-2.461 ± 0.1	-199.95

Reaction: A: WO_{2.96}(c) = 0.44 W₂O₉(g) + 0.04 W₃O₈(g)

B: WO_{2.96}(c) = 0.29333 W₂O₉(g) + 0.04 W₃O₈(g)

C: WO_{2.96}(c) = 0.22 W₄O₁₂(g) + 0.04 W₃O₈(g)

* Third law value adopted in calculation.

Heat Capacity and Entropy.

The tabulated heat capacities and the entropy at 298.15°K were estimated from those of WO₂(c) and WO₃(c). Ackermann and Rauh, loc. cit., have found that the composition WO_{2.96} probably represents the azeotropic composition of the WO₃-x solid solution and is the only single phase which evaporates congruently below 1550°K.

Heat of Formation

P. Qunther, E. Wessmuth, and L. A. Schryver, Z. phys. Chem. 158, 297 (1932), measured ΔE for the reaction O₃(g) → 3/2 O₂(g) in a calorimeter calibrated by means of the reaction CO(g) + 1/2 O₂(g) → CO₂(g), and found the ratio of the ΔE values for these reactions to be 0.5077 ± 0.0024. The temperature of the experiments is not reported and is assumed to have been 18°C. From the above ratio, ΔH_f^o 298.15 is calculated to be 33.89 ± 0.36 cal. mole⁻¹. A. Kallen and S. Jahn, Z. anorg. Chem. 68, 243 (1910), measured ΔH at an unspecified temperature for the reaction O₃(g) → 3/2 O₂(g) in an electrically calibrated calorimeter. If the temperature of the experiments is assumed to have been 18°C and the modern joule-calorie conversion factor is used, ΔH_f^o 298.15 is found to be 34.3 ± 0.6 kcal. mole⁻¹. Variability in the O₃ content of the feed gas is allowed for in the uncertainty. The value adopted here is 34.2 ± 0.4 kcal. mole⁻¹.

Heat Capacity and Entropy

J. S. Gordon, private communication, April, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from L. Pierce, J. Chem. Phys. 24, 139 (1956). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

$$T_m = 1037^\circ \text{K.}$$

Heat of Formation.

The heat of the reaction $\text{PbO}(\text{red}) + \text{SiO}_2 \rightarrow \text{PbSiO}_3(\text{c})$ was reported by K. K. Kelley, U. S. Bureau of Mines, Report Investigation 5501 (1952). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAP values for $\text{PbO}(\text{c})$ (March 31, 1962) and for $\text{SiO}_2(\text{c})$ (Dec. 31, 1962). The above $\Delta H_f^0 298.15 = -3.75 \pm 0.12 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

In the low temperature region (53.25-298.15°K.) the C_p values are those determined by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). Above 298.15 C_p values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.25°K. using the Debye and Einstein functions $D(\frac{140}{T}) + E(\frac{215}{T}) + 2E(\frac{595}{T}) + E(\frac{1440}{T})$ given by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). The $S_{53.25} = 3.662 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m was taken from Geller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

Q = 6

Heat of Formation.

The heat of formation was calculated from the reaction SO₂ + 1/2 O₂ → SO₃ for which three sets of equilibrium constants are available. A summary of the second and third law treatment of the data is given below.

Ref.	Temp. Range	Points	ΔH _f ⁰ kcal. mole ⁻¹	ΔH _f ⁰ kcal. mole ⁻¹	Drift cal. mole ⁻¹ deg. ⁻¹

4. Combination of above references, with one point omitted due to failure of a statistical test.

The combined set was adopted though it appears that the three sets are not in excellent agreement, and the combination heavily favors Ref. 2. Although there is a definite trend in all the data it cannot be considered definitive enough for use in the modification of the SO₃ functions.

Heat Capacity and Entropy.

The bond length and angles were taken from the electron diffraction data of K. J. Palmer, J. Am. Chem. Soc. **80**, 2360 (1958). The vibrational frequencies were taken from the infrared studies of R. W. Loveday, J. H. Colwell, D. F. Eggers and O. D. Halsey, J. Chem. Phys. **36**, 612 (1962), which are in excellent accord with those of R. Bent and W. R. Laidner, Spectrochim. Acta **19**, 931 (1963) using different techniques. These values differ from the assignment used by W. H. Stockmayer, O. M. Kavanagh and H. S. Mickley, J. Chem. Phys. **12**, 408 (1944) in their analysis of the thermodynamic properties of SO₃.

The individual moments of inertia were I_A=I_B = 6.148 X 10⁻³⁹ g. cm.² and I_C = 16.298 X 10⁻³⁹ g. cm.²

DITITANIUM TRIOXIDE (Ti_2O_3)

(CRYSTAL)

GFW = 143.7982

$S^\circ_{298.15} = 18.83$ gibbs/mol	$\Delta H^\circ_0 = -361.50 \pm 2$ kcal/mol
$T_t = 473^\circ\text{K}$	$\Delta H^\circ_{298.15} = -363.49 \pm 2$ kcal/mol
$T_m = 2112^\circ\text{K}$	$\Delta H^\circ = 0.215$ kcal/mol
	$\Delta H_m^\circ = [26.4]$ kcal/mol

Heat of Formation

G. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), determined the enthalpy change $\Delta H^\circ_{298} = -88.11 \pm 0.1$ kcal/mol for the reaction $\text{Ti}_2\text{O}_3(\text{c}) + 1/2\text{O}_2(\text{g}) = \text{TiO}_2(\text{rutile})$ using bomb calorimetry. Based on this result and $\Delta H^\circ_{298}(\text{rutile}) = -225.8$ kcal/mol, the adopted value of ΔH°_{298} for $\text{Ti}_2\text{O}_3(\text{c})$ is calculated to be -363.49 ± 2 kcal/mol. A value of $\Delta H^\circ_{298}(\text{Ti}_2\text{O}_3, \text{c}) = -362.8 \pm 0.6$ kcal/mol was reported by S. M. Ariya, M. P. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (Engl. Transl.) 2, 18 (1957), who measured the heat of combustion of various compositions in the Ti_2O_3 system. Ariya et al. used an estimated correction for the formation of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$, while Humphrey obtained values of 0.1 - 1.3 kcal/mol by grinding the product and reburning it with white oil. Most of the assigned uncertainty arises from this problem. [See $\text{TiO}_2(\text{rutile})$ for further details.]

Heat Capacity and Entropy

The low temperature heat capacities, 53 - 296°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). The data indicate a small anomaly in Cp near 240°K. High temperature enthalpies, 375 - 1750°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by drop calorimetry. The heat capacities, 298 - 473°K, derived by Naylor, loc. cit., are joined smoothly with the low temperature Cp at 298°K. Cp values above 473°K are calculated from the heat capacity equation for the β phase derived by Naylor.

S. Nomura, T. Kawakubo, and T. Yanagi, J. Phys. Soc. Japan, 16, 706 (1961), measured the specific heat in the range 70 - 750°K with a conduction-type calorimeter. A broad anomaly in the specific heat was observed from 160 to 200°K. Below this region the Cp values are unreasonably small, but near 200°K the data are closer to the adopted values. The S°_{298} is calculated from the adopted low temperature Cp based on $S^\circ_{50} = 0.442$ eu. A. D. Pearson, J. Phys. Chem. Solids, 2, 316 (1958), studied the crystal structure of Ti_2O_3 by X-ray method and found that the agreement between calculated and observed density values is good; in other words, there are no significant vacant sites in Ti_2O_3 crystal lattice. This was later confirmed by S. C. Abrahams, Phys. Rev. 130, 2230 (1963). Therefore we do not add vacancy entropy to S°_{298} . Because of the magnetic transition ($\alpha \rightarrow \beta$) at 473°K, we have assumed that no spin-magnetic entropy is likely below 50°K. See Transition Data for more information.

Transition Data

Tt and ΔH°_t were obtained from B. F. Naylor, loc. cit. S. Nomura, T. Kawakubo and T. Yanagi, J. Phys. Soc. Japan 16, 706 (1961), derived the much smaller $\Delta H^\circ_t = 0.036$ kcal/mol from their observations with a conduction-type calorimeter. These authors suggested that the discrepancy may be due to non-stoichiometry or to impurities in the sample studied by Naylor.

Single-crystal neutron diffraction studied by S. C. Abrahams, Phys. Rev. 130, 2230 (1963), indicate that Ti_2O_3 undergoes an antiferromagnetic ordering of small magnetic moment, associated with the Ti^{3+} cations, below a Néel temperature of about 660°K. The temperature of this transition has been reported variously as about 450 to 600°K based on other properties. A. D. Pearson, J. Phys. Chem. Solids 2, 316 (1958), found no change in the Ti_2O_3 corundum-type structure, but noted a rapid change in the lattice parameters between 430 and 473°K. Observations of corresponding changes in magnetic susceptibility, resistivity and thermoelectric power have been summarized by the same authors and by J. B. Goodenough, Phys. Rev. 117, 1442 (1960). Goodenough attempted to interpret the earlier observations in terms of strong cation-cation interactions.

The magnetic nature of the transition suggests that any spin-magnetic entropy in Ti_2O_3 would be included in ΔH°_t and in the observed Cp values for α and β phases. Magnetic contributions are thus unlikely below 50°K.

Melting Data

See $\text{Ti}_2\text{O}_3(\text{l})$ table for details.

DITITANIUM TRIOXIDE (Ti₂O₃) (LIQUID)

S°_{298.15} = [22.952] gibbs/mol

Tm = 2112 ± 10°K

ΔHf°_{298.15} = [-342.087] kcal/mol

ΔHm° = [28.4] kcal/mol

Heat of Formation

The heat of formation, ΔHf°₂₉₈, for Ti₂O₃(l) is obtained from that of the crystal by adding ΔHm° and the difference between H°₂₁₁₂ - H°₂₉₈ for Ti₂O₃(c) and Ti₂O₃(l).

Heat Capacity and Entropy

The heat capacity of Ti₂O₃(l) is estimated on the basis of 7.5 gibbs/g-atom. The S°₂₉₈ is derived in a manner analogous to that of the heat of formation.

Melting Data

The adopted Tm was determined by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 18 (1966). ΔHm° is estimated based on the assumption that at Tm the entropy of melting is 2.5 eu/g-atom. Other Tm values reported are listed as follows:

Tm, °K	Source

June 30, 1962; Mar. 31, 1963; Sept. 30, 1966

$\Delta H_f^\circ = -200.11 \pm 0.2$ kcal/mol

$\Delta H_f^\circ_{298.15} = -201.46 \pm 0.2$ kcal/mol

$\Delta H_f^\circ = 0.355$ kcal/mol

$\Delta H_m^\circ = 17.55$ kcal/mol

$\Delta H_f^\circ_{298.15}$ (to monomer) = 131.46 kcal/mol

$\Delta H_f^\circ_{298.15}$ (to dimer) = 82.36 kcal/mol

$\Delta H_f^\circ_{298.15}$ (to trimer) = 40.26 kcal/mol

$\Delta H_f^\circ_{298.15}$ (to tetramer) = 33.91 kcal/mol

Heat of Formation.

The selected heat of formation, $\Delta H_f^\circ_{298}$ (WO₃, c) = -201.46 $\pm$ 0.2 kcal/mol, was determined by A. D. Mah, J. Am. Chem. Soc. **81**, 1582 (1959), using bomb calorimetry. G. Huff, E. Squitieri and P. E. Snyder, J. Am. Chem. Soc. **70**, 3380 (1948), have reviewed the literature heat of formation data and also measured calorimetrically the heat of formation, -201.84 $\pm$ 0.1 kcal/mol, which is in good agreement with the value selected. Other combustion values were reported as $\Delta H_f^\circ_{298} = -199 \pm 1$ kcal/mol by R. C. Griffiths, J. Electrochem. Soc. **105**, 398 (1958); and $\Delta H_f^\circ_{298} = -205.3$ kcal/mol by I. A. Vasil'eva, V. I. Garasimov, and Y. P. Shmanov, Zh. Fiz. Khim. **31**, 682 (1957). R. C. Griffiths, J. Electrochem. Soc. **106**, 418 (1959), also derived the heat of formation, -202.8 $\pm$ 1.4 kcal/mol from equilibrium data.

Heat Capacity and Entropy.

The low temperature (53-296.7°K) heat capacities and high temperature (399.6 - 1835.8°K) enthalpy changes have been measured by E. G. King, W. W. Kellner, and A. U. Christensen, U.S. Bur. Minea R.I. 5664 (1960); and these data have been used to derive the tabulated heat capacities. Low temperature and high temperature values were joined smoothly at 298.15°K. The entropy was calculated from the heat capacities based on $S^\circ_1 = 1.31$ eu.

King et al. were apparently unaware of the transition near 593°K which was reported by J. A. Perri, E. Banks, and B. Post, J. Appl. Phys. **28**, 1272 (1957), and they did not take sufficient points in that region to fix the precise enthalpy curve. We have adopted only one curve through the region because of the insufficiency of the data and also because the heat effects appear to be small or gradual.

Transition and Melting Data.

The heat of transition, the transition point, the heat of melting and the melting point were derived from the high temperature enthalpy data of King et al., loc. cit.

The melting point, 1746 $\pm$ 1°K, has also been quoted by S. J. Schneider, NBS Monograph **68**, "Compilation of the Melting Points of the Metal Oxides," October 10, 1963.

In the high temperature X-ray diffractometric studies, Perri et al., loc. cit., indicate that WO₃ undergoes a phase transition from monoclinic to orthorhombic at approximately 593°K and from orthorhombic to tetragonal at 933°K.

Heat of Sublimation.

The values of ΔH° at 298.15°K are calculated as the heat of sublimation of one mole of crystal to one mole of monomer, 1/2 mole of dimer, 1/3 mols of trimer and 1/4 mole of tetramer, respectively.

LEAD ORTHOSILICATE (Pb_2SiO_4)

(CRYSTAL)

$\Delta H^\circ_f 0 = -327.3 \pm 3.5 \text{ kcal. mole}^{-1}$

$\Delta H^\circ_f 298.15 = -329.3 \pm 3.5 \text{ kcal. mole}^{-1}$

$S^\circ_{298.15} = 44.654 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_m = 1016^\circ\text{K.}$

Heat of Formation.

The heat of the reaction $2\text{PbO}(c) + \text{SiO}_2(c) \rightarrow \text{Pb}_2\text{SiO}_4(c)$ was reported by O. Kubaschewski and E. L. Evans, Metallurgical Thermochemistry, Pergamon Press, New York (1958). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAF values for $\text{PbO}(c)$ (March 31, 1962) and for $\text{SiO}_2(c)$ (Dec. 31, 1962). The above $\Delta H^\circ_f 298.15 = -7.00 \pm 3.5 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

In the low temperature region ($53.07\text{--}298.15^\circ\text{K.}$) the C_p values are those determined by E. G. King, J. Am. Chem. Soc., 81, 799-800 (1959). Above 298.15°K. values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.07°K. using the Debye and Einstein functions $D(\frac{h\nu}{2kT}) + 2E(\frac{h\nu}{2kT}) + E(\frac{h\nu}{2kT})$ given by E. G. King, J. Am. Chem. Soc., 81, 799-800 (1959). The $S^\circ_{53.07} = 8.248 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m was taken from Geller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

Trilead Tetroxide (Pb_3O_4)
(Crystal) Mol. Wt. = 685.63

$\Delta H^\circ_f 298.15 = -175.31 \pm 0.49$ kcal. mole⁻¹

$S^\circ_{298.15} = 50.4 \pm 1.6$ cal. deg.⁻¹ mole⁻¹

Heat of Formation. Calculated from $\Delta F^\circ_{298.15} = -147.27$ kcal. mole⁻¹ for the reaction: $3\text{Pb}(c) + 2\text{O}_2(g) = \text{Pb}_3\text{O}_4(c)$ given by R. W. Millar, J. Am. Chem. Soc., 51, 207 (1929).

Heat Capacity and Entropy. C_p (71.5° to 292.6°K.) reported by R. W. Millar, loc. cit. Above 298.15°K., heat capacity values were estimated by comparison with C_p values for the other lead oxides. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation.

MOL. WT. = 183.3036

ZIRCONIUM ORTHOSILICATE (ZrSiO₄)
(CRYSTAL)

$\Delta H_f^\circ 0 = -481.1 \pm 0.7$ kcal. mole⁻¹
 $\Delta H_f^\circ 298.15 = -483.7 \pm 0.7$ kcal. mole⁻¹
 $S^\circ_{298.15} = 20.083 \pm 0.3$ cal. deg.⁻¹ mole⁻¹
 $T_d = 1811^\circ\text{K}.$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ was calculated from the $\Delta H_f^\circ 298.15$ of its constituent oxides $\text{ZrO}_2(\text{c}) + \text{SiO}_2(\text{c}) = \text{ZrSiO}_4(\text{c})$ and from the $\Delta H_f^\circ 298.15$ of $\text{ZrO}_2(\text{c})$ (June 30, 1961) and $\text{SiO}_2(\text{c})$ (Dec. 31, 1962) in JANAF tables. The $\Delta H_f^\circ 298.15 = -4.736$ kcal. mole⁻¹ was based on the free energy of formation of its constituent oxides at the decomposition temperature 1811°K.

Heat Capacity and Entropy.

At low temperatures C_p were used from K. K. Kelley, J. Am. Chem. Soc. 63, 2750 (1941). From 298-940°K. C_p was calculated by using the J. P. Coughlin and E. O. King equation $C_p = 31.48 + 3.92 \times 10^{-5} T - 8.08 \times 10^{-8} T^2$, J. Am. Chem. Soc., 72, 2282 (1950), which joined smoothly with the low temperature data. Above 940°K. the data was estimated by extending the curve smoothly. The entropy was calculated at 52.7°K. using the Debye and Einstein functions $D(\frac{h\nu}{kT}) + 2E(\frac{h\nu}{kT}) + 2E(\frac{h\nu}{kT})$ given by K. K. Kelley, J. Am. Chem. Soc., 63, 2750 (1941). $S^\circ_{52.7} = 0.65404$ cal. deg.⁻¹ mole⁻¹.

Temperature of Decomposition.

T_d is the temperature at which $\Delta F^\circ = 0$ for the reaction $\text{ZrSiO}_4(\text{c}) \rightarrow \text{ZrO}_2(\text{c}) + \text{SiO}_2(\text{c})$. $T_d = 1811^\circ\text{K}.$ was taken from C. E. Curtis and H. G. Sowman, J. Am. Soc., 36, 190 (1953).

QFM = 223.697

(CRYSTAL)

TRITITANIUM PENTOXIDE, ALPHA (α -Ti₃O₅)

$\Delta H_f^\circ = -584.63 \pm 0.7$ kcal/mol
 $\Delta H_f^\circ(298.15) = -587.75 \pm 3.0$ kcal/mol
 $\Delta H^\circ = [2.81]$ kcal/mol

$S_{298.15}^\circ = 30.935$ gibbs/mol
 $T_m = 450^\circ\text{K}$

Heat of Formation

The enthalpy change, $\Delta H_f^\circ(298) = -49.65 \pm 0.05$ kcal/mol, for the reaction $\text{Ti}_3\text{O}_5(\text{c}) + 1/2 \text{O}_2(\text{g}) = 3 \text{TiO}_2(\text{rutile})$ has been measured by O. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), using combustion bomb calorimetry. Based on the reported $\Delta H_f^\circ(298)$ and $\Delta H_f^\circ(298)(\text{rutile}) = -225.8$ kcal/mol, the value of $\Delta H_f^\circ(298)$ for $\text{Ti}_3\text{O}_5(\text{a})$ is derived as -587.75 ± 0.7 kcal/mol. A value of -587.0 ± 1.0 kcal/mol was obtained by S. M. Araya, M. P. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (English transl.) 2, 16 (1957), from a similar calorimetric study on Ti-O compounds of various compositions. The latter authors observed that their combustion product had a composition of about $\text{TiO}_{1.9750}$ so they applied an approximate correction to their data. Presumably, the rutile in Humphrey's combustion was also deficient in oxygen, but we have not attempted to make a correction (see TiO_2 (rutile) table for further details).

Heat Capacity and Entropy

Low temperature heat capacities, 53.1 - 236.6°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). High temperature enthalpies, 360.5 - 1340°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by use of drop calorimetry. The heat capacities, 298 - 450°K, derived by Naylor are too high to join smoothly at 298°K with the low temperature data, hence they are not used. The Cp values above 296.6°K are obtained by graphical extrapolation of the adopted low temperature Cp.

The samples used by both Shomate and Naylor were prepared by reduction of titanium dioxide with carbon at 1350°C. Analysis of the product gave 99.1% Ti₃O₅, 0.2% TiO and 0.7% SiO₂. X-ray lines from the sample were weak and fuzzy but no data were given. Thus comparison with subsequent studies is not possible. According to Naylor, the enthalpy measurements showed a transition at about 450°K. When Ti₃O₅ was heated above this temperature, it did not return to the original state on cooling. Enthalpies were then systematically higher by up to 10 percent. The change in the enthalpy curve seemed to depend upon both the temperature and time of heating above Tt. Regrinding was the only method found for returning the sample to its original state. Possible explanations are presented in the Transition Data.

S_{298}° is calculated from $S_{50}^\circ = 0.88$ eu using the low temperature Cp reported by Shomate, loc. cit. It is pertinent to ask if there should be entropy contributions due to vacancies in the crystal lattice or to spin-magnetic effects below 50°K. S. Asbrink and A. Megnell, Acta Cryst. 13, 575 (1959), showed that the X-ray crystallographic density is greater than the experimental density by less than 1%, thus the entropy due to the presence of vacancies is considered to be negligible. We also assume that any spin-magnetic entropy is related to the $\alpha \rightarrow \beta$ transition, by analogy with the $\alpha \rightarrow \beta$ transition of Ti₂O₃. Consistent with this assumption is the observation that the entropy of β -Ti₃O₅ is already larger than the sum of entropies for β -Ti₂O₃ and TiO₂.

Transition Data

See Ti₃O₅(β) table.

$$\Delta H_{298.15}^{\circ} = [-585.354] \text{ kcal/mol}$$

$$\Delta H^{\circ} = [2.81] \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = [35] \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = [35.913] \text{ gibbs/mol}$$

$$T_f = 450^{\circ}\text{K}$$

$$T_m = 2047 \pm 10^{\circ}\text{K}$$

Heat of Formation

The value of $\Delta H_{298}^{\circ}(\beta)$ is obtained from $\Delta H_{298}^{\circ}(\alpha)$ by adding ΔH° and the difference between $H_{450}^{\circ} - H_{298}^{\circ}$ for Ti₃O₅(α) and Ti₃O₅(β).

Heat Capacity and Entropy

The heat capacities are derived from the enthalpy data, 452 - 1340°K, measured by B. P. Naylor, J. Am. Chem. Soc. **69**, 1077 (1946). The Cp values beyond the experimental range are obtained by linear extrapolation.

The S_{298}° is calculated in a manner analogous to that of the heat of formation. For a discussion pertaining to the entropy uncertainty, see the Transition Data.

Transition Data

Tt and ΔH° are based on the β -phase enthalpy data of Naylor, loc. cit., and on the selected enthalpies of the α -phase. ΔH° is thus subject to an unknown error since the β -phase enthalpies correspond to a somewhat different state than do the α -phase values (see α -Ti₃O₅). The enthalpy data also show unusual scatter in the range 452-530°K. Because of these uncertainties, the more recent X-ray studies are summarized below.

S. Abrink and A. Magnelli, *Acta Cryst.* **12**, 575 (1959), found that monoclinic α -Ti₃O₅ transforms to a β form of the ansoovite type (slightly deformed pseudo-brookite) at about 393°K, i. e., over 50° lower than Naylor's value. P. G. Wahlbeck and P. W. Gilles, *J. Am. Ceram. Soc.* **49**, 180 (1966), confirmed that the transition occurs between 373 and 475°K but did not measure the temperature accurately. In both studies only the α form was observed on cooling the samples to room temperature. Abrink and Magnelli noted the following in X-ray studies at elevated temperatures. In a wide region around 393°K, the powder reflections of the unstable phase disappeared, while the general characteristics of the stable one formed within considerably less than one hour. Complete development of some reflections of the stable phase took several hours, while some lines appeared with anomalous intensities at temperatures approaching the transformation point, thus "forewarning" the change of structure. Small contents of Fe or Mg stabilized the β form at room temperature.

These observations suggest that the transformation may be considered as a "permt" which occurs over a range of temperatures. The anomalous enthalpy data observed by Naylor may arise from slow completion of the transition and from stabilization of part of the sample in the β form due to impurities. The latter suggestion is consistent with Naylor's observation that regrounding returned the sample to its normal α form. Correction of the enthalpy data based on these assumptions does not appear practical. Pending new data for a well-characterized sample, we must rely on the results of Naylor.

Melting Data.

P. G. Wahlbeck and P. W. Gilles, *J. Am. Ceram. Soc.* **49**, 180 (1966), found that Ti₃O₅ melts incongruently at 2047 $\pm$ 10°K which is adopted. ΔH_m° is estimated assuming that at T_m the entropy of melting is 2 eu/g-atom. Melting points of 2175 and 1983°K were reported by R. DeVries and R. Roy, *Bull. Am. Ceram. Soc.* **33**, 370 (1954), and G. Brauer and M. Litke, *J. Inorg. Nucl. Chem.* **16**, 67 (1960), respectively.

Mar. 31, 1967

OPM = 223.697

(LIQUID)

TRITITANIUM PENTOXIDE (Ti₃O₅)

ΔH_{298.15}^o = [-560.754] kcal/mol

ΔH_m^o = [33] kcal/mol

S_{298.15}^o = [38.679] gibbs/mol

T_m = 2047 ± 10°K

Heat of Formation

The ΔH_{298.15(1)}^o is obtained from ΔH_{298.15(β)}^o by adding ΔH_m^o and the difference between H₂₀₄₇^o - H₂₉₈^o for Ti₃O₅(β) and Ti₃O₅(1).

Heat Capacity and Entropy

The heat capacity is estimated on the basis of 7.0 gibbs/g-atom. S₂₉₈^o is obtained in a manner analogous to that of the heat of formation.

Melting Data

See Ti₃O₅(β) table for details.

Product of Moments of Inertia: I_AI_BI_C = 4.632 X 10⁻¹¹² g.³ cm.⁶

Heat of Formation. ΔH_f^o 298.15 for liquid P₂O₅ was measured by W. E. Koerner and P. Daniela, J. Chem. Phys. 20, 113 (1952). The measurement was made by burning samples of red phosphorus in nitric oxide in a flow calorimeter. Calculation of the heat of formation of the gas was made using ΔH_f^o 298.15 = 11.46 kcal. mole⁻¹ as reported by T. D. Farr, Tenn. Valley Authority, Chem. Engr. Report No. 6 (1950).

Heat Capacity and Entropy. The vibrational levels are from the Raman data of H. Gerding, H. van Brederode and H. C. J. de Decker, Rec. Trav. Chim. 52, 549 (1942), and infra-red spectra data of T. A. Sidorov and N. N. Sobolev, Optics and Spect. 2, 710 (1957). Bond lengths and angles are from electron diffraction data by G. C. Hampson and A. J. Stosick, J. Am. Chem. Soc. 80, 1814 (1958).

Heat of Formation.

The adopted value, ΔH_f²⁹⁸ (W₂O₆, g) = -278.2 kcal/mol, was reduced from ΔH_f¹⁴⁵⁰ = -272.5 kcal/mol, reported by R. J. Ackermann and E. O. Rauh, J. Phys. Chem. 67, 2596 (1963). They have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion, and X-ray diffraction, and also have determined ΔH_f⁰ (W₂O₆, g) = -272,500 + 54,98T (cal/mol) from partial pressure measurements over the W-W₂O₃(c) system.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, 1964, has also studied the same system in the temperature range from 1418 to 1527° K. Third law calculation of the partial pressure data gives ΔH_f²⁹⁸ = 144.0 kcal/mol for 3 W₂O₃(c) = W₂O₆(g) + W(c) which yields ΔH_f²⁹⁸ (W₂O₆, g) = -278.8 kcal/mol, using all JANAP functions. This value is in good agreement with the value adopted.

J. H. Norman and H. G. Staley, J. Chem. Phys. 43, 3804 (1965), have obtained ΔH_f¹⁸⁰⁰ = -127 kcal/mol for 2 W₂O₃(g) = W₂O₆(g) by mass spectrometric study of the vapor over W₂O₃ dissolved in CaO-Al₂O₃-SiO₂. The value of ΔH_f⁰ was determined by the second law method from ion intensities and leads to ΔH_f²⁹⁸ (W₂O₆, g) = -275 kcal/mol, using all JANAP functions (dated Sept. 30, 1966). The absolute pressure values reported by Norman and Staley appear to be quite inconsistent with the JANAP functions, since they lead to ΔH_f²⁹⁸ (W₂O₆, g) = -246 kcal/mol by the third law method.

Investigator	Chemical Reaction	Temperature (°K)	ΔH _f ²⁹⁸ (kcal/mol)	Drift (eu)	ΔH _f ²⁹⁸ (W ₂ O ₆ , g) (kcal/mol)
Ackermann & Rauh	3 W ₂ O ₃ (c) = W ₂ O ₆ (g) + W(c)	1300-1600	144.54	0.01	-278.2*
Battles	3 W ₂ O ₃ (c) = W ₂ O ₆ (g) + W(c)	1418-1527	142.66	0.85 ± 0.40	-278.8*
Norman & Staley	2 W ₂ O ₃ (g) = W ₂ O ₆ (g)	1700-1900	-135	-106	-275 **

* Third law value adopted in calculation.
** Second law value adopted in calculation.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 600 cm⁻¹ (4), 300 cm⁻¹ (8), and 172 cm⁻¹ (6) in order to give the entropy at 1450°K, S₁₄₅₀ = 164.66 eu, corresponding to ΔS_f¹⁴⁵⁰ = 54.98 eu which was reported by Ackermann and Rauh. The adopted value, S₂₉₈ (W₂O₆, g) = 99.3 eu, was reduced from the entropy at 1450°K, using JANAP functions. Second law calculation of the partial pressure data of Battles gives ΔS_f¹⁴⁷⁰ = 63.5 eu for 3 W₂O₃(c) = W₂O₆(g) + W(c). This yields S₂₉₈ (W₂O₆, g) = 97.9 eu.

The molecular configuration for W₂O₆(g) was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and two of these tetrahedra share a common oxygen edge to form a planar four-member ring. The bond distance W-O was estimated as 1.81 Å and the bond angle O-W-O = 109.47° and W-O₂bridge-W = 70.53°. The three principal moments of inertia are: I_A = 3.481 × 10⁻³⁷, I_B = 1.363 × 10⁻³⁷ and I_C = 1.247 × 10⁻³⁷ g cm².

[350] (4)	[150] (6)
[242] (8)	

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47°]

Product of the Moments of Inertia: $I_A I_B I_C = [7.65 \times 10^{-111}] \text{ g}^3 \text{ cm}^6$

$\sigma = [4]$

Heat of Formation.

R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2596 (1963), have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and X-ray diffraction, and also have determined the $\Delta H^\circ_f(W_3O_8, g) = -400,900 \pm 9054 \text{ T (cal/mol)}$ from partial pressure measurements over $W-WO_2 (c)$. The adopted value, $\Delta H^\circ_{298}(W_3O_8, g) = -408.7 \text{ kcal/mol}$, was reduced from $\Delta H^\circ_{1450}(W_3O_8, g) = -400.9 \text{ kcal/mol}$, using JANAF functions.

Investigator	Chemical Reaction	Temperature (°K)	ΔH°_{298} (kcal/mol)	Drift (eu)
Ackermann & Rauh	4 $WO_2(c) = W_3O_8(g) + W(c)$	1300-1600°	155.05	155.09

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1} (6), 350 cm^{-1} (4), 242 cm^{-1} (8), 199 cm^{-1} (3) and 150 cm^{-1} (6) in order to give the entropy at 1450°K, $S^\circ_{1450} = 208.18 \text{ eu}$, corresponding to $\Delta S^\circ_{1450} = -90.54 \text{ eu}$, which was reported by Ackermann and Rauh.

The molecular configuration for $W_3O_8(g)$ was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, the three tetrahedra are connected by two common edges, and also the three tungsten atoms are in the same axis. The bond distance W-O was estimated as 1.81 Å and the bond angle $\angle OWO = 109.47^\circ$. The three principal moments of inertia are: $I_A = I_B = 4.060 \times 10^{-37}$ and $I_C = 4.641 \times 10^{-38} \text{ g cm}^2$.

June 30, 1962; Mar. 31, 1963; Sept. 30, 1966

The molecular configuration for W₃O₉(g) is estimated by assuming that the oxygen atoms are tetrahedrally located around the tungsten atoms, and that each tetrahedron shares two oxygen atoms to form a planar six-member ring. The bond distance W-O is estimated as 1.61 Å and the bond angles O-W-O = 109.47° and W-O-bridge-W = 130.53°. The three principal moments of inertia are: I_A = I_B = 2.805 × 10⁻³⁷ g cm² and I_C = 4.913 × 10⁻³⁷ g cm².

Point Group [D_{3h}]

[396] (3)
[330] (9)

Bond Distance: W-O = [1.61] Å
Bond Angle: O-W-O = [109.47]°, W-O-bridge-W = [130.53]°
Product of the Moments of Inertia: I_AI_BI_C = [3.885 × 10⁻¹¹⁰] g cm³

Heat of Formation.

The adopted value, ΔH_{f,298}^o(W₃O₉,g) = -483.6 kcal/mol, was reduced from ΔH_{f,1450}^o(W₃O₉,g) = -474.1 kcal/mol of R. J. Ackermann and E. O. Rauh, J. Phys. Chem. **67**, 2596 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 °K by mass spectrometry, mass effusion, and X-ray diffraction, and determined ΔH_f^o(W₃O₉,g) = -474.100 ± 110.267 (cal/mol) from partial pressure measurements over W₂O₅(c). They reviewed the previous determinations 1, 2, 3, 4 of the thermodynamic properties of sublimation of W₃O₉(c), and also pointed out that it was not possible to make quantitative observations on stoichiometric W₃O₉ in vacuo, since it is a "bivalent" system and the ion current is not constant until the composition of the sample reaches W₂O₉. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battien, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of W₃O₉(g) over W₂O₅(c) in the temperature range from 1399° to 1527°K. Third law calculation of the partial pressure data gives ΔH_{f,298}^o = -148.2 kcal/mol for 4.5 W₂O₅(c) = W₃O₉(c) + 1.5 W (c), which yields ΔH_{f,298}^o(W₃O₉,g) = -485.0 kcal/mol, using all JANAF functions.

J. H. Norman and H. O. Staley, J. Chem. Phys. **43**, 3804 (1965), have obtained ΔH_{f,1600}^o = -240 kcal/mol for 3 W₂O₅(c) = W₃O₉(c) by mass spectrometric study of the vapor over W₃ dissolved in CaO-Al₂O₃-SiO₂. The value of ΔH_f^o was determined by the second law method from ion intensities and leads to ΔH_{f,298}^o(W₃O₉,g) = -483.4 kcal/mol, using all JANAF functions (dated September 30, 1965). The absolute pressure values reported by Norman and Staley also appear to be quite inconsistent with the JANAF functions, since they lead to -443 kcal/mol by the third law method.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm⁻¹ (8), 396 cm⁻¹ (3), 330 cm⁻¹ (9), 200 cm⁻¹ (6), and 150 cm⁻¹ (c) in order to give the entropy at 1450°K, S₁₄₅₀^o = 219.14 eu, corresponding to ΔH_{f,1450}^o = 110.26 eu, reported by Ackermann and Rauh. The adopted value, S₂₉₈^o(W₃O₉,g) = 120.6 eu, was reduced from the entropy at 1450°K, using JANAF functions. Second law calculation of the partial pressure data of Battien gives ΔS₁₄₅₅^o = 71.7 eu for 4.5 W₂O₅(c) = W₃O₉(c) + 1.5 W (c). This yields S₂₉₈^o(W₃O₉,g) = 122.4 eu.

$\Delta H_f^\circ = -697.0 \pm 2.1 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -702.7 \pm 2.1 \text{ kcal. mole}^{-1}$
 $\Delta H_g^\circ 298.15 = 25.34 \pm 0.08 \text{ kcal. mole}^{-1}$
 $T_g = 631^\circ \text{K.}$

Heat of Formation.

The heat of formation ($\Delta H_f^\circ 298.15$) of P₄O₁₀(c) has been reported by many investigators. The most recent value, $\Delta H_f^\circ 298.15 = -719.4 \pm 2.0 \text{ kcal. mole}^{-1}$ for the reaction P₄(white, c) + 5O₂(g) = P₄O₁₀(hex., c), was determined by E. P. Egan, Jr. and B. B. Luff, "Heats of Formation of Phosphorus Oxides", June 1, 1963 to Nov. 30, 1963, Tennessee Valley Authority, Office of Agriculture and Chemical Development, Fundamental Research Branch, Wilson Dam, Alabama. This $\Delta H_f^\circ 298.15$ value was derived from energy of combustion, $\Delta_c H^\circ = -716.397 \text{ kcal. mole}^{-1}$, which is an average value of many measurements using three different sample forms, i.e. uncoated phosphorus, lucite-coated phosphorus and cellulose acetate-coated phosphorus. The adopted $\Delta H_f^\circ 298.15$ (P₄O₁₀, c) value was recalculated based on the P(red, V, c) as reference state.

The heat of combustion of white phosphorus was determined as $-713.2 \pm 1.0 \text{ kcal. mole}^{-1}$ by W. S. Holmes, Trans. Paraday Soc. 58, 1916 (1962), yielding $\Delta H_f^\circ 298.15$ (P₄O₁₀, c) = $-696.5 \pm 1.3 \text{ kcal. mole}^{-1}$, based on P(red, V, c) as reference state. The heat of formation of P₂O₅ from red phosphorus was reported to be $-355 \pm 2 \text{ kcal. mole}^{-1}$ by M. S. Koerner and P. Daniele, J. Chem. Phys. 20, 113 (1952). The product, P₂O₅, was considered to be a mixture of two forms, i.e. crystalline and amorphous. The other $\Delta H_f^\circ 298.15$ (P₄O₁₀, c) values reported by early investigators were reviewed by Egan and Luff, loc. cit.

Heat Capacity and Entropy.

The heat capacities (12-324°K.) and $S_{298.15}^\circ$ adopted were taken from R. J. L. Andon, J. P. Counsell, H. McKerrell and J. P. Martin, Trans. Faraday Soc. 59, 2702 (1963). The Cp values above 324°K. were obtained by graphical extrapolation. The $S_{298.15}^\circ$ value was calculated based on $S_{10}^\circ = 0.36 \text{ e.u.}$

Low temperature (15-310°K.) and high temperature (298.15-623.15°K.) heat capacities were also measured by Thermal Laboratory, The Dow Chemical Company, private communication, June 18, 1962, and M. Prandsen, J. Res. Natl. Bur. Std. 10, 35 (1933), respectively. The low temperature data were not adopted because they are less satisfactory than the data of Andon et al. The high temperature data were not used because the sample employed for enthalpy measurements was not explicitly reported as pure hexagonal form.

Sublimation Data.

The value of $\Delta H_g^\circ 298.15$ was derived from the vapor pressure data by both the second and third law analyses. See the P₄O₁₀(g) table for details. T_g is the temperature at which the free energy change of the reaction P₄O₁₀(hex. c) = P₄O₁₀(g) approaches zero. Sublimation temperature for P₄O₁₀(c) was derived to be 632°K., 636°K. (average of three determinations) and 623.7°K. (average of two determinations) by M. Prandsen, loc. cit. from the vapor pressure data reported by J. M. Hoeflaka and M. F. Scheffer, Rec. trav. chim. 45, 191 (1926); A. Saite, Z. physik. Chem. 119, 337 (1930); and A. Saite and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924), respectively.

Product of the Moments of Inertia: I_AI_BI_C = 2.93798 × 10⁻¹¹¹ g.³ cm.⁶

Heat of Formation.

The value of ΔH_f⁰ 298.15 (P₄O₁₀/g) was calculated from the heats of formation and sublimation for P₄O₁₀ (hex., c). The heat of sublimation (ΔH_s⁰ 298.15) was derived from vapor pressure data by the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K	Second Law Value	Third Law Value	Drift, e.u.
Hoeftake and Schaffer ¹	260 -401	25.42±0.07	25.33	-0.39±0.13
Southern and Nelson ²	216.2-300.4	25.59±0.06	25.35	-0.18±0.14
	283.6-389.3	25.45±0.07	25.35	-0.10±0.07

1. J. W. A. Hoeftake and P. E. C. Schaffer, Rec. trav. chim. 45, 191 (1926).

2. J. C. Southern and R. A. Nelson, J. Am. Chem. Soc. 59, 911 (1937).

The value of ΔH_f⁰ 298.15 adopted was 25.34 ± 0.08 kcal. mole⁻¹. There are many vapor pressure measurements reported but only the above two over P₄O₁₀ (hex., c).

It has been shown that P₄O₁₀ has three solid phases and two liquid phases. The three solid phases are hexagonal, orthorhombic and tetragonal. As temperature increases, the thermal stability of P₄O₁₀ follows the same order. The metastable liquid, according to data of Hoeftake and Schaffer, loc. cit., is from hexagonal form. The stable liquid is from tetragonal form. W. L. Hill, O. T. Faust and S. B. Hendricks, J. Am. Chem. Soc. 65, 794 (1943) reported that molecules of P₄O₁₀ having the same structure as in the vapor are present in the hexagonal form of the solid. The vapor pressures of P₄O₁₀ over different condensed phases have been measured by many investigators and reviewed by T. D. Farr, "Phosphorus, Properties of the Elements and Some of Its Compounds", Tennessee Valley Authority, Wilson Dam, Alabama, 1950. The complexity of the solid state of P₄O₁₀ has also been discussed by A. Seits and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924); A. Seits, Z. physik. Chem. A149, 337 (1930); A. Seits, J. A. A. Keteleer and J. L. Meyer, ibid., B11, 87 (1938); and A. Seits, ibid., B45, 43 (1940).

Heat Capacity and Entropy.

The molecular structure and constants were obtained from P. A. Akishin, N. O. Rambidi and E. Z. Zesarin, Kristallografiya, 3, 360 (1959). The molecular structure of P₄O₁₀(g) has also been studied by the electron diffraction method by L. R. Maxwell, S. B. Hendricks and L. S. Deming, J. Chem. Phys. 5, 626 (1937), and O. C. Hampson and A. J. Stoeck, J. Am. Chem. Soc. 50, 1814 (1928). The model of the P₄O₁₀ molecule was later confirmed by the x-ray method reported by H. C. J. Decker and C. H. MacGillivray, Rec. trav. chim. 50, 153 (1941); and spectroscopic studies reported by H. Gerding and H. C. J. Decker, Rec. trav. chim. 64, 191 (1945), and T. A. Sidorov and N. N. Sobolav, Opt. Spectr. (USSR) 2, 717 (1957). All vibrational frequencies were obtained from E. P. Egan, Jr., private communication, Feb. 23, 1960, except nine frequencies, i.e. 170 (3), 470 (3), and 750 (3) cm⁻¹ which were estimated in order to make the second and third law values of ΔH_f⁰ 298.15 agree. The three principal moments of inertia are: I_A = I_B = 1.4322 × 10⁻³⁷ g. cm.² The heat capacities (549-1098°K. or 822-1371°K.) of P₄O₁₀(g) have been determined by M. Prandeaen, J. Res. Natl. Bur. Std. 10, 35 (1933). His results are in fair agreement with the calculated ones.

Mar. 31, 1963; Sept. 30, 1966

Point Group [D_{2h}]
S_{298.15} = [144.6] g/bb/mol
Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	ω, cm ⁻¹
[800] (8)	[240] (8)
[300] (8)	[200] (18)

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47°], W-O₂-bridge-W = [160.53°]

Product of the Moments of Inertia: I_AI_BI_C = [3.854 × 10⁻¹⁰⁹] g³cm⁶

Heat of Formation.

The adopted value, ΔH_{f298} (W₄O₁₂, g) = -670.2 kcal/mol, was reduced from ΔH_{f1450} (W₄O₁₂, g) = -655.6 kcal/mol of R. J. Ackermann and E. G. Reuh, J. Phys. Chem. 67, 2596 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and x-ray diffraction, and determined ΔH_f (W₄O₁₂, g) = -655.600 ± 160.29 T (cal/mol) from partial pressure measurements over the W-WO₃(c). They reviewed the previous determinations 1,2,3,4 of the thermodynamic properties of sublimation of WO₃, and also pointed out that it was not possible to make quantitative observations on stoichiometric WO₃ in vacuo, since it is a "bivalent" system and the ion current is not constant until the composition of the sample reaches WO_{2.98}. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of W₄O₁₂(g) over W-WO₂(c) in the temperature range from 1449 to 1527°K. Third law calculation of the partial pressure data gives ΔH_{f298} = 172.0 kcal/mol for 6 WO₂(c) = W₄O₁₂(g) + 2 W(c), which yields ΔH_{f298} (W₄O₁₂, g) = -673.6 kcal/mol, using all JANAP functions.

Investigator	Chemical Reaction	Temperature (°K)	ΔH _{f298} (kcal/mol)	Drift (eu)	ΔH _{f298} (W ₄ O ₁₂ , g) (kcal/mol)
--------------	-------------------	------------------	-------------------------------	------------	--

Ackermann & Reuh	6 WO ₂ (c) = W ₄ O ₁₂ (g) + 2W(c)	1300 - 1600*	175.41	0.01	-670.2
Battles	6 WO ₂ (c) = W ₄ O ₁₂ (g) + 2W(c)	1449 - 1527*	178.16	-2.90 ± 0.39	-673.6

* Third law value adopted in calculation.

Heat Capacity and Entropy.

The heat capacity was approximated by seeking a tentative choice of the vibrational frequencies of 800 cm⁻¹(9), 300 cm⁻¹(8), 240 cm⁻¹(8), and 200 cm⁻¹(18) in order to give the entropy at 1450°K, S₁₄₅₀ = 278.9 eu, corresponding to ΔH_{f1450} = -160.29 eu, reported by Ackermann and Reuh. The adopted value, S₂₉₈ (W₄O₁₂, g) = 144.6 eu, was reduced from the entropy at 1450°K, using JANAP functions. Second law calculation of the partial pressure data of Battles gives ΔH_{f1487} = 82.3 eu for 8 WO₂(c) = W₄O₁₂(g) + 2W(c). This yields S₂₉₈ (W₄O₁₂, g) = 147.4 eu.

The molecular configuration for W₄O₁₂(g) is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedron shares two oxygen atoms to form a planar eight-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and W-O₂-bridge-W = 160.53°. The three principal moments of inertia are: I_A = I_B = 5.935 × 10⁻³⁷ g cm², and I_C = 1.094 × 10⁻³⁶ g cm².

ΔH°_f 298.15 = 0 kcal. mole⁻¹
 ΔH°_f 298.15 = 7.69 ± 0.1 kcal. mole⁻¹
 T_m = 870°K
 ΔH°_f 298.15 = 0 kcal. mole⁻¹
 S°_{298.15} = 5.45 ± 0.02 cal. deg⁻¹ mole⁻¹
 ΔH°_m = 4.5 ± 0.2 kcal. mole⁻¹

Heat of Formation

Zero by definition below 704°K. See P₂(g) sheet for details above 704°K.

Heat Capacity and Extrapolation

The only reliable low temperature measurements, 15 to 305°K, are reported by R. L. Potter, Dissertation, Massachusetts Institute of Technology (1946). A value at 10°K was obtained by graphical extrapolation and a T³ function was assumed from 0 to 10°K. High temperature heat capacities were obtained from a smooth curve joining the measurements of O. Kubaschewski and G. Schrag, Z. Elektrochem. 46, 675 (1940), in the range 573 to 773°K and that of V. Regnault, Ann. chim. phys. 9, 322 (1843) at 331°K with those of Potter. Measurements of A. Wigand, Ann. Physik, 22, 64 (1907), are too high. The uncertainty in the high temperature heat capacity is about 2%.

Melting

The values of ΔH°_m and T_m were calculated from the functions of the solid and liquid. This may be compared with a reported triple point of 882.7°K by A. Smits and S. C. Bohoret, Akad. Wetenschap. 23, 930 (1914).

Heat of Sublimation

Vapor pressure measurements on the triclinic allotrope, T. V. A. designation V, are reported by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950). These data lead to a sublimation point of 704°K and ΔH°_f 298.15 of 30.77 ± 0.4 kcal. mole⁻¹ of P₄. A. Smits and S. C. Bohoret, Z. phys. Chem. 91, 248 (1916), measured the vapor pressure of a sample whose preparation indicates that it was probably P, V. These results lead to ΔH°_f 298.15 = 30.6 ± 1 kcal. An unpublished value of 30.84 kcal. mole⁻¹ of P₄ by C. C. Stephenson is quoted by J. S. Kane, Thesis Univ. of California (1955).

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), show that the vapor density measurements of A. Stock, O. E. Gibson and E. Stamm, Ber. 45, 3527 (1912) are best explained by a vapor essentially composed of only P₄(g) below 800°K. This conclusion is supported by recent mass spectrometer measurements of J. S. Kane and J. H. Reynolds, J. Chem. Phys. 25, 342 (1956).

PHOSPHORUS, WHITE (P)

(CRYSTAL)

AT. WT. = 30.975

$$\Delta H_f^{\circ} = 3.75 \pm 0.2 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^{\circ} = 3.52 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H_t^{\circ} = 124.62 \pm 0.2 \text{ cal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 157.43 \pm 0.5 \text{ cal. mole}^{-1}$$

Heat Capacity and Extrapolation

Low temperature measurements, 15-315°K, were made by R. T. Maples, Dissertation, Massachusetts Institute of Technology (1949). A Debye θ temperature of 124 was used to extrapolate to 0°K. P. E. Young and J. H. Hildenbrand, J. Am. Chem. Soc. **64**, 859 (1942), obtained heat capacities from enthalpy measurements that are 4% higher than those from the low temperature calorimeter which are preferred because of the proximity to the melting point.

Transition

Observed by Maples.

Melting

The selected heat of fusion is that observed by Maples. Young and Hildenbrand obtain 125 cal. mole⁻¹ for the same quantity. Maples' value is consistent with vapor pressures and other thermochemical data; see P(11q) and P₄(g) sheets.

Heat of Sublimation

The vapor pressure measurements of F. S. Dainton and H. M. Kimberly, Trans. Faraday Soc. **46**, 912 (1950), are the most precise and lead to $\Delta H_g^{\circ} = 14.08 \pm 0.2 \text{ kcal. mole}^{-1}$ of P₄. Measurements of A. Jollibois, Compt. rend. **249**, 287 (1909), A. Smits and S. C. Bokhorst, Z. Phys. Chem. **91**, 249 (1916), and M. Centzner, Z. Phys. Chem. **85**, 99 (1913) lead to values that agree within the assigned uncertainty.

Heat of Formation

The heat of formation is obtained from the heats of sublimation represented by reaction I and II at 298.15°K.

See P, V sheet for details.

Of the calorimetric determinations only those of H. Givan, Ann. Chim. Phys. **30**, 203 (1903) result in a reliable value for the heat of formation, $4.4 \pm 0.4 \text{ kcal. mole}^{-1}$. A comprehensive review is given by H. J. Rode-wald, Helv. Chim. Acta **43**, 878 (1960).

PHOSPHORUS (P)

(LIQUID)

At. Wt. = 30.975

$$\Delta H_{f, 298.15}^{\circ} = 5.2 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{\circ} = 10.25 \pm 0.03 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 317.30 \pm 0.05^{\circ}\text{K}, P_{\alpha} \rightarrow P(\text{liq})$$

$$T_m = 870^{\circ}\text{K}, P_{\gamma} \rightarrow P(\text{liq})$$

$$T_b = 550 \pm 3^{\circ}\text{K}$$

$$T_c = 935.8^{\circ}\text{K}$$

$$\Delta H_{f, 298.15}^{\circ} = 4.32 \pm 0.2 \text{ kcal. mole}^{-1}$$

$$\Delta H_{m, 298.15}^{\circ} = 157.43 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_{m, P_{\gamma}} \rightarrow P(\text{liq}) = 4.5 \pm 0.2 \text{ kcal. mole}^{-1}$$

$$\Delta H_{v, 298.15}^{\circ} = 3.37 \pm 0.03 \text{ kcal. mole}^{-1}$$

$$P_c = [93.3] \text{ atm.}$$

Heat of Formation

Derived from the ΔH_m by the following cycle:

$$(I) \quad P \quad 317.30 = P(\text{liq}) \quad 0.157 \text{ kcal.}$$

$$(II) \quad P_{\alpha} \quad 298.15 = P_{\alpha} \quad 317.30 \quad 0.113$$

$$(III) \quad P(\text{liq}) \quad 317.30 = P(\text{liq})_{298.15} \quad -0.121$$

$$(IV) \quad P_{\gamma} \quad 298.15 = P_{\alpha} \quad 298.15 \quad 4.08$$

The ΔH_f° 289.15 obtained from vapor pressure measurements on P_{γ} and on the liquid is 4.32 kcal. mole⁻¹ in agreement with that derived from the melting point.

Heat Capacity

P. E. Young and J. H. Hildenbrand, J. Am. Chem. Soc. **64**, 839 (1942), obtained an equation from enthalpy measurements which decreased with temperature. However, a better fit to the thermochemical data results if a constant heat capacity is assumed.

Entropy

Derived from low temperature measurements on P_{γ} White. See P, White sheet for details.

Vaporization Phenomena

D. MacRae and C. G. Van Voorhis, J. Am. Chem. Soc. **43**, 547 (1921), determinations of the vapor pressure, 44 to 150°C, are the most precise and lead to a $\Delta H_{v, 298.15}$ of 13.504 ± 0.1 kcal. mole⁻¹ of P_{α} . A vapor pressure equation derived by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950) to fit the measurements reported in the literature leads to a value of 13.6 ± 0.1 kcal. mole⁻¹ of P_{α} . The boiling point is calculated from the functions of $P(\text{liq})$ and $P_{\alpha}(g)$, and may be compared with the values of 552.7 and 553.7 resulting from Farr's equation and observations of A. Smits and S. C. Bokhorst, Proc. Akad. Wetenschap. **16**, 106 (1915) respectively.

Critical Phenomena

T_c determined and P_c estimated by W. Marchwald and R. Helmholz, Z. anorg. Chem. **124**, 81 (1922).

Heat of Formation.

The ΔH_f^o 298.15 was derived by the following cycle:

- (1) $4 P_{red}(v) [298.15^\circ] = P_4(g) [298.15^\circ]$ $\Delta H_f^o = 30.77$ kcal. mole⁻¹ of P_4 See $P_{red}(v)$ sheet under Heat of Sublimation.
- (2) $P_4(g) [298.15^\circ] = 2P_2(g) [298.15^\circ]$ $\Delta H_f^o = 54.59$ kcal. mole⁻¹ of P_4 See $P_2(g)$ sheet under Heat of Formation.
- (3) $2P_2(g) [298.15^\circ] = 2P_2(g) [0^\circ]$ $\Delta H_f^o = 2(-2.128)$ kcal. mole⁻¹ of P_4 See $P_2(g)$ table.
- (4) $2P_2(g) [0^\circ] = 4P(g) [0^\circ]$ $\Delta H_f^o = 2(116.075)$ kcal. mole⁻¹ of P_4 A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, 1953.
- (5) $4 P(g) [0^\circ] = 4 P(g) [298.15^\circ]$ $\Delta H_f^o = 4(1.481)$ kcal. mole⁻¹ of P_4 See $P(g)$ table.

D_0^o for reaction (4) was given by A. G. Gaydon (loc. cit.). He reported a predissociation limit at 51.958 ± 9 cm.⁻¹. He considered the dissociation to be $P_2 \rightarrow P(^4S) + P(^2D)$. From the predissociation limit and the energy level of the excited $P(^2D)$ state [11,360.8 cm.⁻¹] Gaydon (loc. cit.) obtained a $D_0^o = 5.033$ e.v. or 116.075 kcal. mole⁻¹. As a check, a graphical Birge-Sponer extrapolation by Gaydon (loc. cit.) [$\sum_{j=1}^{\infty} (v_j - 4.32)$] agrees with a $D_0^o = 5.0$ e.v.

The vapor equilibrium data of G. Freuner and I. Brockmoller, Z. physik. Chem. **81**, 129 (1913) gave a ΔH_f^o for reaction (4) which was much lower than the spectroscopic value i.e. 31.5(1073°K) vs. 116(0°) kcal. mole⁻¹ of P_2 . D. P. Stevenson and D. M. Yost, J. Chem. Phys. **9**, 403 (1941) reported that the vapor equilibrium measurements of G. Freuner and I. Brockmoller (loc. cit.) were doubtful while the measurements of A. Stock, G. E. Gibson, and E. Stamm Ber **45**, 3527 (1913) were correct. Stock et al. (loc. cit.) have shown that the reaction $P_2(g) \rightarrow 2P(g)$ is extremely slight even at 1473°K which is the highest temperature of the vapor equilibrium studies.

Heat Capacity and Entropy.

The thermodynamic functions were calculated from the electronic levels which were evaluated by averaging the spectroscopic values of W. C. Martin, J. Opt. Soc. Am. **49**, 1071, (1959).

Monophosphorus Monosulfide (PS)
(Ideal Gas) GFW = 63.0378

PS

MONOPHOSPHORUS MONOSULFIDE (PS) (IDEAL GAS) GFW = 63.0378

Ground State Configuration $2^1\Pi$ $\Delta H_f^\circ = 36.9 \pm 10 \text{ kcal/mol}$

$S_{298.15}^\circ = 56 \pm 0.2 \text{ gibbs/mol}$ $\Delta H_f^\circ = 37.3 \pm 10 \text{ kcal/mol}$

Heat of Formation

The dissociation energy (D_0°) of PS(g) is estimated to be $140 \pm 25 \text{ kcal/mol}$ by comparison with the corresponding quantity for PO(g) and from a linear Birge-Sponer extrapolation of the third excited ($C^2\Sigma$) electronic state potential function. It is assumed that the $C^2\Sigma$ state dissociates to S(g) in its ground (3P) state and P(g) in its first excited (3D) state. The fundamental vibrational frequency in the $C^2\Sigma$ state (ω_e) is $531.8 \pm 2.5 \text{ cm}^{-1}$ and the corresponding anharmonic term ($\omega_e X_e$) is $2.6 \pm 0.5 \text{ cm}^{-1}$. These constants are calculated from a reanalysis of the spectral data of Dressler (1). The corresponding heat of formation of PS(g) is $37.3 \pm 25 \text{ kcal/mol}$. The excited state ($C^2\Sigma$) data are used to calculate D_0° instead of the ground state(X $^1\Pi$) data because the vibrational constants of the upper level are known more accurately and because the extrapolation is 50 kcal/mol smaller for this level.

Heat Capacity and Entropy

The spectra of PS(g) have been studied by Dressler (1) in the near UV and visible regions. He reported the above electronic levels which correspond to the doublet pi ground state and two of the excited levels ($^3\Pi$, $C^2\Sigma$). The level of the first excited electronic state ($A^2\Sigma$) is estimated by analogy with NO(g).

Dressler (1) estimated the value of the rotational constant B_e . The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e . The fundamental vibrational frequency ω_e and the anharmonic vibrational term $\omega_e X_e$ are calculated from a reanalysis of the spectral data reported by Dressler (1).

Heat of Formation

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), have shown that the vapor density measurements of A. Stock, O. E. Gibson and E. Stamm, Ber. 45, 3527 (1912), best fit a vapor composed of P₂ and P₄ molecular species. From these data T. D. Parr, Tennessee Valley Authority, Chemical Engineering Report No. 8, calculated the equilibrium constants which lead to e ΔH_f^o of P₂ for I. From which ΔH_f^o of P₂ is obtained based upon a ΔH_f^o 298.15 of 30.77 kcal. mole⁻¹ of P₄(g).

(I) P₄(g) 298.15 = P₂(g) 298.15 ΔH_r^o = 54.59 ± 0.1 kcal. mole⁻¹

Heat Capacity and Entropy

Molecular end spectroscopic constants are those listed by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co. Inc., New York, 1945. More recent measurements of K. Dressler, Helv. Phys. Acta 28, 563 (1955) are in agreement with the values selected by Herzberg.

The dissociation energy is given by A. G. Oaydon, "Dissociation Energies", Chapman and Hall, Ltd., London, 1953.

PHOSPHORUS, TETRATOMIC (P₄) (IDEAL GAS) MOL. WT. = 123.90

ΔH_f[°] 298.15 = 30.84 ± 0.5 kcal. mole⁻¹
ΔH_f[°] 298.15 = 30.77 ± 0.5 kcal. mole⁻¹
S_{298.15} = 86.89 ± 0.1 cal. deg.⁻¹ mole⁻¹

Point Group T_d

Vibrational Levels and Multiplicities

(ω), cm.⁻¹

606 (1)
363 (2)
464.5 (3)

Bond Lengths and Angles P-P = 2.21 ± 0.2 Å
P-P-P = 109°.28
Moments of Inertia I_A = I_B = I_C = 25.1 X 10⁻³⁹ g. cm.² ϕ = 12

Heat of Formation

Taken as the heat of sublimation of P (red, v).

Heat Capacity and Entropy

The frequency and multiplicities are those assigned by H. S. Gutowsky and G. S. Hoffman, J. Am. Chem. Soc. 72, 5751 (1950). Molecular parameters of the gas were determined from electron diffraction measurements by L. R. Maxwell, S. B. Hendricks and V. M. Moseley, J. Chem. Phys. 23, 899 (1955). C. D. Thomas and N. S. Gingrich, J. Chem. Phys. 23, 659 (1955) obtained a P-P distance of 2.25 Å from x-ray studies on the liquid. On the basis of the selected values for P, White (see sheet) a third law entropy of 66.89 cal. deg.⁻¹ mole⁻¹ is derived for P₄(g) at 298.15°K.

Tetraphosphorus Trisulfide (P_4S_3)
(Solid) Mol. Wt. = 220.098

$$\Delta H_{f0}^0 = 0$$

$$\Delta H_{f298.15}^0 = 0$$

$$\Delta H_g^0 298.15 = 46.75 \pm 0.13 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 15.484 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^0 = 1.141 \text{ kcal. mole}^{-1}$$

$$T_m = 800.58 \pm 0.00^\circ \text{K}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacity measurements have been reported by M. Horowitz, A. A. Silvini, S. P. Malaker and J. O. Daunt, (1° to 4°, 14° to 21°, and 84° to 77°K.), Phys. Rev. **89**, 1182 (1952); P. P. Maada, W. R. Foraythe and W. P. Olaque, (15° to 300°K.), J. Am. Chem. Soc. **83**, 1902 (1961); T. B. Douglas and J. L. Dever, (298.16° to 1200°K.), J. Am. Chem. Soc. **76**, 4824 (1954), and many others whose work is listed by K. K. Kelley, U. S. Bur. Mines Bull. **584** (1960).

Heat capacities from 15° to 300° and 1° to 4°K. (in superconducting state) were taken from Neada, Foraythe, and Oiaque, and Horowitz, Silvini, Malaker, and Daunt, respectively. The missing data below the melting point were obtained by graphical extrapolation and joined smoothly to data of Douglas and Dever on approaching the melting point.

Melting.

The melting point of pure Pb(c) was found by E. H. McLaren and E. G. Mardock, Can. J. Phys. **38**, 577 (1960) to be $327.426 \pm 0.002^\circ \text{C}$. ΔH_m given by Douglas and Dever, loc. cit.

Heat of Sublimation.

$\Delta H_g^0 298.15$ was derived from third law analysis of the vapor pressure data of W. H. Rodebush and A. L. Dixon, J. Am. Chem. Soc. **47**, 1036 (1925) and Phys. Rev. **28**, 851 (1925); A. C. O. Egerton, Proc. Roy. Soc. (London) **A103**, 469 (1923); P. Hartack, Z. physik. Chem. **134**, 1 (1928); A. T. Aldeed and J. N. Pratt, Trans. Faraday Soc. **57**, 611 (1961); E. Baur and R. Brunner, Helv. Chim. Acta. **17**, 958 (1934), and J. Fischer, Z. anorg. Chem. **219**, 1, 367 (1934), which are in good agreement. Most weight was given to the results of Rodebush and Dixon. Older vapor pressure data of lower accuracy have not been used.

LEAD (Pb)

(LIQUID)

AT. WT. = 207.21

$$\Delta H_f^o 298.15 = [1.025] \text{ kcal. mole}^{-1}$$

$$T_m = 600.58 \pm 0.00^\circ \text{K}$$

$$T_b = 2026^\circ \text{K}$$

$$S_{298.15}^o = [17.141] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^o = 1.141 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^o = 42.53 \pm 0.13 \text{ kcal. mole}^{-1}$$

Heat of Formation.

Obtained from ΔH_m^o .

Heat Capacity and Extrapolation.

Heat capacity from T_m to 1200°K taken from T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. 76, 4824 (1954). C_p values below T_m and above 1200°K were extrapolated, a glass transition being assumed at 400°K.

Entropy.

Calculated from that of crystal.

Vaporization Phenomena.

T_b and ΔH_v^o calculated from $\Delta H_f^o 298.15$ and functions for condensed and gaseous states.

From the vapor pressure, the free energy functions of Pb(g) and Pb₂(g), and the dissociation energy of Pb₂(g), it appears that below the boiling point the amount of Pb₂(g) in the vapor is negligible.

Mar. 31, 1952; June 30, 1953; Sept. 30, 1953.

Ground State Configuration [3Σ_g⁻]
 $\Delta H_f^{\circ} = 80.4 \pm 4.6 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} = [62.216] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} = 298.15 = 79.5 \pm 4.6 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{\epsilon_i}{\epsilon_1} = \frac{g_i}{g_1}$$

$\omega_e x_e = 2.98 \text{ cm.}^{-1}$
 $\omega_e = [0.01727] \text{ cm.}^{-1}$
 $B_e = 0.01727 \text{ cm.}^{-1}$
 $\sigma = 2$
 $r_g = [3.08] \text{ \AA}$

Heat of Formation.

Heat of formation was calculated from the dissociation energy of Pb₂(g) reported by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953.

Heat Capacity and Entropy.

The values of ω_e and $\omega_e x_e$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950. Those for B_e and σ were estimated according to the method suggested by G. Herzberg, loc. cit. The bond distance (r_g) was calculated from the moment of inertia, $I = 1650 \times 10^{-40} \text{ g. cm.}^2$, estimated by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592, 1961. The ground state configuration was assumed to be 3Σ_g by comparison to that for Si₂(g) reported by A. E. Douglas, Can. J. Phys. 33, 801 (1955).

SULFUR (S)

(CRYSTAL)

AT. WT. = 32.064

$$\Delta H_f^0 = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 298.15 = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H_{f,1}^0 = 96.01 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_{f,2}^0 = 0.38 \pm 0.2 \text{ cal. mole}^{-1}$$

$$\Delta H_m^0 = 410.52 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_g^0 298.15 = 66.68 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 7.63 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_{f,1} = 368.54^\circ \text{K.}$$

$$T_{f,2} = 374^\circ \text{K.}$$

$$T_m = 368.36^\circ \text{K.}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

E. D. Eastman and W. C. McDevock, J. Am. Chem. Soc. 59, 145 (1937), have measured the low temperature heat capacities of sulfur from 15° to 375°K. E. D. West, J. Am. Chem. Soc. 81, 29 (1959), has measured the high temperature heat capacities from 298° to 678°K. These two sets of data were joined smoothly at 298.15 K. by a graphical method.

The values of entropy at 110°C and above in E. D. West's paper (table VIII) have been lowered by 0.5841 joule. deg.⁻¹ mole⁻¹ because of a calculational error which was pointed out by J. P. McCullough and D. W. Scott, private communication, Sept. 27, 1960.

The entropy of rhombic sulfur at 298.15°K. was taken from E. D. Eastman and W. C. McDevock, loc. cit., based on an extrapolation of $S_{15}^0 = 0.12 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

The enthalpies of transition at 368.54°K. and 374°K. were obtained from E. D. West, loc. cit. The first transition at 368.54°K. was the known rhombic-monoclinic transition, but the second one near 374°K. was a previously unreported transition.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Heat of Sublimation.

The heat of sublimation of sulfur (c) is the heat of formation of monatomic sulfur (g). See S(g) table for details. Since S_8 and lower polymers are major vapor species at room temperature, the heat of sublimation to the equilibrium gas is much smaller. See $S_8(g)$ table for details.

Dec. 31, 1960; Dec. 31, 1965

$$S_{298.15}^{\circ} = 8.44 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 388.36^{\circ}\text{K.}$$

$$T_b = 717.75^{\circ}\text{K.}$$

$$\Delta H_f^{\circ} 298.15 = 0.34 \pm 0.01 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 410.52 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_v^{\circ} = [2.30] \text{ kcal. mole}^{-1}$$

Heat of Formation.

The $\Delta H_f^{\circ} 298.15$ (S, l) was obtained from that of the crystal by adding ΔH_m° and the difference between $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was obtained from E. D. West, J. Am. Chem. Soc. **81**, 29 (1959). No simple equation fits the curve of C_p against T which shows a peak.

The value of $S_{298.15}^{\circ}$ (S, l) was obtained in a manner analogous to that of the heat of formation. The heat capacity of sulfur (liquid) below the melting point was assumed to be constant as $7.579 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, and above the boiling point, it was assumed as $7.694 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Vaporization Data.

According to the international practical temperature scale, the boiling point is 717.75°K. The heat of vaporization to the equilibrium vapor mixture was estimated by D. R. Stull and G. C. Sinke, "Thermodynamic Properties of the Elements," American Chemical Society, Washington, D.C., 1956. The equilibrium vapor involves monomeric and several polymeric species; S₂ and S₃ predominate above 1000°K. while S₈, S₆ and possible S₄ and S₃ are favored at lower temperatures.

Heat of Formation.

L. Brewer, J. Chem. Phys. **31**, 1143 (1959), has reviewed the three possible values of $D_0^\circ(S_2)$, i.e. 4.4 e.v., 3.6 e.v. and 3.3 e.v., which were due to the ambiguity of defining the excitation state of the atomic products resulting from predissociation in the spectroscopic measurements. The value of 4.4 e.v. (101.5 kcal. mole⁻¹) was shown to be the most probable one. Since this review, further support for his value have been given by the following investigators. J. R. Marquart, Dissertation Abstract 24, 5027 (1964), has found that the value of $D_0^\circ(S_2)$ to be consistent with the value of 4.4 e.v. in mass spectrometric studies. R. Coln, P. Goldfinger and M. Jeunhomme, Trans. Faraday Soc. **60**, 306 (1964), have found $D_0^\circ(S_2) = 97 \pm 5 \text{ kcal. mole}^{-1}$ in their mass-spectrometric studies of the vaporization of CS_2 , CS_2 and CS_2 , but they reported a revised value, i.e. $D_0^\circ(S_2) = 101 \pm 1 \text{ kcal. mole}^{-1}$, which was given in the note in proof. A. N. Singh and D. K. Rai, J. Chem. Phys. **43**, 2151 (1965), have selected the best value of $D_0^\circ(S_2) = 4.4 \text{ e.v.}$ in theoretical comparisons of the potential-energy curve. As pointed out by L. Brewer, loc. cit., and A. O. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., 2nd. Ed., London, 1953, the old vapor pressure measurements which are not consistent with $D_0(S_2) = 4.4 \text{ e.v.}$ (101.5 kcal. mole⁻¹) are probably not reliable.

The value $D_0(S_2, g) = 4.4 \text{ e.v.}$ (101.5 kcal. mole⁻¹) was selected as the dissociation energy of diatomic sulfur, and combination of this value with heat of formation of monatomic sulfur gives the heat of formation of monatomic sulfur, $\Delta H_f^\circ 298(S, g) = 66.68 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weight were obtained from C. E. Moore, "Atomic Energy Levels", Vol. 1, National Bureau of Standards Circular 467, June, 1949.

Silicon Monosulfide (SiS)

 $r_e = 1.889 \text{ \AA}$

Heat of Formation.

The standard enthalpy of formation of gaseous diatomic sulfur, $\Delta H_f^0 = 30.84$ kcal. mole⁻¹, was calculated from $\Delta H_f^0 = -20.30$ kcal. mole⁻¹ for the reaction $H_2(g) + 0.5 S_2(g) \rightarrow H_2S(g)$ with JANAP value $\Delta H_f^0 = -4.88 \pm 0.15$ kcal. mole⁻¹. The ΔH_f^0 was obtained by the second and third law analyses of equilibrium constants which have been determined by G. Preuner and W. Schupp (ref. 1) and M. Randall and P. R. Bichowsky (ref. 2). The results obtained are presented as follows:

Ref.	Temp. Range	Pointa	2nd law ΔH_f^0 298 kcal. mole ⁻¹	3rd law ΔH_f^0 298 kcal. mole ⁻¹	Drift
1	1023-1405°K	5	-19.92 ± 0.13	-20.295	-0.282 ± 0.097
2	1362-1667°K	4	-20.74 ± 0.40	-20.307	+0.281 ± 0.269
3	1023-1667°K	9	-20.13 ± 0.12	-20.300	-0.066 ± 0.093

3. Combination of above references.

The third law value of the combination set was selected to calculate the heat of formation of diatomic sulfur.

The dissociation energy of gaseous diatomic sulfur, $D_0^0(S_2) = 101.5$ kcal. mole⁻¹, was chosen. For discussions see JANAP monatomic sulfur (g) and sulfur monoxide (g) tables.

Heat Capacity and Entropy.

The molecular constants which were taken from G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, have been modified for the natural isotopic abundances reported by D. Strominger, J. M. Hollander and G. T. Saaborg, Rev. Mod. Phys. 30, 585 (1958).

Silicon Disulfide (SiS₂) (Crystall)

Mol. Wt. = 92.222
 $\Delta H_f^{298.15} = -50.7$ kcal. mole⁻¹
 $S_{298.15}^{298.15} = [16.0]$ cal. deg.⁻¹ mole⁻¹
 $T_m = 1363^\circ K.$
 $\Delta H_m = [5.0]$ kcal. mole⁻¹

Heat of Formation. $\Delta H_f^{298.15}$ was calculated from the measured ΔH_f^0 's of the following reactions:

ΔH_{R1} was taken from R. Rocquet, M. T. Ancey-Maret, Bull. Soc. Chim. France 1954, 1039 (1954); ΔH_{R2} was from D. Torgeson and Th. G. Semak, J. Am. Chem. Soc. 70, 2156 (1948). $\Delta H_f^{298.15}$ of SiS₂ was recalculated using the corrected value for $\Delta H_f^{298.15}$ of SiO₂.

Heat Capacity and Entropy. C_p and $S_{298.15}$ values are estimated.

Melting Data. T_m was from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952. ΔH_m was estimated.

Heat of Formation.

The vapor pressure of S(c) has been measured by many investigators. Using the seven more recent vapor pressure data, the respective heat of sublimation (ΔH_g^0 298.15°) was calculated by both the third and second law methods. The values obtained are tabulated as follows:

Investigator	Temperature Range, °K.	Third Law Value	Second Law Value
West-Menzies 1	376.8 - 448.8	24.29	21.29
Neumann 2	332.6 - 362.1	24.35	26.47
Fourtner 3	304.1 - 351.6	24.36	24.10
Tallade 4	303.6 - 352.5	24.29	24.87
Bradley 5	288.3 - 305.7	24.29	23.80
Magee 6	331.9 - 368.0	24.11	24.44
Brake 7	352.7 - 367.4	24.12	23.88
	275.2 - 313.2	24.28	24.00

1 W. A. West and A. W. Menzies, J. Phys. Chem. **53**, 1880 (1949).2 K. Neumann, Z. physik. Chem. **117**, 416 (1944).3 O. Fourtner, Compt. rend. **218**, 194 (1944).4 M. Tallade, Compt. rend. **218**, 838 (1944).5 R. S. Bradley, Proc. Roy. Soc. (London) **A 205**, 553 (1951).

6 D. W. Magee, Ph. D. Thesis, The Ohio State University, 1955.

7 C. Brake, N. H. Hartshorne and D. R. Stranks, J. Chem. Soc. (London), 1200 (1960).

Due to the presence of S₂(g) in S₈(g), the measured total pressures were corrected to give the partial pressures of S₈(g) for the first five sets of vapor pressure data, according to D. W. Scott, U. S. Bureau of Mines, Bartlesville, Oklahoma, private communication, May 22, 1964. However, the magnitude of the correction is only 0.1 - 0.2 kcal. mole⁻¹. The adopted value is the weighted average of both the third and second law values.

Heat Capacity and Entropy.

The vibrational frequencies were taken from D. W. Scott, J. P. McCullough and P. H. Kruse, "Vibrational Assignment and Force Constants of S₈ (condensed states) from a Normal-Coordinate Treatment", Prepublication Report 64, U. S. Bureau of Mines, May 20, 1963. Four of the eighteen frequencies, i.e. 86(2) and 218(2) cm.⁻¹ were changed to 56(2) and 248(2) cm.⁻¹, respectively, suggested by D. W. Scott, loc. cit., private communication, April 23, 1964. The molecular structure and bond distance and angle were reported by J. Donohue, A. Caron and E. Goldfarb, J. Am. Chem. Soc. **85**, 3748 (1961). The three principle moments of inertia are: I_A = I_B = 1.28594 × 10⁻³⁷ and I_C = 2.36042 × 10⁻³⁷ g. cm.².

$\Delta H_f^\circ = 0$ kcal/mol
 $\Delta H_f^{298.15} = 0$ kcal/mol
 $\Delta H_m^\circ = 12.0 \pm 0.1$ kcal/mol
 $\Delta H_f^{298.15} = 107.7 \pm 1$ kcal/mol

Heat of Formation.
 Zero by definition.

Heat Capacity and Entropy.
 Low temperature heat capacities are based on the precise data (8-300°K) of Flubacher, Leadbetter and Morrison. The entropy is obtained from the heat capacity using $S_0^\circ = 0.0003$ eu. The selected values are consistent with recent data of Keesom and Seidel (1.2 - 4.2°K) and Kalishevich et al. (60-300°K). Earlier data have been reviewed by R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1955.

High temperature studies are summarized below, along with the pertinent low temperature studies. The selected heat capacities above 300°K are obtained from a Shomate plot of the adopted low temperature heat capacities and the enthalpies reported or derived from the work of Dennison (1953), Kantor et al. (1960), Olette (1956), Serebrennikov and Gel'd (1952), and Magnus (1923). Discrepancies are apparent in the enthalpy data, particularly in the range of 370 to 1100°K, where only the recent study of Dennison made use of a high purity sample. Enthalpies from Dennison join most smoothly with the low temperature Cp but deviate increasingly at higher temperatures, being 1-2% lower than the other measurements above 1000°K. The selected functions agree with Dennison below 600°K, with Magnus from 600 to 1200°K, and with Kantor et al. above 1200°K. The resulting heat capacities are slightly different from those selected by Hultgren et al., loc. cit.; the latter are 0.07 gibbs/mol higher at 800°K and 0.21 gibbs/mol lower at the melting point.

Investigators	Method	Quantity Reported	T Range, °K	Sample
1. Flubacher et al. (1959)	Calorimetry	Cp°	7.7 - 300	Single crystal, annealed, resistance (300°K) 10.0 ohm cm, Carrier Concentration $\leq 10^{15}$ cm ⁻³
2. Keesom et al. (1959)	Calorimetry	Specific Heat	1.2 - 4.2	
3. Kalishevich et al. (1965)	Calorimetry	Cp°	60 - 300	99.99%
4. Oerlich et al. (1965)	Temperature Modulation	Cp°	300 - 900	Resistance (300°K) = 0.027 ohm cm, Carrier Concentration = 10^{19} cm ⁻³
5. Dennison (1953)	Drop Calorimetry	Specific Heat	275 - 1375	Resistance (300°K) = 107 ohm cm
6. Kantor et al. (1960)	Drop Calorimetry	Enthalpy Equation	1148 - 1685	"Highly purified"
7. Olette (1956)	Drop Calorimetry	Specific Enthalpy	1467 - 1685	99.9%
8. Serebrennikov et al.	Drop Calorimetry	Specific Enthalpy	302 - 1556	99.3%
9. Magnus (1923)	Drop Calorimetry	Specific Enthalpy	372 - 1175	99.2%

SILICON (Si) (LIQUID) GF_W = 28.086

S_{298.15}^o = 10.826 gibbs/mol
 T_m = 1685 ± 3°K
 T_b = [3513.8] °K (to monomer only)
 T_b = [3492] °K (to equilibrium mixture)

ΔH_f^o_{298.15} = 11.585 kcal/mol
 ΔH_m^o = 12.0 ± 0.1 kcal/mol
 ΔH_v^o = [92.047] kcal/mol
 ΔH_v^o = [85.8] kcal/mol

Heat of Formation.

The heat of formation is obtained from that of the crystal by adding ΔH_m^o and the difference between H_{298.15}^o - H_{298.15}^o for crystal and liquid.

Heat Capacity and Entropy.

Enthalpy data for high purity samples in quartz or vitreous silica capsules have been reported for the range 1698-1915°K by P.B. Kantor, A. M. Kisil and E. M. Fomichev, Ukrain. Fiz. Zhur. 5, 358 (1960), and for the range 1686-1825°K by M. Olette, Phys. Chem. Steelmaking, Proc. Dedham, Mass. 1955, 18-26 (pub. 1958). Due to the limited temperature range and the experimental uncertainty, the data do not appear to justify more than a constant heat capacity. A value of 6.5 gibbs/mol is selected, intermediate between the values of 6.75 and 6.15 obtained from the separate experiments. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data.

Modern determinations of the melting point range from 1683 ± 1 to 1690 ± 4°K, the former from the specific volume study of L. D. Lucas and G. Urbain, Compt. Rend. 255, 2414 (1962), and the latter from the enthalpy study of Kantor et al. The selected value of T_m = 1685°K is taken from R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965, who have reviewed the melting data. The heat of melting is calculated from the selected enthalpy of the crystal and the liquid enthalpy measurements of Kantor et al. and Olette, who reported comparable values of ΔH_m^o = 11.95 ± 0.18 and 12.095 ± 0.1 kcal/mol, respectively.

Vaporization Data.

T_b is calculated as the temperature for which the ΔG_r^o = 0 for Si(l) = Si(g). ΔH_v^o is calculated as the difference between ΔH_f^o(g) and ΔH_f^o(l) at T_b. The normal boiling for the equilibrium vapor is calculated as the temperature at which Si₁, Si₂ and Si₃ attain a total pressure of one atm. ΔH_v^o at this temperature is calculated as the enthalpy of vaporization of one GF_W of liquid to vapor containing 92.1, 7.0 and 0.9 mole percent of monomer, dimer and trimer, respectively. Tetramer and higher polymers, which are ignored in the equilibrium calculation, are probably negligible at this temperature.

Dec. 31, 1960; Dec. 31, 1962; Dec. 31, 1965; Mar. 31, 1967

Heat Capacity and Entropy.

Electronic levels and quantum weights are from L. J. Redziemski and K. L. Andrew, *J. Opt. Soc. Am.* **55**, 474 (1965), and V. Kaufman, L. J. Redziemski and K. L. Andrew, *ibid.* **55**, 911 (1966). An additional level with quantum weight of 200 is estimated above the observed levels and below the dissociation limit; however, the effect of this level on the entropy at 6000°K is negligible. Levels above 39000 cm⁻¹ are averaged.

Heat of Formation.

The selected value is based on the spectroscopic and equilibrium data summarized below. Verma and Worsop¹ concluded from analysis of the absorption spectra that $D_0^\circ = 70 \pm 4$ kcal/mol. Predissociation of the H state suggested the upper limit $D_0^\circ \leq 74.0$, while linear Birge-Sponer extrapolations of the H and K states gave 78.4 and 68.9 kcal/mol for the ground state. By assuming that the true extrapolation would not reduce the linear extrapolation for the H state by more than half, i.e., from 26 to 13 kcal, the authors arrived at the lower limit of $D_0^\circ \geq 65.5$ for the ground state.

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite², SiC-silicon³, and boron-carbon-silicon⁴. Third law analysis of the partial pressures of Si₂ and Si over the three systems yields D_0° values of 73.3, 74.3 and 70.4 kcal/mol, which are in good agreement with the spectroscopic values. The selected value, $\Delta H_f^\circ = 141 \pm 3$ kcal/mol, corresponds to $D_0^\circ = 73.0$ kcal/mol.

Source	Method	Range, °K	No. of Points	ΔH_f° (kcal/mol)*	Drift (kcal/mol)

Heat Capacity and Entropy.

Vibrational and rotational constants are those obtained by Verma and Worsop¹ through combination of their data for the H-X system with those of Douglas⁵. Observation of the same H-X system in matrix isolation by Welner and McLeod⁶ confirms that the lower state is the ground state. Comparison with the isoelectronic molecules C₂, BN, BeO and MgO (7,8,10) suggests that there are several possible low-lying excited states in Si₂. Tentative estimates for these levels are given above, based on this comparison and on the observed states (1,5). These estimates are relatively uncertain and probably yield an upper limit for the entropy at temperatures where Si₂ is significant. A probable lower limit may be obtained by increasing the two $3\Pi_u$ states by 8000 cm⁻¹ and omitting the other estimated levels. This would reduce the entropy by 1.7 eu at 2000°K, corresponding to a change of 3.4 kcal/mol in ΔH_f° values based on equilibrium data.

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the systems SiC-graphite¹ and SiC-silicon². Third law analysis of the partial pressures of Si₃ and Si yields the values 154.0 and 149.9 kcal/mol. Both drifts suggest that the entropy may be lower than the tabulated values. It is unlikely that the entropy is in error by more than 5 eu so that most of the drift is inherent in the data. The adopted value of $\Delta H_f^\circ = 152 \pm 10$ kcal/mol includes allowance for an error of up to 5 eu.

Heat Capacity and Entropy.

Wetner and McLeod³ observed an absorption band near 4660 Å in matrix isolation studies. Their tentative assignment of this band as the $3\Sigma_u^- \leftarrow 3\Sigma_g^-$ transition of Si₃ is adopted here. A $1W_u$ state is assumed at 18000 cm⁻¹, which is 7000 and 2000 cm⁻¹ below the analogous levels³ for C₃ and C₂Si. Also a $3W_u$ level is assumed at 10000 cm⁻¹, presumably arising from the same molecular orbital configuration as the $1W_u$ state. The molecule is assumed to be linear with a bond distance equal to that in Si₂. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 2.16 \times 10^5$ and $kd/1^2 = 0.11 \times 10^5$ dyn/cm. The stretching force constant is obtained from Si₂, while the bending force constant is based on C₂Si and the $1W_u$ excited state³ of C₃. The moment of inertia is 47.22×10^{-39} g cm².

 $\Delta H^\circ_{298.15} = 113.0 \pm 1.0$ kcal/mol

Heat of Formation.
Zero by definition.
Heat Capacity and Entropy.

The low temperature heat capacities, 1.1 - 305.5°K, have been measured by many investigators. Their measured temperature range, specimen purity and value of $S^\circ_{298.15}$ reported are listed in the following table. The Cp values, below 298°K, adopted were mainly derived from the data obtained from reference 3, 5 and 6, which are in good agreement with other sets of Cp data.

Investigator	Temperature, °K	Purity, %	$S^\circ_{298.15}$, eu
1. K. K. Kelley (1944)	53.5 - 295.1	98.75	7.24 ± 0.07
2. Estermann et al. (1952)	1.8 - 4.2	99	-
3. Kothan and Johnston (1953)	15.44 - 305.51	99.96	7.33 ± 0.02

9. R. P. Hake and J. A. Cape, Phys. Rev. 135, A1151 (1964).			

The high temperature heat capacities, 320-1856°K, have also been determined by many investigators. The values above 1155°K are not in good agreement. The measured temperature range, method used, and kind of data reported by these investigators are presented in the table below.

Investigator	Temperature, °K	Method	Property Measured
1. Jaeger et al. (1936)	492.9 - 1475.6	drop calorimetry	$H^\circ_T - H^\circ_{298.15}$
2. Kothan (1952)	1067.0 - 1856.0	drop calorimetry	$H^\circ_T - H^\circ_{298.15}$
3. Scott (1957)	333.2 - 1233.2	adiabatic calorimetry	Cp

4. I. Backhurst, J. Iron Steel Inst. (London) 169, 124 (1958).			
5. Y. M. Golutvin, Russ. J. Phys. Chem. 33, 164 (1959).			
6. L. R. Holland, J. Appl. Phys. 34, 2350 (1963).			
7. R. Kohlhaase, M. Braun and O. Vollmer, Z. Naturforsch. 20a, 1077 (1965). Sample purity 99.96%.			

The adopted Cp values, 298.15 - 1155°K, were mainly derived from the Cp data reported by reference 7. The low temperature and high temperature Cp data were joined smoothly at 298°K. The Cp values above 1155°K were estimated by graphical extrapolation. $S^\circ_{298.15}$ was derived from the adopted Cp, based on $S^\circ_{13} = 0.015$ eu.

Transition Data.

See the Ti (β, c) table for details.

Heat of Sublimation.

$\Delta H^\circ_{298.15}$ is calculated as the difference between $\Delta H^\circ_{298.15}$ for Ti(g) and Ti (α, c).

Sept. 30, 1956

ΔH°_0 = Unknown
 $\Delta H^\circ_{298.15} = 1.433$ kcal/mol
 $\Delta H^\circ = 0.99$ kcal/mol
 $\Delta S^\circ = [4.45]$ kcal/mol
 $\Delta S^\circ_{298.15} = [111.57]$ kcal/mol

$\Delta^\circ_{298.15} = 8.691$ gibbs/mol
 $T = 1155 \pm 3^\circ\text{K}$
 $T_m = 1933 \pm 10^\circ\text{K}$

Heat of Formation.
The heat of formation ($\Delta H^\circ_{298.15}$) was obtained from $\Delta H^\circ_{298.15}(\alpha, c)$ by adding ΔH° and the difference $H^\circ_{\text{Ti}} - H^\circ_{\text{Ti}}(\alpha, c)$ and $T(\beta, c)$.

Heat Capacity and Entropy.

The heat capacities, 1155 - 1856°K, have been determined by many investigators. See the Ti (α, c) table for details. The selected Cp values were evaluated based on the data reported by C. W. Kothen, Ph. D. Dissertation, The Ohio State University, 1952, and R. Kohlhaas, M. Braun and O. Vollmer, Z. Naturforsch. 20A, 1077 (1965). The heat capacities below 1155°K and above 1800°K were estimated by graphical extrapolation. The entropy was obtained in a manner analogous to that of the heat of formation.

Transition Data.

Titanium has two crystal forms, i.e., the hexagonal close-packed low-temperature form and the body-centered cubic high-temperature form. The $\alpha \rightarrow \beta$ transition temperature has been determined and reported over a range of temperatures, 1154-1187°K, by many investigators. The value of Tt is affected by the impurities in the specimen or adsorbed by the specimen during the measurement and the method used for the determination. The following table indicates the values of Tt reported by different investigators. Also included are the heats of transition (ΔH°), purity of specimen and property measured. The value of Tt adopted is 1155 $\pm$ 3°K, and the value of ΔH° is selected as 0.99 kcal/mol.

Melting Data.

See the Ti(l) table for details.

Heat of Sublimation.

$\Delta H^\circ_{298.15}$ is calculated as the difference between $\Delta H^\circ_{298.15}$ for Ti(g) and Ti(β, c).

Dec. 31, 1960; Sept. 30, 1966

TITANIUM (Ti)

(LIQUID)

OPW = 47.90

$$S^{\circ}_{298.15} = [10.695] \text{ gibbs/mol}$$

$$\Delta H^{\circ}_{f298.15} = [5.433] \text{ kcal/mol}$$

$$T_m = 1933 \pm 10^{\circ} \text{K}$$

$$\Delta H_m^{\circ} = [4.45] \text{ kcal/mol}$$

$$T_b = [3591]^{\circ} \text{K}$$

$$\Delta H_v^{\circ} = [101.65] \text{ kcal/mol}$$

Heat of Formation.

The heat of formation ($\Delta H^{\circ}_{f298.15}$) was obtained from $\Delta H^{\circ}_{f298.15}(\beta, c)$ by adding ΔH_m° and the difference between $H^{\circ}_{Tm} - H^{\circ}_{298.15}$ for Ti (β, c) and Ti(l).

Heat Capacity and Entropy.

A glass transition temperature at 1300°K was assumed. The heat capacities below 1300°K were obtained from those for Ti (β, c). The Cp value above 1300°K was estimated by comparison with those for the other transition elements and assumed to be constant in the temperature range 1300 - 4500°K. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

Because of the highly reactive nature of Ti(c), the accurate determination of the melting point is difficult. The results reported by different investigators show wide discrepancies. The T_m value adopted was determined by Schofield and Bacon (1953) and later confirmed by Mastrum and Peick (1963). The other values of T_m reported are presented in the table below. The heat of melting was calculated based on an estimated entropy of melting, $\Delta S_m^{\circ}_{1933} = 2.3 \text{ eu}$.

Vaporization Data.

T_b is the temperature at which the Gibbs energy change (ΔG°) for the reaction $Ti(l) = Ti(g)$ approaches zero. The difference between $\Delta H^{\circ}_f(Ti, g)$ and $\Delta H^{\circ}_f(Ti, l)$ at T_b is ΔH_v° .

Heat of Formation

The vapor pressure of Ti(β), 1510-1822°K, has been measured in three separate investigations. Based on the reported vapor pressures, the enthalpies of sublimation (ΔH_s⁰298.15) are evaluated by both the second and third law methods. The results obtained are presented in the following table. The adopted value of ΔH_f⁰ for Ti(g) is 113.0 ± 1.0 kcal/mol.

Reference	Temperature, °K	Second Law Value	Third Law Value	Drift
1	1510 - 1822	112.23 ± 1.91	110.26 ± 0.81	-1.3 ± 1.2
2	1658 - 1808	112.41 ± 6.30	110.71 ± 1.10	-1.1 ± 3.7
3	1587 - 1764	111.79 ± 0.18	111.22	-0.2 ± 0.6

*Calculation based on the third law ΔH_s⁰298 and ΔH_f⁰298(β) = 1.43 kcal/mol.

1. J. M. Blocher, Jr., and I. E. Campbell, J. Am. Chem. Soc. **71**, 4040 (1949).

2. L. G. Carpenter and W. N. Hair, Proc. Phys. Soc. **54**, 57 (1951). The preliminary results were reported by L. G. Carpenter and F. R. Reavell, Nature, **163**, 527 (1949).

3. J. W. Edwards, H. L. Johnston and W. E. Ditmars, J. Am. Chem. Soc. **75**, 2467 (1953).

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from C. E. Moore, National Bureau of Standards Circular 467 (1949). However, above the level $\epsilon_i = 15877.17$ cm⁻¹, the values of ϵ_i and g_i listed in the above table are average values calculated from those given by Moore. The ²S₀ level of the ground multiplet which has not been observed is estimated to lie at 12000 cm⁻¹ by comparison with the corresponding levels for Ti⁴⁺ ion, Zr and Zr⁴⁺ ion reported by C. E. Moore, loc. cit.

Heat of Formation

The heat of formation is calculated from the reaction $\text{Ti(g)} = \text{Ti}^+(\text{g}) + e^-(\text{g})$ with the JANAF auxiliary value for Ti(g) and an ionization potential = 6.82 eV or 157.276 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. I, 1949.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. I, 1949. The electronic levels above 4700 cm^{-1} are averaged. The $H^\circ - H_{298}^\circ$ value at 0°K is -1.886 kcal/mol.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

There have been several investigations of the low temperature heat capacity of tungsten: F. Lange, Z. physik. Chem. **110**, 343 (1924), covered the range 28-91°K. M. Horowitz and J. O. Daunt, Phys. Rev. **91**, 1099 (1953), reported values in the range 1-77°K, while T. R. Waite, R. S. Craig, and W. E. Wallace, Phys. Rev. **104**, 1240 (1956), worked from 4-15° and W. DeSorbo, J. Phys. Chem. **62**, 985 (1958), from 15-90°K. C. Zwikker and G. Schmidt, Z. Physik. **52**, 668 (1928), covered the range from 90 to 2521°K. K. Cluissius and P. Franzosini, Z. Naturforsch. **14d**, 99 (1959), made a thorough study of the heat capacity in the range 12-274°K, and their measurements were adopted leading to $S_{298}^{\circ} = 7.806$ eu based on $S_{12}^{\circ} = 0.0088$ eu. This value is in disagreement with the quoted value of 7.63 eu but agrees exactly with a separate integration by V. A. Kirillin, A. E. Sheindlin, V. Ye. Chekhovskoi and V. A. Petrov, Zhur. Fiz. Khim. **37**, 2249 (1963). In the intermediate temperature range the adiabatic heat capacity measurements of H. L. Bronson, H. M. Chisholm and S. M. Docketty, Can. J. Res. **B**, 282 (1953), from 253 to 773°K joined well with the low temperature measurements and were adopted. The high temperature enthalpies have been measured by several investigators from which were selected the values of P. M. Jaeger and E. Rosenblum, Rec. trav. chim. **51**, 1 (1932), from 273-1800°K; A. Magnus and H. Holzmam, Ann. Physik Ser. **5**, 3, 585 (1929), who covered the range 373 to 1173°K; M. Hoch and H. L. Johnston, J. Phys. Chem. **65**, 855 (1961) who made measurements between 1382 and 2900°K; Kirillin et al., loc. cit., who have made several determinations over the range 600 to 3100°K, and have also analysed the above data and have presented smooth functions from 0 to 3500°K. The present table agrees with that of Kirillin et al. up to 2700°K. Above this temperature the values of Cp adopted follow those reported by I. I. Novikov and P. G. Streikov, Vestnik. Akad. Nauk SSSR **54**, 26(1964), measured by an electric modulation method, up to the melting point. These values rise rapidly above 2700°K and are not inconsistent with the individual measurements of Kirillin et al. at their highest temperatures.

Melting Data.

I. Langmuir, Phys. Rev. **63**, 138 (1915), determined the melting point as 3540°K from intrinsic brilliance measurements; this was later corrected to 3655 ± 30°K by H. A. Jones, I. Langmuir and O. M. J. Mackay, Phys. Rev. **30**, 201 (1927). M. Firani and H. Alterthum, Z. Elektrochem. **29**, 5 (1923), from pyrometer measurements on a black body hole found 3660 ± 60°K. Using the same technique C. P. Zalabak, NASA Tech. Note D-761 (1961), reports 3680°K on a low carbon specimen; he reports a decrease of the melting point with increasing carbon content. E. Rudy and S. Windisch, Aerojet-General Tech. Rept. No. APWU-VR-65-2 Part 1, Vol. III July 1965, report a melting point of 3698 ± 20°K. The value adopted was 3680 ± 20°K. The heat of melting was obtained by assuming an entropy of melting of 2.3 eu obtained from a comparison of several high melting metals (Fe, Cu, Co, Mg, Al).

Sublimation Data.

See W(g) for details.

Dec. 31, 1961, June 30, 1966

TUNGSTEN (W) (LIQUID)

GFW = 183.85

S°_{298.15} = 10.923 gibbs/molΔHf°_{298.15} = 11.223 kcal/mol

Tm° = 3680 ± 20°K

ΔHm° = [8.46 ± 2.5] kcal/mol

Tb° = [5936]°K

ΔHv° = [192.824] kcal/mol

Heat of Formation.

The heat of formation at 298°K was calculated from that of the crystal by adding ΔHm° and the difference between H°₃₆₈₀-H°₂₉₈ for (c) and (l).

Heat Capacity and Entropy.

The heat capacity was estimated as 8.5 gibbs/g-atom by analogy with other monatomic metals. The entropy at 298°K was calculated in a manner analogous to that of the heat of formation. At 2500°K a glass transition was assumed, below which the heat capacity was that of the crystal.

Melting Data.

See crystal table for details.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Ground State Configuration $5d_0$
 $S_{298.15}^\circ = 41.549 \text{ gibbs/mol}$
 $\Delta H_f^\circ = 203.1 \pm 1.5 \text{ kcal/mol}$
 $\Delta H_f^\circ = 203.4 \pm 1.5 \text{ kcal/mol}$

Heat of Formation.

ΔH_f° is the heat of sublimation of the crystal at 298°K; this has been obtained by 2nd and 3rd law analysis of the vapor pressure data of three investigators. The results are summarized below:

Ref.	Range*°K	Points	$\Delta H_f^\circ, 298.15 \text{ kcal/mol}$		
			2nd law	3rd law	3rd law drift eu
1	2511-3053	12*	200.9 $\pm$ 3.6	201.57 $\pm$ 1.6	0.1 $\pm$ 1.4
2	2383-3123	14	214.8 $\pm$ 1.4	202.17 $\pm$ 2.5	-4.7 $\pm$ 0.5
3	2574-3183	10	202.4 $\pm$ 2.7	203.35 $\pm$ 1.2	0.4 $\pm$ 1.0

*1 point rejected due to failure of a statistical test.

**All temperatures are taken from Ref. 3, in which the earlier measurements have been corrected.

The values are remarkably good, since even at the highest temperature the pressures are less than 10^{-6} atm; all workers used the Langmuir technique. Since the data of Refs. 1 and 3 do not drift, it may be assumed that the accommodation coefficient is unity or close to unity. The drift in the second set cannot be eliminated by assuming a non-unity accommodation coefficient, nor does there appear to be a constant pressure error. Most probably the drift is due to slight errors in temperature. For example, if the readings were 24° high at the low end and 10° low at the high end, the drift would be eliminated; errors of this magnitude are quite possible. The value adopted for $\Delta H_f^\circ, 298.15$ is $203.4 \pm 1.5 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The electronic energy levels were taken from those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467 (1956). Levels above 25000 cm^{-1} were averaged.

Dec. 31, 1961; June 30, 1966

Heat of Formation.

The heat of formation is obtained by adding the heat of ionization at 0°K to the ΔH_f° W(g). The heat of ionization, 184.036 kcal (7.98 eV), is obtained from C. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington D. C. (1959).

Heat Capacity and Entropy.

The electronic energy levels are obtained from C. E. Moore, loc. cit. In the low lying configuration [Xe] $4f^{14}5d^5$ the F_2, G_2, F_2, H and S multiplets have not been observed. The total degeneracy of these levels (70) is split among three estimated levels of 20000, 21000, and 22000 cm^{-1} , obtained by analogy with Mo^+ . A realistic uncertainty in these levels would produce a maximum uncertainty of 0.03 gibbs/mol in the free energy function and 0.09 gibbs/mol in the entropy at 6000°K.

The enthalpy at 0°K is -1.487 kcal/mol.

ΔHf°_{298.15} = 148.3 ± 3.5 kcal/mol

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 1.1 - 288.2°K, have been measured by Todd (1), Skinner (2), Eastermann (3), Wolcott (4), Burk (5), and Kneip (6). Values of Cp_{298.15} were reported as 6.19 and 6.01 Gibbs/mol by Todd (1) and Skinner (2), respectively. The difference (beginning at 150°K) is probably caused by different amounts of impurities (e.g. O₂, H₂, N₂) in the samples. Neither sample was analyzed for hydrogen and oxygen content. Small amounts of either of these impurities would cause important changes in Cp. Remasurement of Cp using a high purity sample is desirable to resolve the difference. Tentatively, we adopt smooth Cp values which are intermediate between those of Todd and Skinner in the temperature range 200 - 298°K. The curve at lower temperatures is based on references 1, 2, 4, 5 and 6. S°_{298.15} is derived from the adopted Cp based on S°₁₁₆ = 0.0008 eu.

Enthalpies have been measured using drop calorimetry by Jaeger (7), Coughlin (8), Skinner (9), Redmond (10), Adenstedt (11) and Douglas (13). Cp above 298°K has been measured by Scott (12) and Vollmer (15) using adiabatic calorimetry and by Klein (14) using pulse heating. The data lead to differences in Cp which are even greater than those noted at 298°K. Observed Cp's are lower than the adopted curve by roughly 3 to 6 per cent, but the observed enthalpies are generally higher by 0 to 10 per cent. Impurities are partly to blame but there also may be a systematic difference between the methods. The purest and best-characterized samples are those of Douglas (13) and Vollmer (15). Even the high-purity sample of Douglas gives H values which are abnormally high at 573°K, suggesting the presence of thermal effects of solid solution and precipitation due to a small amount of hydrogen in the sample (12).

The adopted Cp is based mainly on Douglas (13), but references (7, 8, 15) were also given some weight. Deviations of (13) from the adopted values range from +3.3 per cent at 573°K to +0.3 at 1123°K. Other deviations (each in order of increasing T) are 3 to 0 per cent (7), 1.3 to -1.7 per cent (8), -4 to -6 per cent (15), 5.4 to 1.7 per cent (9) and -1 to 9.5 per cent (10) in terms of enthalpy. Cp is extrapolated linearly above 1133°K.

Transition Data

See Zr(β) table for details.

Heat of Sublimation

ΔH°_{298.15} is calculated as the difference between ΔHf°_{298.15} for Zr(g) and Zr(α).

$$S_{298.15}^{\circ} = 11.152 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = 1.706 \text{ kcal/mol}$$

$$T_c = 1135 \pm 10^{\circ}\text{K}$$

$$\Delta H_c^{\circ} = 0.96 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 5.0 \pm 0.3 \text{ kcal/mol}$$

Heat of Formation

The heat of formation is obtained from $\Delta H_{298.15}^{\circ}(\alpha)$ by adding ΔH_c° and the difference between $H_{T_c}^{\circ}$ for Zr(α) and Zr(β).

Heat Capacity and Entropy

The enthalpies and Cp of Zr(β), at temperatures 1135 - 2118.2 °K, have been measured by many investigators (see Zr(α) table for details). The selected Cp values are based on the data reported by Douglass (1) and Skinner (2). Deviations from the adopted enthalpies are -1.4 to 0.8 per cent (1), -0.4 to 0.3 (2), and 0.2 to 3.0 per cent (3). Deviations of the measured Cp from the adopted values are -5 to -3 per cent (14) and about -6 per cent (10). The heat capacities below 1143.2 end above 1798 °K are estimated by linear extrapolation.

The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

Zirconium has two crystal forms, i.e., the hexagonal-close-packed α -form and the cubic-body-centered β -form (3, 4, 5). The value and range of Tt for $\alpha \rightarrow \beta$ depends strongly on the kind and amount of impurities (5, 13). For example, nitrogen and oxygen increase Tt while hydrogen decreases it. The adopted value is Tt = 1135 $\pm$ 10 °K, although recent measurements using purer samples indicate a somewhat higher value. These are summarized below along with the data for ΔH_c° . The value $\Delta H_c^{\circ} = 0.96 \text{ kcal/mol}$ is derived from the adopted enthalpy and Cp data on Zr(α) and Zr(β).

ZIRCONIUM (Zr)

(LIQUID)

GFW = 91.22

S°_{298.15} = [13.289] gibbs/mol

T_m = 2125 ± 5 °K

T_b = [4776.9] °K

ΔH_f°_{298.15} = [6.351] kcal/mol

ΔH_m° = 5.0 ± 0.4 kcal/mol

ΔH_v° = 141.13 kcal/mol

Heat of Formation

The heat of formation is obtained from ΔH_f°₂₉₈(β) by adding ΔH_m° and the difference between H°₂₁₂₅ - H°₂₉₈ for Zr(β) and Zr(L).

Heat Capacity and Entropy

A glass transition temperature at 1400°K is assumed. The heat capacities below 1400°K are taken from those for Zr(β). The Cp value above 1400°K is estimated by comparison with that of Zr(β) at T_m and assumed to be constant in the temperature range 1400 - 3500°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point of Zr(β) has been determined by many investigators. The results reported show wide discrepancies, probably caused by the differences in purity of the samples used for determination. The T_m value adopted is obtained from Oriani and Jones. The other values of T_m reported are presented in the table below.

The adopted heat of melting was determined calorimetrically by V. P. Elyutin, M. A. Maurakh and G. M. Sverdlov, Izv. Vysshikh Uchebn. Zavedenii, Tsvertn. Met. 10, No. 2, 87 (1967). Zirconium samples from two different sources were melted in an Arc-crucible furnace. The crucible contained an insert of graphite which had a thick lining (presumably of zirconium carbide) in order to minimize carbonization of Zr(L). The molten Zr was poured through an opening in the bottom of the crucible into a calorimeter containing molten Mg as the calorimetric fluid. The method of calculating the value of ΔH_m° was described in detail by V. P. Elyutin, M. A. Maurakh, V. Y. Mishuk, and G. M. Sverdlov, Izv. Vysshikh Uchebn. Zavedenii, Tsvertn. Met. 10, 60 (1967). The authors estimated the uncertainty as about 7 percent in ΔH_m°.

Vaporization Data

T_b is the temperature at which the Gibbs energy change (ΔG°) for the reaction Zr(L) = Zr(g) approaches zero. The difference between ΔH_f°(Zr, g) and ΔH_f°(Zr, l) at T_b is ΔH_v°.

Heat of Formation

The heat of formation is calculated from the reaction $\text{Zr(g)} - \text{e}^-(\text{g}) = \text{Zr}^+(\text{g})$ with the JANAF auxiliary value for Zr(g) ; and an ionization potential = 6.84 eV or 157.737 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. II, 1952 and Vol. III, 1958. The electronic levels above 2500 cm^{-1} are averaged. The $H^\circ - H_{298}^\circ$ value at 0°K is -1.786 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. II, 1952 and Vol. III, 1958. The electronic levels above 2500 cm^{-1} are averaged. The $H^\circ - H_{298}^\circ$ value at 0°K is -1.786 kcal/mol.

Mar. 31, 1965

Electronic Levels and Multiplicities

$$\frac{E_i \text{ cm.}^{-1}}{0} \cdot \frac{g_i}{2}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Calculated by assuming to be an ideal monatomic gas of mass 0.00054876 with two equivalent spin states. The enthalpy between 298 and 0°K. is 1.481 kcal. mole⁻¹ as for all unexcited monatomic gases.

Publications in the National Standard Reference Data Series National Bureau of Standards

You may use this listing as your order form by checking the proper box of the publication(s) you desire or by providing the full identification of the publication you wish to purchase. The full letter symbols with each publication number and full title of the publication and author must be given in your order, e.g. NSRDS-NBS-17, Tables of Molecular Vibrational Frequencies, Part 3, by T. Shimanouchi.

Pay for publications by check, money order, or Superintendent of Documents coupons or deposit account. Make checks and money orders payable to Superintendent of Documents. Foreign remittances should be made either

by international money order or draft on an American bank. Postage stamps are not acceptable.

No charge is made for postage to destinations in the United States and possessions, Canada, Mexico, and certain Central and South American countries. To other countries, payments for documents must cover postage. Therefore, one-fourth of the price of the publication should be added for postage.

Send your order together with remittance to Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

- ☐ NSRDS-NBS 1, National Standard Reference Data System—Plan of Operation, by E. L. Brady and M. B. Wallenstein, 1964 (15 cents), SD Catalog No. C13.48:1.
- ☐ NSRDS-NBS 2, Thermal Properties of Aqueous Uni-univalent Electrolytes, by V. B. Parker, 1965 (45 cents), SD Catalog No. C13.48:2.
- ☐ NSRDS-NBS 3, Sec. 1, Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si II, Si III, Si IV, by C. E. Moore, 1965 (35 cents), SD Catalog No. C13.48:3/Sec.1.
- ☐ NSRDS-NBS 3, Sec. 2, Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si I, by C. E. Moore, 1967 (20 cents), SD Catalog No. C13.48:3/Sec.2.
- ☐ NSRDS-NBS 3, Sec. 3, Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, C I, C II, C III, C IV, C V, C VI, by C. E. Moore, 1970 (\$1), SD Catalog No. C13.48:3/Sec.3.
- ☐ NSRDS-NBS 3, Sec. 4, Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, N IV, N VI, N VII, by C. E. Moore, (in press).
- ☐ NSRDS-NBS 4, Atomic Transition Probabilities, Volume I, Hydrogen Through Neon, by W. L. Wiese, M. W. Smith and B. M. Glennon, 1966 (\$2.50), SD Catalog No. C13.48:4/Vol.1.
- ☐ NSRDS-NBS 5, The Band Spectrum of Carbon Monoxide, by P. H. Krupenie, 1966 (70 cents), SD Catalog No. C13.48:5.
- ☐ NSRDS-NBS 6, Tables of Molecular Vibrational Frequencies, Part 1, by T. Shimanouchi, 1967 (40 cents), SD Catalog No. C13.48:6/Pt.1.
- ☐ NSRDS-NBS 7, High Temperature Properties and Decomposition of Inorganic Salts, Part 1, Sulfates, by K. H. Stern and E. L. Weise, 1966 (35 cents), SD Catalog No. C13.48:7/Pt.1.
- ☐ NSRDS-NBS 8, Thermal Conductivity of Selected Materials, by R. W. Powell, C. Y. Ho, and P. E. Liley, 1966 (\$1), PB189698
- ☐ NSRDS-NBS 9, Tables of Bimolecular Gas Reactions, by A. F. Trotman-Dickenson and G. S. Milne, 1967 (\$2), SD Catalog No. C13.48:9.
- ☐ NSRDS-NBS 10, Selected Values of Electric Dipole Moments for Molecules in the Gas Phase, by R. D. Nelson, Jr., D. R. Lide, Jr., and A. A. Maryott, 1967 (40 cents), SD Catalog No. C13.48:10.
- ☐ NSRDS-NBS 11, Tables of Molecular Vibrational Frequencies, Part 2, by T. Shimanouchi, 1967 (30 cents), SD Catalog No. C13.48:11/Pt.2.
- ☐ NSRDS-NBS 12, Tables for the Rigid Asymmetric Rotor: Transformation Coefficients from Symmetric to Asymmetric Bases and Expectation Values of P_2^2 , P_2^0 , and P_2^{-2} , by R. H. Schwendeman, 1968 (60 cents), SD Catalog No. 13.48:12.
- ☐ NSRDS-NBS 13, Hydrogenation of Ethylene on Metallic Catalysts, by J. Horiuti and K. Miyahara, 1968 (\$1), SD Catalog No. C13.48:13.
- ☐ NSRDS-NBS 14, X-Ray Wavelengths and X-Ray Atomic Energy Levels, by J. A. Bearden, 1967 (40 cents), SD Catalog No. C13.48:14.
- ☐ NSRDS-NBS 15, Molten Salts, Vol. 1, Electrical Conductance, Density, and Viscosity Data, by G. J. Janz, F. W. Dampier, G. R. Lakshminarayanan, P. K. Lorenz, and R. P. T. Tomkins, 1968 (\$3), SD Catalog No. C13.48:15/Vol.1.
- ☐ NSRDS-NBS 16, Thermal Conductivity of Selected Materials, Part 2, by C. Y. Ho, R. W. Powell, and P. E. Liley, 1968 (\$2), SD Catalog No. C13.48:16/Pt.2.
- ☐ NSRDS-NBS 17, Tables of Molecular Vibrational Frequencies, Part 3, by T. Shimanouchi, 1968 (30 cents), SD Catalog No. C13.48:17/Pt.3.
- ☐ NSRDS-NBS 18, Critical Analysis of the Heat-Capacity Data of the Literature and Evaluation of Thermodynamic Properties of Copper, Silver, and Gold From 0 to 300°K, by G. T. Furukawa, W. G. Saba, and M. L. Reilly, 1968 (40 cents), SD Catalog No. C13.48:18.
- ☐ NSRDS-NBS 19, Thermodynamic Properties of Ammonia as an Ideal Gas, by L. Haar, 1968 (20 cents), SD Catalog No. C13.48:19.
- ☐ NSRDS-NBS 20, Gas Phase Reaction Kinetics of Neutral Oxygen Species, by H. S. Johnston, 1968 (45 cents), SD Catalog No. C13.48:20.
- ☐ NSRDS-NBS 21, Kinetic Data on Gas Phase Unimolecular Reactions, by S. W. Benson and H. E. O'Neal, 1970 (\$7), SD Catalog No. C13.48:21.
- ☐ NSRDS-NBS 22, Atomic Transition Probabilities, Vol II, Sodium Through Calcium, A Critical Data Compilation, by W. L. Wiese, M. W. Smith, and B. M. Miles, 1969 (\$4.50), SD Catalog No. C13.48:22/Vol.II.
- ☐ NSRDS-NBS 23, Partial Grottrian Diagrams of Astrophysical Interest, by C. E. Moore and P. W. Merrill, 1968 (55 cents), SD Catalog No. C13.48:23.
- ☐ NSRDS-NBS 24, Theoretical Mean Activity Coefficients of Strong Electrolytes in Aqueous Solutions from 0 to 100° C, by Walter J. Hamer, 1968 (\$4.25), SD Catalog No. C13.48:24.
- ☐ NSRDS-NBS 25, Electron Impact Excitation of Atoms, by B. L. Moiseiwitsch and S. J. Smith, 1968 (\$2), SD Catalog No. C13.48:25.
- ☐ NSRDS-NBS 26, Ionization Potentials, Appearance Potentials, and Heats of Formation of Gaseous Positive Ions, by J. L. Franklin, J. G. Dillard, H. M. Rosenstock, J. T. Herron, K. Draxl, and F. H. Field, 1969 (\$4), SD Catalog No. C13.48:26.
- ☐ NSRDS-NBS 27, Thermodynamic Properties of Argon from the Triple Point to 300 K at Pressures to 1000 Atmospheres, by A. L. Gosman, R. D. McCarty, and J. G. Hust, 1969 (\$1.25), SD Catalog No. C13.48:27.
- ☐ NSRDS-NBS 28, Molten Salts, Vol. 2, Section 1, Electrochemistry of Molten Salts: Gibbs Free Energies and Excess Free Energies From Equilibrium-Type Cells, by G. J. Janz and C. G. M. Dijkhuis. Section 2, Surface Tension Data, by G. J. Janz, G. R. Lakshminarayanan, R. P. T. Tomkins, and J. Wong, 1969 (\$2.75), SD Catalog No. C13.48:28/Vol.2.
- ☐ NSRDS-NBS 29, Photon Cross Sections, Attenuation Coefficients and Energy Absorption Coefficients From 10 keV to 100 GeV, by J. H. Hubbell, 1969 (75 cents), SD Catalog No. C13.48:29.
- ☐ NSRDS-NBS 30, High Temperature Properties and Decomposition of Inorganic Salts, Part 2, Carbonates, by K. H. Stern and E. L. Weise, 1969 (45 cents), SD Catalog No. C13.48:30.
- ☐ NSRDS-NBS 31, Bond Dissociation Energies in Simple Molecules, by B. deB. Darwent, 1970 (55 cents), SD Catalog No. C13.48:31.
- ☐ NSRDS-NBS 32, Phase Behavior in Binary and Multicomponent Systems at Elevated Pressures: *n*-Pentane and Methane-*n*-Pentane, by V. M. Berry and B. H. Sage, 1970 (70 cents), SD Catalog No. C13.48:32.
- ☐ NSRDS-NBS 33, Electrolytic Conductance and the Conductances of the Halogen Acids in Water, by W. J. Hamer and H. J. DeWane, 1970 (50 cents), SD Catalog No. C13.48:33.
- ☐ NSRDS-NBS 34, Ionization Potentials and Ionization Limits Derived from the Analyses of Optical Spectra, by C. E. Moore, 1970 (75 cents), SD Catalog No. C13.48:34.

**Announcement of New Publications in
National Standard Reference Data Series**

Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Dear Sir:

Please add my name to the announcement list of new publications to be issued in the series: National Standard Reference Data Series—National Bureau of Standards.

Name_____

Company_____

Address_____

City_____ State_____ Zip Code_____

(Notification key N-337)

U.S. DEPT. OF COMM. BIBLIOGRAPHIC DATA SHEET		1. PUBLICATION OR REPORT NO. NSRDS-NBS 37	2. Gov't Accession No.	3. Recipient's Accession No.
4. TITLE AND SUBTITLE JANAF Thermochemical Tables, Second Edition			5. Publication Date	
			6. Performing Organization Code	
7. AUTHOR(S) D. R. Stull, H. Prophet, et al.			8. Performing Organization	
9. PERFORMING ORGANIZATION NAME AND ADDRESS NATIONAL BUREAU OF STANDARDS DEPARTMENT OF COMMERCE WASHINGTON, D.C. 20234			10. Project/Task/Work Unit No.	
			11. Contract/Grant No. F04611-67-C-0009 F04611-70-0028	
12. Sponsoring Organization Name and Address The Thermal Research Laboratory Dow Chemical Company Midland, Michigan			13. Type of Report & Period Covered NA	
			14. Sponsoring Agency Code	
15. SUPPLEMENTARY NOTES Superseding PB168-370 and Addenda 1, 2, and 3				
16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) This monograph is the second edition of the JANAF Thermochemical Tables. It contains thermodynamic properties for some 1099 chemical species. The following properties are tabulated as functions of temperatures: C_p° , S° , $(F^\circ - H_{298}^\circ)/T$, $H^\circ - H_{298}^\circ$, ΔH_f° and Log Kp.				
17. KEY WORDS (Alphabetical order, separated by semicolons) Evaluated Data; Thermal Functions; Thermodynamic Properties of Materials; Thermodynamics.				
18. AVAILABILITY STATEMENT ☒ UNLIMITED. ☐ FOR OFFICIAL DISTRIBUTION. DO NOT RELEASE TO NTIS.		19. SECURITY CLASS (THIS REPORT) UNCLASSIFIED	21. NO. OF PAGES 1141	
		20. SECURITY CLASS (THIS PAGE) UNCLASSIFIED	22. Price \$9.75
