INDEX OF DATA TABLES

Parenting Tables

Table 1 Percentage of adults who have ever had a biological child: 2000	125
Table 2 Percentage of adults living with one or more of their own children under age 18: 2001	126
Table P1.1 Percentage of adults ages 18 to 65 who either agree or strongly agree that people who have never had children lead empty lives: 1988 & 1994	129
Table P1.2 Percentage of adults ages 18 to 65 who either agree or strongly agree that a marriage without children is not fully complete: 1988	130
Table P2.1 Percentage of adults ages 18 to 65 who either agree or strongly agree that watching children grow up is life's greatest joy: 1988 & 1994.....	131
Table P2.2 Percentage of adults ages 18 to 65 who either agree or strongly agree that it is better not to have children because they are such a heavy financial burden: 1988	132
Table P3.1 Percentage of adults ages 18 to 65 who either agree or strongly agree that one parent can bring up a child as well as two parents together: 1994	133
Table P4.1 Percentage of parents who reported various qualities as the most important for their child (under age 13) to learn to prepare him/her for life: 1997	134
Table P5.1 Percentage of adults ages 18 to 65 who either agree or strongly agree that it is sometimes necessary to discipline a child with a good, hard spanking: selected years: 1986-2000	135
Table P6.1 Percentage of parents who reported particular responsibility for playing with their child(ren) (under age 13): 1997.....	137
Table P6.2 Percentage of parents who reported particular responsibility for disciplining their child(ren) (under age 13): 1997	138
Table P6.3 Percentage of parents who reported particular responsibility for selecting a child care program, preschool, or school for their child(ren) (under age 13): 1997	139
Table P7.1 Percentage of parents who reported that they often or very often set various limits on their children's activities (ages 3 to 12): 1997	140
Table P8.1 Percentage of parents of children under age 13 who agree or completely agree with various statements about family conflict and various resolution styles: 1997	141
Table P9.1 Degree of closeness child feels to parent: 1996	142

Table P10.1 Percentage of parents of children under age 13 who treated their children with various forms of warmth and affection every day in the past month: 1997	143
Table P11.1 Percentage of parents who had open disagreements with their child age 12 to 18 in the last 12 months about his or her friends, by frequency of disagreement: 1988.....	144
Table P11.2 Percentage of parents who had open disagreements with their child age 12 to 18 in the last 12 months about how late children stay out at night, by frequency of disagreement: 1988	145
Table P12.1 Percentage of parents who reported ever physically abusing their child: 1995	146
Table P13.1 Percentage of children ages 0 to 5 whose father is the primary care provider while mother is working, looking for work, or attending school: 1996	147
Table P14.1 Average daily time in hours children under age 13 are engaged in some activity with parents: 1997	148
Table P15.1 Percentage of parents who engaged in the following activities with their child(ren) at least once a week: 1997	149
Table P16.1 Percentage of children who report having gone to a church-related event with their parent in the last 4 weeks: 1996.....	150
Table P17.1 Percentage of parents with high involvement at their child's school (participation in three or four activities): 1996 & 1999.....	151
Table P18.1 Mean number of days in a typical week parents report the following school encouragement behaviors: 1992	152
Table P19.1 Type of child custody per most recent agreement (in percents): 1994	153
Table P19.2 Type of child custody per most recent agreement (in percents): 1996	154
Table P19.3 Type of child custody per most recent agreement (in percents): 1998	155
Table P20.1 Percentage of children with contact with nonresident parent in the previous year, as reported by resident parent: 1993, 1995, & 1997	156
Table P20.2 Average number of days in the past year child had contact with nonresident parent (among those with any contact), according to resident parent: 1993, 1995, & 1997	157
Table P21.1 Median adjusted income (2000 Dollars) for families with one or more children under age 18 (U.S. Census Bureau)	158
Table P22.1 Characteristics of child support agreements held by resident parents (in percents): 1998.....	159

Table P22.2 Percentage of resident parents with an agreement who received child support payments in the previous year: 1998	160
--	-----

Table P22.3 Mean dollar amounts received in the previous year for families receiving child support payments as reported by resident parent: 1998.....	161
--	-----

Family Formation Data Tables

Table FF1.1 Percentage married among adults ages 18 and older: 1991-2001	164
---	-----

Table FF1.2 Lifetime number of marriages (in percents): 1996	166
---	-----

Table FF2.1 Lifetime number of divorces (in percents): 1990 & 1996.....	167
--	-----

Table FF3.1 Average age at first marriage: 1990 & 1996	168
---	-----

Table FF3.2 Average age at first divorce: 1996	169
---	-----

Table FF4.1 Percentage of respondents by spouse characteristics: 2001	170
--	-----

Table FF5.1 Percentage of adults ages 18 to 65 who agree or strongly agree with the following statements about divorce: 1994.....	172
--	-----

Table FF6.1 Percentage of adults cohabiting: 1991-2001	173
---	-----

Table FF7.1 Average age at first cohabitation: 1988	175
--	-----

Table FF8.1 Percentage of respondents by current partner characteristics: 2001	176
---	-----

Table FF9.1 Percentage of adults ages 18 to 65 who agree or strongly agree that it is all right for a couple to live together without intending to get married: 1994 & 1998.....	178
---	-----

Fertility Data Tables

Table F1.1 Fertility rates for males: selected years: 1980-1999	180
--	-----

Table F1.2 Fertility and birth rates for females: selected years: 1980-1999	181
--	-----

Table F2.1 Percentage of adults ages 18 to 59 who had their first birth at a certain age (among those who have had a live birth): 1992	182
---	-----

Table F3.1 Percentage of adults ages 18 to 59 who have had pregnancies: 1992	183
---	-----

Table F4.1 Percentage of adults ages 18 to 59 who had their first birth before their first marriage: 1992	184
--	-----

Table F5.1 Percentage of adults ages 18 to 59 who had their first sexual intercourse by the specified age: 1992.....	185
---	-----

Table F6.1 Percentage of adults ages 18 to 65 who had two or more sex partners in the last 12 months: selected years: 1988-2000	186
--	-----

Table F7.1 Seriousness of relationship at first sex with current or most recent partner (in percents): 1995.....	188
---	-----

Table F7.2 Length of sexual relationship with first sexual partner (in percents): 1995	190
Table F7.3 Length of sexual relationship with current or most recent partner (in percents): 1995	191
Table F7.4 Race and Hispanic origin of current or most recent sexual partner (in percents): 1995	192
Table F7.5a Current age of current or most recent female partner in past year (in percents), Males: 1988 & 1995	193
Table F7.5b Current age of current or most recent male partner in past year (in percents), Females ages 15-44: 1995	193
Table F8.1 Percentage of adults ages 18 to 65 who had sex two or more times a month during the last 12 months: selected years, 1989-2000	194
Table F9.1 Percentage of adults ages 18 to 59 who used contraceptives at their first sexual intercourse: 1992	195
Table F9.2 Percentage of adults ages 18 to 59 who used some form of contraception during their most recent intercourse: 1992	196
Table F10.1 Percentage of adults ages 18 to 65 who think it should be possible for a pregnant woman to obtain a legal abortion under six different reasons: selected years, 1980-2000	197
Table F10.2 Percentage of adults ages 18 to 65 who think it should be possible for a pregnant woman to obtain a legal abortion if the woman wants it for any reason: selected years, 1980 – 2000	198
Table F11.1 Percentage of adults ages 18 to 59 who have ever had an abortion: 1992	200

Executive Summary

The great majority of Americans will become parents at some point in their lives. The statistics presented in this volume suggest that for the vast majority of parents, raising children is a central focus of their lives.

But how much do we know about the experience of parenting in America today, about the decisions and actions of fathers and mothers, even about the planning (or lack thereof) that precedes conception and childbearing? Where previous efforts have focused largely on the experiences of women and mothers, *Charting Parenthood* greatly expands our understanding in these areas by bringing men systematically into the picture and offering the best available data that include both men and women, fathers and mothers, for more than 40 indicators of parenting, fertility, and family formation. When men and women are both considered we find that, in some critical areas, their views and experiences diverge, while in other areas there is surprising agreement.

The data also provide important insights into the value men place on family life and childrearing, and on the multiple contributions that fathers can make to the lives of children. These insights suggest that many men have a deep commitment to raising children in the context of marriage, and that substantial percentages of fathers are deeply and regularly involved in play, discipline, and primary caregiving. For example:

- Most fathers who live with their children participate regularly in some kind of leisure or play activity with them. While mothers are more likely to do “quiet” activities (reading a book or doing a puzzle, for example), fathers are more likely to play an outdoor game or sports activity. Very high levels of both fathers and mothers report talking at least once a week with their children about their family.
- Substantial percentages of fathers who live with their children are engaged in monitoring their children’s daily activities and in setting limits on these activities. For example, 61 percent set limits on what television programs their children are allowed to watch.
- Men are much more likely than women to believe that two parents are more effective at raising children than one parent alone.
- More than one in five young children in two-parent families have their father as the primary caregiver when the mother is at work, attending school, or looking for work.
- While 40 percent of children whose fathers live outside the home have no contact with them, the other 60 percent had contact an average of 69 days in the last year.

We highlight below some of the key findings in each of the three major sections of this volume: parenting, family formation, and fertility. Unless otherwise specified in this summary, “parents” refers to mothers or fathers that live with their children.

Parenting

The Value of Raising Children. Americans place great personal value on raising children. Most adults, whether or not they are parents, believe that watching children grow up is life’s greatest joy (78 percent of men and 83 percent of women in 1994).

Parental Warmth and Affection. Very high percentages of parents reported showing their children frequent warmth and affection, with 87 percent of mothers and 73 percent of fathers reporting that they hugged their children or showed them physical affection at least once a day. Similarly high percentages reported telling their children daily that they love them.

Time and Activities With Children. The vast majority of mothers and fathers report sharing responsibility with each other for playing with their children, with mothers less likely than fathers to report that playing was a shared responsibility. There are, however, domains in which mothers and fathers tend to lead. Mothers are more likely to engage children in activities like board games, puzzles, and looking at books; while fathers are more likely to play sports or do outdoor activities with children. Mothers are also more likely to be highly involved in their children’s schools, perhaps reflecting different employment patterns and work hours between

mothers and fathers. Adolescents also report that they are more likely to attend a religious observance with their mother than their father.

Setting Limits and Administering Discipline. Both mothers and fathers are substantially involved in setting limits for their children in various areas, with mothers somewhat more likely than fathers to report setting limits for their children on how much television they can watch (48 percent of mothers and 40 percent of fathers); on what programs they can watch (71 percent of mothers and 61 percent of fathers); and on who their children can spend time with (51 percent of mothers and 40 percent of fathers). The vast majority of mothers and fathers report sharing responsibility with each other for disciplining children, with mothers less likely than fathers to report that discipline was a shared responsibility.

Daily Time With Children. Children generally spend more time with their mothers than their fathers on any given day, possibly reflecting higher levels of employment among fathers than mothers. In two-parent families, this time difference is not terribly large: children ages 12 and under spend on average 2 hours and 21 minutes a day with their mothers, compared to 1 hour and 46 minutes with their fathers. In single-parent families, in contrast, children spend about one and a quarter hours a day with their mothers, compared to less than half an hour with their fathers, presumably reflecting the fact that more children in such families live with single mothers than fathers.

One Parent Versus Two. Men and women differ on whether one parent can bring up a child as well as two parents together. In 1994, 42 percent of women agreed that one parent can bring up a child just as effectively as two parents together, compared to just 26 percent of men. Interestingly, mothers and fathers were about as likely as nonparents to agree, though in neither case did a majority believe that one parent could bring up a child as effectively as two parents together. As public debate continues on issues related to single parenthood, it would be both interesting and helpful to obtain more recent data on this question.

Primary Care by Fathers. In 1996, almost one in five children ages birth to five (18 percent) had their fathers as their primary caregivers while their mothers were working, attending school, or looking for work. Such father care was more common for children in two-parent families than for those raised by a single mothers. The likelihood that a father provided primary care also varied by the father's educational level, with college-educated fathers much less likely to provide such care.

Physical Abuse of Children. A small proportion of parents *self-report* ever having physically abused their children, defined as having hit the child with a fist or kicked the child, thrown the child or knocked them down, choked or burned the child, or used a knife or gun against the child (6 percent of mothers and 3 percent of fathers).

Contact with Nonresident Parent. Most children with a parent who lives apart from them have at least some contact with that parent: 60 percent had contact with a nonresident father and 78 percent had contact with a nonresident mother in 1997. These children were in contact an average of 69 days with their fathers and 86 days with their mothers over the course of a year.

Family Formation

Marriage. The percentage of men and women who are married declined modestly between 1991 and 2001. This trend was also evident among parents: 92 percent of resident fathers were married in 1991, compared to 88 percent in 2001; 75 percent of resident mothers were married in 1991, compared to 72 percent in 2001.

Poor men and women were the least likely of any income group to be married, with the proportion married increasing as income increases. For example, 41 percent of poor men were married in 2001, compared to 66 percent of men with incomes at three or more times the poverty level. The marriage gap was even wider for women. Only about one in every three poor women is married, while about two of every three women with incomes at three or more times the poverty are married. This difference undoubtedly reflects both the more advantaged backgrounds of those who marry, and the advantages of having multiple earners in the family that marriage can bring. The percentage of poor men and women who are married has also been declining over the decade.

Divorce. The vast majority of men and women who were married in 1996 had never been divorced (81 percent of men and 82 percent of women). Between 1990 and 1996, the percentage of ever-married adults who divorced remained about the same among men and declined modestly for women. The likelihood of divorce among ever-married men differs little by poverty status. Among ever-married women, however, poor women are much more likely to have been divorced than more affluent women.

About half of all men and women agreed with the statement that “divorce is usually the best solution when a couple can’t seem to work out their marriage problems.” Only 20 percent of men and 12 percent of women thought that parents who don’t get along should stay together when there are children in the family. Women’s views on this question did not vary according to whether or not they were married or had children. In contrast, fathers were more likely than men who were childless to think parents should stay together for the children’s sake.

Cohabitation. While marriage has declined slightly, cohabitation has increased. Eleven percent of unmarried men cohabited in 1991, rising to 13 percent in 2001. During the same period, the percentage of unmarried women who were cohabiting increased from 8 percent to 11 percent. Cohabitation is more common among poor men and women, declining markedly at higher income levels. Overall, 40 percent of all cohabiting relationships involve parents with children in the home.

Fertility

Birth Rates. Overall, birth rates among men and women have declined modestly since 1980. However, this modest decline was not consistent across age groups. Between 1980 and 1999, birth rates among men and women at older ages (ages 30 and older) have increased, while birth rates among female teens have declined.

Age at First Birth. One in three females had their first birth in their teens, with females three times as likely to be teen parents than males (33 percent compared to 11 percent in 1992). In contrast, almost half of males reported that their first birth occurred after age 25, compared to one-quarter of females.

Premarital Births. The percentage of adults ages 18 to 59 who had a premarital birth prior to their first marriage is slightly higher among women than men: 19 percent compared to 15 percent in 1992 (the most recent year for which data are available for both men and women). This gender gap is much wider for younger adults. Women ages 18 through 24 are more than five times as likely as men in the same age group to have a premarital birth (21 percent compared to 4 percent). In general, poor adults were more likely than other adults to have had a premarital birth.

Age at First Sexual Intercourse. Among adults ages 18 to 59 in 1992, 55 percent of men and 43 percent of women reported having their first sexual intercourse before age 18. (These percentages may well have changed in ensuing years.) Age at first sex varies tremendously by education. Women college graduates are much less likely to report having had sex before age 18 than women without a high school education (21 percent compared to 67 percent). The gap for men is similar, though less dramatic – 39 percent and 64 percent.

Contraceptive Use. Younger adults are more likely than older adults to report using any method of contraception at first sex, indicating that contraceptive use at first sex has increased over time. For both males and females, contraceptive use at first sex increases with educational attainment.

Conclusion

This pathbreaking report brings together important information on fathers and mothers, including many new analyses produced specifically for the report. While available data leave important gaps in our understanding of these issues, federal statistical agencies are making important efforts to fill many of those gaps. Even with current limitations, however, the report extends our understanding of fatherhood in particular and parenting as a whole, and provides a hint of what might be accomplished in the future.

Introduction

Until quite recently, men and fathers were largely missing from statistical portraits of families. Research and data on parenting, fertility, and family formation has focused primarily on women and mothers. In the last several years, however, researchers, policy makers, advocates for fathers, and federal agencies have led the charge for more and better information on the male role in fertility, parenting, and family formation. The result has been several recent ground-breaking efforts, including the production of this report. It provides the public with the first comprehensive portrait of mothers and fathers in America, offering a systematic comparison that will increase our understanding of and appreciation for the contributions of both parents to the raising of our children.

The report draws on thirteen federal and privately collected national surveys to present information on more than 40 measures of parenting, family formation, and fertility in a format that is accessible to broad audiences. It is intended to provide a factual foundation to improve public understanding and policymaking in each of these areas, and to inform federal agencies as they work to improve the breadth, timeliness, and quality of data on fathers and mothers.

The report was produced by Child Trends, a non-partisan, non-profit research organization dedicated to improving the lives of children and youth through better research and improved data collection. The report benefited greatly from the support of the Federal Interagency Forum on Child and Family Statistics (the Forum), whose member agencies provided some data for the report and carefully reviewed relevant sections. The Forum, formally established in 1997 to foster coordination and collaboration in the collection and reporting of Federal data on children and families, includes 20 federal statistical agencies.

History of the Report

Beginning in 1996 the Forum worked in collaboration with private foundations, including the Ford Foundation, and leading researchers and research centers, sponsoring a year-long series of related conferences and meetings to review current approaches to gathering information on fathers and to explore new ways of conceptualizing, measuring and collecting data about fatherhood and male fertility. Products from these activities included a series of widely disseminated synthesis reports and a comprehensive final report published in March 1998, titled *Nurturing Fatherhood: Improving Data and Research on Family Formation and Fatherhood*.

The *Nurturing Fatherhood* report included ten recommendations or “targets of opportunity” for increasing our understanding of male fertility, family formation and fathering, all of which were endorsed by the Forum in February 1998. The second of these ten recommendations was:

To publish a baseline fatherhood indicators report that includes information on male fertility, family formation and fathering.

Child Trends and members of the Forum’s Data Collection Committee began work to identify what data were available for such a report, and to assess data quality. Key measures to include in the report were chosen through a consultative process involving members of the NICHD Family and Child Well-Being Research Network (the Network), Child Trends, and members of the Forum. This initial work was supported with funding from the Network and the National Center for Education Statistics.

In 1999 Child Trends was awarded a grant from the Ford Foundation to produce this report. Additional funding and in-kind support was provided by the Forum, the NICHD Family and Child Research Network, the Annie E. Casey Foundation, the David and Lucile Packard Foundation, and the Administration for Children and Families of the U.S. Department of Health and Human Services.

Overview of the Report

The report presents information on more than 40 indicators in three broad areas: parenting, family formation, and fertility. Each indicator consists of about a page of text beginning with a brief discussion of its importance

based on current research, followed by a review of basic trends and population subgroup differences. The text is supported by one or two data figures. More detailed data are presented in tables in the Appendices.

Topics related directly to parenting include attitudes about parenting, parenting practices, qualities of the parent/child relationship, activities with children, child care, parents and schools, and income. Custody arrangements and activities between children and nonresident parents are also covered. The family formation section looks at marriage, divorce and cohabitation experience and attitudes, and at the characteristics of partners. The fertility section includes pregnancy and birth-related outcomes, sexual activity, and contraception.

While the report grew out of a project to portray data about fathers, contributors understood that such information would be more useful in the context of data about mothers as well. The intent of the project was to ensure that both mothers and fathers were brought fully into the parenting picture.

Looking to the Future

This report is one expression of an ongoing joint effort by private organizations and federal statistical agencies to improve our understanding of fatherhood, and to improve our ability to measure and track key aspects of the parenting, fertility, and family formation experiences of both sexes. Several ongoing efforts are worth mentioning.

Members of the Forum recently held a “Counting Couples” conference to address how federal statistical agencies could improve the way they measure family structure in their surveys and administrative data sources. A report from that conference is scheduled for release at the same time as this report.

Several federal agencies are already making significant changes in their data collection efforts in order to collect additional information on men and fathers. For example, the National Survey of Family Growth (NSFG), which is repeated about every 6 years, is the nation’s premier survey for studying the dynamics of fertility and family formation. Historically the survey has been limited to females. This year, the National Center for Health Statistics, which oversees the survey, is interviewing males as well. They are gathering detailed information on men’s fertility history (birth, pregnancies, abortion), sexual activity and contraception, characteristics of current partner, and a variety of parenting activities such as feeding, bathing, diapering, and playing with infants; eating meals together, going to religious services and outings, and helping with homework. This expansion of the NSFG to men, which was funded by a number of agencies within the Forum, represents a major advance in the collection of data on fathers, and should substantially enrich our understanding of fatherhood. If it is sustained in subsequent rounds of the survey, it will allow us to track changes in fathering and male fertility over time and on a regular basis.

The National Center for Education Statistics has also made a substantial effort to collect new data on fathering in the design of its Early Childhood Longitudinal Study-Birth Cohort. In addition to information obtained from the mother, residential fathers are asked questions about their involvement with the baby. Nonresidential fathers who are in regular contact with the baby are also being given a short questionnaire to complete. Questions on father involvement are also being collected in the 1997 cohort of the National Longitudinal Survey of Youth, a major survey funded by several agencies within the Forum.

Over the last five years, the public/private partnerships that have formed around the topic of fatherhood have borne substantial fruit in the form of new research, expanded data collection, and innovative dissemination. Collecting the necessary data is not an inexpensive proposition, however. To secure recent advances and implement further improvements, additional financial resources are required. We believe that this report, and the other efforts described here, demonstrate the value of such an investment for the public and for better policy. They also demonstrate the potential for continued public/private partnerships in this area.

Who is a Parent?

Who is a parent? This answer is not as obvious as one might think. Definitions of parenthood can include genetic, legal, and practical criteria. Throughout this report we do not use any single definition of parenthood. For this indicator, however, we define parenthood in two ways: genetically (have you ever had a biological child), and practically (are you living with your own child under age 18, regardless of the type of relationship). Both measures have their limitations: the genetic definition does not say anything about the current relationship, and is doubtless under-reported for men; the practical definition adopted here leaves out nonresident parents of minor children, an important group. Together, however, they give us a good starting point for the report.

Estimates for the percentage of adults ages 18 and older who have ever had a biological child come from the 2000 National Health Interview Survey (refer to *Who is a Parent?* Table 1). Estimates of the proportion of adults ages 18 and older who are living with one or more of their own children (under age 18) come from the March 2001 Current Population Survey (refer to *Who is a Parent?* Table 2).

Figure 1 Percentage of adults ages 18 and older who have ever had a biological child: 2000

SOURCE: National Health Interview Survey, 2000

By Gender. In 2000 nearly three quarters (74 percent) of all women age 18 and older reported having had at least one biological child in their lifetime, compared to 65 percent among men. Interestingly, this gender gap gets smaller with age, practically disappearing among those ages 45 and older (84 percent for men and 86 percent for women, see Figure 1).

Women are also more likely than men to report living with one or more of their own children under age 18 (45 percent compared to 38 percent in 2001).

By Race and Hispanic Origin. Hispanic women report the highest rates of ever having had a child (79 percent), followed by black, non-Hispanics (76 percent); white, non-Hispanics (74 percent); and other (mostly Asian) non-Hispanics (70 percent). The same pattern exists for men, though the differences are even smaller and generally not statistically significant.

Among males, Hispanics and Asian or Pacific Islanders are most likely to report living with their own children (47 percent and 45 percent, respectively), followed by non-Hispanic, white; non-Hispanic, blacks; and American Indian and Alaskan Natives (at 37, 34, and 36 percent, respectively). Among females, Hispanics are the most likely to live with their own children (61 percent) followed by Asian or Pacific Islanders, non-Hispanic blacks, and American Indians (53, 51, and 50 percent). Non-Hispanic white females were the least likely to report living with their own minor children at 41 percent.

By Marital Status. Married adults are much more likely than single adults to be living with their own minor children, though the percentages differ substantially by gender. Among those who are not married, 11 percent of men and 29 percent of females live with their own child. Among those who are married, 54 percent of men and 56 percent

of women live with at least one of their own children.

By Educational Attainment. Men who have graduated from college are more likely to live with one or more of their own children than those who did not graduate from high school (42 percent compared to 33 percent). Women are about equally likely to be living with their own children regardless of education level, with values ranging from 44 percent to 46 percent across education levels.

The patterns are quite different when the measure is whether one has ever had a child. Among women, more education is associated with a lower likelihood of having had a child; 62 percent among college graduates compared to 85 percent for those with less than a high school degree. Among men, rates range from 60 percent to 69 percent, with the lowest rates among those with some college.

Parenting Section

P1 – Importance of Becoming a Parent

By the age of 35, it has been estimated that eighty-three percent of adults in the U.S. will be the parent of a child.^{1,2} Research indicates that the proportion of women that expect to be permanently childless remains low, and the proportion voluntarily childless even lower.^{3,4}

Attitudes about becoming a parent can change over time, and are not perfect predictors of future behavior. One study reports that a quarter of women who were “very sure” that they did not want to have children changed their minds over just two years.⁵ Still, adults’ attitudes about the importance of becoming a parent provide insight into how critical being a parent is to feeling fulfilled as an adult.

In order to assess the attitudes of adults concerning the importance of having children, two questions from the General Social Survey (GSS) are examined. Adult respondents were asked to report how much they agreed with the following two statements: 1) “People who have never had children lead empty lives;” and 2) “A marriage without children is not fully complete.” The first item was measured in 1988 and 1994, while the second was only measured in 1988 (refer to Table P1.1 and P1.2).

Attitudes About The Fulfillment Of Having Children

By Gender. Males and females were just as likely to agree or strongly agree that people who never have children lead empty lives, although the overall percentage is low (about one-fifth of the total male and female respondents in 1994). The percentage of women in this category dropped from 28 to 18 percent between 1988 and 1994.

By Parental Status. Not surprisingly, parents of both sexes were significantly more likely than nonparents to believe that people who have never had children lead empty lives (28 percent compared to 9 percent among males, and 21 percent compared to 9 percent among females).

By Age. Those ages 45 and over were significantly more likely than younger adults to agree or strongly agree that people who have never had children lead empty lives. For males in 1994, 11 percent of respondents ages 18 to 24, 16 percent of the respondents ages 25 to 44, and 29 percent of respondents ages 45 and older agreed or strongly agreed. Among females the percentages were 15, 11, and 25 percent, respectively.

By Educational Attainment. Respondents with less than a high school education place greater emphasis on the importance of having a child than those with higher levels of educational attainment (see Figure P1.1). In 1994, 41 percent of males and 38 percent of females with less than a high school education agreed or strongly agreed that people who never have children lead empty lives as compared to 13 percent of males and 7 percent of females with a college degree.

By Employment Status. Males and females who are not in the labor force are considerably more likely than others to feel that those without children lead empty lives. For example, among males in 1994 the percentage ranged from 33 percent among those not in the labor force to 19 percent for those working 35 or more hours per week.

Attitudes About The Fulfillment of Having Children in a Marriage

By Gender. Almost one-half of all respondents in 1988 agreed or strongly agreed that a marriage without children is not fully complete. There was no significant difference between males and females. In fact, with few exceptions there was no substantial difference between men and women in any population category on this issue.

By Marital Status. Married men were more likely (49 percent) than nonmarried men (38 percent) to agree or strongly agree that a marriage without children was not complete; however, no significant difference was noted for women.

By Parental Status. Parents were substantially more likely than nonparent respondents to agree or strongly agree that a marriage without children is not fully complete (52 percent compared to 28 percent among males and 49 percent compared to 30 percent among females).

By Age. Adults ages 45 and over were more likely than younger respondents to believe that a marriage without children is not fully complete. For males, 35 percent of respondents ages 18 to 24, 33 percent of the respondents ages 25 to 44, and 59 percent of respondents ages 45 and older agreed or strongly

agreed. Among females, the numbers were 41, 35, and 55 percent, respectively.

By Educational Attainment. Substantial differences were also found by education level. For males in 1988, 53 percent of respondents with less than a high school education agreed or strongly agreed with the statement as compared to 45 percent of those with a high school diploma or equivalent and only 33 percent of college graduates. The same pattern emerges for females with 56, 44, and 34 percent, respectively.

By Employment Status. Adults who were not in the labor force were significantly more likely to agree or strongly agree that a marriage without children is not fully complete compared to their counterparts who worked more than 35 hours per week. In 1988, 55 percent of men and 53 percent of women who were not in the labor force agreed or strongly agreed with this statement as compared to 38 percent of men and 37 percent of women who worked 35 hours or more per week.

Figure P1.1 Percentage of respondents who agree or strongly agree that people who have never had children lead empty lives, by level of educational attainment: 1994

SOURCE: General Social Survey, 1994

P2 – Adult Attitudes About the Value of Children

Parents' attitudes about children's worth and importance play a large role in shaping the ways in which they interact with their children and the types of expectations that they set for them.^{6,7} Research suggests that the different styles of valuing children that parents adopt are often related to parents' desired outcomes for their children. For instance, parents that value children for their economic utility tend to seek obedience from them, and more educated parents tend to encourage their children toward finding good jobs in adolescence and adulthood. In contrast, children valued for their love and companionship tend to have parents who are seeking pleasant and sociable children. Across these different styles, children who are valued more tend to be less likely to end up the victims of maltreatment⁸ or verbal abuse.⁹

More broadly, the degree to which adults value children highly has implications for public policy and social programs aimed at the welfare of children. A society that places great emphasis on children and their development is more likely to make the social investments critical to children's well-being.

In order to assess the attitudes of adults concerning the value of children, two questions from the General Social Survey (GSS) are examined. Adult respondents were asked to report how much they agreed with the following two statements: 1) "watching children grow up is life's greatest joy;" and 2) "it is better not to have children because they are such a heavy financial burden." The first item was measured in both 1988 and 1994, while the second was only measured in 1988 (refer to Table P2.1 and P2.2).

Attitudes about the Joys of Watching Children Grow Up

By Gender. The overwhelming majority of adults agreed or strongly agreed with the statement that "watching children grow up is life's greatest joy." There was a modest decline between 1988 and 1994, however, from 84 to 78 percent among males, and from 88 to 83 percent among females. In both years a greater percentage of females than males endorsed this statement (see Figure P2.1).

Figure P2.1. Percentage of men and women who agree or strongly agree that watching children grow up is life's greatest joy: 1988 and 1994

SOURCE: General Social Survey, 1988 and 1994

By Parental Status. Parents of both genders are considerably more likely than nonparents to believe that watching children grow up is life's greatest joy. In 1994, 87 percent of fathers compared to 62 percent of nonfathers agreed or strongly agreed with this statement. The results were similar among women.

By Educational Attainment. As educational attainment increases, adults are generally less likely to agree with the statement that "watching children grow up is life's greatest joy." In 1994, 94 percent of women with less than a high school education agreed or strongly agreed compared to only 62 percent of women who were college graduates. The percentages for men were 87 and 71 percent, respectively.

Attitudes about Whether It Is Better Not To Have Children Because They Are Such A Heavy Financial Burden

By Gender. In general, adults do not tend to think that children are such a heavy financial burden that they would refrain from having them. In 1988, only 5 percent of men and 4 percent of women agreed or strongly agreed with the statement that "it is better not to have children because they are such a heavy financial burden."

By Educational Attainment. Men and women with less than a high school education are more likely than are college graduates to agree or strongly agree that it is better not to have children

because they are such a heavy financial burden. In 1988, 16 percent of men and 7 percent of women with less than a high school education agreed or strongly agreed with the statement, compared to 2 percent of men and 2 percent of women who were college graduates.

P3 – Parents: Can One Be as Good as Two?

The number of children living in households with two biological parents has been steadily declining over the past two decades and has only recently begun to level off.^{10,11} Although the majority of single parents are mothers,¹² in recent years the number of single-father families has increased, accounting for 18 percent of all single parent families with children under age 18 in 1998.¹³ There are several possible routes – both voluntary and involuntary – to single parenthood including getting a divorce, becoming a widow or widower, and being an unmarried parent. Regardless of the reason, most researchers agree that the fewer economic resources that single parents are able to offer and subsequent time restraints of single parenting place children raised in single-parent homes at a disadvantage.^{14,15,16} Children raised by single parents have lower levels of social and academic well-being^{17,18} and more behavior problems¹⁹ than those from intact families. In addition, McLanahan and Sandefur (1994, p. 1) report that “...adolescents who have lived apart from one of their parents during some period of childhood are twice as likely to drop out of high school, twice as likely to have a child before age twenty, and one and a half times as likely to be ‘idle’ – out of school or out of work – in their late teens and early twenties.”²⁰ It is important to note however, that the absolute differences between children with one parent and children with two biological parents are moderate to small.²¹

In order to assess the attitudes of adults concerning single parenting, one question from the General Social Survey (GSS) is examined. Adult respondents were asked to report how much they agreed with the following statement – “One parent can bring up a child as well as two parents together.” The question was asked in 1994 only (refer to Table P3.1).

By Gender. Women were significantly more likely than men to agree or strongly agree that one parent can bring up a child as well as two parents together, 42 percent of women compared to 26 percent of men (see Figure P3.1).

Figure P3.1 Percentage of adults who agree or strongly agree that one parent can bring up a child as well as two parents together, by gender: 1994

SOURCE: General Social Survey, 1994

By Race and Hispanic Origin. Differences among men by race and Hispanic origin were comparatively modest, ranging between 25 and 35 percent. Among women, however, non-Hispanic whites were far less likely than other groups to believe that one parent can bring up a child as well as two parents together. In 1994, only 38 percent of white, non-Hispanic women agreed as compared to 64 percent of black, non-Hispanic, 61 percent

for Hispanic women, and 58 percent for American Indian/Alaskan Native women.

By Parental Status. Interestingly, parents were about as likely as nonparents to believe that one parent can be just as effective as two in raising a child. However, female parents were significantly more likely than male parents to believe this (44 percent compared to 25 percent).

By Age. Adults ages 45 and older were less likely than younger adults to believe that one parent can be just as effective in raising a child as two parents. Among women in 1994, 32 percent ages 45 and older agreed or strongly agreed with this compared to 66 percent of those ages 18 to 24. For men, the numbers were 18 percent and 34 percent for the respective age groups.

By Employment Status. Differences across employment categories were more pronounced among women than men. Estimates for men across employment categories ranged between 22 and 32 percent. Among females, however, those who were not in the labor force were substantially less likely than those in all other employment categories to believe that one parent can bring up a child as well as two parents together. In 1994, 35 percent of females not in the labor force believed that one parent can be as effective as two in raising a child as compared to 66 percent of those looking for work, 51 percent of those working less than 35 hours a week, and 45 percent of those working 35 or more hours per week.

P4 – Parents' Beliefs About Raising Children

The types of values that parents seek to instill in their children provide the foundation and direction for their moral and ethical growth. Contemporary research suggests that the development of children's moral sense is contingent upon many factors including experiences with parents and peers and wider cultural influences.²² Research examining family interactions indicates that children achieve more advanced levels of moral reasoning when their parents engage them in rational styles of discourse.²³ Evidence suggests that parental modeling plays a key role in the formation of prosocial behaviors, such as volunteering and charitable giving,²⁴ and that such influence is well underway by the age of 30 months²⁵.

Five items from the Panel Study of Income Dynamics - Child Development Supplement (PSID-CDS) are examined to assess the sorts of values parents would like to see instilled in their children. Parents were asked to report which of five qualities (i.e., obedience, popularity, independence, hard worker, helper) they thought was the most important quality for their child (under age 13) to learn to prepare him or her for life. These items were all asked in 1997 (refer to Table P4.1).

Figure P4.1 Qualities that fathers think are most important for their child (under age 13) to learn, by race of father: 1997

SOURCE: Panel of Study of Income Dynamics – Child Development Supplement, 1997

By Gender. Mothers and fathers both thought that the most important quality for their child to learn to prepare him or her for life is the ability to think for oneself. Fifty-nine percent of mothers and 52 percent of fathers thought that this was the most important quality for their child to learn. The second most important quality ranked by mothers (17 percent) and fathers (21 percent) was obedience, followed by working hard, helping others in need and, finally, being liked.

By Race and Hispanic Origin. While thinking for oneself was most highly prized among white and black, non-Hispanic parents, obedience was considered most important by Hispanic parents. Among fathers, 59 percent of white, non-Hispanics, 40 percent of black, non-Hispanics, but only 18 percent of Hispanics reported thinking for oneself as the most important quality for their child to learn. Fifty percent of Hispanic fathers report that obedience is the most important quality,

compared to 16 percent of white, non-Hispanic and 28 percent of black, non-Hispanic fathers (see Figure P4.1). The same pattern is seen with mothers. Sixty-eight percent of white, non-Hispanic mothers and 41 percent of black, non-Hispanic mothers report that thinking for oneself is the most important quality that their child can learn, compared to 29 percent of Hispanic mothers. Forty-three percent of Hispanic mothers favored obedience as the most important quality compared to 31 percent of black, non-Hispanic and 10 percent of white, non-Hispanic mothers (see Figure P4.2).

By Poverty Status. Nonpoor mothers and fathers were more likely than poor parents to endorse thinking for oneself as the most important quality for their child to learn, while poor parents were more likely to report obedience as the most important quality.

By Educational Attainment. As parental education level rises, the appreciation for thinking for oneself goes steadily up, while the relative importance of obedience decreases. Seventy-four percent of mothers with a college degree but only 35 percent of mothers with less than a high school education ranked thinking for oneself as the most important quality their child can learn. This can be contrasted with the fact that 34 percent of mothers with less than a high school education report obedience as the most important quality for their child to learn, compared to only 8 percent of mothers with a college degree. A similar pattern exists among fathers.

By Age. Parents under 25 years of age are significantly less likely than parents who are older to report that thinking for oneself is the most important quality that their child can learn. Thirty six percent of fathers and 37 percent of mothers under age 25 report that thinking for oneself is the most important quality, compared to 61 percent of fathers and 67 mothers who are ages 45 and older. The fact that young parents are more likely to have very young children may account in part for these differences.

Figure P4.2 Qualities that mothers think are most important for their child (under age 13) to learn, by race of mother: 1997

SOURCE: Panel of Study of Income Dynamics – Child Development Supplement, 1997

P5 – Adults' Attitudes Toward Spanking

One of the most frequently used strategies to discipline a child, especially a younger child, is spanking.²⁶ Research suggests that about 90 percent of parents in the United States report having spanked their children.²⁷ At the same time, however, use of corporal punishment is often linked to negative outcomes for children (e.g., delinquency, antisocial behavior, and low self-esteem), and may be indicative of ineffective parenting.^{28, 29} Positive child outcomes can be obtained when parents refrain from spanking and other physical punishment and alternatively discipline their children through firm, rational control and nurturing communication.³⁰ Studies show that this type of disciplinary style may foster positive psychological outcomes such as high self-esteem and cooperation with others, as well as improved achievement in school.³¹

The type of discipline employed is often influenced by both the age and the reasoning ability of the child.³² For example, younger children may have greater difficulty responding to rational communicative discipline, whereas older children may respond more readily to firm and nurturing communication. For younger children, an alternative strategy may be to redirect the child's attention, rather than use rational communication or spanking.

In order to assess the attitudes of adults about spanking a child, a question from the General Social Survey is examined. Adults were asked to report the degree to which they agreed or disagreed that it is sometimes necessary to discipline a child with a good, hard spanking. These items were all asked in 1986 and 1988 through 2000 (refer to Table P5.1).

By Gender. In the period between 1986 and 2000, the percentage of men who agreed that it is sometimes necessary to spank a child hard varied between 73 and 84 percent, with no clear historical pattern. Women exhibited a similar pattern, with estimates ranging between 69 and 82 percent. Approval of spanking was at its highest in 1986 for both sexes. In general, men are more likely than women to agree that sometimes it is necessary to spank a child. For example, in 2000, 79 percent of men agreed that spanking a child is sometimes necessary, compared to 71 percent of women.

By Educational Attainment. Adults who are college graduates were less likely than parents without a high school diploma or equivalent to say that spanking a child is sometimes necessary. In 2000, 66 percent of men who were college

graduates agreed that spanking is sometimes necessary compared to 87 percent of men with less than a high school education. Among women, 55 percent of college graduates agreed that it was sometimes necessary to spank a child, compared to 80 percent of those who did not graduate from high school (see Figure P5.1).

By Race and Hispanic Origin. For both men and women, white, non-Hispanic adults are less likely than black, non-Hispanic adults to say that spanking a child is sometimes necessary. For example, in 2000, 87 percent of black men, compared to 79 percent of white men, agreed that a child sometimes needs a good hard spanking. In 2000, black men were also more likely than Hispanic men (69 percent) to agree that spanking a child was sometimes necessary.

Figure P5.1 Percentage of men and women who agree that it is sometimes necessary to give a child a good hard spanking, by educational attainment: 2000

SOURCE: General Social Survey, 2000

P6 – Parents' Responsibility for Children

Mothers and fathers often assume different roles with regard to their children. Researchers find that fathers are more likely to assume a greater role in play activities with young children, while mothers generally assume the role of primary caretaker.^{33,34} Despite these differences, both parents have a significant effect on children's development.³⁵ It is through the gradual developmental process of interpreting, transforming, and evaluating the norms of their parents that children acquire their own moral values.³⁶ Similarly, parental input and involvement in choosing and engaging in their child's school is crucial. Children with involved parents are more likely to have positive educational outcomes, higher aspirations, and increased graduation rates.³⁷ Father involvement, particularly involvement in their children's school activities, is associated with decreases in problem behaviors (e.g., drug use, delinquency) among their children.³⁸

The responsibilities of parents for their children were assessed by examining three questions from the Panel Study of Income Dynamics – Child Development Supplement (PSID-CDS). Parents were asked if they shared, performed alone, or if someone else performed three responsibilities for their children (under age 13): 1) playing with their children; 2) disciplining their children; and 3) selecting a child care program, preschool, or school for their children (refer to Table P6.1, P6.2, and P6.3). These items were all asked in 1997.

By Gender. The majority of mothers and fathers reported that they shared responsibility for playing with their children (77 and 91 percent, respectively), and for discipline (70 and 89 percent). When it came to selecting a child care program, preschool, or school, however, only 38 percent of mothers and 60 percent of fathers reported sharing responsibility. Sixty percent of mothers reported sole responsibility for this activity, compared to 7 percent of fathers (see Figure P6.1 and P6.2).

By Race and Hispanic Origin. White, non-Hispanic mothers were more likely to report sharing responsibility for playing with their child, disciplining them, or choosing their care or school than were Hispanic or black, non-Hispanic

mothers. Among fathers, Hispanics were more likely than white, non-Hispanic or black, non-Hispanic fathers to report having sole responsibility for taking care of these three sorts of activities with their children.

By Poverty Status. Poor mothers and fathers were more likely than nonpoor parents to report sole responsibility for playing with their children, disciplining them, and choosing their care program or school (refer to Table P6.1, P6.2, and P6.3). For example, 55 percent of poor mothers reported sole responsibility for disciplining their children compared to 22 percent of nonpoor mothers. The difference among fathers is less pronounced (18 percent compared to 7 percent).

Figure P6.1 Parental responsibility for playing with and disciplining their children, and for choosing a child care, preschool, or school according to fathers of children under age 13: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

Figure P6.2 Parental responsibility for playing with and disciplining their children, and for choosing a child care, preschool, or school according to mothers of children under age 13: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

By Educational Attainment. Mothers and fathers with less than a high school education are more likely than more educated parents to report having sole responsibility for play, discipline, and choosing a school or child care provider. For example, 42 percent of mothers and 21 percent of fathers with less than a high school education reported sole responsibility for disciplining their children, compared to 15 percent of mothers and 4 percent of fathers who had graduated from college.

By Employment Status. Patterns of responsibility are similar for working mothers and mothers who are not in the labor force. About three quarters of mothers in both categories report sharing responsibility for discipline, eight in ten share responsibility for play, and four in ten share responsibility for choosing a child care program, preschool, or school. The responsibility of fathers for these activities was only modestly affected by whether the mother worked or not, with fathers slightly more likely to share responsibility for discipline and play when the mother worked.

P7 – Limit Setting

Setting guidelines or rules for children teaches them the difference between right and wrong and clarifies what sorts of behavior are considered acceptable and unacceptable. Thus, limit setting constitutes a critical element in shaping children's judgement, developing conscience, and learning how to understand one's surroundings.³⁹ In addition, it has been found that parenting that combines limit setting and responsiveness to a child's needs (i.e., "authoritative parenting") is associated with positive outcomes for children. Limit setting not only enhances child development, but also increases the likelihood of compliance with parental expectations.^{40,41}

In order to gauge the limit setting patterns of adults, three questions from the Panel Study of Income Dynamics – Child Development Supplement (PSID-CDS) are examined. Parents of children ages 3 to 12 were asked to report how often they: 1) set limits on the time their children can watch TV in a day; 2) set limits on what television programs their children watch; and 3) control who their children spend time with (refer to Table P7.1). These items were all asked in 1997.

Figure P7.1 Percentage of fathers and mothers of children ages 3 to 12 who (often or very often) set limits on who their children spend time with, by race and Hispanic origin: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

By Gender. Mothers are somewhat more likely to set all three types of limits for their children than are fathers. For example, in 1997, 48 percent of mothers and 40 percent of fathers set limits often or very often on how many hours of television their children could watch in a day. Seventy one percent of mothers and 61 percent of fathers set limits often or very often on the types of programs their children can watch on television. The same pattern is seen for the percentage of mothers and fathers who regulate their children's interactions with peers. In 1997, 51 percent of mothers and 40 percent of fathers often or very often controlled with whom their children spent time.

By Race and Hispanic Origin. There are considerable differences in patterns of limit setting among mothers and fathers of different racial/ethnic backgrounds. Hispanic fathers (30 percent) are less likely to set limits on what television programs their children watch compared to fathers of other racial/ethnic backgrounds (64, 68, and 65 percent, respectively, for white, black,

and other racial/ethnic groups), while white, non-Hispanic mothers (78 percent) are the most likely to set limits on what television programs their children watch, compared to mothers of other racial/ethnic backgrounds (61, 48, and 58 percent, respectively, for black, Hispanic, and other racial/ethnic groups). Black, non-Hispanic fathers (60 percent) are the most likely and Hispanic fathers (21 percent) are the least likely to set limits on who their children spend time with. Similarly, Hispanic mothers (37 percent) are less likely than other mothers to set limits on who their children spend time with (see Figure P7.1).

By Educational Attainment. Parents who are college graduates are generally more likely than parents without a high school education to set limits for their children. For each of the activities examined, mothers with college degrees were more likely than mothers with less than a high school education to set limits. For instance, while only 56 percent of mothers with less than a high school education often or very often set limits on the types

of television programs their children watch, 80 percent of mothers who are college graduates do so. For fathers, this pattern holds true for the degree to which they set limits on whom their children spend time with and which television programs they allow their children to watch, but not for the amount of time they allow their children to spend watching television.

P8 – Conflict Resolution in Families

Children who are exposed to styles of conflict resolution that involve positive verbal communication are more obedient and less belligerent than those who are not.⁴² Research points to poor communication and problem-solving skills for resolving disputes as a contributing factor to negative outcomes, such as an increased likelihood of adolescent criminal behavior.⁴³ When examining conflict resolution, researchers have primarily focused on how parents and children respond to conflict with one another.⁴⁴

To evaluate the conflict resolution tactics of parents, three questions from the Panel Study of Income Dynamics – Child Development Supplement (PSID-CDS) are examined. Parents of children under age 13 were asked to report if they agreed or disagreed with three statements: 1) we fight a lot in our family; 2) family members hardly ever lose their tempers; and 3) family members always calmly discuss problems. These items were all asked in 1997 (refer to Table P8.1).

By Gender. More than half of mothers (52 percent) and fathers (56 percent) report “calmly discussing problems” as a way of resolving family conflicts. Twelve percent of both mothers and fathers report that there is a lot of fighting in their family.

By Race and Hispanic Origin. Hispanic mothers and fathers are more likely to report a lot of family fighting than are white, non-Hispanic or black, non-Hispanic mothers and fathers. Twenty-one percent of Hispanic mothers report that they fight a lot in their family, compared to 7 percent of black, non-Hispanic and 13 percent of white, non-Hispanic mothers. Similarly, 20 percent of Hispanic fathers report that they fight a lot in their family compared to 8 percent of black, non-Hispanic fathers and 11 percent of white, non-Hispanic fathers.

By Poverty Status. While there do not appear to be significant differences between poor and nonpoor fathers in the degree to which they are likely to report “fighting a lot” in their family, or “calmly discussing problems,” the same does not

hold true for mothers. Poor mothers (18 percent) are more likely to report “a lot of family fighting” than are nonpoor mothers (11 percent). However, poor mothers (60 percent) are also more likely than nonpoor mothers (50 percent) to report “calmly discussing problems” in their family.

By Educational Attainment. The same pattern that emerges for poor compared to nonpoor mothers regarding their reported conflict resolution styles emerges for mothers with less than a high school education compared to mothers who are college graduates (see Figure P8.1). Nineteen percent of mothers with less than a high school education, compared to only 8 percent of mothers with a college degree, report a lot of family fighting. Seventy percent of mothers with less than a high school education report calmly discussing family problems compared to 46 percent of mothers with a college degree. Fathers with less than a high school education (24 percent) are significantly more likely than fathers who are college graduates (8 percent) to report a lot of family fighting.

Figure P8.1 Percentage of parents of children under age 13 who report that the family fights a lot, by educational attainment: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

P9 – Degree of Closeness Adolescent Feels Toward Parent

Recent research suggests that a positive, close relationship between parents and adolescents is related to lower rates of adolescent early sexual activity, drug use, and emotional distress.⁴⁵ Negative relationships, on the other hand, have been found to be related to negative psychological functioning.⁴⁶ Research also shows that adolescents may react differently to certain types of parental behavior depending on whether it involves the mother or the father.⁴⁷ Adolescents tend to express negative feelings for mothers who demonstrate high levels of control, but have more positive feelings for fathers who show high levels of control.

In order to assess the degree to which adolescents feel close to their parents, a question from the National Longitudinal Study of Adolescent Health is examined. Adolescents in grades 7 through 12 in 1995 (Wave I) and in grades 8 through 12 in 1996 (Wave II) were asked to report the degree of closeness they feel toward their parents. Closeness was reported on a scale from 1 to 5 (1- not close at all, 2 - not very close, 3 - somewhat close, 4 - quite close, 5 - extremely close; refer to Table P9.1).

Figure P9.1 Degree of closeness adolescent feels toward his or her parent, by residence of parent: 1996

SOURCE: National Longitudinal Study of Adolescent Health (Add Health), Wave II, 1996

By Gender. Boys and girls reported feeling very close to both their resident parents but adolescents of both sexes also report being somewhat closer to their mothers than to their fathers. The same pattern holds true for feelings toward nonresident parents.

By Residential Status of Parent. Adolescents of both genders report being closer to their resident mothers and fathers than to their nonresident counterparts (see Figure P9.1). They are least close to nonresident fathers.

By Biological or Step Relationship. Among adolescents in two-parent families, relationships with biological parents are closer than those with step-parents, regardless of the sex of the parent.

By Gender of Child. Boys report being somewhat closer to their mothers and their fathers than do girls. This finding holds regardless of parental residential status.

P10 – Warmth and Affection

Many studies have shown that warmth in the parent-child relationship predicts positive child outcomes. Higher self-esteem, better parent-child communication, and fewer psychological and behavior problems have been linked to warmth and affection between parent and child.⁴⁸ Parental warmth and affection is also positively related to adolescent academic competence and negatively related to teen pregnancy and associations with deviant peers.⁴⁹ Parental warmth is even found to encourage children's use of social support and proactive, problem-focused coping styles.⁵⁰ Conversely, receiving insufficient levels of parental support fosters feelings of alienation, expressions of hostility and aggression, diminished self-esteem, and antisocial and risk behaviors.⁵¹

To assess the amount of warmth and affection parents show their children, three questions from the Panel Study of Income Dynamics – Child Development Supplement (PSID-CDS) are examined. Parents of children ages 12 and younger who are living with their children were asked to report how often, in the past month, they: 1) hugged or showed physical affection to their child; 2) told their child that they loved him/her; and 3) told their child that they appreciated something he/she did. These items were all asked in 1997 (refer to Table P10.1).

Figure P10.1. Percentage of resident fathers and mothers of children under age 13 who hugged their child every day in the past month: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement (CPS), 1997

By Gender. Mothers are more likely than fathers to report showing their children warmth across all three behaviors. Eighty-seven percent of mothers compared to 73 percent of fathers hug or show physical affection to their child at least once a day. Eighty-five percent of mothers and 62 percent of fathers tell their child that they love him or her at least once a day. Though the percentage of mothers and fathers who tell their child that they appreciate something he or she did is lower than the previous two behaviors, the difference between mothers and fathers is found here as well (55 percent and 37 percent, respectively).

By Race and Hispanic Origin. White, non-Hispanic mothers were more likely than Hispanic and black, non-Hispanic mothers to report daily hugging and telling their child that he or she is loved. For example, 93 percent of white, non-Hispanic mothers report hugging their child at least once a day, compared to 81 percent of Hispanic

mothers and 75 percent of black, non-Hispanic mothers. Among fathers, more white, non-Hispanics and Hispanics report daily hugging (76 percent and 73 percent, respectively) than do black, non-Hispanics (56 percent). White, non-Hispanic and Hispanic fathers (65 percent and 63 percent, respectively) are also more likely than black, non-Hispanic fathers (45 percent) to tell their child he or she is loved. The percentage of parents reporting that they told their child that they appreciated something he or she did varied little across these groups for mothers or fathers.

By Age of Child. Overall, displays of warmth by both mothers and fathers decrease with the increased age of the child for all three behaviors. For example, over 90 percent of mothers and fathers report hugging children under the age of 3 on a daily basis, compared to 74 percent for mothers and 50 percent for fathers of children ages 10 to 12 (see Figure P10.1).

By Educational Attainment. For all three behaviors, mothers with less than a high school education are less likely to show their child warmth than are parents with higher levels of educational attainment. For example, 75 percent of mothers with less than a high school education hug or show physical affection to their child at least once a day, compared to 87 percent of mothers with a high school diploma, 91 percent of mothers with some college, and 94 percent of mothers with college degrees. Among fathers, educational attainment generally did not seem to affect the amount of warmth and affection directed to children. However, more college-educated fathers (77 percent) report hugging their child daily than do fathers with less than a high school education (68 percent) or fathers with a high school diploma (70 percent).

P11 – Conflict Between Parents and Adolescents

Conflict between parents and youth is a routine aspect of family life, and it should be understood as a process that can have both positive and negative effects for the youth and the entire family.⁵² As they become older, adolescents often show a greater willingness to openly disagree with parents, feel less close, and question parental authority.⁵³ Conflict with parents is a normal part of the development process for adolescents, however, and can be positive within the context of a warm and supportive parent-child relationship.⁵⁴

Data from the National Survey of Families and Households (NSFH) are used to assess parent-adolescent conflict. Parents were asked to report the frequency with which they had disagreements in the last 12 months with their adolescent (ages 12-18) regarding: 1) his or her friends; and 2) how late the child stays out at night (refer to Table P11.1 and P11.2).

By Gender. The overall frequency of disagreement between parents and adolescents on these subjects is relatively modest, with only 10 percent of fathers and 11 percent of mothers reporting disagreements once a week or more often about staying out too late (see Figure P11.2). Eight percent of fathers and 10 percent of mothers reported disagreements about the youth's friends at that level.

Figure P11.1 Percentage of parents that report disagreements between parents and adolescents regarding friends, by frequency of disagreements: 1988

SOURCE: National Survey of Families and Households, 1988

By Educational Attainment. Parents who have graduated from college reported a lower level of disagreement regarding the adolescent's friends and staying out late than parents with less than a high school education. For example, among those with a college degree, 6 percent of mothers and 7 percent of fathers reported disagreeing once per

By Family Structure. Disagreements over staying out late are more common in single-parent families than in two-parent families. Twenty-two percent of mothers in single-parent families reported disagreeing once per week or more on this topic compared to 8 percent of mothers in two-parent families. The percentages for fathers are 20 percent and 9 percent, respectively.

Figure P11.2 Percentage of parents that report disagreements between parents and adolescents regarding staying out late, by frequency of disagreements: 1988

SOURCE: National Survey of Families and Households, 1988

week or more about friends, compared to 15 percent of mothers and 18 percent of fathers with less than a high school education (refer to Table P11.1). Similar differences exist for disagreements over staying out late (refer to Table P11.2).

P12 – Incidence of Harsh Punishment, Violence, or Abuse

In 1999, approximately 826,000 children were identified as victims of substantiated (i.e., confirmed) or indicated (i.e., reported) abuse or neglect.⁵⁵ Research shows that abused children lag behind nonabused children in learning new cognitive and social skills and have shown delayed academic achievement.⁵⁶ Current findings indicate that children who are hit repeatedly and with more frequency develop behavior problems, especially aggression, and have more emotional and mental health problems, particularly with depression, and are more likely to experience future family violence.^{57,58,59} Childhood abuse predicts higher rates of criminality and arrests for violent offenses in adolescence and adulthood.⁶⁰

The incidence of harsh punishment and physical abuse is based on data from a 1995 Gallup Survey on Disciplining Children in America.⁶¹ The rates are derived from the Physical Abuse subscale on the Conflict Tactics Scale (CTS)⁶² which includes a number of items assessing physical abuse. Parents responded either “ever” or “never” when asked if they had used any of the following forms of physical abuse: hitting child with fist or kicking, throwing child or knocking them down, beating up child, hitting child with hard objects not on the bottom, choking child, burning child, or using a knife or gun on child (refer to Table P12.1).

By Gender. Few parents report ever having physically abused their children: 6 percent among mothers and 3 percent among fathers (see Figure P12.1).

Figure P12.1 Percentage of fathers and mothers who have ever physically abused their child: 1995

SOURCE: Gallup Survey on Disciplining Children in America, 1995

By Race and Hispanic Origin. Eighteen percent of black, non-Hispanic mothers report having ever physically abused their child, as compared to 4 percent of White, non-Hispanic mothers and 4 percent of Hispanic mothers. Differences among fathers are modest and not statistically significant.

By Annual Household Income. Mothers living in a household with less than \$20,000 in income a year are more likely to report physically abusing their child (10 percent) than are mothers in households with over \$20,000 in annual income (4 percent). Differences among fathers are not statistically significant.

By Family Structure. Children, while generally unlikely to be abused, are more likely to be physically abused by their mothers in single-parent families than in two-parent families. Nine percent of mothers in single-parent families report ever physically abusing their child compared to 4 percent of mothers in two-parent families. The differences between fathers in single- and two-parent families were similar in magnitude, but not statistically significant.

P13 – Direct Care of Pre-school Children by Fathers

Child care is a particularly relevant issue in contemporary America. Many mothers no longer fulfill the traditional primary caregiver role; they populate the work force in increasingly high numbers and take significantly shorter leaves from employment following the birth of a child.⁶³

Research shows that, nationally, fathers are spending more time providing care for children while mothers are engaged outside of the home.^{64,65} This phenomenon seems promising, as father-child relations may have significant effects on certain positive child outcomes (e.g. social competence,⁶⁶ academic success,⁶⁷ and personality development⁶⁸) that are distinct from the effects of mother-child relations.

Data from the Survey of Income and Program Participation (SIPP), 1996, are used to calculate the percentage of children ages 0 to 5 whose fathers provide primary care for them while their mothers are working, looking for work or attending school.⁶⁹ In the surveys, mothers were asked for child care information, including usage of a particular type of care arrangement (yes/no), and number of hours each type of care was used. Such questions were asked for eleven types of child care arrangements (e.g., father, grandparent, day care center, nursery/preschool, Head Start program) for up to five children ages 0 to 5.⁷⁰ If a respondent reported the most hours for using father care among all types of arrangements, father care was considered the “primary arrangement”⁷¹ (refer to Table P13.1).

By Gender. In 1996, approximately 18 percent of children ages 0 to 5 had their fathers as their primary caregivers while their mothers were working, attending school, or looking for work. Nineteen percent of preschool boys and 18 percent of preschool girls had their fathers as primary caregivers in 1996.

By Race and Hispanic Origin of Mother. White, non-Hispanic mothers (21 percent) are more likely than are black, non-Hispanic (10 percent) or Hispanic (15 percent) mothers to rely on preschoolers’ fathers for providing primary care while they are at work, school, or looking for work. Hispanic mothers are also more likely than black non-Hispanic mothers to report fathers as primary caregivers of their preschoolers.

By Poverty Status. Mothers who are living at or below the poverty threshold are less likely than mothers who are not poor to report fathers as primary caregivers of their preschoolers. For example, 23 percent of nonpoor mothers report fathers as primary caregivers, compared to 18 percent of poor mothers.

By Family Structure.⁷² Preschoolers in two-parent families are far more likely than children in single mother households to have their father as their primary caregiver (23 percent compared to 6 percent).

Figure P13.1 Percentage of preschoolers whose fathers are their primary care giver, by father’s educational attainment: 1996

SOURCE: Survey of Income and Program Participation, 1996, TM2 and TM4

By Educational Attainment of Father. Fathers with college degrees are less likely than those with any other level of educational attainment to provide primary care for their child (see Figure P13.1). For example, in 1996, 27 percent of fathers with less than a high school education were primary caregivers to their preschoolers, compared to 18 percent of college-educated fathers. Fathers with high school or some college-level training were also more likely than college-educated fathers to be children’s primary caregivers when mothers were at school or working (24 percent, respectively). The likelihood of fathers being primary caregivers to their preschoolers does not vary by mothers’ level of educational attainment.

P14 – Time Spent with Children

The time that parents and children spend together is instrumental in the social and intellectual development of the child.^{73,74} It is during this time that children benefit from important emotional supports and exposure to parental values and behavior.

On average, mothers occupy the majority of the total parental hours spent in direct care in two-parent families.⁷⁵ Nonetheless, children who spend a substantial amount of time with their fathers benefit greatly. Research finds that children whose fathers assumed 40 percent or more of the family's care tasks had greater positive outcomes (e.g., better performance on tests and cognitive achievement), than those children whose fathers were less involved.⁷⁶ Overall, studies show that involvement by both parents yields the most positive effects on the development of children.⁷⁷

Data from the Panel Study of Income Dynamics – Child Development Supplement, 1997 are used to calculate the average daily time children under age 13 spend with their parents doing some type of activity (refer to Table P14.1). The data are presented for two-parent families and for single-parent families.

By Gender. Children spend more time with their mothers than with their fathers. In two-parent families, the average daily time spent with a mother is 2 hours and 21 minutes, and 1 hour and 46 minutes with fathers. In single-parent families, children spend about one and a quarter hours daily with mothers, compared to less than half an hour with fathers.

By Family Structure. Children in two-parent families spend far more time with their parents than do those in single-parent families (see Figure P14.1). The average time spent with fathers is four times greater for children in two-parent families than for those in single-parent families, which are often headed by mothers (1 hour and 46 minutes compared to 25 minutes). The average time spent

with mothers is almost twice as high for children in two-parent families as for those in single-parent families (2 hours and 21 minutes compared to 1 hour and 16 minutes).

By Race and Hispanic Origin. Black, non-Hispanic children spend less time with their mothers and fathers than parents from other racial and ethnic backgrounds. This is the case for children in two-parent and single-parent families. For example, for children in two-parent families the average daily time spent by black, non-Hispanic children with their fathers was an hour and 11 minutes, compared to slightly more than an hour and 45 minutes for white, non-Hispanic and Hispanic children, and about 2 hours for children of other racial/ethnic backgrounds.

Figure P14.1 Average daily time children under age 13 spend with their mothers and fathers in an activity, by family structure: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

By Poverty Status. Poor children in two-parent families spend less time with their fathers than do those in two-parent families with relatively high incomes. The average time spent per day with fathers was about an hour and a half for poor children compared to an hour and 51 minutes for those in families with incomes at 3 times the poverty level. By contrast, The time children spend with mothers in single- and two-parent families does not differ by their poverty status.⁷⁸

By Educational Attainment. Children in two-parent families whose fathers have a college degree spend more time with their fathers than those whose fathers have less than a high school education (an hour and 52 minutes compared to an hour and 38 minutes). The time spent by children with mothers in single- or two-parent families does not substantially differ by the level of mother's educational attainment.⁷⁹

By Employment Status. Children in two-parent families with mothers who are not in the labor force spend more time with their mothers (slightly

more than 2 hours and a half) than those with mothers working part-time or full-time (about 2 hours and 15 minutes) or mothers looking for work (an hour and 51 minutes). Time spent with fathers in two-parent families does not vary significantly by fathers employment status. Among children in single-parent families, those with mothers who work either part-time or full-time spend substantially less time with their mothers than those with mothers who are not in the labor force or who are looking for work.⁸⁰

By Age of Child. As children get older they spend less time with their parents. For example, children in two-parent families spend 3 hours and 14 minutes per day with their mother at ages 0 to 2, compared to an hour and 45 minutes by ages 9 to 12. Time with father in two-parent families decreases from two hours and 7 minutes at ages 0 to 2 to one and one-half hours by ages 9 to 12. (see Figure P14.2). A similar pattern emerges for children in single-parent families.

Figure P14.2 Average daily time children under age 13 in two-parent families spend with mothers and fathers in an activity, by age of child: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

P15 – Parents’ Activities with Children

Parents’ participation in activities with their children is an important part of healthy cognitive, social, and emotional development. The range of activities in which children engage with their parents can span from the academic (e.g., reading books, helping with homework), to sports and games, to simply going to the store or movies. Research suggests that parent-child literacy activities in the home improve children’s language skills and their interest in books, and enhance parent’s self-esteem and sense of efficacy.^{81,82} In addition, children who are high academic achievers tend to have parents who use more specific strategies to help their children with their schoolwork and who have more supportive conversations with them.⁸³ Similarly, higher levels of parent-child number-related activities at home (e.g., helping with math homework, counting exercises) improved young children’s performance on tests of early mathematical ability.⁸⁴ Fathers’ participation in play activities with their children especially contributes to the formation of a secure father-child relationship.⁸⁵

In order to track the frequency that parents engage in various activities with their children, four questions from the Panel Study of Income Dynamics – Child Development Supplement (PSID-CDS) are examined. Parents of children ages 3 to 12 were asked to report how often they engaged in the following activities with their child: 1) played a board game, card game, or did puzzles; 2) looked at books; 3) talked about family; or 4) played sports or did outdoor activities. These items were all asked in 1997 (refer to Table P15.1).

Figure P15.1 Percentage of mothers and fathers of children ages 3 to 12 participating in various activities with their children at least once a week: 1997

SOURCE: Panel Study of Income Dynamics – Child Development Supplement, 1997

By Gender. Mothers are generally more likely to engage in activities with their children than are fathers, though there are domains in which fathers participate more frequently. Mothers are more likely than fathers to play board games, cards, or puzzles with their children; look at books with their children; and have conversations with their children about the family at least once a week (see Figure P15.1). Fathers are more likely than mothers to play sports or do outdoor activities with their children at least once a week.

By Age of Child. Parents tend to spend more time in activities with their younger children than with their older children. For example, more fathers of children ages 3 to 5 play sports and outdoor activities with their children at least once a week

(81 percent) than do fathers of children ages 6 to 9 (68 percent) or 10 to 12 (57 percent). Similarly, more mothers of children ages 3 to 5 play board games, cards, or puzzles with their children at least once a week (55 percent) than do mothers of children ages 6 to 9 (47 percent) or 10 to 12 (30 percent). This same pattern holds true for parents’ book reading activities with children. For talk about the family, fewer parents have conversations with their 10- to 12-year-old children than with younger children ages 3 to 9.

By Educational Attainment. Mothers who have a high school education or equivalent are more likely to engage in activities with their children than are mothers who have less than a high school education. This pattern was true of fathers also,

but only for two of the four activities: looking at books and playing games. For example, 56 percent of mothers (and 42 percent of fathers) who attained a high school diploma or equivalent looked at books with their children at least once a week, compared to 39 percent of mothers (and 27 percent of fathers) with less than a high school education. Fathers who are college graduates are more likely to play sports (72 percent) and talk about the family (76 percent) with their children than are fathers with less than a high school education (60 and 68 percent, respectively).

By Race and Hispanic Origin. Among fathers, activities with children do not seem to vary across racial/ethnic groups. For example, Hispanic fathers are just as likely as white and black, non-Hispanic fathers to play games, talk about their family, and play sports or outdoor activities with their children. There is more variation among mothers of different racial/ethnic backgrounds, however. Hispanic mothers are less likely than white, non-Hispanic mothers to engage in activities such as playing games, looking at books, talking about the family, and playing sports with their children. For example, only 40 percent of Hispanic mothers looked at books with their children, compared to 60 percent of white, non-Hispanic mothers. Hispanic mothers are also less likely than black, non-Hispanic mothers to play games or look at books with their children. Hispanic fathers are less likely than white and black non-Hispanic fathers to look at books with their children (26 percent, compared to 40 and 45 percent, respectively).

By Family Structure. Interestingly, there is no difference between single mothers and mothers in two-parent households in the degree to which mothers engage in activities such as playing games, looking at books, talking about family, or playing sports with their children. There is insufficient data to report on single father families.

P16 – Religious Activities With Children

For many, a key component of fostering moral and spiritual guidance in children and youth is participation in religious activities (e.g. attending church, synagogue, mosque, or temple) on a regular basis. Religiosity has been found to be positively related to volunteering,⁸⁶ positive mother-child relationships,⁸⁷ openness, and friendliness.⁸⁸ Research suggests that a significant portion of men experience important changes in external behaviors (e.g., church attendance) and commitment to religion after becoming fathers.⁸⁹ However, evidence suggests that mothers' personal religious practices are a more powerful predictor of children's religiosity than are those of their fathers.⁹⁰ Higher parental religiosity is associated with more cohesive family relationships, lower levels of interparental conflict, and fewer behavior problems among children.⁹¹

In order to assess the extent to which adolescents participated in religious activities with their parents, a question from the National Longitudinal Study of Adolescent Health (Add Health) is examined. Adolescents in grades 7 through 12 in the 1994 and 1995 (Wave I) and in grades 8-12 in 1996 (Wave II) were asked to report if they had gone to a church-related event with their parent in the last four weeks (refer to Table P16.1).

Figure P16.1. Percentage of students in grades 8-12 who report having gone to a church-related event with their parent in the last 4 weeks: 1996

SOURCE: National Longitudinal Study of Adolescent Health, Wave II 1996

By Gender. Adolescents are more likely to attend religious activities with their mothers than with their fathers, regardless of residential status. For instance, in 1996, 39 percent of girls attended a church-related event with their resident mother compared to 29 percent who attended an event with their resident father. In addition, a significantly larger percentage of girls attended religious activities with their nonresident mothers (13 percent) than with their nonresident fathers (9 percent). A similar pattern is found for boys' activities with their mothers and fathers. For example, 34 percent of boys attended events with resident mothers compared to 28 percent who attended with resident fathers (see Figure P16.1).

By Parental Residence Status. Adolescents are far more likely to attend religious activities with resident parents than with nonresident parents (see Figure P16.1). For example, in 1996, 39 percent of

girls attended a church-related event with their resident mother, whereas only 13 percent of girls attended such events with their nonresident mother.

By Age of Child. Younger adolescents are somewhat more likely to engage in religious activities with their resident parents than are older adolescents. In 1996, 38 percent of boys and 43 percent of girls under age 15 attended a religious activity with their resident mothers in a four-week period. Thirty-three percent of boys and 37 percent of girls age 15 and older did so.

By Education Attainment. In general, children of college graduates are more likely to attend religious activities with their parents than are children of less well-educated parents. For example, in 1996, 39 percent of adolescent boys who had at least one parent with a college degree attended a church-related event with their resident

father. Only 18 percent of boys whose most educated parent had only a high school diploma or equivalent attended religious activities with their resident father. A similar pattern emerges for girls' religious activities with their parents, regardless of residential status. However, this pattern does not hold true for nonresident fathers and their sons.

P17 – Parental Participation in Child’s School Activities

Studies report that children whose parents are involved in their schooling are more likely to earn high grades and enjoy school than children whose parents are not involved in their children’s schooling. This result holds for students in both elementary and secondary school.^{92,93} Children of involved parents are also more likely to have higher educational aspirations and motivation to achieve.⁹⁴ In addition, parent involvement in school is related to fewer student suspensions and expulsions, and higher levels of student participation in extracurricular activities. Data also suggest that schools that welcome parental involvement are more likely to have highly involved parents.⁹⁵

To assess parental participation in their child’s school, data from the National Household Education Survey Program (NHES) were examined. The question asked if parents of children ages 3 to 17 participated in any or all of the following activities: a general school meeting, parent-teacher conference, class event, and volunteering at school. Parents who responded “yes” to 3 or 4 of the activities were categorized as “highly involved.” This question was asked in 1996 and 1999 (refer to Table 17.1).

Figure P17.1 Percentage of fathers and mothers who are highly involved in their child’s school, by age of child: 1999

SOURCE: National Household Education Survey Program, 1999

By Gender. Mothers are much more likely to be highly involved (i.e., participate in three or four of the following school activities: general school meeting, parent-teacher conference, class event, or volunteering at school) in their children’s school than are fathers, regardless of the age of the child. For example, in 1999, among parents of 6- to 11-year-olds, 65 percent of mothers and 33 percent of fathers were highly involved in their children’s school.

By Age of Child. Parents are more likely to be highly involved in their children’s school when their children are between the ages of 6 to 11 than when they are older (see Figure P17.1). In 1999, 33 percent of fathers of 6- to 11-year-olds were highly involved as compared to 25 percent of fathers of 12- to 17-year-olds. Among mothers, the gap was even larger. In 1999, 65 percent of mothers of 6- to 11-year-olds were highly involved, while only 41 percent of mothers of 12- to 17-year-olds were highly involved.

By Educational Attainment. Better educated parents are generally more likely to be highly involved than are less educated parents. In 1999, 10 percent of fathers of 6- to 11-year-olds with less than a high school education were highly involved, compared to 25 percent of high school graduates, and 44 percent of college graduates. Similarly, for children ages 6 to 11, 42 percent of mothers with less than a high school education were highly involved, compared to 78 percent of mothers with a college degree.

By Age of Parent. In 1999, the youngest parents (ages 18 to 24) were less likely to be highly involved in their children’s schools than were older parents. For example, 6 percent of fathers ages 18 to 24 were highly involved in their 6- to 11-year-olds’ schools compared to 32 percent of fathers ages 25 to 44 and 35 percent of fathers ages 45 to 65. This pattern held true for mothers and fathers of 3- to 5-year-olds and 6- to 11-year olds in 1999.

P18 – Encouragement of Child(ren)’s School Achievement

Children’s academic achievement, including their competitiveness and drive to succeed, is largely influenced by their experience at home. For example, children whose parents encourage them and stimulate their intellect through enriching materials at home are more likely to have higher educational aspirations.⁹⁶ In addition, involvement of parents in their child’s education, at home and in school, serves as a form of social capital for that child, improving the quality and density of the relationships that he or she can utilize.⁹⁷ Based on existing research, it has been hypothesized that maternal involvement is beneficial for the social and emotional adjustment of children to school, and that the involvement of fathers, while often less frequent but more engaged, is critical for academic achievement.⁹⁸ Most research uses parental education and income as indicators of a child’s educational success, but there are other ways parents influence a child’s academic success, such as quality parental involvement in school-related activities.

Data from the National Survey of Families and Households (NSFH) is presented. Three variables are examined: 1) the number of days in a typical week that the parent talks with his/her child about the things she/he has learned in school; 2) the number of days in a typical week the parent talks with his/her child about school activities or events; and 3) the number of days in a typical week the parent checks whether his/her child did homework or other school assignments. These items were all asked in 1992⁹⁹ (refer to Table P18.1).

Figure P18.1 Number of days per week mothers and fathers talk about school-related events with their child: 1992

SOURCE: National Survey of Families and Households, 1992

By Gender. Mothers appear to be more likely than fathers to talk with their child about school-related events and about things that he or she has learned in school. Mothers talk to their child about these topics about 4.3 days during the week compared to fathers, who do so about three and a half days a week. Mothers are also more likely than fathers to check on whether or not their child has done homework or other school assignments (see Figure P18.1).

By Age of Parent. Generally, younger mothers and fathers spend more time talking to their children about school and checking on their assignments than do older parents. For example, fathers ages 25 to 44 talk with their child about things they learned in school about 3.6 days a week, and fathers ages 45 and older talk about these things 3 days a week.

By Educational Attainment. Parents with a college degree generally talk with their child about school more frequently than parents without a high school education. This difference is particularly pronounced among fathers. Fathers with a college degree talk with their child about school activities 4.2 days a week, and about the things she or he has learned in school about 3.7 days a week, which is a day more a week than fathers with less than a high school education (3 days and 2.7 days, respectively).

P19 – Child Custody Arrangements

Child custody can most easily be divided into two categories: legal custody and physical custody. Legal custody refers to “the parental right to make major decisions regarding the child’s health, education and welfare,” while physical custody refers exclusively to the living arrangements of the child.¹⁰⁰ These privileges can be awarded to either or both parents. Sole custody is the most common arrangement currently in the United States, and is most often awarded to the mother. Joint custody is a less common but increasingly popular arrangement, especially in states that encourage its application. Joint physical custody, in which the child spends roughly 25 or more of his or her time at each parent’s home,¹⁰¹ was the chosen arrangement in over 20 percent of post-divorce families in the late 1990’s.¹⁰² Other forms of custody exist but are awarded rather infrequently compared to sole and joint arrangements. Split custody, which allows “one or more children [to] live with one parent while the remaining live with the other parent,” is uncommon because courts discourage the separation of siblings.¹⁰³ Divided, or alternating, custody is similarly uncommon. This arrangement alternately gives each parent full custody of the child over long periods of time, often of one to two years. Each parent maintains visiting rights during their off-custody period.¹⁰⁴

Theoretically, all types of custody arrangements have the potential to be beneficial for the child. Several studies indicate that it is ultimately the quality of parent-child contact within these arrangements that determine child outcomes.¹⁰⁵ See indicators on “Contact with Nonresident Parent” and “Parental Time with Children” for further discussion of the influences of parental contact on child well-being.

Data from the Current Population Survey (CPS), April Supplement, 1994, 1996, and 1998 are used to describe the types of custody awarded under the most recent agreement in the previous year. The percentages are calculated only for households with a child (under age 21) who lives with one biological parent and whose other parent is absent from the household. The data are presented by the socio-demographic characteristics of the resident parent who reported the information (refer to Table P19.1, P19.2, and P19.3).¹⁰⁶

By Gender. Sole legal and physical custody awarded to mothers was the most common arrangement in 1994, 1996, and 1998. Sixty-eight percent of households with nonresident parents reported that mothers had sole custody. The percentage in each arrangement remained virtually the same between 1994 and 1998 except for a slight decline in the award of physical custody to fathers (12 percent compared to 10 percent).

By Poverty Status of Resident Parent. Poor mothers are more likely to have full custody whereas poor fathers are less likely to have full custody (see Figure P19.1). In 1998, 82 percent of poor resident parents reported mothers had sole custody compared to 55 percent of those in the highest income bracket (incomes at 3 times the poverty level or above). On the other hand, parents with relatively high incomes are more likely than poor parents to report other types of arrangements. For instance, 15 percent of resident parents with incomes at three times the poverty level or more reported father’s physical custody (with either sole or joint legal custody) whereas 4 percent of poor resident parents reported the same arrangement (see Figure P19.1).

Figure P19.1 Type of custody by poverty status of resident parent: 1998

SOURCE: Current Population Survey, April Supplement, 1998

By Employment Status of Resident Parent.

Mothers who are working full-time are less likely to have full custody of their children than mothers in all other employment categories. In 1998, only 62 percent of households where the mother works full-time reported that the mother had legal and physical custody compared to 77 percent of those working part-time, 77 percent of those looking for work, and 79 percent of those not in the labor force. On the other hand, full-time workers are more likely than those who are not working to report other types of arrangements including joint and sole father custody, except the “other” arrangements (e.g., split custody). For example, 12 percent of resident parents who work full-time reported a joint custody arrangement compared to 4 percent of those who were not working in 1998.

By Marital Status of Resident Parent. Resident mothers who have never married are more likely to have sole custody of their children than resident mothers who are currently married or who were once married (85 percent compared to 65 percent and 58 percent, respectively) (see Figure P19.2). On the other hand, resident parents who were once married are more likely to have joint custody than those with another marital status. Similarly, resident fathers who were previously married are more likely to have physical custody of their children than resident fathers with another marital status.

By Educational Attainment of Resident Parent.

Custody arrangements differ by educational attainment of the resident parent. Sole custody by mother is more frequently reported among households where the resident parent has less than a high school education (77 percent) than when a parent has a college degree (53 percent). Better-educated parents are more likely to have joint custody, or joint legal custody with mother’s physical custody. The likelihood of fathers being awarded physical custody (with either sole or joint legal custody) does not substantially differ by level of educational attainment.

By Race and Hispanic Origin of Resident Parent.

Black, non-Hispanics are more likely to report mothers having sole custody of their children than most other ethnic groups (excluding American Indians and Alaskan Natives). Eighty-five percent of non-Hispanic black resident parents report the sole custody of mothers compared to 60 percent of non-Hispanic whites, 72 percent of Hispanics, and 62 percent of Asians. On the other hand, non-Hispanic whites are more likely than

non-Hispanic blacks and Hispanics to have other types of arrangements, including mother physical and joint legal custody, joint custody, and father’s sole custody. This statement does not hold true however when comparing non-Hispanic whites and Hispanics where the father has physical custody.

Figure P19.2 Type of custody by marital status of resident parent: 1998

SOURCE: Current Population Survey, April Supplement, 1998

By Age of Resident Parent. Younger resident mothers are more likely to have sole custody of their children than are older mothers. In 1998, 84 percent of resident parents under age 25 were mothers with sole custody compared to 60 percent of parents ages 45 and older. On the other hand, resident parents that are 45 and older are more likely to have joint custody than parents under the age of 25 (12 percent of parents age 45 and older compared to 3 percent of those under age 25). Older resident parents are more likely to have agreements where the father has physical custody or sole custody of their children than younger parents. Eighteen percent of resident parents ages 45 and older are fathers with physical custody or full custody, compared to 4 percent of parents under age 25.

P20 – Contact With Nonresident Parent

Due to the increase in divorce, separation, and nonmarital childbearing over recent years, a significant number of children in the United States today have experienced living separately from at least one biological parent during their childhood. This phenomenon has inspired a great deal of research regarding contact between children and their nonresident parent. Most of this work investigates contact experiences of fathers, who represent 85 percent of nonresident parents.¹⁰⁷

There are many factors that influence whether nonresident parents maintain contact with their child. Employment status, level of education, age at birth of the child, the character of the relationship with resident parent, the geographical proximity to the child,¹⁰⁸ and the presence of a step-parent in the residential home all affect the likelihood as well as the frequency of visitation and phone or letter contact.¹⁰⁹ The likelihood and frequency of contact between nonresident parents and their children also varies over time and by the age of the child. Specifically, several studies show that contact becomes less frequent with time after marital separation.^{110,111} In addition, several studies have found contact between unwed fathers and their children to be relatively frequent soon after the child's birth, but contact declines significantly as the child reaches school age.^{112,113}

Regular contact with a nonabusive, nonresident parent has the potential to encourage positive development and life satisfaction in the child.¹¹⁴ Indeed, several studies have shown that involvement of the nonresident parent is beneficial to children's cognitive and social development.¹¹⁵

Data from the Current Population Survey (CPS), April Supplement, 1994, 1996, and 1998¹¹⁶ were used to calculate a) the percentage of children who had contact with their nonresident parent in the previous calendar year, and b) of those who had any contact, the average number of days children had contact with their nonresident parent in the previous calendar year. The percentages were calculated only for households with a child (under age 21) who lives with one biological parent and whose other parent is absent from the household. The data are presented by the socio-demographic characteristics of resident parents who reported the information (refer to Table P20.1 and Table P20.2).

By Gender. The majority of children with a nonresident parent have at least some contact with that parent: 60 percent in the case of fathers and 78 percent for mothers in 1997. The number of days

they have contact with such parents also varies by the gender of the parent; 69 days with the father and 86 days with the mother.

Figure P20.1 Percentage of children with contact with their nonresident parent, by poverty status of the resident parent: 1997

SOURCE: Current Population Survey, April Supplement 1998

By Poverty Status of Resident Parent. Children in poor families are less likely than those in high income (300 percent or more above poverty) families to have contact with their nonresident parent: 50 percent compared to 71 percent in the case of nonresident fathers, and 72 percent compared to 84 percent for nonresident mothers (see Figure P20.1). Among those who do have contact, poverty status is not related to the number of days of contact with nonresident fathers, but is strongly related to days of contact with nonresident mothers (58 days for poor children compared to 91 days for those living at 300 percent or more above poverty).

By Educational Attainment of Resident Parent. Children who are living with better-educated parents are more likely to have contact with their nonresident parent. In 1997, the percent that have contact with a nonresident father ranges from 44 percent of those living with a parent who has not graduated from high school to 74 percent for those living with a parent who has graduated from college. Percentages are higher for nonresident mothers (69 percent and 88 percent, respectively). For those who have some contact, the number of days with nonresident fathers does not differ by education level. For nonresident mothers, however, education level is a factor. Children living with a father who did not complete high school spend fewer days with their nonresident mother than those living with fathers who completed college (63 days compared to 96 days).

By Race and Hispanic Origin of Resident Parent. The children of white, non-Hispanic resident parents are more likely than Hispanic children or children of other races to have contact with their nonresident parent. For nonresident fathers and mothers in 1997 the percentages are, respectively, 68 percent and 81 percent for non-Hispanic whites, 51 percent and 70 percent for non-Hispanic blacks, and 48 percent and 63 percent for Hispanics.

P21 – Earnings and Income

A family's income can affect children in a variety of ways. Family income, which is influenced by parental education and employment, affects the family's material level of living; neighborhood and housing quality; and opportunities for stimulating recreation and cultural experiences. Money can be used to buy things which promote children's cognitive growth and physical development, and to purchase health insurance and health care, which are associated with positive health outcomes for children and families. Economic advantage is also associated with increased academic success among children.^{117,118} Income is also related to the psychological well-being of the parent.^{119,120,121,122,123} In addition, the ability of parents to provide an emotionally stable home for their children is related to economic stability, as lower income is associated with higher levels of marital conflict.¹²⁴

The median income data provided are from the Current Population Survey and include families with at least one child under 18 years of age. The data are for 1987 and 1990-2000 and are presented in constant year 2000 dollars (refer to Table P21.1).

Figure P21.1 Median income for families with children, by race and Hispanic origin (in constant 2000 dollars): Selected years 1987-2001

SOURCE: Current Population Survey (CPS), 1987, 1990-2001

Trends. In the period from 1987 through 1996, the median income of all families with at least one child under 18 fluctuated between a low of \$42,579 in 1993 and a high of \$44,931 in 1995. However, after 1996, the median income rose almost \$6,000, to \$50,777 in 2000. Overall there has been a 13 percent increase in median family income between 1987 to 2000 (see Figure 21.1).

By Family Structure. From 1987 to 2000, the median family income for female-headed households where no husband was present increased from \$16,575 to \$21,520, a 30 percent increase. Married couple families enjoyed an income increase as well, approximately 18 percent from \$53,124 to \$62,934. Conversely, male householders with no wife present have actually shown a slight decline in real wages from 1987 to 2000 from \$33,832 to \$32,490. Still, male householders enjoy an income about 51 percent greater than female householders.

By Race and Hispanic Origin.¹²⁵ The median income for white, non-Hispanic families with

children under 18 is considerably higher than that of blacks and Hispanics. For instance, in 2000, white, non-Hispanic families (\$60,225) had 95 percent higher income than black families (\$30,839) and 81 percent higher income than Hispanic families (\$33,285).

Since 1987, female householders of all racial and ethnic backgrounds where no husband is present have seen increases in their income levels. Over that period the income of single, white, non-Hispanic women has increased by 23 percent (from \$21,066 to \$25,977 in 2000 dollars), the income of single, black women by 45 percent (from \$12,618 to \$18,250), and the income of single, Hispanic women by 56 percent (from \$12,116 to \$18,841). Among married couples, white, non-Hispanic couples have had the greatest income increase since 1987 (over \$13,000 or 24 percent), whereas Hispanic married families have only seen an 11 percent increase (\$4,073) in income. Black married couples have had an 18 percent income increase (\$7,963).

P22 – Receipt of Child Support

In 1997, roughly a third of American children had a parent living outside of the home.¹²⁶ About half of all nonresident parents have a legal agreement to pay child support, the amount of which is determined by a variety of factors.¹²⁷ In addition, a small percentage of nonresident parents have an informal agreement to pay support, while the remainder have no agreement.¹²⁸ Certain factors have been shown to influence the likelihood of receiving child support payments. For example, those nonresident parents in a legally binding contract are twice as likely to pay child support as those without.¹²⁹ However, almost 40 percent of legal child support agreements are satisfied irregularly.¹³⁰ Furthermore, the amount of child support received is strongly associated with the amount initially established in each agreement.

Child support can benefit all types of families, as its receipt is positively related to child outcomes such as educational attainment, standardized test scores, school behavior, and access to health care and nutrition.¹³¹ However, children in certain families may especially benefit from the protective effects that child support can have against poverty.¹³² Many poor families rely on child support for over one-quarter of their income.¹³³

Payment of child support has other added benefits as well. The nonresident parent's payment of child support is positively related to contact with the child, a sense of involvement in the child's upbringing, and a positive relationship with the resident parent.¹³⁴

Research from the early 1990s indicates that women who are black, Hispanic, never-married, less educated, of lower socioeconomic status, and/or who began childbearing as teens are markedly less likely to arrange child support agreements and, therefore, are less likely to receive payments;^{135,136} this population is also much less likely to win large support awards.¹³⁷

In order to examine the characteristics of child support and those who receive child support payments, three variables from the Current Population Survey (CPS) are reviewed: the characteristics of child support agreements held by resident parents; the percent of resident parents with an agreement who receive child support payments; and the mean dollar amount received in the previous year for families receiving child support (refer to Table P22.1, P22.2, and P22.3). These data were collected in 1998.

By Gender. Resident mothers (50 percent) are more likely than resident fathers (35 percent) to have a child support agreement (refer to Table P22.1). Among resident parents who have an agreement, less than half are likely to receive full payment. Specifically, mothers are also more likely than fathers to receive full child support payments (48 percent and 35 percent, respectively) (refer to Table P22.2). Among families receiving child support payments, mothers receive more than fathers, (\$3,702 compared to \$3,185, respectively) (refer to Table P22.3).

By the Presence or Absence of an Agreement. Resident mothers who have child support agreements receive larger child support payments than resident mothers without agreements (refer to Table P22.3). In 1998, resident mothers with an agreement received almost 50 percent more annually than those without agreements (\$3,978 and \$2,681, respectively).

By Age. Mothers who are older are more likely than younger mothers to receive full child support payments (refer to Table P22.2). Only 36 percent of mothers 18- to 24- years old receive full payment, compared to 48 percent of 25- to 44-year-old mothers and 55 percent of mothers 45 or older. In addition, mothers 18- to 24- years old are less likely than older mothers to have a child support agreement.

By Educational Attainment. Education is strongly related to receipt of child support for resident mothers but not resident fathers. For example, mothers with a college degree (63 percent) are more likely to have a child support agreement than are mothers with less than a high school education (36 percent); this is not the case for fathers (refer to Table P22.1). However, both mothers and fathers with a college education are more likely than mothers and fathers without a high school education to receive full child support payment.

Figure P22.1 Percentage of resident mothers with an agreement, by marital status: 1998

SOURCE: Current Population Survey, 1998

By Marital Status. Among mothers, those that were never married were less likely to have an agreement, less likely to receive full support payments if they had an agreement, and most likely to receive the least amount of money compared to mothers that were single but previously married or those that were currently married (see Figures P22.1 and P22.2). Mothers that were single but previously married were the most likely to have an agreement and those that were never married were least likely to have an agreement (64 percent and 38 percent, respectively). Those with an agreement that were currently married were most likely to receive full payment (58 percent). Mothers that were single but previously married and those that were currently married received about the same amount annually in child support payments (\$4,263 and \$4,162, respectively) while mothers that were never married received less than half the amount of money as mothers in the other two categories (\$1,990).

Figure P22.2 Percentage of resident mothers with an agreement who received the full amount last year, by marital status: 1998

SOURCE: Current Population Survey, 1998

Among fathers, those that were currently married were the least likely to have a child support agreement. Fathers that had an agreement were equally as likely to receive full payment and the amount of money received did not vary significantly by marital status.

By Race and Hispanic Origin. White, non-Hispanic mothers are more likely than black, non-Hispanic, and Hispanic mothers to have a child support agreement and to receive full payment of support. For example, 61 percent of white, non-Hispanic mothers have a child support agreement, compared to 40 percent of black, non-Hispanic and 34 percent of Hispanic mothers. In addition, the amount of child support received is higher for white, non-Hispanic mothers than it is for black, non-Hispanic mothers and Hispanic mothers.

- ⁶⁹ Although SIPP has collected this information in previous years, historical data are not presented due to the fact that data were not collected at comparable times during the year. Child care arrangement data were collected in the spring in 1996, whereas in previous years these data were collected in the fall.
- ⁷⁰ Data were collected for children of female respondents only.
- ⁷¹ When father care was tied with other types of care for "primary arrangement," one of the "tied" types of care was randomly chosen as the primary arrangement.
- ⁷² All demographic information is based on Wave 2 of 1996 SIPP data. Since the information on child care was collected during Wave 4, there is an 8 month difference between the demographic data and child care data. In particular, residential status of parents may have changed between the two waves but households were classified into two parent families or single parent families based on the residential status of parents at Wave 2.

¹⁰⁶ Households are classified into having one of the following 5 types of custody: 1) physical and legal custody awarded to mother, 2) physical custody awarded to mother combined with joint legal custody, 3) physical and legal custody awarded to father or joint legal custody, 4) joint physical and legal custody, and 5) other types (e.g., split custody). The categories are mutually exclusive, meaning that households are classified into having one type of agreement or another. For households with multiple arrangements, one of the arrangements was selected by a hierarchical decision rule. For instance, if a household had both written and verbal agreements, the written agreement took precedence over the verbal agreement, and the household was classified according to the written agreement.

Family Formation Section

FF1 – Marriage

Marriage is one of the most beneficial resources for adults and children alike. Children in married parent families tend to have fewer behavior problems, better emotional well-being, and better academic outcomes, on average, than children in single parent or divorced families.^{1,2} Marriage is less beneficial for children's emotional and behavioral well-being in families marked by high parental conflict.^{3,4} Fathers' attachments to their children are often contingent upon marriage - fathers tend to disengage from children they no longer live with, making less frequent visits and calls to them over time.⁵ The benefits of marriage for adults help shape a positive environment for their children. For example, married men and women have higher levels of wealth than those who are separated, divorced, widowed or never married; and married people, men in particular, engage in healthier behaviors than those who divorce.⁶

Since marriage extends many resources that benefit child well-being, it is important to monitor trends in the marital status of adults. The Current Population Survey is used to track the current marital status of males and females, 18 years old and older, over the period of 1991 through 2001 (refer to Table FF1.1). The Survey of Income and Program Participation is used to report a more comprehensive classification of marital status – lifetime number of marriages – for the most recent year available, 1996 (refer to Table FF1.2).

By Gender. The percentage of men and women who are married declined modestly between 1991 and 2001 from 64 percent to 61 percent. Importantly for children, this trend is also evident among parents. Ninety-two percent of fathers were married in 1991, whereas 88 percent were married in 2001; seventy-five percent of mothers were married in 1991, whereas 72 percent were married in 2001. These numbers indicate that not only has the percentage of single parents risen for both men and women since 1991, but also that there is a higher percentage of single mothers than single fathers.

By Parental Status. Most fathers and mothers have been married at some point in their life. In 1996, 97 percent of fathers and 91 percent of mothers report that they have been married at least once in their lifetime. Among single parents, however, 94 percent of single fathers have been married previously, but only 74 percent of single mothers have.

By Race and Hispanic Origin. Among men and women, black, non-Hispanics are the least likely to be married. In 2001, 46 percent of black, non-Hispanic men were married, compared to 64 percent of white, non-Hispanics, 60 percent of Hispanic origin, 64 percent of Asians or Pacific Islanders, and 52 percent of American Indians or Alaskan natives. Among women, 38 percent of black, non-Hispanics were married, compared to about 60 percent of white, non-Hispanics and women of Hispanic origin, 65 percent of Asians or Pacific Islanders, and 56 percent of American Indians or Alaskan natives. When considering lifetime number of marriages, black, non-Hispanic

men and women are still less likely than others to ever marry.

By Age. The likelihood of being married increases with age for both men and women. However, among younger adults, women are more likely to be married than men. Twenty percent of women under 25 were married in 2001, compared to only 10 percent of men. Further, among those ages 45 and older, the odds of having two or more marriages go up to about 1 in 4.

By Poverty Status. Only 41 percent of poor men were married in 2001, and as income rises, so does one's probability of being married, such that 66 percent of men living at 300 percent of the poverty level were married in 2001. The marriage gap between women who are poor and those who are not is even wider. One out of every 3 poor women is married, while about 2 out of every 3 women at 300 or more percent of the poverty level are married. The difference between poor women and poor men is also notable: forty-one percent of poor men were married in 2001, compared to 33 percent of poor women.

Furthermore, the percentage of poor men and women who were married declined between 1991 and 2001, from 48 percent to 41 percent for men, and 37 percent to 33 percent for women. At the other end of economic stability, the percentage of men and women with incomes at 300 percent or more of the poverty level stayed about the same (67 percent of men and 69 percent of women at this income bracket were married in 1991).

By Educational Attainment. Seventy-two percent of men with a college education were married in 2001, compared to 59 percent of men with a high school diploma or equivalent and only 55 percent with less than 12 years of schooling. This pattern is similar for women: Sixty-five percent of women with a college degree were married in 2001, compared to 60 percent of women with a high school diploma or equivalent and 46 percent with less than 12 years of schooling.

Persons with less than a high school education are less likely to be married than they were ten years ago. For example, 61 percent of men and 50 percent of women with less than a high school education were married in 1991, compared to 55 percent of men and 46 percent of women of this level of education in 2001. Conversely, the percent of married men and married women with a college education remained relatively stable between 1991 and 2001 (72 percent of college educated men and 64 percent of college educated women were married in 1991).

Figure FF1.1 Percentage of married adults by poverty status and educational attainment: 1991 & 2001

SOURCE: Current Population Survey, 1991 and 2001 March Supplement

FF2 – Divorce

Divorce is linked to behavior problems among children, including depression, antisocial behavior, impulsive/hyperactive behavior, and school behavior problems.⁷ It places daughters at greater risk of having nonmarital births.⁸ Often these outcomes are the result of the processes that are set into motion when parents divorce. Children living with one parent are more likely to have household income below the poverty line than children living with both parents,⁹ and these children are often uprooted to new neighborhoods and schools supported by fewer financial resources.¹⁰ Spending time in a family that is not headed by two married parents increases the likelihood that a child will experience subsequent changes in his or her family status.¹¹ Thus, changes in a child's family situation can cause short-term instability and also interrupt important pathways for a child's social-economic well-being in adulthood.

Data from *The Survey of Income and Program Participation* is used to report the prevalence of divorce among adults who have ever married. We include information for the years 1990 and 1996 (refer to Table FF2.1).

By Gender. Between 1990 and 1996, the percentage of ever-married adults who divorced remained about the same among men and declined modestly for women. In addition, only slightly more ever-married women than men reported having experienced a divorce (32 percent of ever-married females compared to 30 percent of ever-married males in 1996).

By Parental Status. Resident parents are less likely to have experienced divorce than those without children: Seventy-nine percent of ever-married fathers had never divorced by 1996 compared to 61 percent of ever-married men without children; 72 percent of ever-married mothers have never divorced by 1996 compared to 63 percent of ever-married women without children (see Figure FF2.1).

Figure FF2.1 Percentage of ever-married parents and nonparents who have never divorced: 1996

SOURCE: Survey of Income and Program Participation, 1996

By Marital Status. The majority of those who were married in 1996 had never had a divorce (81 percent of men and 82 percent of women). Experiencing one divorce, however, may lead to another divorce. About 27 percent of previously married men and women had actually experienced two divorces or more.

By Race and Hispanic Origin. Hispanics are the least likely to divorce among race and ethnic groups. In 1996, seventy-nine percent of Hispanic males (and 75 percent of females) had never divorced, 69 percent of white, non-Hispanic males

(68 percent of females), and 63 percent of black, non-Hispanic males (58 percent of females).

By Poverty Status. For ever-married men, the likelihood of divorce differs little by poverty status (see figure FF2.2). Among ever-married women, however, the poor are more likely than higher income women to have been divorced at least once (44 percent among the poor compared to 29 percent for those at or above 300 percent of the poverty line in 1996).

The likelihood of divorce among ever-married men and women who are currently poor decreased slightly between 1990 and 1996. Among women,

for example, the percentage decreased from 53 percent to 44 percent.

Figure FF2.2 Percentage of ever-married adults who have experienced divorce, by poverty status: 1996

SOURCE: Survey of Income and Program Participation, 1996

FF3 – Age at First Marriage and Divorce

The age at which parents marry helps determine the stability of a child's living arrangements. Marriage at a young age increases the likelihood of future instability. For example, 59 percent of marriages to brides under age 18 end in separation or divorce within 15 years, compared to 36 percent of those married at age 20 or over.¹² When women delay marriage in pursuit of higher education and stable employment, this may foster the attainment of economic resources that make them attractive marriage partners; these resources also bode well for child health, social and emotional well-being, and academic achievement.¹³ The probability of remarriage is significantly higher for women who are younger at divorce, although, once again, a younger age at remarriage (e.g., under 25) places women at higher risk of experiencing future marital dissolution.¹⁴

Data from The Survey of Income and Program Participation is used to track age at first marriage for respondents in the years 1990 and 1996, and age at first divorce in 1996 (refer to Tables FF3.1 and FF3.2).

Age at First Marriage

By Gender. Consistent with traditional patterns, men marry at a later age than women. In 1996, the average age at first marriage for men was 25 years; women first married at 23, on average.

By Parental Status. Age at first marriage is similar for those who are currently parents than it is for men and women who do not have children. However, between 1990 and 1996, it did rise one full year for parents. Fathers married, on average, at the age of 24 in 1990 and 25 in 1996. Mothers married, on average, at the age of 22 in 1990 and 23 in 1996.

By Race and Hispanic Origin. In 1996, black, non-Hispanics had the highest ages at first marriage (26 and 23 years for males and females, respectively). They are followed by Hispanics (25

for men and 23 for women), and white, non-Hispanics (25 for men and 22 for women).

By Educational Attainment. College educated women first married at an average age of 25 years, while those with a high school education or equivalent married at 22, on average, and those with less than that first married at 21 years of age, on average. Among men, differences by level of education are more modest (see Figure FF3.1).

Age at First Divorce

By Gender. The age at first divorce is higher for men than it is for women. Men first divorce at an average age of about 34, while women first divorce at an average age of about 31. There is little difference across any of the other subgroups studied.

Figure FF3.1 Average age at first marriage by educational attainment: 1996

SOURCE: Survey of Income and Program Participation, 1996

FF4 – Characteristics of Current Spouse

The characteristics of parents provide resources for their children. The stable employment of both spouses gives families an economic advantage over other families. Higher levels of education and age among parents yield an increased ability to garner not only economic resources, but also other resources needed by families.¹⁵ For example, higher levels of income and education may provide family members with more knowledge of good health habits and better access to health and preventive services, and is related to higher educational achievement in children.¹⁶ Higher levels of men's education appear to support marriage and increase its stability, which bodes well for children.¹⁷

The Current Population Survey is used to track the characteristics of the spouses of males and females in 2001 (refer to Table FF4.1).

By Age. While men and women tend to marry other men and women of the same general age group, men tend to marry spouses younger than themselves. For example, 58 percent of married women under age 25 have a spouse who is 25- to 44-years-old. Only 18 percent of married men under 25 years of age have a spouse who is 25- to 44-years-old.

By Employment Status. Fifty-four percent of men working 35 or more hours a week have a wife who also works those same hours. However, 85 percent of wives working full-time have husbands who work full-time. When the wives of full-time working husbands aren't working full-time themselves, they are mainly out of the labor force (27 percent), or working less than 35 hours a week (17 percent). (see Figure FF4.1).

Figure FF4.1 Employment status of spouse for men and women working full-time: 2001

SOURCE: Current Population Survey, 2001 March Supplement

By Educational Attainment. Men and women are both most likely to marry someone with the same level of educational attainment. In the year 2001, college graduates are far more likely to marry each other than to marry someone with less education: 60 percent of male college graduates and 69 percent of female college graduates have spouses that are college graduates. Only 15 percent of male college graduates (and 13 percent of female college graduates) marry spouses with a high school education or less.

By Race and Hispanic Origin. The majority of married white, non-Hispanics; black, non-Hispanics; Hispanics; and Asian and Pacific Islanders have spouses of the same racial background. American Indians and Alaskan Natives, however, are equally likely to marry white, non-Hispanics as they are to marry someone of their same race.

Other differences also emerge. Black, non-Hispanic men are less likely to have a black, non-Hispanic spouse than are black, non-Hispanic women (92 percent compared to 96 percent). In addition, when black, non-Hispanic men do not marry other black, non-Hispanics, they are more likely than black, non-Hispanic women to have a white, non-Hispanic spouse (6 percent compared to 2 percent, respectively).

The opposite pattern seems to be true for Asian and Pacific Islanders. Ninety percent of these men, but only 83 percent of these women, have a spouse of the same ethnic background. Fifteen percent of Asian and Pacific Islander women are married to white, non-Hispanic spouses, whereas only 8 percent of Asian and Pacific Islander men have a white, non-Hispanic spouse. Hispanic men and women are about equally likely to have a Hispanic spouse (85 and 83 percent, respectively). White, non-Hispanic men and women are the most likely to have a spouse of the same race (96 and 97 percent, respectively).

FF5 – Attitudes Toward Divorce

Public attitudes toward divorce became more favorable in the mid-1970's, and they likely helped contribute toward the passing of no-fault divorce legislation.¹⁸ Since the 1970's, Americans have held attitudes that are by and large tolerant of divorce and divorce rates have remained quite high.¹⁹ At the same time that the public is tolerant of divorce, most young and old Americans place great emphasis on marriage and children and plan to devote much of their lives to their roles as parent and spouse.²⁰

Children with divorced parents score lower on average than children with continuously married parents on measures of academic success, conduct, psychological adjustment, social competence, and long-term health outcomes.²¹ Nevertheless, the great majority of children from divorced families do well, and the differences in well-being between children from divorced families and those from intact families tend to be moderate to small.²²

Two questions from the General Social Survey (GSS) are used to depict adult attitudes toward divorce. Respondents were asked to report how much they agreed with the following two statements: 1) "When there are children in the family, parents should stay together even if they don't get along" and 2) "Divorce is usually the best solution when a couple can't seem to work out their marriage problems." Both items were measured in 1994 (refer to Table FF5.1). It is worth noting that these two questions represent divorce in two circumstances; these attitudes are not necessarily indicative of all attitudes such as cases involving child and spousal abuse or infidelity.

Attitudes about divorce when there are children in the family

By Gender. A minority of men (20 percent) agree or strongly agree with the statement that "when there are children in the family, parents should stay together even if they don't get along." Even fewer women support this notion (12 percent).

By Marital and Parental Status. Women's low levels of support for the notion that parents should stay together even if they don't get along does not vary according to their marital or parental status. However, parenthood does have an effect on men— only 14 percent of male nonparents believe that parents should stay together even if they don't get along, compared to 23 percent of fathers (see Figure FF5.1).

By Educational Attainment. Support for maintaining a troubled marriage if it involves children varies according to educational status. Males and females with less than a high school education are much more likely than others to agree or strongly agree that parents should stay together even if they don't get along. For example, 37 percent of men with less than a high school education support this notion, compared to 14 percent of men with a high school education or equivalent and 17 percent of men with a college education; 25 percent of females with less than a

high school education agree or strongly agree with this notion, compared to 9 percent with a high school education or equivalent and 12 percent with a college education.

Figure FF5.1 Percentage of respondents who agree or strongly agree with the statement that "when there are children in the family, parents should stay together even if they don't get along," by gender and parental status: 1994

SOURCE: General Social Survey, 1994

Attitudes about divorce when a couple can't seem to work it out.

By Gender. About half of all men and women agreed or strongly agreed with the statement that “divorce is usually the best solution when a couple can’t seem to work out their marriage problems.”

By Race and Hispanic Origin. Over half (62 percent) of black, non-Hispanic women agree or strongly agree that divorce is the best solution when a couple can’t seem to work out their marriage problems, while less than half of white, non-Hispanic, Hispanic, and American Indian/Alaskan Native women support this statement.²³ In addition, about 50 percent more black, non-Hispanic women than black, non-Hispanic men support divorce.

By Marital and Parental Status. About fifty percent of men, regardless of their marital or parental status, agree with the statement that divorce is the best solution to marital problems. Women who are married, however, are somewhat less likely to endorse this view than unmarried women (44 percent compared to 51 percent). Women who do not have children are less likely than mothers to agree with this point of view (37 percent compared to 51 percent).

By Age. Tolerance of divorce varies by age among women. Women under 25 years old are less likely to endorse divorce than females age 45 or older (35 percent and 55 percent, respectively). Men, however, hold about the same opinion of divorce, regardless of age.

By Employment Status. Men and women who work full-time are less likely than others to support divorce. Forty-seven percent of men working full-time agree or strongly agree that divorce is a good solution in the face of marital problems compared to 62 percent of men who work less than 35 hours a week. Forty-two percent of women working full-time agree that divorce is a good solution to marital problems compared to 56 percent of women working less than 35 hours a week and 53 percent who are not in the labor force.

FF6 – Cohabitation Status

Cohabitation among adults is an increasingly common element in the formation of children's families. The majority of marriages and remarriages now begin as cohabiting relationships.²⁴ Among cohabitating couples with children, 70 percent have the biological children of only one partner.²⁵ Further, about 40 percent of all 'nonmarital' births can actually be attributed to cohabiting couples.²⁶ The birth of a child to a cohabiting couple tends to lead to marriage for white, non-Hispanic parents, but not for black, non-Hispanic parents.²⁷

While some research suggests that children living in cohabiting families are worse off economically compared to children living with married parents²⁸ and are at risk of experiencing future instability in their living arrangements,²⁹ it is important to note that children already disadvantaged in terms of parental income and education are relatively more likely to experience this family form.^{30,31}

Data from the Current Population Survey March Supplements are used to track current cohabitation status in the years 1991 through 2001 (refer to Table FF6.1).

By Gender. The percentage of adult men and women who cohabit rose between 1991 and 2001 (see Figure FF6.1). Four percent of all men cohabited in 1991, rising to about 5 percent in 2001. Three percent of all women cohabited in 1991, rising to about 5 percent in 2001.

These percentages are higher when considering only those who are "available" to cohabit – men and women who are not married. Eleven percent of unmarried men cohabited in 1991, rising to 13 percent in 2001. Eight percent of unmarried

women cohabited in 1991, rising to 11 percent in 2001 (see Figure FF6.1).

By Poverty Status. Cohabitation is clearly linked to poverty status. Thirteen percent of poor men and 11 percent of poor women cohabited in 2001. These percentages shrink at higher income levels, such that only 3 percent of men and women with family incomes at 3 times the poverty level cohabited in 2001 (see Figure FF6.2).

Figure FF6.1 Percentage of cohabitators, by gender: 1991-2001

SOURCE: Current Population Survey, 1991-2001 March Supplement

By Parental Status. Men cohabit at similar rates, whether or not they are parents (about 5 percent in 2001). However, mothers cohabit at lower rates (4 percent in 2001) than women with no children (5 percent in 2001). Overall, 40 percent of all cohabitations among men and women involve parents with children in the household.³²

By Age. Females under age 25 are more likely to cohabit than men of the same age (9 percent of females and 6 percent of men), mirroring patterns of age at marriage by gender. Also, the proportion of cohabitators among those ages 45 and older is much smaller than among those under 45 years old. Only three percent of men and two percent of women ages 45 or older cohabited in 2001.

Figure FF6.2 Percentage of cohabitators, by poverty status: 2001

SOURCE: Current Population Survey, 2001 March Supplement

FF7 – Age at First Cohabitation

Although marriage rates have been on the decline, increasing rates of cohabitation have largely offset this trend.³³ Furthermore, the proportion of births to unmarried women in cohabiting families increased in the period between 1980-84 and 1990-94, accounting for almost all of the increase in unmarried childbearing.³⁴ In short, cohabitation has increasingly become an alternative to marriage for couples, and may influence child development. Cohabitation at a young age may increase the likelihood of a nonmarital birth, and children born into cohabiting unions are likely to experience future instability in their living arrangements.³⁵ Births to older, and likely more economically stable, cohabitators may have different implications for children's living arrangements.

Data from *The National Survey of Families and Households* are used to track age at first cohabitation for respondents in 1988 (refer to Table FF7.1).

By Gender. The average age at first cohabitation was about one-and-a-half-years older for men than women in 1988. In general, it is notable that age at first cohabitation did not vary widely across other demographic groups. College graduates and high income men and women (300+ percent of poverty) first cohabited at older ages, on average, than those with less than a college degree or who were living in poverty (see Figure FF7.1).

Compared to Age at First Marriage. Age at first cohabitation was about one year lower for both men and women compared to age at first marriage in the late eighties. The average age at first cohabitation was 23 for men and 21 for women in 1988 (refer to Table FF7.1). The average age at first marriage was about 24 for men and 22 for women in 1990 (refer to Table FF3).

Figure FF7.1 Average age at first cohabitation: 1988

SOURCE: National Survey of Families and Households, 1988

FF8 – Characteristics of Current Partner

Cohabitation is often short-lived—about 50 percent of these couples are likely to marry or disrupt their relationship within one year, and up to 90 percent within the first five years.³⁶ Parents of children in cohabiting unions typically have much lower earnings and higher rates of poverty than parents of children in married couple families.³⁷ Cohabiting parents are likely to have lower levels of parental education and income than married parents,³⁸ and their children may not have legal access to paternal resources.

The Current Population Survey (CPS) is used to identify the characteristics of men's and women's opposite-sex partners in 2001 (refer to Table FF8.1). The CPS is also used to identify the characteristics of men's and women's spouses (refer to Table FF4.1).

By Race and Hispanic Origin. Like married adults, the majority of men and women cohabit with someone of their same race; however, it appears that there is slightly more heterogeneity among cohabiting couples than among married couples (see Figures FF8.1 and FF8.2). Ninety-two percent of married black, non-Hispanic men have a black, non-Hispanic spouse, whereas only 82 percent of cohabiting black, non-Hispanic men have a black, non-Hispanic partner. Eighty-five percent of married Hispanic men have a Hispanic spouse, whereas only 74 percent of cohabiting

Hispanic men have an Hispanic partner. Ninety-seven percent of married white, non-Hispanic women have a white, non-Hispanic spouse, whereas only 91 percent of cohabiting white, non-Hispanic women have a white, non-Hispanic partner. Finally, 90 percent of married Asian or Pacific Islander men (and 83 percent of women) marry someone of the same ethnicity, whereas only 63 percent of cohabiting men (and 46 percent of women) have a partner who is also of Asian or Pacific Islander descent.

Figure FF8.1 Percentage of married/cohabiting men who have spouses of the same race or ethnicity, by race/ethnicity of respondent: 2001

SOURCE: Current Population Survey, 2001 March Supplement

Figure FF8.2 Percentage of married/cohabiting women who have spouses of the same race or ethnicity, by race/ethnicity of respondent: 2001

SOURCE: Current Population Survey, 2001 March Supplement

By Age. Like married adults, the majority of cohabiting men and women have partners their own age. However, it appears that there is more heterogeneity in cohabiting partners, especially among those ages 45 and older. Ninety-six percent of married women 45 or older have a spouse in their same age group, whereas only 78 percent of cohabiting women have a partner in this age group, and 22 percent have younger partners. Eighty-five percent of married men 45 and older have a spouse of the same age group, whereas only 68 percent of cohabiting men have a partner in this age group.

Among younger cohabitators, as among married couples, women tend to cohabit with older men. Forty-six percent of cohabiting women ages 15 to 24 have a partner ages 25 to 44, whereas only 20 percent of cohabiting men ages 15 to 24 have a partner ages 25 to 44.

By Educational Attainment. Married women with college educations are more likely to have a college-educated spouse than cohabiting college-educated women. Sixty-nine percent of married women with college degrees have a spouse who is a college graduate, whereas only 56 percent of cohabiting women with a college degree have a partner with a college degree.

By Employment Status. Married women who work full-time are more likely to have a spouse who also works full-time than cohabiting women with full-time jobs. Eighty-five percent of married women working full-time have a spouse who is also working full-time, whereas only 79 percent of cohabiting women have a partner who also works full-time. However, only 54 percent of married men working full-time have a spouse who is also working full-time, and 68 percent of cohabiting men who work full-time have a partner who also works full-time.

FF9 – Attitudes Toward Cohabitation Without Intent to Marry

Approximately 4 in 10 children will spend some of their childhood living in families headed by a cohabiting couple.³⁹ Children living in cohabiting families are more likely to be worse off economically than children living with married parents,⁴⁰ and are at a higher risk of experiencing future instability in their living arrangements as well as fewer legal claims to child support or to other sources of family income.⁴¹ Furthermore, parental attitudes and experiences, including those related to marriage, are associated with their children's behaviors throughout their lives.⁴² For example, young females whose mothers believed cohabitation was acceptable cohabited at higher rates than young females whose mothers opposed cohabitation.⁴³

Cohabitation between adults, and births to unmarried cohabiting couples, have risen in the 1990s. It is essential to monitor attitudes towards cohabitation, as well as current policies that affect an adult or child's experience of this event. To capture adult attitudes toward cohabitation without intent to marry, respondents of the General Social Survey (GSS) were asked to report how much they agreed with the following statement: "it is all right for a couple to live together without intending to get married." This item was measured in 1994 and 1998 (refer to Table FF9.1).

By Gender. Women are substantially less likely to support cohabitation without intent to marry than men. For example, in 1998, only 38 percent of women either agreed or strongly agreed with the statement that "it is all right for a couple to live together without intending to get married," whereas about half of men supported cohabitation without the intent to marry.

By Marital Status. Married men and women are less likely to support cohabitation without an intention to marry than those who are not married. For instance, only 40 percent of married men supported cohabitation in 1998 compared to 59 percent of unmarried men. Similarly, only 30 percent of married women compared to 42 percent of unmarried women supported cohabitation in 1998.

By Parental Status. Fathers and mothers are less likely than nonparents to support living together without an intention to marry (see Figure FF9.1). For instance, 44 percent of fathers supported cohabitation in 1998 compared to 64 percent of men who were not parents. Similarly, only 32 percent of mothers supported cohabitation compared to 57 percent of women who did not have children.

By Age. Those who were young adults in 1998 were more likely than older men and women to agree that living together without intending to get married was all right. Seventy-seven percent of males under age 25 in 1998 supported cohabitation without intent to marry compared to 58 percent of males ages 25 to 44, and 39 percent of those aged 45- to 65-years-old. Females show a similar

pattern, albeit with lower percentages in each age group.

By Employment Status. Men and women who are not in the labor force are less likely than those who work to believe that it is all right to live together without intending to get married, though that relationship is partly accounted for by the fact that those not in the labor force are more likely to be older and retired.

Figure FF9.1 Percentage of respondents who agree or strongly agree that it is all right for a couple to live together without intending to get married, by parental status: 1998

Fertility Section

F1 – Birth Rates

The birth rate measures the number of births that occur to 1,000 adults of reproductive age in any given year. The characteristics of parents at the time of birth, such as age and marital status, are strong predictors of children's developmental outcomes.¹ For example, teenage fathers tend to be emotionally and financially less prepared for undertaking parental responsibilities,² and thus have a lower level of involvement in parenting. Teenage mothers are less likely to complete school, more likely to be a single parent, and more likely to be poor.³

Birth rates are based on information collected from birth certificates, combined with population estimates generated by the U.S. Bureau of the Census. Rates for males should be interpreted with caution, however, due to potential biases from underreporting. Over 14 percent of births in 1998, for example, did not have the age of fathers listed on the birth certificate.⁴ This is due in part to restrictions on reporting paternal information for birth certificates when the parent are not married.⁵ Refer to Tables F1.1 and F1.2 for birth and fertility rates from the National Vital Statistics Report.

Trends. In general, birth and fertility rates of males and females have declined modestly since 1980. For example, the fertility rate for females (the number of births per 1,000 females ages 15 to 44) decreased from 68.4 births in 1980 to 65.9 births in 1999. Rates for males (reported for males

ages 15 to 54) declined from 57.0 to 50.8 during that same period. The birth rates for males are based on the population up to age 54 rather than 44, and are thus not directly comparable to the estimates for females.

Figure F1.1 Birth rates by age and gender: 1999

SOURCE: Ventura, S. J. et al. (2001). Births: Final data for 1999. *National Vital Statistics Report*, 49(1). Hyattsville, MD: National Center for Health Statistics.

By Age. Males tend to have children at older ages than females (see Figure F1.1). While rates for both sexes now peak at ages 25 to 29, females have higher rates than males for ages 15 to 29 and males have higher rates than females beyond that age. Birth rates among teenage females are more than twice as high as teenage males (49.6 compared to 21.0 per 1,000 in 1999), which may reflect both the under-identification of teen fathers on birth certificates, and the fact that the fathers of the children of teen mothers are often not teens themselves.⁶ By ages 35 to 39, birth rates are 1.4

times higher for males than females (54.9 compared to 38.3 in 1999).

While birth rates declined overall between 1980 and 1999, they increased for males and females at older ages, particularly for females. Among females ages 30 to 34, rates increased from 61.9 to 89.6 per 1,000 during that period, and from 19.8 to 38.3 per 1,000 females ages 35 to 39. Increases for males were more modest, from 91.0 to 101.6 births per 1,000 males ages 30 to 34, and from 42.8 to 54.9 per 1,000 males ages 35 to 39.

At the other end of the age spectrum, rates among young males and females ages 15 to 19 rose between 1980 and the 1990s before declining

again. By 1999, birth rates for teenage females were slightly below their 1980 rates while those for teenage males were slightly above.

Figure F1.2 Birth rates for females of reproductive ages by race and Hispanic origin¹: 1980 - 1999

¹Persons of Hispanic origin may be of any race. Estimates for all race categories include persons of Hispanic origin.

SOURCE: Ventura, S. J. et al. (2001). Births: Final data for 1999. *National Vital Statistics Report*, 49(1). Hyattsville, MD: National Center for Health

By Race and Hispanic Origin. During the past two decades, among females birth rates were highest among Hispanics, lowest among whites and Asian or Pacific Islanders, with blacks and American Indians in between (see Figure F1.2). The differences between Hispanics and other racial/ethnic groups have been increasing due to opposing trends. Since 1980, birth rates among females have fallen by 17 percent for blacks, 16 percent for American Indians, and 10 percent for Asian or Pacific Islanders, and have remained relatively constant among whites. During the same time period the rates for Hispanic females rose from 95.4 births per 1,000 Hispanic women to 102.0.

For males, published birth rates are available only for whites and blacks. Rates for black males were

substantially higher relative to white males throughout the period with rates of 66.9 births per 1,000 black men ages 15 to 54 compared to 48.2 per 1,000 white men ages 15 to 54 in 1999. Birth rates have declined for both groups, but more dramatically among black males, dropping from a high of 84.9 births per 1,000 black males in 1990 to 66.9 per 1,000 in 1999.

By Marital Status. Birth rates among unmarried females have increased substantially from 29.4 births per 1,000 unmarried females ages 15 to 44 in 1980 to 44.4 births per 1,000 in 1999. During the same period, rates for married females fell from 97.0 births per 1,000 married females ages 15 to 44 to 86.5 per 1,000. Birth rates by the marital status of males are not available at this time.

F2 – Age at First Birth

The timing of childbearing has significant implications for the well-being of parents and children. Early childbearing often reflects socioeconomic disadvantage.⁷ Although it is difficult to disentangle the relative effects of early childbearing and preexisting socioeconomic disadvantage, young mothers face more negative educational and employment outcomes than women who delay childbearing.⁸ The effect of early childbearing may not be as strong for fathers as for mothers. For example, one study indicates that early fatherhood is associated with lower levels of schooling, income, and working hours, but its impact disappears when other socio-economic factors are taken into account.⁹

Young parents have limited economic, social, and developmental resources available for children, which may have negative effects on their development. Younger mothers have a higher risk of having a low birthweight infant, and their children are more likely to experience long-term morbidity and infant mortality.¹⁰ Children born to teenage mothers are more likely to repeat a grade in high school, less likely to graduate from high school, and more likely to become victims of abuse and neglect than are those born to older parents;¹¹ they are also more likely themselves to have a teenage birth.¹²

Although childbearing at older ages has become more common compared to several decades ago, mothers older than 45 are still at higher risk of having a low birthweight infant, mainly due to their higher likelihood of having multiple births.¹³

This section presents the data from the National Health and Social Life Survey, 1992, one of the few surveys that collected fertility information from both males and females (refer to Table F2.1).

By Gender. Females were three times more likely than males to experience their first birth before age 20 (33 percent compared to 11 percent), suggesting that teenage mothers' partners are not necessarily teenagers themselves. Almost half of males have their first birth after age 25 compared to a quarter of females (see Figure F2.1). This is due in part to the tendency of some unmarried females to not report paternal information for birth certificates.¹⁴

By Race and Hispanic Origin. Regardless of gender, black, non-Hispanics and Hispanics are more likely than white, non-Hispanics and Asians to have had their first birth before age 20. Among females, the percentage having a birth before age 20 was 57 percent for black, non-Hispanics and 41 percent for Hispanics, compared to 28 percent for white, non-Hispanics and 8 percent for Asians. The same pattern holds true for males although they have lower percentages in each racial group.

Figure F2.1 Age at first birth by gender: 1992

SOURCE: National Health and Social Life Survey, 1992

By Marital Status. Currently unmarried adults are more likely than married adults to have had their first birth before age 20 (see Figure F2.2). Almost half (45 percent) of mothers who are not currently married had their first birth before age 20 compared to 29 percent of currently married mothers. The same pattern holds true for fathers.

By Poverty Status. Poor parents, particularly mothers, are more likely to have had their first birth during adolescence (see Figure F2.2). Slightly more than half of mothers in poverty had their first birth before age 20 compared to 29 percent of nonpoor mothers. The same pattern holds true for fathers. Fathers in poverty are twice

as likely as nonpoor fathers to have had their first birth before age 20 (21 percent compared to 10 percent).

By Employment Status. Early childbearing (before age 20) is related to the current employment status of mothers. Mothers working full-time are more likely to have had their first birth before age 20 than part-time workers (36 percent compared to 28 percent). The percentage having children before age 20 does not differ by employment status for males.

Figure F2.2 Percentage of adults ages 18 to 59 who had the first birth before age 20 by poverty status, marital status, and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

F3 – Number of Pregnancies

Information about pregnancy has typically been available only for women. Increased attention to the roles of men as they become fathers has led to an interest in basic descriptive information on male fertility. Here we present comparable data for males and females on the incidence of pregnancy by varied social and demographic factors.

Although we do not present data here on pregnancy intention, many studies have found negative consequences related to unintended pregnancies and births. Females with an unintended pregnancy are more likely to experience maternal depression during the pregnancy,¹⁵ less likely to receive prenatal care, and more likely to engage in behaviors such as smoking that may cause health problems related to pregnancy and birth.^{16,17} Reflecting these disadvantages, research has also found that children who were unwanted or mistimed are more likely to receive fewer developmental resources at home during their childhood.^{18,19} Little is known about the effects of unintended births on the fathers or about the implications of paternal intentions for children.²⁰

This section reviews data from the 1992 National Health and Social Life Survey (NHSLS), one of only a few national surveys that collected fertility information from both males and females (refer to Table F3.1). (Note: Analyses of survey data indicate that abortions and pregnancies are underreported in surveys. However, certain analyses of NHSLS data suggest that responses are not “systematically biased downward,” and that discrepancies may, in fact, reflect individuals’ and medical institutions’ dissimilar definitions of these events.²¹ We report these data because they are currently the only data on pregnancy for adult males.²²)

By Gender. Females are more likely than males to report pregnancies. In 1992, 44 percent of females and 29 percent of males reported three or more pregnancies. Conversely, 34 percent of males reported no pregnancies compared to 21 percent of females.

By Race and Hispanic Origin. Non-Hispanic white females are less likely to report ever having been pregnant than non-Hispanic black females. In 1992, 78 percent of white, non-Hispanic females reported that they had any pregnancies compared to 87 percent of black, non-Hispanic females. Additionally, black, non-Hispanic females are about 1.7 times more likely than non-Hispanic white and Hispanic females to report five or more pregnancies. Little variation by race or ethnicity in the number of pregnancies is found among males.

By Age. Not surprisingly, the number of females and males reporting any pregnancies increases with age. Ninety-two percent of females ages 45 to 59 report at least one pregnancy compared to 85 percent of females ages 25 to 44, and 40 percent of females ages 18 to 25. The pattern is similar for males, except that fewer males report one pregnancy or more.

By Poverty Status. Males in poverty are less likely to report any pregnancies (56 percent) than nonpoor males (71 percent). Females are just as likely to report any pregnancies, regardless of

poverty status (78 percent of poor women, compared to 81 percent of nonpoor women).

By Marital Status. Not unexpectedly, those who are currently married are more likely to have had pregnancies than those who are not married. At least 90 percent of married males and females reported at least one pregnancy (see Figure F3.1). Among those who are not currently married, females are more likely than males to report one or more pregnancies. One-third of unmarried males reported one or more pregnancies, compared to 56 percent of females.

Figure F3.1 Percentage of adults ages 18 to 59 reporting one pregnancy or more by marital status and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

By Educational Attainment. The percentage of females reporting three pregnancies or more decreases substantially as education increases (see Figure F3.2), though a similar pattern is not found among males. In 1992, 32 percent of females with a college degree reported three or more pregnancies compared to 63 percent for those without a high school education.

By Employment Status. Current employment status is strongly related to pregnancy among males, but not among females. In 1992, close to half (45 percent) of part-time male workers reported any pregnancy compared to 73 percent of full-time workers.

Figure F3.2 Percentages of adults ages 18 to 59 reporting three pregnancies or more by educational attainment and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

F4 – Premarital Birth

Childbearing outside of marriage has continuously increased for several decades among women of all ages.²³ Premarital births, births occurring before first marriage, have received considerable attention²⁴ due to socio-economic disadvantages prevalent among unmarried parents and their children.²⁵ Marital status at first birth is strongly associated with poverty status and welfare receipt, regardless of the age of the mother.²⁶ Similarly, women with nonmarital births are more likely to have lower educational attainments, less likely to work full-time, and more likely to earn lower incomes.²⁷ It is important to note, however, that women who have nonmarital births tend to be disadvantaged before the birth²⁸ and therefore it is difficult to clearly differentiate the effects of nonmarital births from their pre-existing disadvantages.

Children born to unmarried parents are more likely to be disadvantaged than children born to married parents.²⁹ Children born to unmarried parents are more likely to grow up in a single-parent family,^{30,31} which has been associated with poverty status³² and lower educational attainment.³³ Research suggests that two-parent families are more likely to provide more developmental resources for children than single-parent families.³⁴ Nonmarital births increasingly occur to cohabiting couples.³⁵ Therefore, being born to unmarried parents does not necessarily mean that the child is growing up in a single-parent household. However, cohabiting relationships tend to last for a relatively short period of time.³⁶ Instability in family structure, such as multiple living arrangements among children born to unmarried parents, has been found to be associated with recurring risky sexual behaviors, such as premarital sex during adolescence, as well as having a premarital birth.^{37,38,39}

This section reviews the percentages of premarital births⁴⁰ among males and females ages 18 to 59 from the 1992 National Health and Social Life Survey, which is one of the few national datasets that collect fertility information from both males and females (refer to Table F4.1).

By Gender. The percentage of adults ages 18 to 59 who had a premarital birth is slightly higher among females than males (19 percent compared to 15 percent). The difference is larger for younger adults. Females ages 18 and 24 are more than five times as likely as their male counterparts to have a premarital birth (21 percent compared to 4 percent), which may indicate that male partners of unmarried mothers are older.

By Race and Hispanic Origin. Non-Hispanic blacks are more likely to report a premarital birth than other racial/ethnic groups. Slightly more than half of non-Hispanic black females reported a premarital birth compared to 28 percent of Hispanics, 12 percent of non-Hispanic whites, and 6 percent of Asians or Pacific Islanders. These estimates for women ages 18 to 59 in 1992 are similar to the estimates obtained from women ages 15 to 44, as reported in the National Survey of Family Growth, 1995 (see Figure F4.1). A similar pattern holds true for males, with non-Hispanic blacks being more likely than men from other racial/ethnic backgrounds to have had a premarital birth.

Figure F4.1 Percentage of females ages 15 to 44 who had a pre-marital birth by race and Hispanic origin: 1995

SOURCE: National Survey of Family Growth, 1995⁴¹

By Educational Attainment. The percentage of females with a premarital birth declines significantly as education increases (see Figure F4.2). Thirty-five percent of females without a high school education reported a premarital birth compared to 24 percent of high school graduates or

GED recipients, 14 percent of those with vocational or technical training or some college education, and 10 percent of college graduates. A similar pattern is found among males. Males with a high school education or less were more likely to report a premarital birth than males with some college, vocational/technical school or college degree.

By Poverty Status. Poor adults are far more likely than nonpoor adults to have had a premarital birth (22 percent of males and 35 percent of females in poverty compared to 15 percent of nonpoor males and females).

By Marital Status. Current marital status is related to having had a premarital birth, but in opposite directions for males and females. Currently married males are more likely than unmarried males to have had a premarital birth (18 percent compared to 10 percent) whereas unmarried females are more likely than married females to have had a premarital birth (24 percent compared to 17 percent).

Figure F4.2 Percentage of adults ages 18 to 59 who had a pre-marital birth by educational attainment and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

F5 – Age at First Sexual Intercourse

An indicator of age at first sexual intercourse compares the characteristics of those who had an early sexual debut with those who delayed first sexual intercourse. It also shows the proportion of sexually experienced populations by age. Because of the negative consequences of early sexual initiation, monitoring early sexual initiation has been of great interest to researchers and policy makers. Those who become sexually active at an earlier age have a longer period of exposure to risks such as unintended pregnancies.⁴² Furthermore, early initiation of sex has been found to increase the likelihood of having more sexual partners and the frequency of sexual intercourse,^{43,44} which in turn increases the chances of contracting sexually transmitted diseases and experiencing unintended pregnancy.⁴⁵

This section reviews data from the National Health and Social Life Survey, 1992, one of the few national surveys that collected fertility information from both males and females (refer to Table F5.1).

By Gender. Among adults ages 18 to 59 in 1992, over half (55 percent) of males and 43 percent of females reported having their first sexual intercourse before age 18 (see Figure F5.1). Fifteen percent of males and 6 percent of females report early sexual initiation (sexual intercourse prior to age 15). By age 18-19, 78 percent of males and 71 percent of females are sexually experienced (i.e., have ever had sexual intercourse).

By Race and Hispanic Origin. Non-Hispanic blacks were more likely than other racial/ethnic groups to report first sexual intercourse before they turn 18 (see Figure 5.2). Before age 18, over three quarters of non-Hispanic black males had their first sexual intercourse compared to 60 percent of Hispanics, 52 percent of white, non-Hispanics, 36 percent of American Indians and 21 percent of

Asian Americans. A quarter of non-Hispanic black males reported having their first sexual intercourse between the age of 13 and 14 compared to 16 percent of Hispanics and 10 percent of non-Hispanic whites.

Asians and Pacific Islanders were far more likely to delay their first sexual intercourse until at least age 18 than other racial groups. The vast majority of Asian females (84 percent) had their first sexual intercourse after they turned 18, whereas 57 percent of Hispanics, 54 percent of non-Hispanic whites, and 37 percent of non-Hispanic blacks did the same. In particular, 23 percent of Asian females did not have their first sexual intercourse until they turned 25 compared to between 1 and 9 percent for other racial groups. The same pattern holds true for males.

Figure F5.1 Percentage of adults age 18 to 59 who had their first sexual intercourse by the specified age, by gender: 1992

SOURCE: National Health and Social Life Survey, 1992

Figure F5.2 Percentage of males ages 18 to 59 who had sexual intercourse by the specified age, by race and Hispanic origin: 1992

SOURCE: National Health and Social Life Survey, 1992

By Educational Attainment. College graduates are far more likely than those without a high school education to delay their first sexual intercourse until they turn 18. The differences are particularly pronounced among females. Twenty-one percent of females with a college degree had their first intercourse prior to age 18 compared to 67 percent of females without a high school education. For males, the rates are 39 percent and 64 percent, respectively.

By Poverty Status. Females in poverty are more likely to have their first sexual intercourse at a very young age than those who are not poor. Fourteen

percent of poor females had their first sexual intercourse before age 15 compared to 6 percent of nonpoor females. The same pattern holds true for males but the difference is not statistically significant.

By Age. Average age at first sexual intercourse has been declining. Sixty-eight percent of males ages 18 to 24 had their first sexual intercourse before age 18 compared to 41 percent of males ages 45 and older. The same pattern also holds true for females (56 percent of younger females compared to 30 percent of older females).

F6 – Number of Sexual Partners

Having sexual intercourse with multiple partners increases the chances of being exposed to, contracting, and transmitting STDs and AIDS. Even a person with a single partner can be at a high risk of sexually transmitted infections when their partner is involved in other sexual relationships.⁴⁶ The high number of sexual partners among adolescents, particularly adolescent males,⁴⁷ is of special concern for these reasons. Additionally, a strong association has been found between having multiple sexual partners and other risk behaviors among youth including the use of alcohol and illicit drugs, early sexual initiation,⁴⁸ and violence and aggression.⁴⁹

Data from the General Social Survey, 1988 to 2000, are used for this indicator. The data show the percentages of males and females ages 18 to 65 who had two or more sexual partners (either concurrent or serially) in the last 12 months (refer to Table F6.1).

By Gender. The percentage of adults who report having two or more sexual partners in the last 12 months remained fairly stable during the last decade. In 1988, males were almost twice as likely as females to report having two or more sexual partners (22 percent of males compared to 12 percent of females). The percentages remained virtually the same a decade later (22 percent of males in 2000 compared to 11 percent of females).

By Race and Hispanic Origin. Racial/ethnic differences are found only among males. Non-Hispanic black males are more likely to report having two or more partners than other racial/ethnic groups except Hispanics (see Figure F6.1). In 2000, 33 percent of non-Hispanic black, 20 percent of non-Hispanic white, and 13 percent of Asian or Pacific Islander and American Indian males had at least two sexual partners. The percentage of Hispanics with multiple partners (34 percent) is also higher than most other racial groups but the difference between Hispanics and non-Hispanic whites is not statistically significant.

By Age. Adults ages 45 and older are far less likely than adults under the age of 45 to report having multiple sexual partners. In 2000, 11 percent of males age 45 and older had two or more partners compared to 39 percent of males ages 18 to 24 and 29 percent of males ages 25 to 44. The same pattern holds true for females.

By Marital Status. Not surprisingly, single adults are far more likely than those who are married to report having multiple sexual partners within the last 12 months. Thirty three percent of single males and 4 percent of married males had two or more sexual partners in the past 12 months. Although less frequent, the same pattern holds true for females (15 percent of single females compared to 2 percent of married females).

Figure F6.1 Percentage of adults ages 18 to 65 reporting two or more sexual partners in the last 12 months by race and Hispanic origin and gender: 2000

SOURCE: General Social Survey, 2000

By Parental Status. Males without children were twice as likely as fathers to report having two or more partners in the last 12 months (31 percent compared to 15 percent). The same pattern holds true for females (15 percent compared to 9 percent respectively).

By Employment Status. The number of sexual partners in the past 12 months differs by employment status. Males who are not in the labor force are far less likely than full- or part-time workers to report having multiple sexual partners in the last 12 months. In 2000, 8 percent of those who were not in labor force, 27 percent of full-time workers and 18 percent of part-time workers had two or more partners in the past 12 months. Some variations are also found among females but differences are often not statistically significant.

F7.a – Characteristics of Sexual Partners – Type of Relationship

This section reviews four indicators related to the characteristics of sexual partners: (1) seriousness of relationship with the current or most recent sexual partner, (2) length of relationship with the first and current or most recent sexual partner, (3) race/ethnicity of the current or most recent sexual partner, and (4) age of the current or most recent sexual partner.

The level of seriousness of sexual relationships has been found to be associated with sexual behaviors, particularly contraceptive use.⁵⁰ Females in steady relationships are more likely to report contraceptive use than those who are “just friends with,” or who “just met” their sexual partners.⁵¹ On the other hand, steady and close relationships have been found to be inversely related to the use of condoms among males.⁵² Males are more likely to use contraceptives to prevent sexually transmitted diseases in casual relationships than in more serious, committed relationships.⁵³

This section reviews data on the seriousness of relationships at first sexual intercourse with the current or most recent sexual partner. Data for males and females are reviewed separately except for adolescents due to the lack of comparable data. Two national surveys asked the same question but to different age groups: the National Survey of Family Growth (NSFG) collected data from females ages 15 to 44 and the National Survey of Adolescent Males (NSAM) collected data from males ages 15 to 19 and 21 to 27 (refer to Table F7.1). The NSFG is expected to start collecting comparable data from both genders in 2002.

Adolescents. Adolescent males and females are most likely to wait to have sexual intercourse until their relationship has become somewhat formalized (going together or going steady) (see Figure F7a.1). However, of those who report first sexual intercourse at earlier stages, adolescent males are more likely than females to report a casual

relationship at first sexual intercourse with their current or more recent sexual partner. Of the three categories of casual relationships (just met, just friends and went out once in a while) males were significantly more likely than females to report sexual intercourse at the just friends and going out stages.

Figure F7a.1 Percentage of males and females ages 15 to 19 reporting the seriousness of relationship with the most recent sexual partner at the first sexual intercourse: 1995

	Just Met	Just Friends	Went Out Once in a While	Going Together/ Going Steady	Engaged	Married
Males	6	18	16	57	2	1
Females	4	10	11	69	4	2

SOURCES: For males, National Survey of Adolescent Males, 1995. Population estimates calculated by the Urban Institute. For females, National Survey of Family Growth, 1995. Population estimates calculated by the National Center for Health Statistics.

Males Ages 15 to 19 and Ages 21 to 27

By Race and Hispanic Origin. White, non-Hispanic teenage males are more likely than black, non-Hispanic males to report a serious relationship (going together/going steady, engaged, married or living together) at the time of first sexual intercourse with their current or most recent sexual partner (see Figure F7a.2). In 1995, 63 percent of white, non-Hispanic adolescent males reported a formal relationship compared to 51 percent of black, non-Hispanic adolescent males.

Black, non-Hispanic males ages 15 to 19 are more likely than white, non-Hispanic males in that age group to report casual relationships (just met, just friends, went out once in a while) at first sexual intercourse with their most recent partner. In contrast, there is no significant difference between non-Hispanic blacks and whites in the 21 to 27 year age group. The percentages of those reporting first sexual intercourse within a casual relationship are not substantially different across race/ethnicity categories.

Figure F7a.2 Seriousness of relationship with the current or most recent sexual partner at the first sexual intercourse by race and Hispanic origin for males ages 15 to 19: 1995

SOURCE: National Survey of Adolescent Males, 1995. Population estimates calculated by Urban Institute.

Females Ages 15 to 44

Total. About three quarters of females ages 15 to 44 were relatively committed to their current partner the first time they has sexual intercourse with them. In 1995, more than half of females (55 percent) were “going steady,” 8 percent were engaged, and 12 percent were married when they first had sexual intercourse with their current or most recent partner (refer to Table F7.1). Relatively few (5 percent) reported having casual sexual intercourse with someone they just met.

By Poverty Status. Females in the highest income bracket (incomes at 3 times the poverty level or more) are more likely than those in extreme poverty (incomes at 50 percent of the poverty line or less) to report a relatively stable and exclusive relationship with their current partner (i.e., going steady, engaged or married) when they first had sexual intercourse. For example, at the time of first sexual intercourse with their most recent partner 58 percent of females in the highest income bracket were going steady compared to 50 percent of

females in extreme poverty, 8 percent were engaged (compared to 4 percent in extreme poverty) and 12 percent were married (compared to 4 percent in extreme poverty).

By Race and Hispanic Origin. Although some racial/ethnic variations are found, the majority of females in any racial/ethnic group report an exclusive relationship with their most recent sexual partner. Seventy-eight percent of Hispanic females, 76 percent of white, non-Hispanic females and 67 percent of black, non-Hispanic females were in a committed relationship (i.e., going steady, engaged or married) with their current or most recent partner when they first has sexual intercourse with them. Hispanic females (34 percent) and those in the “other” category (26 percent) are more likely to be married when they first have sex with their current partner than are white, non-Hispanic (11 percent) and black, non-Hispanic females (4 percent).

F7.b – Characteristics of Sexual Partner – Length of Relationships

The duration of an individual's first sexual relationship provides one measure of the circumstances of their first sexual experience. The length of an individual's most recent sexual relationship provides a snapshot of other sexual relationships that an individual may have had.

The length of relationships has been associated with sexual behaviors that directly affect pregnancy and birth rates, including contraceptive use, although findings differ by types of contraceptives. For example, longer relationships were associated with an increased likelihood of contraceptive use among unmarried young males and females⁵⁴ but were associated with reduced condom use among young males.⁵⁵ Furthermore, the length of sexual relationships may be associated with a reduced perceived risk of contracting sexually transmitted diseases (STDs) from a partner,⁵⁶ which in turn may affect sexual behaviors.

Data from the National Survey of Family Growth (NSFG) 1995, are used to estimate the length of sexual relationship with one's first partner as well as current or most recent partner.⁵⁷ Data were reported by females ages 15 to 44 only (refer to Table F7.2 and F7.3). The NSFG did not collect information from males but is expected to start collecting comparable data for both genders in 2002.

The first sexual relationship of most females (62 percent), lasted a year or more. In particular, 36 percent of females reported their first sexual relationship lasted four years or more. Nevertheless, for 21 percent of females, the first sexual relationship lasted for two months or less. (see Figure F7b.1).

Most recent or current sexual relationships have lasted for four years or more for the majority of females (64 percent). Fifteen percent reported that their relationship has lasted for less than a year (see Figure F7b.1).

By Race and Hispanic Origin. For Hispanic females, first sexual relationships are more likely to be long-term and less likely to be short-term than for non-Hispanic whites or blacks. In 1995, half of Hispanic females reported that their first relationship lasted for 4 years or more compared to 30 percent of non-Hispanic blacks and 34 percent of non-Hispanic whites. Fourteen percent of Hispanic women reported that their relationship with their first sexual partner lasted for 2 months or less compared to more than one fifth of non-Hispanic blacks and whites.

The racial/ethnic pattern is different for the most recent relationship. For black, non-Hispanic females, the length of current or most recent sexual relationship is less likely to be long-term than any other race/ethnicity. About half (52 percent) of non-Hispanic blacks reported that their current or most recent sexual relationship had lasted for four years or more compared to approximately two thirds of Hispanics, non-Hispanic whites and females in the "other" race category.

Figure F7b.1 Percentage of females ages 15 to 44 reporting length of sexual relationships: 1995

SOURCE: National Survey of Family Growth, 1995. The percentages calculated by National Center for Health Statistics.

By Parental Status. Parents are two and a half times more likely than nonparents to report long-term first sexual relationships that lasted for four years or more (46 percent compared to 18 percent), and less likely to report short-term first relationships that lasted for 2 months or less (18 percent compared to 26 percent). A similar pattern holds true for the current or most recent sexual relationship.

By Age. For younger females, first sexual intercourse is more likely to occur in a short-term relationship than for older females. Nearly half of young females ages 15 to 25 reported that their first relationship lasted for less than a year. Specifically, 28 percent of young females reported their length of first sexual relationship lasted for two months or less compared to 19 percent of older females ages 25 to 44. Older females are also more likely to report that their first sexual relationship lasted for 4 years or more (43 percent of older females compared to 14 percent of younger females). It should be noted that the length of the first relationship may be underestimated for those, particularly for younger females, whose current partner may be the same as the first partner.

Differences in relationship length by age are even larger for the most recent or current sexual relationship. Not surprisingly, older females are more likely than younger females to report a long-term relationship lasting for four years or more (76 percent compared to 21 percent). The magnitude of the difference shows the degree to which the nature of sexual relationships change as women get older.

By Poverty Status. Substantial differences in relationship length by poverty status are found only for the most recent or current relationship. Females in poverty, and particularly those in extreme poverty, are much less likely than nonpoor females to be in a long-term relationship lasting for four years or more. Forty-nine percent of poor females, 38 percent of females in extreme poverty, and 66 percent of nonpoor females have current or most recent sexual relationships that lasted 4 years or more.

By Educational Attainment. Substantial differences by educational attainment are also found only for the current or most recent sexual relationship. For females without a high school diploma length of most recent relationship is more likely to be short-term and less likely to be long-term than for females with any other educational status. For example, 11 percent of females without a high school diploma compared to 4 percent of college graduates report their most recent sexual relationship was short-term and lasted for 2 months or less. Half (49 percent) of respondents with less than a high school diploma report long-term sexual relationships lasting for four years or more, compared to 68 percent of college graduates.

By Marital Status. Not surprisingly, married females' current or most recent sexual relationships are mostly long-term. In 1995, 87 percent of married females reported long-term relationships lasting for four years or more compared to 23 percent of nonmarried females.

The same pattern holds true for first sexual relationships. Females who are currently married are far more likely to have had long-lived first sexual relationships than unmarried females (49 percent compared to 19 percent lasting four years or more).

F7.c – Characteristics of Sexual Partners – Race/Ethnicity

The characteristics of sexual partners often influence decisions about contraceptive use, and risk of pregnancy and childbearing.⁵⁸ Additionally, shifts in racial/ethnic patterns in choosing sexual partners can reflect larger social and demographic trends. For example, the degree to which certain racial/ethnic groups choose sexual partners from within or outside their own race/ethnicity may mirror larger patterns in society.

The data for males and females are presented separately because they come from two different national data files. In 1995, the National Survey of Family Growth (NSFG) collected data from females ages 15 to 44 and the National Survey of Adolescent Males collected data from males 15 to 19 and 21 to 27. The NSFG will collect comparable data from both genders in 2002 (refer to Table F7.4).

By Gender. Figure F7.1 shows the percentage of males and females with a current or most recent sexual partner outside their own racial/ethnic group. Hispanics are more likely than non-Hispanic whites and blacks to have a sexual partner outside of their own racial/ethnic group. In 1995, 29 percent of Hispanic females ages 15 to 44 reported a current or most recent sexual relationship with males outside of their own racial/ethnic group, compared to 6 percent of black, non-Hispanic females and 7 percent of white, non-Hispanic females. Hispanic males were even more likely than Hispanic females to report an interracial sexual partner. For example, almost half of Hispanic males ages 21 to 27 (48 percent) reported that their current or most recent sexual partner was outside of their own ethnic group, compared to 8 percent of white, non-Hispanic males and 19 percent of black, non-Hispanic males. Males ages 15 to 19 show a similar pattern.

white, non-Hispanic than black, non-Hispanic. For example, 23 percent of Hispanic females ages 15 to 44 reported that their current or most recent sexual partner was white, non-Hispanic, while 4 percent had a black, non-Hispanic partner. Likewise, 35 percent of Hispanic males ages 21 to 27 had a white, non-Hispanic partner whereas 4 percent had a black, non-Hispanic partner. It should be noted, however, that a large difference in the population size between, non-Hispanic whites and blacks may have affected this pattern.

Black, non-Hispanic males in their twenties are more than twice as likely as white, non-Hispanic males to have a sexual partner outside of their own racial/ethnic group (21 percent of non-Hispanic blacks aged 15-19 compared to 8 percent of non-Hispanic whites). No substantial difference is found between black, non-Hispanic and white, non-Hispanic females (see Figure F7c.1).

When Hispanics have partners outside of their own ethnic group, their partners are more likely to be

Figure F7c.1 Percentage of interracial/ethnic sexual partners by race and Hispanic origin⁵⁹ and gender: 1995

Race and Hispanic Origin of Respondents	Percentage of males and females with a current or most recent sexual partner outside their own racial/ethnic group		
	Males 15 to 19	Males 21 to 27	Females 15 to 44
White, non-Hispanic	8	8	7
Black, non-Hispanic	21	19	6
Hispanic	35	48	29

SOURCE: For males, *National Survey of Adolescent Males*, 1995; the percentages were calculated by Urban Institute. For females, *National Survey of Family Growth*, 1995; the percentages were calculated by National Center for Health Statistics.

F7.d – Characteristics of Sexual Partners - Age

Age of partners, and the age differences between partners in particular, may affect the nature of relationships, which in turn may affect sexual behaviors. Female adolescents with an older partner are less likely to report using contraception at their first sexual intercourse⁶⁰ as well as at their most recent sexual intercourse, and are more likely to become pregnant than female adolescents with a partner closer in age.⁶¹

Data for males and females are reviewed separately due to the lack of comparable data. Two national surveys asked the same question but to different age groups. The 1995 National Survey of Family Growth (NSFG) collected data from females ages 15 to 44. The National Survey of Adolescent Males (NSAM) collected data from males ages 15 to 19 and 21 to 27 in 1988 and 1995. The NSFG is expected to start collecting comparable data from both genders in 2002 (refer to Table F7.5).

Males. Although the percentage of adolescent males reporting a current or most recent sexual partner under age 20 remained about the same (92 and 91 percent) between 1988 and 1995, the percentage of adolescent males ages 15 to 19 with a current or most recent sexual partner under age 15 doubled from 4 percent in 1988 to 8 percent in 1995 (see Figure F7d.1).

Figure F7d.1 Percentage of males ages 15 to 19 and 21 to 27 by most recent partner's age: 1988 & 1995

Age of respondents	Age of Partner		
	Under age 20	Under age 15	Ages 15 to 19
15 to 19 in 1988	92	4	88
15 to 19 in 1995	91	8	83
21 to 27 in 1995	9	0	9

SOURCE: National Survey of Adolescent Males, 1988 and 1995. The estimates were calculated by Urban Institute.

Females. Among sexually experienced females ages 15 to 19, 22 percent reported their current or most recent sexual partner was age 20 or older. A fairly large percentage (16 percent) of females ages 25 to 44 reported having an adolescent partner under age 20 (see Figure F7d.2).

F8 – Regular Sexual Intercourse

The frequency of sexual intercourse is a primary indicator of pregnancy risk and risk of sexual transmitted diseases (STDs).^{62,63} Individuals who engage in sexual intercourse more frequently and those who do so consistently (e.g., on a regular basis) are more frequently exposed to the risk of becoming pregnant or contracting STDs. It is worth noting however, that although those who are married (or monogamous) may be more likely to report frequent sexual intercourse, they are not necessarily at higher risk of unintended pregnancy or STDs. These individuals may, in fact, be more likely to practice contraception and/or safe-sex habits.⁶⁴

Data from the General Social Survey, 1989 to 2000, show the percentages of all males and females ages 18 to 65 who had sexual intercourse two times or more per month during the last 12 months⁶⁵ (refer to Table F8.1).

Trends. The percentage of adults ages 18 to 65 who had regular sexual intercourse has remained fairly constant for the last decade with slightly more than 60 percent of males and about half of females reporting having had sexual intercourse more than once a month during the last 12 months.

By Gender. Males report a higher likelihood of regular sexual activity than females. In 2000, 60 percent of males compared to 48 percent of females reported having sexual intercourse twice or more per month during the last 12 months.

By Age. The percentage of adults having regular sexual intercourse declines significantly with age for females (more than three-quarters of females ages 18 to 24 compared to slightly more than a quarter of those age 45 and older) (see Figure F8.1). The pattern is somewhat different for males. The percentage of males having regular sexual intercourse was not significantly different between the two younger age groups. The percentage of males having regular sexual intercourse was lower among males ages 45 and older (46 percent) than among those ages 25-44 (74 percent) or ages 18-24 (65 percent). Older males are more likely to report having regular sexual intercourse than their female counterparts (46 percent compared to 27 percent at ages 45 and older).

By Race and Hispanic Origin. Hispanic females are more likely than non-Hispanic black and white females to report having regular sexual intercourse (69 percent of Hispanic females compared to 48 percent of non-Hispanic black females and 46 percent of white, non-Hispanic females). For males, non-Hispanic blacks are more likely to report regular sexual intercourse than non-Hispanic whites (72 percent and 58 percent respectively). The percentage of Hispanic males having regular sexual intercourse is also high but the differences with other races are not statistically significant.

Figure F8.1 Percentage of adults ages 18 to 65 who report having sexual intercourse two or more times a month for the last 12 months, by age and gender: 2000

SOURCE: General Social Survey, 2000

By Marital Status. Not surprisingly, married adults are much more likely than single adults to report having regular sexual intercourse. In 2000, 78 percent of married males and 73 percent of married females reported having regular sexual intercourse compared to about half of single males and 37 percent of single females.

By Poverty Status. Nonpoor males report a higher level of sexual activity than males in poverty. In 1993 (the last year in which estimates were available by poverty status), 65 percent of nonpoor males compared to 43 percent of those in poverty reported having regular sexual intercourse. The same pattern holds true for females; however, differences by poverty status are not statistically significant among females.

By Educational Attainment. Adults without a high school education are much less likely to report having regular sexual intercourse than those with other levels of educational attainment. In 2000, 45 percent of males without a high school education reported having sexual intercourse two or more times a month compared to 59 percent of college graduates. For females, 30 percent with less than a high school education reported sexual intercourse compared to 53 percent of females with a college degree.

By Employment Status. Those who are not in the labor force are about half as likely as full-time workers to report having regular sexual intercourse, regardless of gender. For males, 35 percent of those who were not in the labor force reported regular sexual intercourse compared to 70 percent of full-time workers. For females, 31 percent who were not in the labor force compared to 59 percent of full-time workers reported regular sexual intercourse.

F9 – Contraceptive Use

The use of contraceptives has significant implications for pregnancy rates, birth rates, and the prevention of sexually transmitted diseases (STDs).⁶⁶ Consistent contraceptive use reduces unintended pregnancy,⁶⁷ and consequently reduces abortions and unwanted, mistimed, or unplanned births. Unintended pregnancies continue to affect many in the United States. An analysis of the National Survey of Family Growth, 1995, found that half of all pregnancies were unintended, and almost half of unintended pregnancies occurred to women who did not use any contraceptives.⁶⁸ Therefore, proper contraceptive use and the adequate provision of contraceptives and services are of critical concern to the public.

Data on the types of contraceptives used have implications for STD contraction. The methods that are most effective against unintended pregnancies, such as oral contraceptives, are often different from the methods that are most effective against STDs,⁶⁹ such as condoms.⁷⁰

Although many national surveys collect information on contraceptive use among women, this section uses data from the 1992 National Health and Social Life Survey, one of the few national surveys that collect contraceptive data from both women and men. The percentages were calculated for adults ages 18 to 59 who ever had sexual intercourse.

Contraceptive use at first sexual intercourse is an important marker of unintended pregnancy risk.⁷¹ Furthermore, contraceptive use at first sexual intercourse is a strong predictor of subsequent contraceptive use.⁷² Contraceptive use at most recent sexual intercourse is a better proxy for regular or current use of contraceptives. Three measures of contraceptive use are presented: 1) any contraceptive use at first sexual intercourse, 2) any contraceptive use at most recent sexual intercourse, and 3) the type of method used at most recent sexual intercourse⁷³ (refer to Tables F 9.1 and F 9.2). For questions about “most recent sexual intercourse” respondents were asked about “the most recent time they had sex in the last 12 months.”

Contraceptive Use at First Sexual Intercourse

By Gender. About one-third of males and females ages 18 to 59 used contraception at first sexual intercourse (34 percent of males and 37 percent of females).

By Age. Contraceptive use at first sexual intercourse has increased over time and is more prevalent among younger adults than older adults (see Figure F9.1). Half of males and females ages 18 to 24 used any method of contraception at first sexual intercourse compared to 26 percent of males and 32 percent of females ages 45 to 59.

By Race and Hispanic Origin. Non-Hispanic white males are more likely than non-Hispanic black or Hispanic males to have used any method of contraception at first sexual intercourse (37 percent of non-Hispanic whites compared to 24 percent of non-Hispanic blacks and 20 percent of Hispanics). The same pattern holds true for females, but the differences are not statistically significant.

Figure F9.1 Percentage of adults ages 18 to 59 who used contraceptives at first sexual intercourse, by age and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

By Educational Attainment. Contraceptive use at first sexual intercourse among females increases with education (see Figure F9.2). Females with a college degree are twice as likely as females without a high school education to have used any method of contraception at first sexual intercourse (46 percent compared to 23 percent). A similar pattern is found among males.

Figure F9.2 Percentage of adults ages 18 to 59 who used contraceptives at first sexual intercourse, by educational attainment and gender: 1992

SOURCE: National Health and Social Life Survey, 1992

Contraceptive Use at the Most Recent Sexual Intercourse

By Gender. Both males and females are much more likely to have used some form of contraceptive at their most recent sexual intercourse than at first sexual intercourse (see Figure F9.3). At their most recent sexual intercourse, half of males and 56 percent of females used contraception, whereas 34 percent of males and 37 percent of females used any method of contraception at first sexual intercourse.

Males and females were equally likely to report *condom* use at the most recent sexual intercourse (17 percent of males and 15 percent of females). However, females are more likely than males to have used *other* types of contraceptives (45 percent of females compared to 36 percent of males) (see Figure F9.3).

By Age. Contraceptive use decreases with age (see Figure F9.4). Males under 25 years old are more than twice as likely as those ages 45 to 59 to have used any contraception at their most recent sexual intercourse (74 percent compared to 33 percent). In particular, 35 percent of males under age 25 compared to 5 percent of males ages 45 to 59 used condoms. The same pattern holds true for females.

By Marital Status. Contraceptive use at most recent sexual intercourse differs significantly by marital status, particularly among males (see Figure F9.3). Unmarried males are far more likely to have used contraception at most recent sexual intercourse than married males (69 percent compared to 41 percent). Interestingly, married females are more likely than married males to report using contraceptives (53 percent compared to 41 percent).

Unmarried males are three times more likely than married males to use condoms (32 percent compared to 9 percent). Condom use shows a similar pattern by marital status among females as among males. However, the percentage of females using other types of contraceptives does not differ by marital status.

Figure F9.3. Percentage of adults ages 18 and 59 who used contraceptives at first and most recent sexual intercourse: 1992

	At First Sex		At Most Recent Sex					
	Males Any	Females Any	Condoms	Males Other	Any	Condoms	Females Other	Any
Total	34	37	17	36	50	15	45	56
Current Marital Status								
Not Married	39	38	32	44	69	26	46	64
Married	30	37	9	32	41	11	44	53

SOURCE: National Health and Social Life Survey, 1992

By Race and Hispanic Origin. Non-Hispanic black males are more likely to have used condoms at their most recent sexual intercourse than non-Hispanic white or Hispanic males (28 percent compared to 16 percent, and 12 percent respectively). Similarly, black, non-Hispanic females are more likely than white, non-Hispanic females to report condom use at most recent sexual intercourse (20 percent compared to 14 percent).

By Poverty Status. Poverty status shows significant differences for condom use among males only. Males in poverty are more likely to have used condoms at their most recent sexual intercourse than nonpoor males (25 percent compared to 15 percent).

By Parental Status. Contraceptive use at most recent sexual intercourse differs by parental status but only for males. Males without children are more likely than males with children to have used any method of contraception at most recent sexual intercourse (54 percent compared to 47 percent). The difference was mostly due to the difference in condom use (20 percent of nonfathers compared to 13 percent of fathers).

F10 – Attitudes Toward Abortion

Abortion remains one of the most controversial social issues in the United States, lending increased importance to, and interest in, public opinion regarding abortion. Studies have indicated that public opinion affects abortion rates primarily through its influence on abortion policies and access to abortion services.⁷⁴ Higher levels of public support have been linked to the formation of more lenient laws and public policy related to abortion,⁷⁵ more access to abortion services and higher utilization, which in turn may affect abortion rates. One study suggests that the recent decline in abortion rates may be, at least partially, attributed to the enactment of more restrictive laws.⁷⁶

Attitudes on abortion may vary depending on the reason cited for having an abortion. Furthermore, when women receive abortions, the vast majority of them cite multiple socioeconomic and family-related factors in their decision to obtain an abortion.⁷⁷

To assess attitudes towards abortion as a function of the reasons cited for the abortion, several questions from the General Social Survey (GSS) are examined. Adult respondents were asked whether they felt it should be possible for a woman to obtain a legal abortion if: 1) there is a strong chance of serious defect in the baby, 2) the woman is not married and does not want to marry the man, 3) the family has a very low income and cannot afford any more children, 4) the woman's own health is seriously endangered by the pregnancy, 5) the woman is married and does not want any more children, 6) the woman became pregnant as a result of rape, and 7) the woman wants an abortion for any reason. The items were measured in selected years between 1980 and 2000 (refer to Table F10.1 and F10.2).

By Gender. Males and females have strikingly similar attitudes toward abortion (see Figure F10.1). The vast majority of adults ages 18 to 65 (87 percent of females and 91 percent of males) support legal abortion when the woman's health is endangered. About 80 percent of adults support legal abortion when the woman became pregnant as a result of rape (79 percent of females and 84

percent of males) or when there is a strong chance of serious defect in the baby (77 percent of females and 82 percent of males). On the other hand, only about 40 percent of adults support legal abortion for any reason or the following three reasons: 1) the woman's desire not to marry the man, 2) low income, and 3) the woman's desire not to have more children.

Figure F10.1 Percentage of respondents supporting abortion for six different reasons: 2000

	Male	Female
The woman's health is endangered by the pregnancy	91	87
The woman became pregnant as a result of rape	84	79
There is a strong chance of serious defect in the baby	82	77
The woman does not want to marry the man	41	39
The family cannot afford any more children	44	43
The woman is married and does not want any more children	44	39
Any reason	40	41

SOURCE: General Social Survey, 2000

Support For Abortion

Trends. Attitudes towards abortion have generally remained stable and similar across gender over the last two decades. However, the levels of support for abortion have been slowly declining since 1980 for three circumstances: 1) the woman does not want to marry the man, 2) the woman is not married and does not want any more children, and 3) the family cannot afford any more children (although the difference between 1980 and 2000 was not statistically significant for males). For example, in 1980, 53 percent of males supported legal abortion “when the family cannot afford any more children,” and the level of support decreased to 44 percent in 2000.

For the remainder of the reasons for having an abortion, attitudes essentially remained the same. For example, about 38 percent of females and 41 percent of males supported legal abortion for any reason in 1980. The percentages remained virtually the same a decade later (41 percent of females and 43 percent of males in 1990) and two decades later (41 percent of females and 40 percent of males in 2000). The following sections review the support for abortion for *any* reason by socio-demographic characteristics.

By Parental Status. Parents are less likely to support abortion for any reason (see Figure F10.2). Slightly more than half of females who were not parents supported legal abortion for any reason in 2000 compared to 38 percent of mothers. The same pattern holds true for males (45 percent of nonparents compared to 37 percent of fathers).

By Educational Attainment. Adults with higher educational attainment are much more likely to support legal abortion for any reason than those with lower educational attainment (see Figure F10.2). In 2000, slightly more than half of college graduates supported legal abortion for any reason compared to about 30 percent of those without a high school education.

By Employment Status. Attitudes toward abortion differ by employment status but only among females. Females with full-time work are more likely to support legal abortion than those who are not in the labor force. In 2000, 46 percent of female full-time workers supported legal abortion for any reasons compared to 34 percent of those who were not in labor force.

Figure F10.2 Percentage of adults ages 18 to 65 who support legal abortion for any reason, by parental status and educational attainment: 2000

SOURCE: General Social Survey, 2000

F11 – Incidence of Abortion

Reducing the number of unintended pregnancies and consequently the number of abortions continues to be a challenging policy goal. According to analyses of the National Survey of Family Growth, half of all pregnancies in 1994 were unintended, and half of these unintended pregnancies ended in abortion.⁷⁸ Unintended pregnancies have been found to be the primary reason for abortions.⁷⁹ Other factors, most associated with the woman's perceived financial, social, and opportunity costs of parenthood, appear to predict the incidence of abortion as well. Characteristics such as being under 20 years old, over 35 years old, unmarried, without previous conception, and/or more highly educated or from a highly educated family are associated with higher rates of abortion.⁸⁰

It is important to note that, compared to counts reported by abortion providers, abortions are underreported in national surveys.^{81,82} This may be due to individual reluctance to report having had an abortion, or to differences in the way that individuals and medical institutions define abortion.⁸³

This section reviews the data from the 1992 National Health and Social Life Survey (NHSLs), one of few national surveys that collect fertility information from both males and females. Two types of data are presented: 1) the percentage of all adults who ever had an abortion; and 2) of adults who had pregnancies, the percentage of those who ever had an abortion. The first indicator shows the overall patterns of abortions while the second indicator shows what percent of adults resort to abortions when they experience pregnancies, and whether such percentages differ by socio-demographic characteristics (refer to Table F11.1).

By Gender. Among all adults ages 18 through 59, 16 percent of females and 12 percent of males have ever had a pregnancy terminated by an abortion. For those who have experienced a pregnancy, the numbers increase to 21 and 18 percent, respectively.

By Age. Among males who ever caused a pregnancy and females who have ever had a pregnancy, the likelihood of having an abortion decreases with age (see Figure F11.1). Among females in this group, 39 percent of those under age 25 have had an abortion compared to 24 percent among those ages 25 to 44, and 9 percent for ages 45 through 59. The pattern is similar among men. When considering all adults, regardless of pregnancy history, males and females ages 18 to 24 are somewhat less likely than those ages 25 to 44 to have had an abortion due to the fact that fewer of them have ever been pregnant.

By Educational Attainment. Adults without a high school education are less likely to report having had an abortion than those with at least some college or more (see Figure F11.2). Among females who have ever had a pregnancy, 15 percent of those without a high school education had had an abortion compared to 26 percent of college graduates. Among males, the rates are 13 percent and 21 percent, respectively.

Figure F11.1 Percentage of females ages 18 to 59 who ever had an abortion by age: 1992

SOURCE: National Health and Social Life Survey, 1992

Figure F11.2 Of those who had pregnancies, percentage of adults ages 18 to 59 who ever had an abortion, by educational attainment and gender: 1992

SOURCE: National Health and Social Survey, 1992

By Marital Status. While the likelihood of an abortion does not differ significantly by marital status for the population as a whole, among those who have ever had a pregnancy the rates are far higher among those who are not currently married than for married adults (for example, 39 percent compared to 13 percent among males).

By Poverty Status. Nonpoor males are twice as likely as poor males to report an abortion (20 percent compared to 10 percent among those who have ever had pregnancies). For females, the difference by poverty status was much smaller and not statistically significant.

- ⁷² Pleck, J.H., Sonenstein, F.L., & Swain, S.O. (1988). Adolescent males; sexual behavior and contraceptive use: Implications for male responsibility. *Journal of Adolescent Research*, 3(3-4): 275-284.
- ⁷³ Respondents may have used both condoms and other types of contraceptives simultaneously, and in such cases, the same respondent was counted twice and included in both percentages. Thus, the aggregated percentage for condom users and 'other methods' users is either equal to or greater than the percentage of respondents who used 'any' contraceptives.

Appendix A:

Data Dictionary

Data Source Descriptions

Data tables in this report have been pulled from thirteen nationally-representative data sources. This section presents both general and detailed information about each data source to facilitate a more comprehensive understanding of the data presented in this book. Definitions apply to data presented in this book only, not the capability of the data set as a whole.

General information on each data source is provided, including the funder, principal investigator(s), the design of the survey, population, and sample selection. Information specific to the data presented in this book is also provided, including the unit of analysis, estimate restrictions, age of the respondent, and age of the child. In this book we have attempted to show the data in a consistent, comparable format across data sets. As such, data is presented for several standard demographic breaks. These breaks and their descriptions are provided in the table below. In those cases where the standard definitions do not apply or where further clarification is required to accurately define the data that is presented from a particular data source, more detail is provided in the section titled “unique demographic definitions.” Finally, a list of the indicators from each data set is provided.

It is important to note that the reference period for each data set varies. For example, depending on the survey, respondents may be asked how many hours they worked in the last week, month, or year. Data are presented to reflect the status during the reference year, unless otherwise noted.

Demographic Break	Standard Description	Standard Breaks
Race	Race of the respondent	White non-Hispanic Black non-Hispanic Hispanic Asian/Pacific Islander American Indian/Alaskan Native
Poverty	Poverty measures compare the respondent report of household income to the official U.S. poverty thresholds for household size based on the year of survey.	Poor (0-99% of poverty) Extreme poverty (at 50% or less) Nonpoor 100 to 199% of poverty 200 to 299% of poverty 300% or more of poverty
Parental Status	This measure varies across data sets. This demographic break may describe whether the respondent has ever had a child or whether the respondent lives with a child. In most cases, a respondent is considered a parent if they live with one or more of their own children under age 18. See unique demographic definitions to determine how parent was defined for each data set.	Resident parent Nonparent
Age of Respondent	Age of respondent at time of survey	18 to 24 years old (or Under 25 years old) 25 to 44 years old 45 years and older
Age of Child	Age of child(ren) referenced for the particular indicator. This is provided only if a question is asked about a specific child.	0 to 2 years old 3 to 5 years old 6 to 9 years old 10 to 12 years old

Demographic Break	Standard Description	Standard Breaks
Marital Status	Current marital status of respondent	Currently married Not currently married
Family Structure	Number of parents living in household with a child	One parent Two parent
Educational Attainment	Highest level of educational attainment at time of survey	Less than high school High school diploma or GED Vocational/technical or some college College graduate
Employment Status	Average number of hours worked per week in the reference period	Not in labor force Looking for work Less than 35 hours per week 35 hours or more per week

Current Population Survey (CPS)
--

Name:	Current Population Survey (CPS)
Funder(s):	The core survey is funded by the U.S. Bureau of the Census and the Bureau of Labor Statistics. The supplements are also funded by a variety of sponsors including the Department of Health and Human Services, the Department of Education, and the National Institute of Child Health and Human Development.
Principal Investigator:	U.S. Bureau of the Census
General Description:	The CPS is primarily designed to supply estimates of employment, unemployment and other characteristics of the general labor force, the population as a whole, and various subgroups of the population. In addition to collection of labor force data, the CPS's basic funding provides annual data on work experience, income, and migration (the annual March income and demographic supplement), and school enrollment of the population (the October supplement). Other supplements are conducted including the child support and alimony supplement (April), the fertility and birth expectations supplement (June), and the supplement on the immunization status of the population (most recently collected in September 1995).
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; The CPS has been conducted monthly since 1942. The fieldwork is conducted during the calendar week that includes the 19th of the month. In January 1994 a redesigned questionnaire was introduced for the development of official CPS estimates. This was the most substantial change to the survey since its inception. This new survey included longer and more detailed questions allowing for more accurate and detailed estimates. The CPS questionnaire is a completely computerized document that is administered by Census Bureau field representatives across the country through both personal and telephone interviews. Households are in the survey for four consecutive months, out for eight, and then return for another four months before leaving the sample permanently.
Population:	The CPS is representative of the civilian, non-institutionalized population of the U.S.
Sample Selection and Description:	The CPS is administered using a scientifically selected sample of some 50,000 occupied households nationwide. The CPS design over-sampled for Hispanics only. (For more detail see Design and Methodology: http://www.census.gov/prod/2002pubs/tp63rv.pdf)
Website:	http://www.bls.census.gov/cps/cpsmain.htm
Unit of Analysis:	Data are collected for all household members. Employment and earnings information are collected for persons ages 15 and over, but tabulated for all persons 16 and over. One member of each household contacted is the respondent, and this individual must be a knowledgeable household member 15 years or older.
Estimate Restrictions:	Estimates based on a weighted denominator (row size) less than 75,000 are not reported.
Age of Respondent:	Respondents are 15 years and older. It is this primary respondent who provides information for each household member. No upper age limit is used, and full-time students are treated the same as non-students. For this report the age of the adult population is 18 years and older.
Age of Child:	0 to 17 years old

Unique Demographic Descriptions:

Parental Status -	Parent is defined as an adult living with one or more of their own children under age 18. An individual who has had a child but is not currently living with a child would be classified as nonparent.
Poverty-	Families and unrelated individuals are classified as being above or below the poverty level using an adjusting index that takes into account family size, number of children, and age of the family householder or unrelated individual. The poverty cutoffs are updated each year to reflect changes in the Consumer Price Index. For a more detailed explanation please see Current Population Reports, Series P-60, No. 154, Money, Income, and Poverty Status of Persons in the U.S.: 1988.
Employment -	Respondents are classified as full time if they worked 35 or more hours per week during a majority of the weeks in which they worked during the year. Respondents are classified as part-time if they worked less than 35 hours per week for a majority of the weeks worked during the year. Respondents classified as looking for work are those persons during the survey week who have no employment but are available for work, and satisfy one or more of the three following conditions: 1) have sought a job in the last 4 weeks, 2) are waiting to be called back to a job from which they had been laid off, or 3) are waiting to report to a new job within 30 days. All respondents who lack employment and who fail to meet the criteria of unemployment “looking for work” outlined above are classified as not in labor force.
Cohabitation -	Cohabitation was coded using adjusted persons of the opposite sex sharing living quarters (POSSLQ). Households with a reference person and 1) one other adult (age 15+) of the opposite sex who is not in a related subfamily, not a secondary individual in group quarters, and not related to, or a foster child of, the reference person; and 2) no other adults (age 15+) except foster children, children or other relatives of the reference person, or children of unrelated subfamilies. See Casper, L.M., Cohen, P.N. & Simmons, T. (1999, May). <i>How does POSSLQ measure up?: Historical estimates of cohabitation</i> (Population Division Working Paper No. 36). Washington, DC: U.S. Census Bureau.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	Who is a Parent? P19 - Child Custody Arrangements P20 - Contact With Non-Resident parent P21 - Earnings and Income P22 - Receipt of Child Support FF1 - Marriage FF4 - Characteristics of Current Spouse FF6 - Cohabitation Status FF8 - Characteristics of Current Partner

Gallup Child Abuse Survey

Name:	Gallup Child Abuse Survey
Funder(s):	Gallup Organization
Principal Investigator:	Murray Straus, Family Research Laboratory, University of New Hampshire, Durham, NH 03824
General Description:	The Child Abuse Survey is part of the Gallup Organization's National Social Audit Program. The overall purpose of this study was to measure the incidence of family violence nationally and look at the underlying causes of child abuse and family violence.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; The Gallup Child Abuse Survey was conducted in 1995 via a one-time telephone survey.
Population:	The Gallup Child Abuse Study represents households with one or more children under age 18 living in the household.
Sample Selection and Description:	Telephone numbers were randomly selected to ensure all telephone households in continental U.S. have equal probability of selection. In two-parent households, one parent was randomly selected for the interview. In multi-child households, one child was randomly identified, and a parent of that child interviewed. There were 1,000 parents in the sample.
Website:	www.unh.edu/frl
Unit of Analysis:	Parents
Estimate Restrictions:	Estimates based on row sizes less than 20 are not reported.
Age of Respondent:	Respondents range from 18 to 72 years old
Age of Child:	Under age 18
Unique Demographic Descriptions:	
Parental Status -	Parent is defined as an adult having one or more children under age 18 living in the household. An individual who has had a child but is not currently living with a child would be classified as nonparent.
Family Structure -	Presented in terms of the number of parents living in the household with the child.
Poverty -	Poverty status can not be created for this data set due to income being categorical, not continuous. Income ranges are reported instead.
Employment -	No employment variable available.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	P12 - Incidence of Harsh Punishment, Violence, Abuse

General Social Survey (GSS)

Name:	General Social Survey (GSS)
Funder(s):	National Science Foundation
Principal Investigator:	James A. Davis (NORC), Tom W. Smith (NORC), and Peter Marsden (Harvard University); Data collection by National Opinion Research Center (NORC)
General Description:	The General Social Survey (GSS) is a major source of data on social attitudes and behaviors facilitating the study of social trends. Additionally, it is a source of trend data on family-related attitudes, marital happiness, and satisfaction with family.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; The GSS was conducted annually from 1972 until 1978, then again in 1980, 1982 through 1991, 1993 and biennially since 1994. The most recent data was collected in 2000. The survey is conducted through personal interviews. Since 1985 the GSS has also had a cross-national component, the International Social Survey Program (www.issp.org) which measures many items on families, children, and fatherhood.
Population:	The GSS represents the total noninstitutionalized population of the U.S. ages 18 and older.
Sample Selection and Description:	An adult is randomly selected as the respondent. Individuals in households containing many adults are less likely to be selected for an interview. The full-probability GSS samples used since 1975 are designed to give each household an equal probability of inclusion in the sample. Thus for household-level variables, the GSS sample is self-weighting. In those households which are selected, selection procedures within the household give each eligible individual equal probability of being interviewed. There were over-samples of blacks in 1982 and 1987. There is a weight factor to adjust for all sampling issues.
Website:	http://www.icpsr.umich.edu/GSS
Unit of Analysis:	Adult respondent.
Estimate Restrictions:	Estimates based on row sizes less than 20 are not reported.
Age of Respondent:	18 years and older
Age of Child:	0 to 17 years old
Unique Demographic Descriptions:	
Parental Status -	Those who have had one or more children, ever, counting all those that were born alive at any time (including any from a previous marriage).
Poverty -	GSS respondents reported their income in categories therefore, it was unclear whether income for some respondents fell above or below the poverty threshold. These cases were designated "borderline poor." Poverty was not calculated for 1994, 1996, 1998, and 2000. For more detail see Ligon, E. (1988, September). <i>Rationale and construction of poverty measures in the General Social Survey</i> . Chicago: NORC.
Employment -	Respondents were asked "Last week were you working full time, part time, going to school, keeping house, or what?" Working Full time, Working Part time, Looking for work (Unemployed, laid off, looking for work), Not in Labor Force (retired, in school, keeping house, other). Respondents who did not work within the last week, but normally do were categorized accordingly.

Significance Level: All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.

Indicators:

- P1 - Importance of Becoming a Parent
- P2 - Adults' Attitudes About the Value of Children
- P3 - Parents: Can One Be As Good As Two?
- P5 - Adults' Attitudes Toward Spanking
- FF5 - Attitudes Toward Divorce
- FF9 - Attitudes Toward Cohabitation
- F6 - Number of Sexual Partners
- F8 - Regular Sexual Intercourse
- F10 - Attitudes Toward Abortion

National Health Interview Survey (NHIS)
--

Name:	National Health Interview Survey (NHIS)
Funder(s):	Data collection is conducted by the U.S. Bureau of the Census under an interagency agreement with the National Center for Health Statistics (NCHS).
Principal Investigator:	National Center for Health Statistics
General Description:	The National Health Interview Survey (NHIS) is the most comprehensive source of data about the health status and conditions of residents of the United States. Data are collected at the household, family, and person levels, and range from information about past and current disabilities and illnesses to health-related behaviors and occupation and income. In addition to the information collected about each person within each family, one adult and one child from each family are randomly selected as sample respondents and are asked a more detailed and extensive list of questions.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; NHIS is a survey of a nationally-representative sample of households in the United States. The sample is based on a stratified multistage sampling design that is changed following each decennial census. The NHIS began in 1957 and has been conducted each year since then, with data released annually. Data used for this analysis were from interviews with one sample adult randomly selected from each family. Data are collected through personal household interviews with each family.
Population:	Civilian, non-institutionalized households within the United States
Sample Selection and Description:	The 2000 sample adult section of the NHIS had 32,374 respondents. The survey over-sampled for blacks and Hispanics.
Website:	http://www.cdc.gov/nchs/nhis.htm
Unit of Analysis:	Adult respondents
Estimate Restrictions:	None
Age of Respondent:	18 and older
Age of Child:	Children not included in analysis
Unique Demographic Descriptions:	
Employment -	Persons who reported working at a job or business last week were asked how many hours they worked last week. Respondents who worked at least 35 hours last week were considered to be working full-time.
Race and Hispanic Origin-	Categories include white non-Hispanic, black non-Hispanic, Hispanic and other non-Hispanic
Poverty -	Extreme poverty is defined as below 50% of the poverty level
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	Who is a Parent?

National Health and Social Life Survey (NHSLS)

Name:	National Health and Social Life Survey (NHSLS)
Funder(s):	Robert Wood Johnson Foundation, Henry J. Kaiser Family Foundation of Menlo Park, the Rockefeller Foundation, the Andrew Mellon Foundation, the John D. and Catherine T. MacArthur Foundation, the New York Community Trust, the American Foundation for AIDS Research, and the Ford Foundation.
Principal Investigator:	Edward Laumann (University of Chicago), Robert Michael (University of Chicago), Stuart Michaels (University of Chicago), and John Gagnon (SUNY-Stony Brook); data collection by the National Opinion Research Center (NORC) - University of Chicago
General Description:	The NHSLS was conducted in order to provide useful and comprehensive information on the sexual behavior of the general population in the U.S.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; The NHSLS was conducted from February to September of 1992. The survey was administered through one-time face-to-face interviews.
Population:	The NHSLS is representative of the population of all persons aged 18 to 59 with adequate English proficiency living in households located in the 50 states and DC. Persons living in institutions or groups quarters were excluded from the sample.
Sample Selection and Description:	An adult aged 18-59 was selected randomly from each household. The final data set contains 1,604 variables from a nationwide sample of 3,432 adults. Multistage area probability sampling design produced a cross-sectional sample of 3,159; and over-sampling of blacks and Hispanics produced a supplemental sample of 273.
Website:	http://cloud9.norc.uchicago.edu/faqs/sex.htm
Unit of Analysis:	Adult respondent.
Estimate Restrictions:	Estimates based on row sizes less than 20 are not reported.
Age of Respondent:	18 to 59 years old
Age of Child:	Not applicable
Unique Demographic Descriptions:	
Parental Status -	Parent is defined as an adult having one or more children under age 18 living in the household. An individual who has had a child but is not currently living with a child would be classified as nonparent.
Poverty -	Poverty is a pre-defined variable in NHSLS, a dichotomous variable indicating whether respondent household income was less than the poverty line in the previous year.
Employment -	Employment status was determined by number of hours at job per week. Respondents were asked: if they worked for pay in a usual week, how many hours they worked for pay last week, at all jobs. It was not possible to break out 'not employed' respondents.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.

Indicators:

- F2 - Age at First Birth
- F3 - Number of Pregnancies
- F4 - Premarital Brith
- F5 - Age at First Sexual Intercourse
- F9 - Contraceptive Use
- F11 - Incidence of Abortion

National Household Education Survey Program (NHES)

Name:	National Household Education Survey Program (NHES)
Funder(s):	National Center for Education Statistics (NCES), U.S. Department of Education
Principal Investigator:	Chris Chapman, NCES
General Description:	The National Household Education Survey Program provides information on education-related issues, such as the care arrangements and educational experiences of young children, children's educational activities and the role of the family in the children's learning, and parental involvement in their children's schooling.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; The NHES was conducted in 1991, 1993, 1995, 1996, 1999, and 2001 via computer-assisted telephone interviews. There are plans to continue in 2003 and periodically thereafter.
Population:	The NHES is a representative sample of the non-institutionalized civilian population of the U.S.
Sample Selection and Description:	In each survey, between 54,000 and 64,000 households are screened. One or more household members may be selected to complete more extensive interviews on specific topics. The NHES design also over-samples minorities for reliable estimates for these groups. In 1996, 21,000 parents of children from age 3 through 12 th grade were interviewed. In 1999, 24,000 parents of children from newborns up to 12 th grade were interviewed.
Website:	http://nces.ed.gov/nhes
Unit of Analysis:	Child
Estimate Restrictions:	Estimates based on row sizes less than 30 are not reported.
Age of Respondent:	18 to 65 years old
Age of Child:	In 1996 questions were asked about children 3 years old up to 12 th grade. In 1999 questions were asked about newborn children up to 12 th grade.
Unique Demographic Descriptions:	
Parental Status -	Parent is defined as an adult having one or more of their own children, under age 18, living in the household. An individual who has had a child but is not currently living with a child would be classified as nonparent. Parental status is based on the household member's relationship to the sampled child.
Family Structure -	Based on whether a father and mother reside in the home with the child.
Poverty -	Poverty estimates for 1991 and 1993 are not comparable to later years because respondents were not asked about their exact household income.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests. Bonferroni adjustments were made for statements requiring multiple t-tests.
Indicators:	P17 - Parental Participation in Child's School Activities

National Longitudinal Study of Adolescent Health (Add Health)

Name:	National Longitudinal Study of Adolescent Health (Add Health)
Funder(s):	National Institute of Child Health and Human Development (NICHD) and 17 other federal agencies
Principal Investigator:	J. Richard Udry (University of North Carolina); Fieldwork was conducted by the National Opinion Research Center - University of Chicago.
General Description:	The National Longitudinal Study of Adolescent Health (Add Health) focuses on the causes of health-related behaviors of adolescents, collecting data from surveys of students, parents, and school administrators.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Longitudinal; Four surveys were conducted during Wave I (1994 through 1995) consisting of in-school, in-home, school administrator, and parent surveys. Wave II (1996) consisted of in-home and school administrator surveys. Wave III (expected to be available in Fall 2002) will consist of an in-home survey. Wave I (1995) was made up of subjects in grades 7-12. Wave II (1996) was made up of these subjects one year later (grades 8-12), but did not include those who were 12th graders at Wave I. Already existing databases provided information about neighborhoods and communities. Questionnaires were administered directly to students using Computer-Assisted Personal Interview (CAPI) and Computer-Assisted Self-Interview (CASI) systems.
Population:	Representative sample of students in grades 7 through 12 in the U.S.
Sample Selection and Description:	The Wave I In-School Survey collected information from 90,188 students in 80 pairs of schools (each pair consisted of one high school and one of its feeder middle schools, or a single school if it included grades 7 to 12). Approximately 200 adolescents from each school pair were selected for in-home interviews at Wave I; however, in 16 schools, in-home interviews were conducted with all students in order to collect information about adolescent social networks. The sample size for the Wave I In-home Survey was 20,745. The Wave II In-Home Survey sampled 14,738 adolescents who participated in the Wave I survey. The study over-sampled African Americans with college-educated parents, Chinese, Cuban, Puerto Rican, and physically-disabled adolescents (although this sample seems to be less reliable than the others) as well as genetic samples of pairs of siblings who resided in the same household (twins, full and half-siblings, and unrelated teens in the same household). In addition, in-home interviews were conducted with all students from 16 samples schools (versus the approximately 200 adolescents selected for in-home interviews from each of the other pairs of schools) in order to collect information about adolescent social networks.
Website:	http://www.cpc.unc.edu/projects/addhealth/
Unit of Analysis:	Adolescent respondent
Estimate Restrictions:	Estimates based on row sizes less than 25 are not reported.
Age of Respondent:	Adolescents in grades 7 to 12
Unique Demographic Descriptions:	
Family Structure -	Family structure is based on the living arrangements of the adolescent. The step-parent category includes cohabiting (nonmarried) partners of the biological parent.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.

Indicators:

P9 - Degree of Closeness Adolescent Feels Toward Parent
P16 - Religious Activities With Children

National Survey of Adolescent Males (NSAM)

Name:	National Survey of Adolescent Males (NSAM)
Funder(s):	National Institute of Child Health and Human Development (NICHD)
Principal Investigator:	Freya L. Sonenstein, Ph.D., Director, Population Studies Center, The Urban Institute
General Description:	The NSAM provides information on the adolescent male population including: demographic characteristics, family background, educational history and aspirations; sexual, contraceptive and HIV-related behaviors; use of alcohol and drugs, attitudes about condom use; gender role attitudes; and knowledge about sex, AIDS and contraception.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Longitudinal; Data was collected for two cohorts. The first cohort was collected in three waves: 1988, 1990-1991, and 1995. Data for the second cohort was collected in 1995 only. It is a household-based survey collected primarily through face-to-face interviews and the most sensitive topics were assessed with self-administered questionnaires.
Population:	The two cohorts of the NSAM represent the adolescent male population ranging from age 15 to 27 in the U.S. Only never married, non-institutionalized males were sampled.
Sample Selection and Description:	Old cohort: 1,880 males age 15-19 in 1988; 1,676 males age 16-21 in 1990-1991; and 1,377 males age 21-27 in 1995. New cohort: 1,729 males age 15-19 in 1995. The survey over-sampled for blacks and Hispanics. For the estimates provided in this report the sample was limited to those who have ever had sex.
Website:	http://www.nichd.nih.gov/about/cpr/dbs/res_national3.htm
Unit of Analysis:	Adolescent male
Estimate Restrictions:	Estimates based on cell sizes less than 25 are not reported.
Age of Respondent:	15 to 27 years old
Unique Demographic Descriptions:	
Parental Status -	Parent is defined as having had a live birth or adopting a child by the time of interview.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	F7 - Characteristics of Sexual Partners

National Survey of Families and Households (NSFH)
--

Name:	National Survey of Families and Households (NSFH)
Funder(s):	Wave 1: National Institute of Child Health and Human Development (NICHD), Center for Population Research Wave 2: National Institute of Child Health and Human Development (NICHD) & National Institute on Aging
Principal Investigator:	Larry Bumpass and Jim Sweet (University of Wisconsin-Madison). Field work carried out by Institute for Survey Research of Temple University.
General Description:	The National Survey of Families and Household (NSFH) was developed to gain more information on the causes and consequences of the changes in American family and household structure.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Longitudinal; Wave I data collection took place from 1987 to 1988. In Wave I, information about the primary respondent for each family was collected using a combination of personal interviews and self-administered questionnaires. A shorter self-administered questionnaire was also given to the primary respondent's spouse/partner. In addition information about one focal child (if there were any children in the family) was collected from the primary respondent. The Wave II, Five-Year Follow-Up was conducted from 1992 to 1994. In Wave II, personal interviews were conducted with the original respondent and his or her partner. Telephone interviews were conducted with the focal child and a randomly-selected parent of the original respondent. For original respondents with focal children ages 18 to 33 in 2001 – 2002, the NSFH Wave III Follow-Up will include telephone interviews with primary respondents, their spouses or cohabiting partners, and the eligible focal children. For original respondents without focal children ages 18 to 33 in 2001-2002, the Wave III Follow-Up will include only telephone interviews with primary respondents who are ages 45 or older and their spouses/cohabiting partners.
Population:	The NSFH is representative of the U.S. population of noninstitutionalized adults ages 19 and older who were able to be interviewed in either English or Spanish. Persons under the age of 19 were ineligible to be interviewed unless they were currently married or no one in the household was over age 19.
Sample Selection and Description:	Wave I consisted of a nationally-representative sample of 13,007 primary respondents, representing 9,637 households. The survey over-sampled minorities, single-parent families, parents with step-children, cohabiting persons and recently married persons. The sample size for Wave II was 10,008.
Website:	http://www.ssc.wisc.edu/nsfh/home.htm
Unit of Analysis:	For this report, the individual adult respondent
Estimate Restrictions:	Estimates based on row sizes less than 20 are not reported.
Age of Respondent:	Primary respondent was 19 years old or older, cohabiter/spouse age was not limited.
Age of Child:	At Wave I - 0 to 18 years old At Wave II - only those 10 to 17 years old (short focal interview) or 18 to 23 years old (full focal interview)
Unique Demographic Descriptions:	
Parental Status -	Parent is defined as an adult having one or more of their own children, under age 18, living in the household. An individual who has had a child but is not

	currently living with a child would be classified as nonparent.
Family Structure -	Presented in terms of the number of parents living in the household with the child.
Poverty -	The Poverty threshold is computed only if the primary respondent is the householder or spouse/partner of the householder. In Wave I published poverty thresholds for 1984 were used and adjusted to 1986 dollars [adjusting for the increase in the CPI]. For Wave II 1992 CPS data was used. Cohabiting couple households were treated in exactly the same way as married couple households in computing the poverty threshold.
Employment -	Employment was coded as standard occupation codes with some additions for military. The initial code structure tied employment to number of hours working per the last week before the interview as the entrée into employment status.
Cohabitation -	A respondent is considered to be “cohabiting” if they are living together with a partner and are not married to that partner.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	P11 - Conflict Between Parents and Adolescents P18 - Encouragement of Children’s School Achievement FF7 - Age at First Cohabitation

National Survey of Family Growth (NSFG)

Name:	National Survey of Family Growth (NSFG)
Funder(s):	For Cycle 5: U.S. Department of Health and Human Services (DHHS) - Office of Population Affairs, Office of the Secretary, and the Children's Bureau, Administration for Children and Families (ACF); Centers for Disease Control and Prevention (CDC) - National Center for Health Statistics (NCHS) and National Center for HIV, STD, and TB Prevention (NCHSTP); National Institutes of Health (NIH), National Institute for Child Health and Human Development (NICHD). For Cycle 6: Funders included those listed above as well as the CDC – Division of Reproductive Health (DRH) and the Office of the Assistant Secretary for Planning and Evaluation (OASPE).
Principal Investigator:	William Mosher, National Center for Health Statistics
General Description:	The NSFG was primarily designed to provide national information on childbearing, factors which affect childbearing, and related aspects of maternal and child health, particularly marriage, divorce, contraception, and infertility.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Cross-sectional; Survey conducted in 1973, 1976, 1982, 1988, and 1995. Personal interviews were conducted in the homes of a national sample of women (ages 15 to 44). In 2002 the NSFG will be conducted again, this time interviewing both men and women ages 15 to 44. Questionnaires for men and women will be similar but not identical. The interview will include a self-administered section done on laptop computers.
Population:	The NSFG is representative of the civilian, non-institutionalized population of the U.S.
Sample Selection and Description:	10,847 women were included in the 1995 sample. In 2002, up to 19,000 interviews will be conducted (including both men and women). The 1995 survey over-sampled for black and Latino women.
Website:	http://www.cdc.gov/nchs/nsfg.htm
Unit of Analysis:	Adult
Estimate Restrictions:	Estimates based on a denominator less than 100 are not reported. In these tables, no denominators are smaller than 100, so no cells are suppressed.
Age of Respondent:	Interviewed women ages 15 to 44 of all marital statuses.
Unique Demographic Descriptions:	
Parental Status -	Women are coded as parent if they had ever had a live birth by the time of the interview and coded as nonparent otherwise.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	F7 - Characteristics of Sexual Partner

Panel Study of Income Dynamics (PSID)
--

Name:	Panel Study of Income Dynamics (PSID) – Child Development Supplement (CDS)
Funder(s):	Original funding agency: Office of Economic Opportunity of the U.S. Department of Commerce. Current major funding source: National Science Foundation. Additional funders: the National Institute on Aging, the National Institute of Child Health and Human Development, the Office of the Assistant Secretary for Planning and Evaluation of the U.S. Department of Health and Human Services, the Economic Research Service of the U.S. Department of Agriculture, the U.S. Department of Housing and Urban Development, and the U.S. Department of Labor.
Principal Investigator:	Frank Stafford, Jacquelyn S. Eccles, Jeanne Brooks-Gunn and Hiromi Ono; Survey Research Center, Institute for Social Research, University of Michigan
General Description:	The Panel Study of Income Dynamics (PSID) emphasizes the dynamic aspects of economic and demographic behavior. The Child Development Supplement, which was used for this report, aims to provide comprehensive data on children and their families with which to study the dynamic process of early human capital formation.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Longitudinal; The data were collected annually from 1968 to 1997, and biennially starting in 1999. Information on 0 to 12 year old children was collected from the parents, teachers, and from the children themselves in 1997. The Child Development Supplement provides data on parents and their 0- to 12-year-old children, http://www.isr.umich.edu/src/child-development/home.html#A
Population:	The PSID reports on a representative sample of U.S. individuals (men, women, and children) and the family units in which they reside.
Sample Selection and Description:	Based on a probability sample of about 4,800 households, a combination of a cross-section of about 3,000 families selected from the Survey Research Center's master sampling frame and a subsample of about 2,000 families from the Census Bureau's Survey of Economic Opportunity. If the family has a child age twelve or younger, the entire PSID Household Unit was eligible for the Child Development Supplement. The Supplement had a sample of 2,394 child households and about 3,600 children. The data collection includes the following: (1) reliable, age graded assessments of the cognitive, behavioral, and health status of 3,563 children (including about 329 immigrant children), obtained from the mother, a second caregiver, an absent parent, the teacher, the school administrator, and the child; (2) a comprehensive accounting of parental and caregiver time inputs to children as well as other aspects of the way children and adolescents spend their time; (3) teacher-reported time use in elementary and preschool programs; and (4) other-than-time use measures of other resources for example, the learning environment in the home, teacher and administrator reports of school resources, and decennial-census-based measurement of neighborhood resources.
Website:	http://www.isr.umich.edu/src/psid/

Unit of Analysis:	P4 - All children ages 0-12 P7 - All children ages 3-12 P10 - All children ages 0-12 P15 - All children ages 3-12	P6 - All children ages 0-12 P8 - All children ages 0-12 P14 - All children ages 0-12
Estimate Restrictions:	Estimates based on row sizes less than 20 are not reported.	
Age of Respondent:	18 to 65 years old	
Age of Child:	0 to 12 years old. Age of child calculated based on months.	
Unique Demographic Descriptions:		
Parental Status -	Parent is defined as an adult having one or more of their own children under age 12 living in the household. An individual who has had a child but is not currently living with a child would be classified as nonparent.	
Family Structure -	Questions were asked of resident parents only. Family structure reflects the living arrangements the child, not the biological relationship to the child. For most indicators, the number of "father only" families was too small to report and are therefore not shown in the tables.	
Poverty -	Poverty status based on income in the previous year.	
Employment -	Employment status based on average hours worked over the last year. Due to the limited number of cases mothers and fathers who were working are not broken into "less than 35 hours per week" and "35 hours per week or more."	
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.	
Indicators:	P4 - Parents' Beliefs About Raising Children P6 - Parents' Responsibility For Children P7 - Limit Setting P8 - Conflict Resolution Styles in Families P10 - Warmth and Affection P14 - Time Spent With Children P15 - Parents' Activities With Children	

Survey of Income and Program Participation (SIPP)

Name:	Survey of Income and Program Participation (SIPP)
Funder(s):	U.S. Bureau of the Census
Principal Investigator:	U.S. Bureau of the Census
General Description:	The Survey of Income and Program Participation (SIPP) is a major source of information on the economic and demographic situation of persons and families in the U.S.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Longitudinal; This is a continuous survey in which overlapping panels are added and existing panels are rotated out after completing their period of approximately two and a half to four years in the sample. From 1984 to 1993 the duration for each panel was approximately two and a half years. In 1996 a four year panel was introduced. In general each assigned household is interviewed once every four months and the reference period is the preceding four months. The four-month period of interviewing that it takes to give the entire panel the same interview schedule is called a wave. Beginning in February 1992, Waves 1, 2, and 6 are personal interviews, but Waves 3, 4, 5, 7, and 8 are conducted by telephone. In addition to the core section, several “topical modules” are included. Topics covered by these modules include personal history, child care, wealth, program eligibility, child support, disability, school enrollment, taxes, and annual income.
Population:	The SIPP represents the non-institutionalized civilian population (adults 15 years or older).
Sample Selection and Description:	Multi-staged stratified sample. Sample size ranges from approximately 14,000 to 36,700 interviewed households. The survey over-sampled for blacks, Hispanics and women with no spouse present and living with relatives. Households under 150% of the poverty level were also over-sampled. In this report estimates are provided from the two topical modules: Child Care and Personal History. The Child Care Topical Module is asked of respondents who are the designated parents or guardians of children under age 15 who are living in the household. The Child Care Topical Module is asked of every panel. The Personal History Topical Module consists of eight submodules, of which one is reported in this book marital history. The Personal History Topical Module is asked of all persons age 15 years and older in the household. This module is asked once in every panel.
Website:	http://www.sipp.census.gov/sipp/
Unit of Analysis:	Indicators FF1, FF2, FF3 – Adult Indicator P13 – Child. For this indicator all demographic information is based on Wave 2 of 1996 SIPP data. Since the information on child care was collected during the Wave 4, there is an 8 months difference between the demographic data and child care data. In particular, residential status of parents may have changed between the two waves but households were classified into two-parent families or single-parent families based on the residential status of parents at Wave 2.
Estimate Restrictions:	Estimates based on weighted cell sizes less than 20 are not reported.

Age of Respondent:

All household members 15 years old and over are interviewed by self-response, if possible; proxy response is permitted when household members are not available for interviewing. In this report, estimates are restricted to those respondents 18 years or older.

Age of Child:

P13 - Direct Care by Fathers indicator is based on children ages 0 to 5 years old.

Unique Demographic Descriptions:

Parental Status Parent is defined as an adult living with one or more of their own children under age 18. An individual who has had a child but is not currently living with a child would be classified as nonparent.

Significance Level: All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.

Indicators: P13 - Direct Care by Fathers
FF1 - Marriage
FF2 - Divorce
FF3 - Age at First Marriage and Divorce

Vital Statistics

Name:	Vital Statistics
Funder(s):	National Center for Health Statistics, Division of Vital Statistics; U.S. Department of Health and Human Services
Principal Investigator:	National Center for Health Statistics
General Description:	Vital Statistics is a major collection of data at the federal, state, and sub-state levels of births and deaths from the 50 states and the District of Columbia.
Design (cross-sectional vs. longitudinal; periodicity; mode of administration):	Data collection is continuous. Data is collected via birth, death, and fetal death records. All certificates are collected from the 50 states and the District of Columbia and reported to the Division of Vital Statistics. Monthly and annual reports of provisional data and annual and special subject reports based on final data are issued. All states have been included in the birth registration area since 1933.
Population:	All certificates are collected from the 50 states, the District of Columbia, and the territories, and reported to the Division of Vital Statistics.
Sample Selection and Description:	Not applicable
Website:	http://www.cdc.gov/nchs/nvss.htm
Unit of Analysis:	Individual
Estimate Restrictions:	Not applicable. Data are collected from actual records.
Age of Respondent:	Records are included for all persons who have had a child.
Significance Level:	All statements discussed in the text are significant at the .05 level, using two-tailed t-tests.
Indicators:	F1 Birth Rates

Appendix B:
Who is a Parent? – Data Tables

Table 1 Percentage of adults who have ever had a biological child: 2000

	Males	Females

¹ 1996 SIPP, Wave 4, had a considerable number of imputed data. Imputed cases are excluded from the calculation of the percentages.

² All demographic information is based on Wave 2 of 1996 SIPP data. Since the information on child care was collected during the Wave 4, there is an 8 months difference between the demographic data and child care data. In particular, residential status of parents may have changed between the two waves but households were classified into two-parent families or single-parent families based on the residential status of parents at Wave 2.

³ Estimates for all race categories exclude Hispanics of those races. Persons of Hispanic origin may be of any race.

* = This information has been suppressed due to an insufficient number of cases.

¹ All demographic characteristics (excluding income and poverty status) are as of March the following year.

² Estimates are calculated only for households with a child (under age 21) who lives with one biological parent and whose other parent is absent.

³ Estimates for all race categories exclude Hispanics of those races. Persons of Hispanic origin may be of any race.

* = This information has been suppressed due to an insufficient number of cases.

¹ Families as of March the following year. Income in 2000 CPI-U-RS adjusted dollars. The CPI-U-RS is a price index of inflation that incorporates most of the improvements in methodology made to the current CPI-U since 1978 into a single, uniform series. See Money Income in the United States: 1999 or the appendix of Money Income in the United States: 1998 for more information.

² Data reflect implementation of a new March CPS processing system.

³ Data reflect implementation of 1990 census population controls.

⁴ Data collection method changed from paper and pencil to computer-assisted interviewing. In addition, the March 1994 income supplement was revised to allow for the coding of different income amounts on selected questionnaire items. Child support and alimony limits decreased to \$49,999. Limits increased in the following categories: earnings to \$99,999; social security to \$49,999; supplemental security income and public assistance income to \$24,999; and veterans' benefits to \$99,999.

⁵ Data reflect introduction of 1990 census-based sample design.

⁶ Data reflect full implementation of the 1990 census-based sample design and metropolitan definitions, 7,000 household sample reduction, and revised race edits.
